Mr. Rothery asked the gentlemen who have been operating gas plants to say what is the cost of operation per kilowatt-hour. Also whether it is not necessary to provide additional units to take care of overload? The speaker understands that a gas engine will develop simply its rated capacity, and positively no overload, the rated capacity being based upon the highest number of heat units in the gas which is to be used in that locality. If there is any deficiency in the heat units the capacity of that engine is reduced pro rata. Thus there must be considered (1) the number of units required in order to produce a given amount of power; (2) what reserve is it necessary to have on hand? and (3) what is the actual operating cost per kilowatt-hour? With the fixed charges what is the cost on the bus-bar? We know what it is by a reciprocating engine and by steam turbines from actual experience; but with the gas engine there seems to be the broad statement that they can operate so much more cheaply than they can by steam.

Mr. Adams replied that he had not the data in hand, but would send it in to the secretary. His company measures everything off the switchboard. They had difficulty in getting the full rated capacity out of the gas engines, but nevertheless think so much of them that they are still putting them in. In Elyria during the last 18 months various factories there have installed about 1,500 horsepower in gas engines running electrical equipment.

Ways of Selling Day Current.

Aside from the regular programme, the subject of ways of selling day current was discussed by Messrs. Gwynn, Bechstein, Russell, Townsend, Rothery, Conkling, Martin, Lockwood, Adams, Selig, Plaice, Rust and others, and it developed that, owing to local conditions, such as difference in cost of fuel, and other causes, there was a wide divergence of rates charged for day-power load.

High-efficiency Lighting Units.

At 2 p. m. the joint paper by Messrs. C. C. Collins and A. N. Cope of Columbus was taken up, the former being superintendent of the Columbus Railway and Light Company, and the latter of the Columbus Public Service Company. The paper was in the nature of a report, showing results in the use of lights in tabulated form as obtained by various central stations in Ohio and elsewhere. The paper in full, with an abstract of the discussion, appears elsewhere in this issue.

Helps to a Solicitor.

J. D. Kenyon of the Sheldon School, Chicago, addressed the convention on the general subject of "Helps to a Solicitor," outlining the elements of scientific salesmanship. His address was much appreciated and the subject of a good deal of favorable comment privately among the members.

A. S. Miller of the Dayton Lighting Company read his paper on "Helps to a Solicitor, and what Fifty Cents' Worth of Electricity Will Do," full of practical suggestions to the solicitor.

Professor Caldwell emphasized the great convenience of many household appliances in the electrical way, saying that the suggestion as to drying in the laundry by electric fan was much appreciated and used in his own household. The great convenience is worth all the cost. President Engel gave a like illustration.

Mr. Bechstein referred to the opportunity for putting out motors to run refrigerating plants. The time is coming when private ice plants run by electric motors will supplant the ice man at $6 a ton. One installation in his city was giving good satisfaction, and has been in operation since last December, on a meter basis. Mr. Adams reported several refrigerating plants on a meter basis, experiencing no trouble. It was not so desirable if the peak is overloaded. Mr. Tait stated that by the use of a modern equipment such a plant can be run, with current at four cents per kilowatt-hour, to compete successfully with ice at $6. An automatic regulator is very essential.

Wiring by Central Stations.

At the suggestion of Mr. Gwynn the rest of the afternoon was given over to a discussion on wiring, and the advisability of the central station undertaking same. It seemed to Mr. Gwynn that turning wiring over to outside contractors does not encourage new-business getting. This department can be made a profitable one.

In Massillon, a town of 15,000, there are no wiring contractors. Here the plan of Mr. Russell's company is to offer free wiring, provided the houseowner will pay a minimum bill of $1.50 a month for two years; that is, figuring that it will cost $9 to wire the house; the ordinary minimum being $1, this allows 50 cents monthly to pay for the wiring. If he does not want to pay $1.50 for two years he can have the option of $1.25 for four years. In this way the company has taken on 120 new customers of this kind in the last two months and a half.

Mr. Martin bought a municipal plant in his town and has built up a good business. There is only one local contractor, and the speaker never bids against him. He has two forms of wiring applications to choose from. The customer pays for the material, which in schedule A includes everything that is properly chargeable to the wiring, beginning at the fuse plug and the wires down to the point where the wires come through the ceiling. Switches are charged extra in schedule B, covering all switches, drops and everything that is in the way of a chandelier or lighting device. If the aggregate of A and B is $25, of which A is $15, and B, $10, the customer pays the $25, and the collector receipts for same; at the bottom the collector certifies that, having paid his bill, the customer is entitled to a credit of $15, to apply against all future light bills.

The meter is read monthly, but no bill presented until the customer has exhausted his credit memorandum, schedule A. In the meantime the family has contracted the habit of using electricity. The customer is urged to take irons and as many devices as possible that consume current, something that under a different introduction plan would require two or three years to educate him to.

Mr. Kermode reported that in Cleveland the company had arrived at an average unit price per outlet on wiring and a separate price for all switches, receptacles and drop lights installed. Contractors were asked to furnish bids covering what they would wire old houses for. It is easy to get new houses, but hard to get old ones, where the fixtures are already in for gas. A company can always get business by extending its lines, whether profitably or not, but it is hard to increase the business on old lines; for that reason a liberal policy is desirable on old-house wiring. The Cleveland office is allowing 15 per cent. of this wiring cost to apply on light bills. It takes about three months to take up that allowance. Are now gradually taking off company solicitors and paying contractors so much for each house added; the contractors have some ten men in the field soliciting, on a commission basis. As to furnishing free-lamp renewals, many customers do not appreciate anything you give them; in Cleveland lamps are sold at 15 cents, and about 185,000 handled annually.

Meeting Gas and Gasoline Competition.

On Thursday morning papers were presented on the subject of "Best Ways to Meet Gas and Gasoline Competition" by the following: F. H. Golding, Dayton Lighting Company; Samuel Rust, Greenville Electric Light and Power Company; W. E. Russell, Massillon Light, Heat and Power Company; Arthur Pomeroy, Cleveland Illuminating Company; E. T. Selig, Mount Vernon Electric Light Company, and W. C. Anderson, Canton Light, Heat and Power Company. Many valuable suggestions were offered.

In the discussion following, Mr. Beil said that small current-consuming devices, negligible themselves as to their effect in increased revenue, were often the means of introducing electricity and securing patronage that otherwise would not have been secured. He instances renting fans for the summer months, particularly to those who had sickness in the family, as one of the ways of inducing patronage that would extend to lighting, etc.

Mr. Kermode stated that in 600 houses wired in Cleveland on the installment plan, the contractor had made no investigation as to the man's standing, but took his order for wiring his house and took chances on getting the money on the installment plan. The central station pays the contractor a bonus as compensation to him for carrying the account 8 or 10 months. Out of the 600 houses only two failed to pay. The company does not guarantee any account, neither is there anything in the contract that is in the nature of a lien or mortgage. Are not now paying the contractors a bonus, but making property owners a rebate of 15 per cent. to apply against lighting bills.

Secretary Gaskill stated that an electric central station that does its wiring has always the statutory provision in regard to mechanic's lien to fall back on, and can file said lien any time within four months from date of the last item of the account.

Mr. Custar said he was rather prejudiced against a central station doing wiring, as tending to interfere with proper attention to other business. The gas company does not do any plumbing in his town, and why should the electric-light company do wiring? People will run to the office for small repairs and alterations, which they will want done for nothing, and if not done free bad feeling is created. Better have a private contractor do the wiring, and encourage him in this as much as possible. People will think you are making money out of the wiring.

In response to query by the chair as to how many stations do their own wiring, 12 responded in the negative; 21 stations reported that they did wiring.

Mr. Martin reported that at first they let somebody else do the wiring, but unsatisfactory work done by wiring contractors had opened their eyes to the necessity for doing this work themselves. They accordingly bought out the local contractors with the exception of one. By reason of the fact that they do the wiring they hear of troubles promptly and can as promptly correct and remedy them. Mr. Townsend reported that the only wiring his company does is of arc lamps. They work in conjunction with the contractors and get better results that way than if doing own wiring.

Mr. Selig said that a great many stations are probably staying in the wiring business simply because they cannot get a good wiring contractor; but in many cases they can make a better man out of a contractor by proper inspection. The people in the inspection bureau ought to be encouraged. The farther a company stays away from doing wiring and the less responsibility they have, the better for them. If they will encourage this inspection by the regular insurance inspection bureau they will relieve themselves of a great deal of liability. Did some wiring when there were no good contractors to be had, but are now fortunate in having two good firms, who do business in five different towns in the state, and there is enough competition between them to insure moderate prices. Do not like to do the inspection ourselves, but prefer to escape that liability when we can place it on the inspection bureau. At present the inspection bureau has arranged to put one inspector in our territory, who takes care of four towns. The charges for inspection are very moderate and are added to cost of wiring, so that the customer pays for same.

At this point there was a long discussion on the subject of theft of current, in which Messrs. Adams, Bechstein, Kermode and Golding took part

Closing Business.

Secretary-Treasurer Gaskill submitted his report, which was duly audited and found correct. The report shows the association in good financial standing. A recommendation to increase the salary of the secretary was approved. The secretary recommended that the dues of associate members be increased to $10 a year, which recommendation, on motion of Mr. Hanley, was adopted.

Election of Officers.

The nominating committee, Messrs. Hanley, Rust and Hubbell, submitted its report, which was unanimously adopted, the officers elected being as follows:

President—F. M. Tait, Dayton.

Vice-president—E. H. Beil, Youngstown.

Secretary-treasurer—D. L. Gaskill, Greenville.

Executive committee—W. P. Engel, Defiance; M. E. Turner, Cleveland; D. W. Low, Alliance; W. F. Hubbell, Wauseon; J. C. Rothery, East Liverpool.

Advisory committee—Samuel Scovil, Cleveland; C. R. McKay, Toledo; D. L. Gaskill, Greenville.

Publicity committee—W. J. Hanley, Cleveland; Samuel Rust, Greenville; J. T. Kermode, Cleveland.

Finance committee—W. E. Miller, Mt. Gilead; T. D. Buckwell, Toledo; G. N. Clapp, Middletown.

President Engel paid a high compliment to the work of the secretary. He recommended that central-station men not only come to the meetings of the association with their ladies, but to see that their directors come also, as they can learn much that will be of benefit.

Secretary Gaskill, by request, read a communication inviting the convention to come to Cleveland, signed by a number of those in attendance on this meeting. The matter of choice of the next meeting place will come up at the January meeting of the executive board.

President Engel extended thanks to the active and associate members for valued assistance rendered during the year. Out of some 180 central stations in the state there are now but 50 that are not members of the association.

A suggestion was made by Mr. Golding of Dayton that it is important to secure legislative control of the use of gasoline. Mr. Canfield of Delphos spoke along the same line, and on his motion a committee of three was authorized to be appointed by the incoming president, to consider the matter of gasoline, and suitable measures for its control, and the committee was given power to act, or to report at next meeting at its option.

Entertainment Features.

The amusement features of the convention were worthy of notice and consisted, for the evenings, of a theater party at the Casino, supper at Toledo Beach, a boat ride on the Greyhound, with the usual accompaniments of music and dancing, and the various ladies' contests scattered throughout the afternoons and evenings. The dinner at Toledo Beach, in charge of Douglas Buckwell, was an especially enjoyable affair.

The winners in the various contests arranged for the ladies were as follows, the beautiful prizes having been presented by the associate members and others:

Informal euchre contest—Mrs. George Williams, Cleveland.

Formal euchre party—First prize, Mrs. F. C. Colwell, Cincinnati; second prize, Miss E. McKnight, Bowling Green; third prize, Mrs. W. B. Wilkinson, Columbus; fourth prize, Mrs. W. S. Meeker, Greenville.

Riddle contest—First prize, Mrs. A. B. Pyke, Cleveland; second prize, Miss Esther Gaskill, Greenville; third prize, Mrs. Z. T. Dorman, Greenville; fourth prize, Miss Helen Gaskill, Greenville.

Peanut contest—First prize, Miss Elmina McKnight, Bowling Green; second prize, Miss Letha May Engel, Defiance; third prize, Mrs. E. A. Bechstein, Sandusky; fourth prize, Mrs. G. H. Porter, Chicago.

Euchre—First prize, Mrs. A. A. Serva, Fort Wayne, score 67; second prize, Mrs. H. S. Cook, score 65; third prize, Miss Elmina McKnight, score 63; fourth prize, Miss E. R. Martin, score 62.

Pedro contest—First prize, Mrs. C. B. Rodgers, Tiffin; second prize, Mrs. A. G. H. Jennsen; third prize, Mrs. W. P. Engel, Defiance; fourth prize, Mrs. Folsom.

Ladies' bowling contest—First prize, Miss Quail, score 155; second prize, Mrs. Haring, score 150; third prize, Mrs. Rogers, score 139; fourth prize, Mrs. Jennsen, score 130.

Convention Notes.

The Oneida galvanized chain for suspending arc lamps was exhibited in parlor N.

The W. G. Nagel Electric Company of Toledo entertained in parlor I, represented by W. G. Nagel, H. E. Adams, R. G. Kendrick, A. L. Carney and J. P. Thompson.

The Western Gas Fixture Company hung a chandelier in the convention hall with five two-glower Nernst lamps attached. The company was represented by Edward N. Riddle.

The Westinghouse Electric and Manufacturing Company was in parlor C, represented by G. E. Miller, manager, Mr. Wagenhorst, C. P. Billings, Mr. Beebe and G. S. Vail of Cleveland, Mr. Hughes of Pittsburg and J. C. McQuiston.

J. Robert Crouse of the Co-operative Electrical Development Association, Cleveland, showed three sets of mounted photograph display cards, illustrating the work of the companies of Dubuque, Lincoln, Neb., and Providence, R. I.

The Electric Appliance Company, Chicago, represented by F. J. Alderson, Chicago, and George H. Porter, Columbus, exhibited in the lobby Sangamo direct-current and alternating-current integrating wattmeters. Souvenir pocket mirrors were distributed.

The John A. Stewart Electrical Company, Cincinnati, Paul Stewart, treasurer and manager, kept open house in parlor 64, and gave away souvenirs in the shape of a combined paper-knife and letter-opener. The mission was to buy second-hand machinery.

Parlor K was reserved for the Allis-Chalmers Company, Milwaukee, showing electrical apparatus and steam turbines, five-horsepower induction motor, 7.5-horsepower direct-current motor and samples of turbine blading. Representing the company were George A. Williams, Cleveland, and F. C. Colwell of Cincinnati.

Nernst-lamp people had parlor C, distributing handsome and up-to-date printed matter, including photographs of typical Nernst installations. A six-glower Nernst hung in a canopy housing. The convention hall was beautifully illuminated with Nernst lamps; one hung in front of the Westinghouse exhibit. Charles H. Davis and G. R. Clover, both of the Chicago office, represented the company.

The W. J. Barr Electrical Manufacturing Company, Cleveland, Ohio, was represented by W. J. Barr, president, and Lawrence W. Cady, electrical engineer. The company showed in parlor J an interesting line of electrical heating devices and exhibited for the first time the Barr ventilated stand, which will carry a heavy overload without scorching or burning.

The Western Electric Company, Chicago, in parlor H, was represented by H. D. Haring, Indianapolis; D. G. Guest, Chicago, and F. A. Henderson, Cleveland. The company showed multiple and series arcs, a full line of high-tension porcelain and electrose insulators and new indestructible coil arcs. An interesting feature of the display was the discovery by visitors that they could light a cigar by short-circuiting the new indestructible coil arc and applying cigar to the resistance coils.

H. P. Folsom of the Universal Pole and Post Preserving Company, Circleville, Ohio, was in Parlor L, expounding the merits of his new method patented December 4, 1906, which can be applied to poles at any time after erection by digging down around the pole about 16 inches, placing a layer of cement immediately around the pole, then setting a sleeve or jacket about 16 inches high in the cement, and filling in between the pole and the jacket with a specially prepared chemical, which is a germicide and insecticide. A cement cap is put on top, coming down to the ground line, which protects the chemicals from the action of rain and snow and at the same time excludes outside infection. The cement cap is reinforced by wires embedded both laterally and perpendicularly. The method has been applied to poles that were partially rotted for about an inch or more at the ground line, and after seven years the poles were found still in the same condition, no further decay having taken place.

The Cleveland Electrical Supply Company, represented by L. Griesser, manager, W. C. Marker, secretary, Warner Jones, salesman, and H. H. Cudmore, distributed watch fob souvenirs and celluloid statistical cards. Warner Jones sat up a whole night inventing the striking menu, that had in it everything electrical, and nothing to eat.

Parlor A was the headquarters of the Fort Wayne Electric Works, and was illuminated by the smiling countenance of Tom Ryan, district manager, and George B. Edgar of Cincinnati, flanked by A. A. Serva, assistant sales manager, of Fort Wayne. The company exhibited fan motors, a new wattmeter calibrator just being put out on the market, a line of literature, etc. Mr. Ryan was highly pleased with the practical nature of the papers read at the convention.

The Wagner Electrical Manufacturing Company of St. Louis was represented by N. Emerson of Cincinnati, who is a regular attendant at these meetings, and T. Richards of St. Louis, showing alternating-current single-phase variable-speed motors with auto-transformer control, having all good points of former direct-current machines, with many of the bad points eliminated. When the motor comes to full speed it runs as an induction motor, the brushes being cut out. Another new device was in the shape of a portable lamp-testing voltmeter and wattmeter, eight instruments in one.

The Excello Arc Lamp Company, New York, represented by G. W. Armstrong, hung two 10-hour Excello flaming-arc lamps at the Superior Street entrance of the Boody, and two 17-hour flaming arcs on the St. Clair side entrance. The latter is used principally in factory lighting, on account of the long-hour burning. This concern has put in some large installations this year, notably with the National Tube Works, Mester Machine Company, United Engineering and Foundry Company, General Casting Company and Pennsylvania Steel Company.

The General Electric occupied parlor B, with a host of good entertainers, H. C. Houck, manager, Cincinnati; F. W. Willcox and G. C. Osborn of Harrison, N. J.; A. E. Alley, Cincinnati; A. S. Hertz, Cleveland; Percy Worth, Indianapolis, and the old reliable in Ohio state association work, W. J. Hanley, now of Cleveland. Exhibited were the new type high-efficiency units, tantalum in 50 and 80 watts; new street series lighting, tungsten; 25-watt 20-candlepower tungsten for use four in series in commercial lighting, and 100-watt 80-candlepower multiple tungsten lamps; a five-light fixture hung on the stairway.

Another Los Angeles Power Project.

Although the primary purpose of the city of Los Angeles in building the Owens River Aqueduct is to obtain a large supply of water and make provision for the great increase of population that is inevitable, the development of electric power is an important feature of the project. In the estimates of the aqueduct no provision was made for power plants, but the engineers have so planned the conduit that the water may be used to generate power whenever the city determines to install the necessary plant.

At present the average amount of electric power used in the locality of Los Angeles is about 40,000 horsepower. During the hours of heavy load this increases to 67,000 horsepower, and only a little more than half of that is derived from water-power, the rest being supplied by steam plants. In addition, there are small private steam and gas plants supplying about 25,000 horsepower, which could be replaced if cheap electricity were available. The demand for power is now in excess of the supply, and at the present rate of increase it is estimated the demand will be more than doubled in five years.

Three-fourths of the total available power along the conduit can be developed in San Francisquito Canyon, 40 miles from the city, where there is a drop of 1,475 feet.

The cost of power plants, transmission line and receiving sub-station, including extra hydraulic work incident to development of power, is estimated at $4,500,000. There are other power sites along the aqueduct, and from all of them combined 93,000 horsepower could be delivered in the city.

Rails have been ordered for the electric road between Mason and Lansing which is to run to Jackson and is being built by the Northern Construction Company, a subsidiary company of the Michigan United Railways. There are to be 1,800 tons delivered by October 1st.

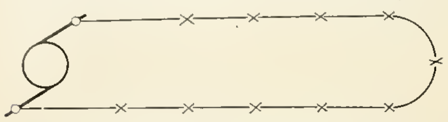
ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXXI.—Electric Lighting.

Street Lighting.

Arc lamps are used almost exclusively for street lighting, although incandescent lamps used in series are found occasionally in some locations where the density of foliage is too great to permit the use of arc lights. Except in narrow streets with tall buildings there is little reflection to aid the general illumination, and therefore it is quite necessary to utilize reflectors for throwing downward that part of the light which is naturally projected above the horizontal plane. If the distance to which the light is to be thrown is known, together with the distribution curve of the lamp to be used, the illumination in candle-feet can be calculated. This, however, does not give the actual quality of the proposed lighting, for the reason that a street lighted with very high candlepower units appears considerably better lighted than one having the same minimum value of illumination but using smaller units more closely distributed.

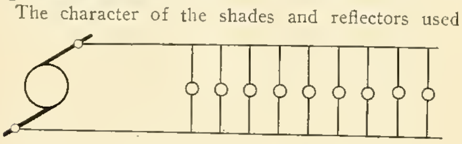


SERIES SYSTEM OF DISTRIBUTION.

In studying the distribution curves of different types of arc lamps it will be found that one type will be superior to another for a short distance from the lamp, whereas for longer distances the same lamp may be inferior. For example, the open arc will give a superior illumination close to the pole, but at a little distance from the pole the enclosed arc is superior. The latter, moreover, does not offer such strong contrast of bright and dimly lighted zones, and consequently the dimly lighted sections appear brighter than when in contrast with a very brilliantly lighted section.

The enclosed arcs give a very steady light and almost total absence of shadow cast by the rods holding the carbon, while the open arc is subject to considerable fluctuation of light, and parts of the lamp itself cast very dense shadows. All things considered, the enclosed arc is very much superior to the open arc of the same watt consumption. There is but little difference between the direct-current and alternating-current enclosed arc lamp. The former gives slightly more light, while, on the other hand, the latter gives a better light distribution.

The character of the shades and reflectors used in street lighting has a marked effect upon the general illumination. The subject of illumination, however, forms a considerable study in itself, and only a few of the salient points have been mentioned here.



MULTIPLE SYSTEM OF DISTRIBUTION.

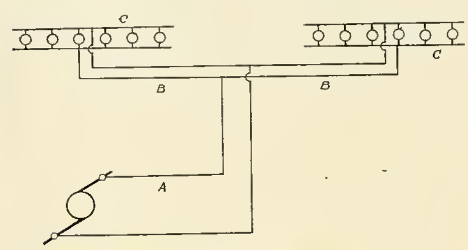
Distribution of Current.

In supplying power to either incandescent or arc lamps, two general methods are employed for the distribution of current. These systems are known as the series system and the multiple or parallel system. In some cases these systems are combined to a certain extent in what is known as the series-multiple system.

Series System.—The accompanying diagram illustrates the series system of current distribution in which all of the lamps are connected in series, that is to say, the negative terminal of one lamp is connected to the positive of the next throughout the circuit, so that the entire current of the circuit passes through each lamp successively. This is the most simple system of distribution, and is used to some extent for both arc and incandescent street lighting. It has the advantage of being very economical, as only a small wire is necessary; one of sufficient size to carry the current required for a single lamp.

The series system has the disadvantage of requiring very high voltages, and it is obvious that if any one lamp of the series has a broken connection so that current cannot pass through it, the circuit of the entire series will be broken, unless some means is provided for short-circuiting the defective lamp. The number of lamps which can be used in series is limited by the voltage for which the generators can be insulated. The open arc lamp requires about 50 volts and a little less than 10 amperes to operate. If, therefore, we have 100 lamps in series the circuit will require 100 times 50, or 5,000 volts. From 5,000 to 6,000 volts is as high a potential as is used, on account of the difficulty of insulating the generators.

The series system is used to considerable extent for alternating-current arc lighting. By the use of a special transformer a number of circuits can be operated from one machine. These transformers are called constant-current regulating transformers and they are built in various capacities up to 100 lamps. The regulating transformer has fixed primary coils and movable secondary coils. The primary coils are connected to the generator circuit and the secondary coils to the lamp circuit. The secondary coils, which are free to move, are repulsed by the primary coils, and this repulsive force is balanced by weights. When the current is on both circuits, therefore, the secondary coil takes such a position that only its rated current will flow through it. In starting the transformer the coils are brought close together and the transformer is short-circuited. The short-circuit is then

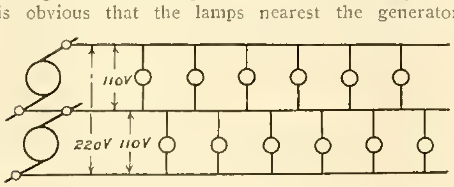


MULTIPLE DISTRIBUTION WITH FEEDERS, MAINS AND DISTRIBUTING LINES.

removed and the coils take a position according to the load on the transformer. These transformers operate at an efficiency in the neighborhood of 95 per cent., and give very close regulation from one-quarter to full load. The power factor is about 75 per cent. at full load, but falls off quite rapidly as the load decreases. For this reason it is desirable to run the circuits as fully loaded as possible.

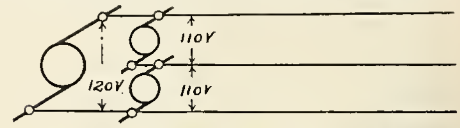
Multiple System.—The multiple system of distribution is the system which is in use for the great majority of lamps. In this system a constant voltage is maintained, and the current varies with the number of lamps connected in multiple. The great advantage of this system is that each lamp is independent of all the others, and so may be turned on or off at will without affecting any other lamps in the system. A multiple system of distribution is far more expensive to install than a series system, as the wiring must be of sufficient size to carry the combined current of all lamps connected to the circuit. Its advantages, however, in the way of regulation, and the ability to use any part or all of the lamps connected in the circuit, has made this the almost universal system of distribution.

An accompanying diagram represents the simplest arrangement of multiple connection for lamps. It is obvious that the lamps nearest the generator



THREE-WIRE SYSTEM WITH TWO GENERATORS

will burn at a higher potential than those farther away, and at the end of a long line the drop in voltage would be very apparent, as this drop is equal to the product of the amount of current flowing in the circuit, and the resistance of the conductor. This drop in potential is a serious difficulty in the multiple system, and in order to make the potential as nearly equal as possible in all parts of the system, methods of wiring are used which make the distance of each lamp from the generator as nearly equal as possible. One of the diagrams shows, in an elementary way, how this is accomplished. In this illustration the wires marked (A) correspond to the feeders which run directly from the generator or central-station bus-bars. (B) represents the wires known as mains, and (C) the distributing wires from the mains to the lamps. In a central-station distributing system the mains running through the different streets are preferably interconnected wherever possible, so that the voltage over the whole system tends to



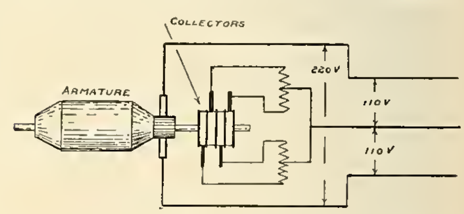
THREE-WIRE SYSTEM WITH BALANCING SET.

equalize itself. This system of mains does not run directly to the generator, but is fed at various points, determined by the load, by feed wires running from the station bus-bars to the various load centers on the mains.

The multiple system of distribution so far considered includes only distribution by two parallel wires, that is, the outgoing or positive wire, and the return or negative wire. This two-wire distribution at the usual commercial voltage of 110 volts is far too expensive for general use on account of the very large size of copper wire which it requires. Its use is therefore limited to isolated plants, in dwellings or industrial establishments, where the distances to which the wires are run are very short.

For direct-current distribution over areas of larger extent, what is known as the three-wire system is now universally used. The three-wire system was developed in the early days of electric lighting on account of the economy in copper which it effects. An accompanying diagram shows the connections of a three-wire system, from which it will be understood that current is distributed at double the voltage of the lamps, and the middle wire, which is called the neutral, only carries an amount of current represented by the difference in the loads on each side of the system. By thus doubling the voltage at which the current is distributed, nearly two-thirds of the cost of copper is saved, compared with a two-wire system of the same capacity.

The diagram previously mentioned shows the oldest and most common arrangement of the three-wire system. In this arrangement two generators are connected together in series, each generator being wound for the voltage of the lamp. The two outside wires of a three-wire system are led out from the two outside brushes of the generators, and the neutral wire is led out from the connection



THREE-WIRE SYSTEM WITH BALANCE COILS.

between the two machines. With this arrangement two machines must always be used together, but later modifications were introduced which permitted the three-wire system to be run from a single generating unit. There are two methods of doing this. One is by the use of a generator having double the voltage of the lamps, and across the leads from this generator is connected a small motor-generator known as a balancing shaft. This consists of two small machines connected in series across the lines. The neutral line is led out from the connection between the two parts of the balancing set, thus forming the third wire of the system.

The operation of the balancer is as follows: When there is a difference in the load on the two sides of the system the voltage of the side having the least load is highest. This higher voltage drives the side of the balancer connected across it as a motor, which in turn drives the other side of the set as a generator, and the latter supplies current for the unbalanced load on each side of the system. The balancing set is of very small capacity, just sufficient to take care of the difference in load which may occur on the system. The other type of three-wire generator is made by placing collector rings on the shaft of a direct-current generator in addition to the commutator. A two-phase connection is made between the armature windings and the collector rings, and a pair of balancing coils

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

are also connected across the collector rings. The balancing coils are similar to transformers with only a single winding. The general arrangement of the system is shown diagrammatically in the accompanying sketch. The middle points of the balancing coils are interconnected, as shown, and the neutral wire is led out from this connection.

[*To be continued.*]

QUESTIONS AND ANSWERS.

Static Converter.

A. A., Chicago: What is a static converter and what is its use?

ANSWER.

"Converter" is a name which is sometimes given to a transformer. Static converter, then, is another name for the ordinary static transformer, or the device usually known simply as a transformer and used for transforming an alternating current to another of a different voltage.

Star Connection and Voltage.

J. H. O., French Gulch, Cal: (1) How may a plant be starred to increase the voltage? (2) Does the starring affect the transformers, and in what way? (3) Can transformers be starred as well as generators? If so, how?

ANSWER.

The word "starred" as used is not a generally accepted term. The questioner probably refers to a three-phase Y connection, often called "star" connection. In the delta connection the high-voltage coils of the transformers are connected so as to form an equilateral triangle or delta. By changing these connections so that one end of each coil is tied to a common point and the other ends one to each line wire, a "star" or "Y" connection is obtained. The voltage between wires in the second case is 1.732 times that in the delta connection of coils. With the Y connection the strain on the insulation to ground is, of course, increased for the section of coils at the line end.

Resistance of Telegraph Relays.

W. T. H., Hammond, Ind.: Please state the difference in the resistance of a telegraph relay connected up in a circuit in series and one connected up in multiple.

ANSWER.

The resistance of a relay does not differ with the manner in which it is connected in the circuit, the resistance being an individual physical property of the instrument just as its length, weight or any other physical attribute. All commercial telegraph circuits are worked as series lines and the multiple connection of sets is practically unknown. The resistance of the relays designed for taps off the wire at a number of stations on a line of any length would necessarily be very high in order to divide the current among all the stations. The exact value would depend on the resistance of the line and the number of stations. In order to take advantage of the small current the relay winding must consist of a great many turns and varying adjustment would be necessary. On account of these and other difficulties attendant upon parallel connection the series arrangement has been found much more efficient and is the one in general use.

The Biggest Electric Sign.

C. F. W., Evanston, Ill.: Can you tell me where the biggest electric sign in the country is located?

ANSWER.

Perhaps, all things considered, this distinction belongs to the well-known sign, consisting of the single word "Butterick," on the western side of the Butterick Building in New York city. It is pretty certain that the sign has larger letters than any other electric sign, and possibly it covers a greater area. Whether it contains a greater number of lamps than any other is more doubtful. The initial B is 68 feet high, about the height of an ordinary five-story building. The smaller letters are 50 feet high and 5 feet wide. About 1,400 electric lights are used for the illumination. It practically requires all the time of one man to watch the sign and replace burnt-out lights. On account of the fact that the western side of the Butterick Building has more than 300 windows and double rows of fire escapes, considerable ingenuity was required to design the sign so as not to block the windows.

Electrification of Chicago Steam Roads Again Broached.

It is the wish of Mayor Busse of Chicago, who was in New York several days last week, that Vice president W. J. Wilgus of the New York Central Railroad visit Chicago and make an exhaustive report on the practicability of electrifying the terminal lines of Chicago's trunk system, embracing in all 23 lines. The main object of the proposed electrification is to do away with the smoke nuisance in Chicago.

It is likely that Mayor Busse will make a recommendation to that effect to Chicago's City Council when that body meets.

Mayor Busse was accompanied on his inspection trip by a party of Chicago city officials. While in New York they took a trip over the New York Central electrical zone under the guidance of Mr Wilgus, who gave them every opportunity to witness the practical working of the newly installed system. The resignation of Mr. Wilgus as vice-president of the New York Central, which will take effect on October 1, leaves him at liberty to entertain any proposition which Chicago may have to offer.

"It is quite probable that Mr. Wilgus, by reason of his experience here, will be employed to make an engineer's report of the matter should the council decide to have a report made," said Mayor Busse. "It seems to me that this would be desirable in any event, so that we would have something tangible before us."

State Inspection of Meters.

In New York state the new Public Utilities Commission is preparing to take up the work of the state inspector of meters. For years past the state inspector has had his seal placed on all gas meters. After they have been inspected and tested for accuracy by him or his assistants the law makes it a misdemeanor for any person to break the seal. The purpose of the law has been to prevent tampering with the meters by the consumers on the one hand or by representatives of the gas companies on the other.

The case of the electric companies is very different, however, and while the new law will mean work for representatives of the people rather than an increase of work for the employes of the companies, it will place the electric meters used for measuring the amount of electricity supplied for light or power to consumers on the same basis as the gas meters, which has not been the case in the past. No state testing of electric meters has heretofore been in order. When new meters are received from their makers local experts adjust and test the meters until they have them as near perfectly correct as it is possible to make them. Then they are sealed by the company and are installed as the demand for them arises.

The new law makes it obligatory that the representatives of the Public Utilities Commission shall also test these meters and that the seal of the commission shall take the place of the seal of the company. This proposition seems to be entirely satisfactory from the standpoint of the electric companies, as it will operate to remove any doubts in the minds of consumers as to the accuracy of the meters. The companies feel, as the consumers undoubtedly will, that the latter will be better satisfied to know that the meters have been tested by men employed by the state rather than by men employed by the companies, so that the new plan will afford some relief to both the producers and consumers of electric power and heat.

COMMUNICATION.

To Prevent Crystallizing in Gravity Cells.

To the Editor of the Western Electrician.

I have always had considerable trouble with crystallization in my gravity cells, the copper forming on the plate increasing its size until it is almost impossible to renew the cell without breaking the jar. I have made different experiments to eliminate this trouble, and have now found a scheme which I am using in my batteries with the best results. The copper plate lasts longer and the cell stands twice as long at full strength under the same conditions.

Following is the way I set up the cell:

Take an ordinary three-ply copper as used in telegraph work and twist it on the rivet into a rosette shape so it will sit on the bottom of the jar. If the copper is large turn up the ends slightly to fit the jar. Put in about 3 or 3½ pounds of medium-sized copper-sulphate crystals and add water and solution in the usual way. Then allow the cell to stand until the zinc solution separates and comes to the top, when the zinc plate can be put in and the cell connected up. To secure longer life and prevent evaporation or the solution creeping out over the sides of the jar, I add paraffine oil, but common coal-oil will do equally as well.

This style cell lasts as long again and is easier to renew than anything I have tried yet.

W. T. HOLDEMAN.

Hammond, Ind., August 21st.

Progress in High-efficiency Lighting Units.[1]

BY C. C. COLLINS AND A. N. COPE.

In order to secure data for this report the committee sent out circular letters to practically all of the electric-lighting companies in Ohio. Some 65 such letters were sent out, but only 19 replies were received, and some of these replies were so meager as to be of very little value in compiling a report such as the committee had wished. It is very evident that the information asked for was not at hand and possibly not even considered necessary for economical operation. We are unable to account for the lack of interest shown, as the committee feels that this report ought to be representative of the progress made by the state organization and not of a few individually. The members of this committee know of some that are using high-efficiency units, but have reported none, and others that are using them that have not reported at all, so that it is to be hoped that those who have reported are representative of users of high-efficiency units.

The questions asked included the following subjects:

1. Flaming Arc Lamp.—Number in use, make, amperes, volts.
2. Magnetite Lamp.—Number in use.
3. Cooper Hewitt Lamp.—Where used (class of service).
4. Moore Tube (feet of).—Number of installations.
5. Gem Filament Lamp.—Number in use (100 to 250 watt), number in use (50 watt).
6. Tantalum Lamp.—Number in use.
7. Tungsten Lamp.—Number in use.
8. Helion Lamp.—Number in use.
9. Nernst Lamp.—Number glowers in use, number lamps in use.
10. Others not named above.
11. What do you find the average life in hours of each kind of unit used?
12. On what basis do you put the units on your lines? (Sale, with profit or at cost. Free. On rental.)
13. What is your renewal cost per kilowatt-hour? Do you consider it excessive as compared with your 16-candlepower lamps? What is the wattage per candlepower of your 16-candlepower lamps.
14. How do these units affect your revenue?
15. Where do you find these units best adapted?
16. Would you favor a unit more highly efficient than any now known? Where would you use such a unit?
17. Will high-efficiency units be of any aid in meeting the demand for lower rates for current?
18. Will they assist in quieting the public sentiment toward municipal commercial lighting?
19. Have high-efficiency units improved your regulation? What is your regulation at point where units are used?
20. Have you noticed a reduction in incandescent-lamp renewals due to improved regulation?
21. Have high-efficiency units improved your load curve? Give sketch if possible.
22. How do these units please the public?

The committee thinks that high-efficiency units would be far more generally used if the matter were more carefully looked into and such information obtained, under existing conditions, that the heads of the various companies could deal intelligently with such questions that must come up in this day of progress.

It is to be hoped that central stations are taking more interest in securing new business and furthering the use of their product than they have shown in reporting to this committee. If their progress has not been all they could have wished, we hope that by the perusal of this incomplete report they may be able to decide in their minds whether or not they should adopt high-efficiency units.

We know from personal observation that consumers are becoming more liberal from year to year in the use of current, which means an increase of burning hours, or an increased revenue from the same investment.

The committee fears that in some cases high-efficiency units are condemned for high renewal cost when the fault is entirely with the central station's regulation, though they be loath to admit it. Central stations using the 3.1-watt incandescent report low maintenance cost, so that if maintenance costs are high it must be due to poor regulation, which makes it very expensive to operate any type of lamp.

On the data sheet attached the names of the companies are signified by the letters A, B, C, etc., and the answers by each company to the questions can be read horizontally across the sheet. Under the number of each kind of unit used has been put the equivalent kilowatts, also, opposite the name of each company the total kilowatts connected of high-efficiency units is given. At the bottom of the sheet is given the total kilowatts represented by each type of unit. This compilation covers only 10 companies, but we consider it a fair sample of what the majority are doing.

1. Report of a committee read before the Ohio Electric Light Association, held at Toledo, Ohio, August 20, 21, 22, 1907.

Taking up the questions in their order, it will be noted that the flaming arc lamp is used by five of the 19 companies, but its use is very restricted, being equal to only 38 kilowatts. This goes to show that not only must a unit be efficient but also must fill many other requirements.

The magnetite lamp is used by two companies for street lighting. Its adaptability is shown by the satisfaction which it is giving and by extremely low rates secured by cities using it.

The Cooper Hewitt lamp is used by five of the companies, but its use is limited to photograph galleries, printing offices and machine shops.

No Moore tubes are in use.

Twelve companies are using the Gem lamp. It is regretted that three of them, two being among the largest cities in the state, gave no record of the number on their lines. This unit seems to be in very general use. The connected kilowatts of the 11 companies replying being 834, nearly 90 per cent. of which is in lamps of 100 watts or more.

Two companies are using the tantalum lamp. This restricted use is no doubt due to the first cost of the lamp and its failure on alternating current.

One company is using the tungsten lamp, and from its reply to question No. 14 we judge it was found necessary to use this extremely high-efficiency unit to outdo a competitor. The committee understands, however, that this lamp for use on constant potential circuits of 100 volts or more has been found so extremely fragile that its use is practically prohibited. Its cost is also excessive.

No Helion lamps are in use.

The Nernst lamp, like the Gem, is in very general use; 11 companies are using it. The connected kilowatts are 1,334. The average number of glowers per lamp is three, which indicates the demand to be for high-efficiency units of moderate size; also that its use is limited to the sphere of units of less than 250 watts.

The above-named lamps seem to cover all the various high-efficiency units on the market, as no company has reported as having any not named.

The replies to question No. 11 indicate that we may expect a life from the magnetite lamp of 180 hours, the Gem lamp of 500 to 600 hours, the Nernst lamp 600 to 700 hours. One reply of "low" was received, but this was not used in our compilation since the short life obtained is no doubt due to local conditions.

Answers to question No. 12 indicate that the units are generally put on the lines at cost and free renewals given. The Nernst lamps are in some cases loaned, but this is found to run up a very large investment.

The cost of renewals, as indicated by answers to question No. 13, is not very well known. It can only be arrived at by keeping records of installations consisting of one kind of units only, and it is apparent that very few, if any, of the companies have done this. However, taking a sort of average of the replies we may expect under fair conditions a renewal cost of ½ cent on the Gem and Nernst lamps.

This cost is not considered high as compared with the carbon filament lamp.

No less than seven companies are using the 3.5-watt carbon filament lamp, which is due, in a majority of cases, to poor regulation of voltage.

The answers to question No. 14 are indeed satisfactory, every company replying stating that an increase in revenue has been noted after introducing high-efficiency units. The effect on its revenue has been the first question asked by the central station when considering the introduction of these units. It is very evident that business has been secured which could not have been gotten in any other way.

The replies to question No. 15 indicate that the adaptability of the unit is beyond question.

As indicated under question No. 16 a unit more highly efficient than any now known would be welcomed. A number of these replies come from the gas belt where natural gas at extremely low prices is a competitor. One reply contains the modification that the units should be of 50 watts or more. This is hardly consistent with his reply to question No. 14, where he states he has noted a "marked increase."

With only one exception the replies to question No. 17 indicate that these units will assist in meeting the demand for lower rates. It is also generally believed that they will help quiet municipal ownership agitation.

It has been found that an improved regulation is not necessary, although desirable, where these units are used. The replies in regard to regulation are very vague and indicate that sufficient attention is not being given this most important factor.

At the end of the accompanying table are given replies received from four of the largest electric-lighting companies in the United States. Their replies coincide very closely with those from Ohio central stations, except that they have evidently had better success in the introduction of these units. This may be partly due to better conditions, but we think no mistake will be made if the smaller companies follow their lead wherever conditions will permit.

PROGRESS IN HIGH-EFFICIENCY LIGHTING UNITS.

DISCUSSION (IN ABSTRACT).

Numerous questions from members of the association concerning various new lamps brought out some lengthy answers, of which the following is an abstract:

H. O. Dutter of Bucyrus, Ohio, quoted a case in his city where a merchant ran 10 lamps in each show window, putting them on averaging two nights a week; these have been replaced by four tantalum lamps in each window, and these are being used until 10 o'clock every night, paying the central station more money and giving the patron more satisfaction. Both the Gem and tantalum are pleasing people. The result of the 400 installed by this station has been to broaden the peak. The speaker had found the tantalum lamp more successful on a 110-volt direct-current three-wire system for window lighting and more advantageous than incandescent 16 candlepower.

F. W. Willcox of the General Electric Company said that the new units had the advantage that there is no antiquation or writing-off depreciation considered; the lamp renews itself; there is no depreciation of the renewal cost. The Gem lamp costs so little more than the ordinary carbon lamp that the majority of stations can afford to furnish them on the same liberal basis of renewals as the ordinary lamp. The tantalum is a different proposition, as it is a more expensive lamp. Central stations that are furnishing free renewals of ordinary lamps on a rate of two cents per kilowatt-hour can furnish the tantalum for three cents or 2½ cents to cover the additional cost of renewals. A similar course can be pursued with regard to the introduction of tungsten lamps, the renewal cost of which would be still higher than the tantalum. Another plan would be to adopt the practice of the gas companies and charge a fixed maintenance charge. On the tantalum a charge of five cents per month would amply cover it. At present there is no complete data as to the life service of the tantalum lamp. The problem of how best to introduce the new lamps and how to meet conditions as established with the lower efficiency lamps formerly in use is a very interesting one to the central-station manager. In some way or other the central station should maintain the control of the lamp, because the ordinary user does not know how and will not take proper care of the maintenance of his lamps. The service should be kept up to standard by intelligent care on the part of the station. Mr. Willcox stated that the actual number of tantalum lamps sold in this country has been probably 250,000 or 300,000. More could have been sold if supplied faster. The life of the Gem filament lamps has been materially improved the past year as the result of steady and careful work. If possible to produce a Gem filament of an efficiency of two watts per candle, you would have a lamp which, by reason of its other advantages, cost, flexibility and strength, would perhaps be a very serious competitor with the metal-filament, such as the tungsten and the tantalum. Tests made of some series tungsten lamps have shown that the candlepower is practically maintained to the end of the life. The multiple tungsten has a very good life; just how much cannot yet be stated. The life seems to be in the neighborhood of 1,000 hours. Tungsten lamps are produced in similar sizes to the present Gem units. Perhaps the lamps of 100 watts give about 80 candlepower mean horizontal; lamps of 50 watts give about 40 candlepower, mean horizontal; 40 watts, about 32 candlepower mean horizontal. The tungsten has not been as yet listed, but will probably be higher than the tantalum lamp. By using the lamp in the large size the cost will not be so great as in the smaller sizes. It costs pretty nearly as much to make a small candlepower lamp as a large one.

Otto Foell, chief engineer, Nernst Lamp Company, Pittsburg: Viewing the situation from an engineering point, I feel that there is no immediate need for a higher efficiency lamp than the multiple-glower type of Nernst lamp. In the endeavor to secure new business and to meet competition successfully there has been a tendency on the part of the central-station managers all over the country to reduce rates for current, and it is only a question where does the higher efficiency lamp help the central-station manager to check the reduction in rates. Undoubtedly what a customer wants is light; and he wants plenty of it, and not current. On the other hand, he wants a light which he can maintain with advantage to himself, for should the central station maintain the lamps, same must be done on a basis to insure a profit on the business.

Taking, for example, the 40-candlepower 50-watt tungsten lamp which is listed at $1.50, and which may be obtained in large quantities, at, say, $1.10. This lamp, according to the manufacturer's statement, has an average life of 1,000 hours, which is equivalent to a current consumption of 50 kilowatt-hours, that is, the maintenance cost per kilowatt-hour for such a lamp amounts to 2.2 cents, which, in the case of free renewals, must be added to the price of current to insure the same net revenue on the connected load. Two of these lamps are equivalent to the new 110-watt higher efficiency Nernst lamp, which can be maintained, according to the inquiries of your committee, at one-half cent per kilowatt-hour.

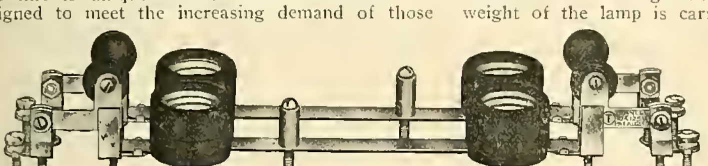
Bringing both types of lamps on the same candlepower basis, and for 1,000 hours' use, you have a renewal cost for the tungsten lamp of 4.4 cents against 0.55 cent for the Nernst lamp, while the current consumption is 100 kilowatts, against 110 kilowatts; that is a slight increase in current consumption against a considerable saving in maintenance. At the present time, however, the tungsten lamp is in its infancy, and personally I do not believe that it can be manufactured commercially now or in the near future. I will admit that by employing the same principles which govern the construction of the 110-watt lamp, lamps of the multiple-glower type may be obtained of still higher efficiency. We are working along these lines, and while I cannot say when such lamps will be perfected, we can hope for them in the near future.

A. N. Cope of the Columbus Public Service Company stated that an important factor in maintenance of the illuminating power of the new lamps is the matter of keeping them clean; they should be as frequently cleaned as the Nernst lamps in order to secure cleanliness of the globes. Many complaints come to him from the customers who are located near the markets of the condition of their globes and glassware. The cost from Nernst trimming, including labor in the laboratory and on the customers' premises, means about 40 per cent. of total cost. The speaker gave results of a careful account of material and time of seven store installations, from January 18th to March 29th, amounting to $78.09, yielding 18,089 kilowatt-hours, or an average of 43.436 cents per kilowatt-hour.

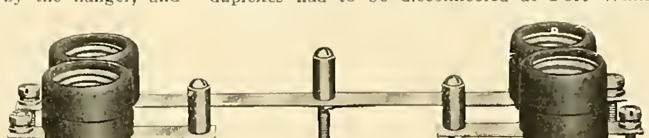
C. H. Davis, Nernst Lamp Company, Chicago: A comparison of the cost of one system which is furnished to the consumer in toto, as in the case of the Nernst lamp complete, should not be made with the cost of the renewable element only of another system. If to the cost of the Gem lamp we add the cost of the necessary shade, shade holder and socket, the investment per kilowatt connected will not be materially less than with the Nernst lamps. If the central station recognized no advantages in the free-lamp policy with reference to the Nernst lamps, they can just as consistently and just as readily require the consumer to purchase that portion of the Nernst equipment which is permanent; that is, the lamp body and the globe, as to require the consumer to purchase the reflector and holder for the Gem lamp. The two systems should thus be placed on a parity before comparisons in cost are made. Again, the central stations desire, of course, to keep their investment in load installation as low as possible in order to secure and hold the business, and it would seem more consistent to compare the investment with the amount of illumination required. On this basis the one-glower and two-glower Nernst lamps cost about the same as the Gem lamps with their necessary equipment, while the larger sizes of Nernst lamps cost materially less, that is, per candlepower of light produced.

A New Line of Panel Circuits and Switch Parts.

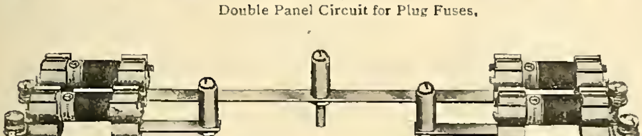
The Trumbull Electric Manufacturing Company of Plainville, Conn., has recently put out a complete new line of panel circuits and switch parts. The line is unique in the market and has been designed to meet the increasing demand of those



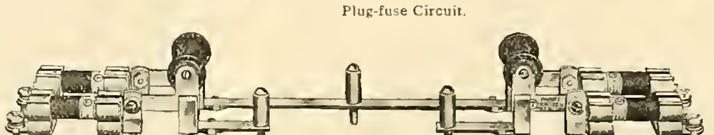
Double Panel Circuit for Plug Fuses.



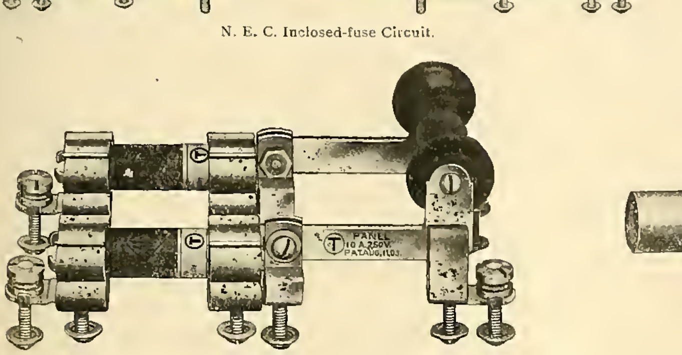
Plug-fuse Circuit.



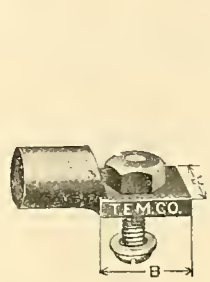
N. E. C. Inclosed-fuse Circuit.



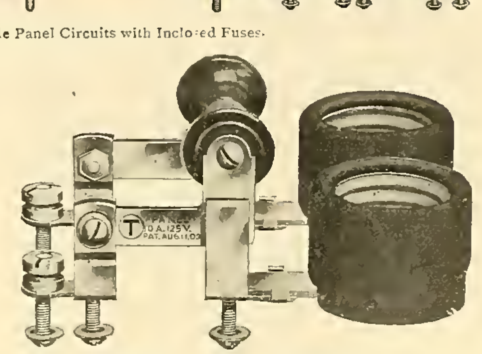
Double Panel Circuits with Inclosed Fuses.



Double-pole Panel Switch with N. E. C. Inclosed Fuses.



Lug.



Double-pole Panel Switch for Plug Fuses.

A NEW LINE OF PANEL CIRCUITS AND SWITCH PARTS.

who wish to purchase their slate or marble separately and arrange the circuits as they desire. Since these fittings are obtainable, one does not have to depend on the factory when an additional circuit or some slight change is needed. The freight rates are much lower on slate than on completed panels, so it may be expected that the saving in transportation charges will be influential in increasing the demand for these panel parts. The provisions for fusing are constructed for both National Electric Code and plug fuses. In addition to any particular complete panel set, bus bars and lugs can be furnished, so that complete unmounted panels can be obtained.

The illustrations on this page show several of the combinations which are listed by the manufacturers. An inspection of these cuts will suggest many convenient uses to which this elastic form of panel construction easily lends itself.

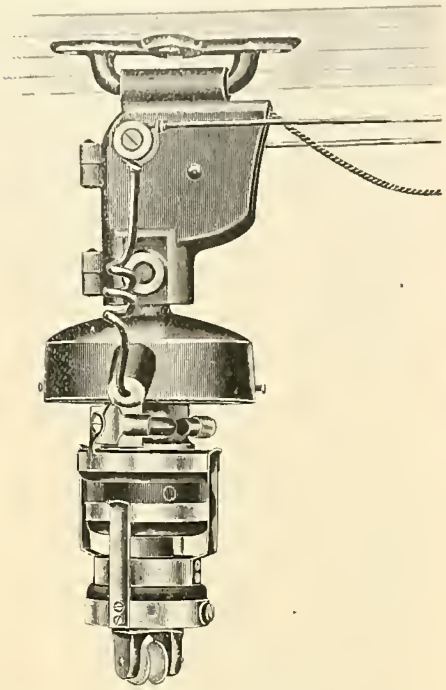
The usefulness of an arc lamp hanger that avoids unsightly hanging and loose wires or the necessity

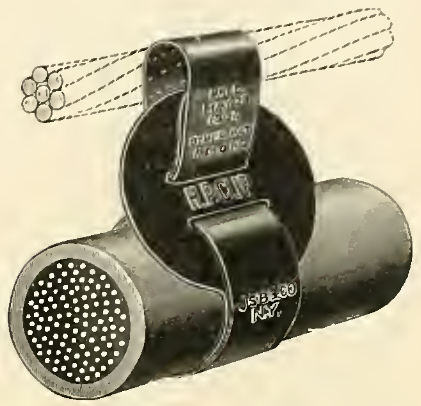


IMPROVED MAYO ARC LAMP HANGER.

of a ladder to reach the lamp for trimming, is self-evident, and the general installation of a device of this kind which will operate positively will be hailed with delight by lamp-trimmers. The improved Mayo automatic hanger, manufactured by the National Sewing Machine Company at Belvidere, Ill., adds as well an ingenious device by which the weight of the lamp is carried by the hanger, and the raising and lowering operations are accomplished by a single pull of the rope. As shown in the accompanying illustration, there is no strain on the rope when the lamp is in place. When lowered the lamp is cut out of circuit so that there is assured perfect protection from live wires during trimming. The contact is made by clips bearing against two rings in the hanger so that a good contact and proper poling of the carbons are secured in whatever position the lamp is pulled into the hanger. The hanger is weatherproof and the insulation is of micanite. There is a carbon pointed switch, and the contacts at the rings are kept clean by the friction of the springs. The hanger measures about six by eight inches and its parts are interchangeable. The manufacturer believes that where this hanger is used, one man can do the work of three.

Rustless Cable Hanger.

The H P rustless cable hanger, for suspending telephone and telegraph cables from messenger wires, is manufactured by James S. Barron & Co., 200-206 West Broadway, New York. It is made of one piece of sheet zinc so that no electrolytic action can take place between separate parts. As the hanger completely encircles the messenger suspension, it cannot jump off. The cable is gripped



RUSTLESS CABLE HANGER.

tightly, preventing slipping. As shown in the illustration, the hanger consists of a zinc strap ending in a circular clip which is slotted.

In installing, after running the cable over temporary supports, as hooks or cable blocks, the hangers are applied from a car drawn along the messenger. The circular end of the hanger is held against the cable and the free end wound around and passed through the lower slot, then around again and through the upper slot, over the suspension wire, and finally the end hooked into the upper slot, with the result shown in the illustration.

A Severe Earth Current.

W. J. Camp, electrical engineer of the Canadian Pacific Railway Telegraphs, reports that recently earth currents were so severe in Canada that all duplexes had to be disconnected at Fort William, Ont., and even then were unable to work the lines single. At times the currents were so large as to set fire to the switchboard, and there was considerable difficulty in controlling the fire, which had broken into small flame.

Notes on Transformer Testing.[1]

By H. W. Tobey.

Generally speaking, it may be said that transformer tests are required for the purpose of determining the chief characteristics of the finished apparatus, thus enabling it to be compared with the original calculations and designs and with the guarantee. They may be classified as follows: Conversion; polarity; resistance; copper loss; core loss and exciting current; regulation; high potential;[2] high voltage;[2] temperature rise.

Conversion.—The most satisfactory method of test is without doubt one employing a standard multiratio transformer and a single voltmeter, provided

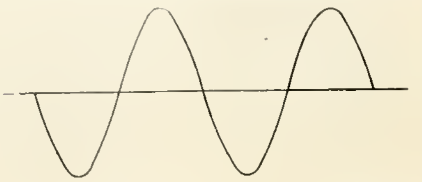


FIG. 1. INFLUENCE OF WAVE FORM UPON CORE-LOSS AND EXCITING CURRENT.

the potential of the source of current supply does not fluctuate. Then, by applying a suitable common voltage to the high-tension side of the transformer under test and the standard the two low-tension voltages may readily be compared and the true ratio obtained.

Where the supply is at all unsteady or where the ratio of the standard varies considerably from that of the transformer under test, the two-voltmeter method is preferable. Accurate results may then be obtained by taking two sets of simultaneous readings, between which the instruments are interchanged to eliminate any dissimilarity between them.

The opposition method is also sometimes used to good advantage. With this, however, care should be used to see that the low-tension voltage of the standard and of the transformer under test are exactly in phase.

As an additional precaution single-phase transformers which are required to operate in parallel on single-phase circuits or delta on three-phase circuits, also delta-connected phases in three-phase transformers should be connected, as they are eventually intended to operate, and a test made for circulating current.

Polarity.—The relative position of primary and secondary leads is ordinarily determined either by direct comparison with a standard transformer or by applying direct current to the high-tension winding, noting the position of positive and negative connections by means of a direct-current voltmeter, then shifting the voltmeter leads to the low-tension winding and noting the voltmeter deflection upon breaking the direct-current circuit. When testing large numbers of small transformers having approximately the same voltage and ratio, the first method is quicker and more satisfactory. For power transformers having as a rule widely differing voltage the second method is usually preferable.

Resistance and Copper Loss.—In the measurement of resistance for the determination of copper loss and total resistance drop the fall of potential method

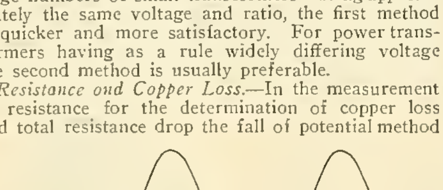

FIG. 2. INFLUENCE OF WAVE FORM UPON CORE-LOSS AND EXCITING CURRENT.

gives in general the most satisfactory results of any of the standard methods. The instruments required are less delicate than the galvanometer used in bridge measurements, may be readily calibrated, and will give accurate results over a wide range.

When measuring resistances of small transformer windings the instruments come to rest very quickly and little time is required for taking the readings. With large transformers, however, unless special precautions are taken, this is seldom true; for even with the terminals of the opposite winding short-circuited on themselves, some seconds, or even several minutes, often elapse before the instruments settle, so to speak, to a final value, and until this settling has stopped, readings will not indicate the true resistance.

Fortunately this condition of affairs may be overcome by forcing through the winding under test a direct current of 10 or 12 times that finally required for the measurement, and after a moment or two dropping it to normal before taking the reading. (Of course during the passage of this increased current the voltmeter should be disconnected and the ammeter short-circuiting switch closed.)

Core Loss and Exciting Current.—The influence of wave form upon core loss and exciting current has already been carefully investigated, and the importance of using a sine-wave source of current supply is well known. It is doubtful, though, if all fully realize how far from a sine wave the electromotive force of some generators really is under actual conditions of test; that is, when supplying core loss to transformers. This may occur, even though the wave form of the generator is entirely satisfactory under normal conditions, from the fact that the wave becomes badly distorted at low power factors which occur when transformers, particularly those designed for low frequencies, are operated on open circuit. The extent to which this distortion may reach and its effect on core loss and exciting current are clearly indicated in the accompanying curves and data which follow:

The curve, Fig. 1, was taken on one of the generators in question while on open circuit. The curve, Fig. 2, was taken on the same machine while furnishing core loss and exciting current to a transformer. It will be noted that both approximate very closely a sine wave. The oscillograph curve shown in Fig. 3 was taken while a generator having a very peaked wave was exciting the same transformer at the same voltage. The resulting core-loss and exciting-current measurements are given as follows:

First case: Sine wave, core loss 1,177 watts, current 33.5 amperes.

Second case: Peaked wave, core loss 924 watts, current 15.4 amperes.

By comparing these sets of readings it will be seen that in changing the source of supply from one, giving very nearly a sine electromotive force

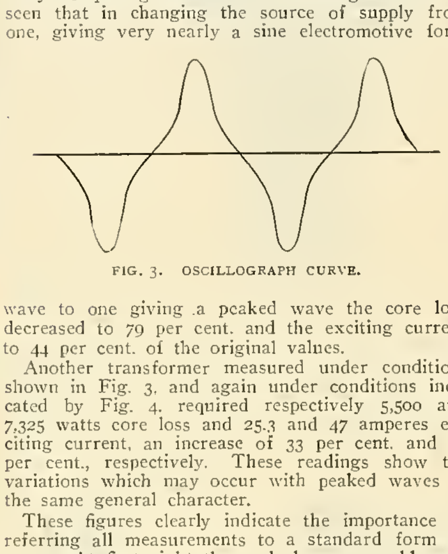

FIG. 3. OSCILLOGRAPH CURVE.

wave to one giving a peaked wave the core loss decreased to 79 per cent. and the exciting current to 44 per cent. of the original values.

Another transformer measured under conditions shown in Fig. 3, and again under conditions indicated by Fig. 4, required respectively 5,500 and 7,325 watts core loss and 25.3 and 47 amperes exciting current, an increase of 33 per cent. and 87 per cent., respectively. These readings show the variations which may occur with peaked waves of the same general character.

These figures clearly indicate the importance of referring all measurements to a standard form of wave. At first sight the peaked wave would seem to have some advantages over the sine wave, owing to the lower core loss and exciting current values which result. After all sides of the question are considered, however, including among other things the effect of wave-shape on insulation strains, etc., a sine-wave electromotive force is undoubtedly the best. And what is equally important, the generator from which the supply is obtained should not only maintain the standard form on open circuit and on non-inductive loads, but also on low power-factor inductive loads, i. e., under the conditions of test.

In the measurement of core loss on three-phase transformers the windings across which the readings are taken should be Y-connected and the opposite windings left open in case they are intended for delta connection. Otherwise the circulating current due to unequal distribution of flux in the core and to the short-circuiting of the odd harmonics will show up as an increase in core loss, thus giving incorrect results. In case the transformer windings on one side are delta connected and for any reason cannot be changed it is preferable to connect both sides in delta before taking the core-loss measurement. The resulting circulating current will then occur in two windings instead of one, and being proportionately less will produce smaller disturbing losses in the copper than if but one winding alone is delta connected.

Regulation.—In general it is now customary to determine the regulation of a transformer by one of the several methods which require impedance measurements with one of the windings short-circuited on itself, this having entirely superseded the old way of measuring the voltage with transformer free and loaded.

Here, too, it is important to employ a generator which will give a sine wave at low power-factor loads, for while it is true that the wave shape does not affect the measurements so seriously as those mentioned under the preceding heading, nevertheless the variation is fairly well marked.

High-potential Test.—If the testing transformer has extremely close inherent regulation, and the charging current under conditions of test is but a small proportion of its normal current capacity it is reasonably safe to rely upon the low-tension voltmeter reading, and to consider that this times the ratio of conversion is an approximate indication of the high-tension voltage. If these conditions do

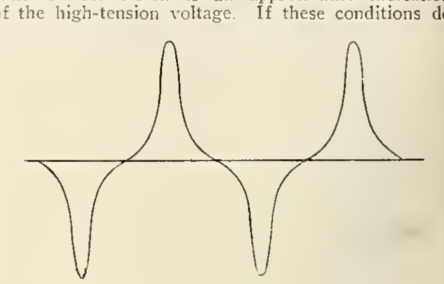

FIG. 4. VARIATION OCCURRING WITH PEAKED WAVE OF THE SAME GENERAL CHARACTER.

not exist the spark-gap method must be relied upon. It should be used, however, with great care.

As the conditions under which the testing outfit operate are changed entirely by the introduction of the transformer under test, it is obviously not right to measure the high-tension voltage by spark-gap before this transformer is connected. On the other hand, if the transformer is connected in, together with the properly adjusted spark-gap, and the voltage is raised until the latter arcs over, high-frequency oscillations almost invariably occur and result in a rise in voltage. The final value of this voltage may be considerably higher than that required, resulting possibly in an uncalled-for breakdown of insulation.

Such a disturbance may be overcome in one of two ways, both of which have been tried with satisfactory results. The first consists of inserting in series with the gap a high resistance,[3] the presence of which prevents the occurrence of a high-frequency disturbance when the spark-gap breaks down. The only precaution necessary in the use of this auxiliary resistance is the calibration of the spark-gap with the resistance in series, as its presence will in general increase the effective value of the gap. In other words, the distance between needle points, as given in the standard Institute table, may need to be decreased by from five to 10 per cent. to obtain correct results.

The other method referred to above consists in making all connections for the high-potential test and placing the spark-gap across the circuit, the gap previously having been set, however, for a

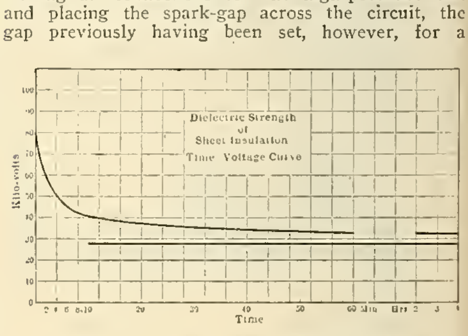

FIG. 5. RELATION BETWEEN TIME AND VOLTAGE.

somewhat lower voltage than that required, two-thirds for example. The voltage is then increased and the low-tension voltmeter reading is noted at the moment the spark-gap breaks. The gap is now disconnected and the electromotive force again raised until the voltmeter reading, in the case cited, is 50 per cent. greater than before. The desired potential is thus obtained with fair accuracy without any disturbance in the circuit.

The importance of using a sine-wave generator for supplying current to the testing transformer is hardly to be questioned. Otherwise it will be extremely difficult to obtain the desired testing strain.

As to varying the voltage of the high-potential transformer, several methods are possible, including the use of a variable resistance, a variable reactance, or changing the excitation of the generator field. The first, except perhaps in the case of low-voltage tests on small apparatus, should not be resorted to, as it has a very disturbing effect on the wave form. The second gives more satisfactory results in this respect and serves very well when the required range is not too great.

A discussion of this branch of the subject would hardly be complete without some reference to the

1 Abstract of a paper presented at the convention of the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 28, 1907. The author is a member of the engineering department of the Stanley-G. I. Company.

2 Both of these are essentially insulation tests. The terms "high potential" and "high voltage" are used arbitrarily to distinguish between a test applied between primary and secondary windings and iron and one applied across terminals of the same winding. The first tests the strength of the insulating barriers and canvas while the second tests the insulation between turns and between layers.

3 For potentials ranging from 100,000 to 200,000 volts, a resistance consisting of a dozen U-shaped glass tubes one-half inch inside diameter and two feet in length will be found satisfactory. These should be mounted in a suitable rack, filled with water and connected in series.

effect which the time of application of the high potential has on the resisting strength of insulation. In other words, if an insulating material will safely withstand 50,000 volts for one minute, what potential will it withstand if the test is continued for five minutes, and what will it resist indefinitely?

This relation between time and voltage is fairly well represented by the curve shown in Fig. 5. This was obtained from a series of tests on sheet insulation, potential from a 60-cycle sine-wave generator being applied to two brass discs arranged on opposite sides of the test piece.

It will be noted that for periods of one minute the sample safely withstood a pressure of 65,000 volts. For five-minute tests it was necessary to lower the pressure to about 70 per cent. of this value, or 46,000 volts; while in order to resist the test indefinitely the applied voltage had again to be lowered to 27,500, or about 40 per cent. of its original value.

These figures can hardly be taken as general, for they change considerably with different kinds of insulation and the resulting curves assume widely varying forms. In most cases the reduction in strength as the length of the test increases is much

FIG. 5. RELATION BETWEEN TIME AND VOLTAGE.

less than indicated above, so that in comparing the instantaneous test and continuous test, for example, the reduction is nearer 50 per cent. or 60 per cent. instead of 70 per cent. as in the sample noted. These figures serve to emphasize, nevertheless, the undesirability of long-continued strains and tend to confirm the advisability of retaining the present one-minute standard.

High-voltage Tests.—The test which determines the strength of insulation between turns, between layers and between leads is equally as important as the "high-potential" test just referred to. If the transformer windings withstand double voltage, or, in the case of lightning transformers, triple voltage, their internal condition is reasonably well assured.

In applying this test it is usually advisable, and in most cases necessary, to use a frequency considerably higher than that for which the transformer was designed; otherwise the exciting current will become so excessive as to make it difficult or even impossible to obtain the desired increase in voltage. In general, satisfactory results are obtained by employing a frequency as much above that for which the apparatus is designed as the test voltage is above normal terminal voltage. With a 60-cycle transformer under consideration, for example, 120-cycle current gives good results for double-voltage tests, while 180 cycles is usually satisfactory for triple voltage. A 180 to 200-cycle generator answers very well therefore in the majority of instances.

Temperature Tests.—Except, perhaps, in the case of special tests on small transformers, or where a single transformer is to be tested, the differential method of applying load for the temperature test or heat run is the most satisfactory and probably the one most universally used. This insures very nearly the conditions of actual operation, enables the work to be carried on with a minimum waste of power and requires a comparatively small amount of auxiliary apparatus. The total losses occurring are in general somewhat in excess of those which would take place if the transformer were normally excited and loaded on a dead resistance, or if it were operating under actual conditions of service, therefore the results are always on the safe side.

The resistance readings taken at intervals during the run for the purpose of temperature determinations should obviously be made with the shortest possible delay in view of the necessary removal of load at such times. It is here therefore that the precaution mentioned under the subject of "Resistance and Copper Loss" is most useful. By observing this and by employing a suitable arrangement of double-throw switches to which the measuring instruments and source of direct-current supply may be permanently connected the time required to take a resistance reading is reduced to a minimum.

General.—The order in which tests should be made depends more or less upon local conditions, so that no fixed rule can be given, nor, in fact, is one necessary. The general order in which the tests have here been described is perhaps as good as any. The question of instruments with which to carry on the various tests has not been touched upon, for this forms a complete subject in itself.

Assistant Examiner for Patent Office.

The United States Civil Service Commission announces an examination on October 16-17, 1907, at a number of cities to secure eligibles from which to fill vacancies as they may occur in the position of assistant examiner in the Patent Office at an entrance salary of $1,200 per annum.

As the number of eligibles for this position has always been insufficient to meet the needs of the service, qualified persons are urged to enter this examination. For several years past practically all who have passed the examination for this position have been offered appointment.

The examination will consist of the following subjects: Physics, embracing the requirements of a general college course, chemistry, inorganic and organic, quantitative and qualitative analysis; mathematics up to differential calculus, the general field of mechanics, mechanic arts, industrial arts and processes, and applied chemistry; mechanical drawings and French or German. Applicants should at once apply either to the United States Civil Service Commission, Washington, D. C., or to the secretary of the board of examiners at any of the usual cities for application form 1312.

Commutating-pole Direct-current Railway Motors.[1]

By E. H. Anderson.

In order to appreciate the development and reasons for the existence of a commutating pole railway motor, it is well to discuss in some degree some other developments. In the beginning, railway-motor designers had many difficulties to contend with. The question of gearing was possibly foremost, whether it should be single or double reduction, or possibly gearless. All these were tried with more or less success. Possibly insulation is next in order, various methods having been tried. The conductors have been covered with a variety of materials, but double or triple cotton-covered insulation has practically become standard. The present method of lubricating the bearings with oil has resulted from a process of elimination, many forms of grease-cups, oil-cups, wicks, etc., having been tried; in fact, the preferred lubrication at one time was grease.

During this period of development the armature was changed from a smooth to a slotted core, and much thought was given to the size of commutator, number of segments, turns per coil, etc., in the effort to produce successful operation of the commutator. Some means had thus to be adopted for radically improving commutation, and the following deals more particularly with this subject:

Armature Forces.—The armature in its simplest

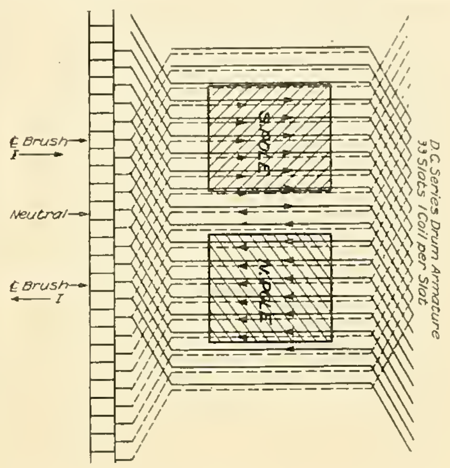

FIG. 1.

conception is a drum, divided into four sections for four poles; under a north pole is a broad distributed sheet of current running parallel to the shaft; under a south pole is also a broad distributed sheet of current, but in reverse direction. Fig. 1 is a diagrammatic representation of a direct-current series drum armature having 33 slots with one coil per slot.

This distributed armature current produces a magnetizing force which changes the distribution of the main flux in the pole faces, as shown in Fig. 2. It will be seen that in the center of the pole there is no distributing effect, but in the center between poles there is the maximum magnetizing effect from the armature. This is where the conductors are commutated by the brush and the direction of the current reversed in passing from the zone of one pole to the zone of the next.

The magnetizing effect of the armature, being a maximum midway between poles, produces a flux through the air space to the frame. The conductors in motion cut this flux, producing a voltage in the coil to be commutated.

The combined result of armature and field-magnetizing effect is to cause a flux to leak from the pole tip over into the armature just where the conductors are being commutated.

The two leakage fluxes are alike and add to produce voltage in the coil which is being commutated. Thus there is a potential between commutator bars, and when these are short-circuited by the brush, a local current is caused to flow in the coil under commutation. This local current adds to the line current already there. Any conductor carrying current has lines of force interlinked about itself, caused by the current in the conductor. The conductors, imbedded in and surrounded on three sides by iron, have a good opportunity of surrounding themselves with a lot of leakage flux. The interlinkage of leakage flux is similar to the inertia in mechanics.

The combined current (line and local) has still greater interlinkage of leakage lines and becomes more difficult to reverse. The reversing has been done heretofore by the increasing resistance of contact between the brush and the commutator bar as the latter is passing out under the brush, the rate of change of current ever increasing. This causes the reactance or kicking voltage to become higher and higher. As the bar leaves the brush the change in current in the coil becomes so rapid that an appreciable voltage is induced and arcs through the air from the bar to the brush, or vice

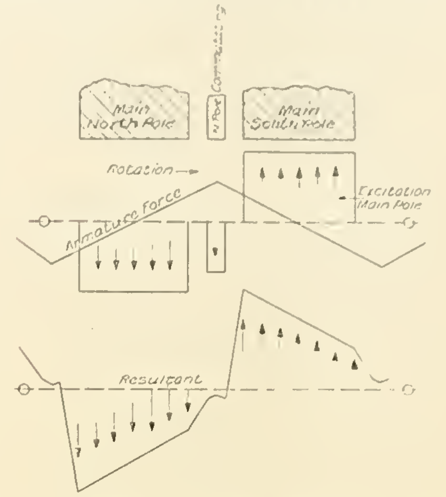

FIG. 2. ARMATURE FORCES.

versa, thus producing what is commonly known as sparking.

The object is, then, to remove the sparking by counteracting one, or all, of its causes. Should we place midway between the main poles another coil, having the same magnetizing power as the armature, but so connected as to magnetize in the reverse direction to the armature there would be nothing to cause a leakage flux from the armature to the frame. Then again, should we further excite this coil so as to overcome and balance the combined effect of armature and field forces, commonly known as distortion and leakage of the main flux from the pole tip, we would annul this troublesome cause of sparking. After the above two effects are taken care of, there remains a force necessary to produce a potential sufficient to reverse the current in the armature coil.

In order to produce this potential there must be such a density of flux as will generate this required voltage by the conductors cutting same in revolving. The width of such magnetic density should be sufficient to embrace the conductors commutated by the brush when running in either direction or rotation.

The commutating voltage produced by the flux of the commutating pole is the accelerating force required to change the direction of current in the armature coils one by one as they come under the brush. It must be sufficient to accomplish this in the time that the coil, being connected to two

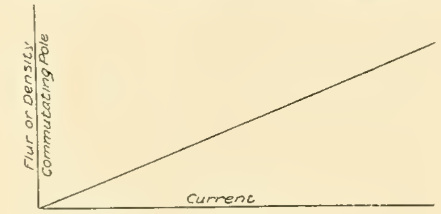

FIG. 3. RELATION BETWEEN COMMUTING-POLE DENSITY AND CURRENT.

adjacent commutator bars, is under the brush. When the commutator bar leaves the brush, the current is already reversed, flowing in proper direction, and is of the proper amount, so there is no tendency to spark. Commutation may then be said to be perfect.

The next question is: Can the action be automatic for varying current as well as speed? The commutating pole may be excited by the main current of the motor, being connected permanently in series with the armature. The commutating-pole flux will then vary almost directly as the current, which is the desired result. When the current is half, the commutating-pole flux is half, and the commutating voltage corresponding thereto. Thus the action is entirely automatic for variation in current or speed, or both.

Fig. 3 shows that the relation between commutating-pole density and current should be a straight line, rising and falling directly with the current.

It is well understood that an absolutely straight line between current and density cannot be obtained when a more or less saturated iron circuit carries the flux, but it can be approached suffi-

1. Abstract of a paper presented at the convention of the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 27, 1907. The author is a designing engineer with the General Electric Company.

ciently close for all practical purposes by careful design and experience in these matters. In a series motor the density of the whole iron circuit increases as the load comes on, and there is an increased stability in commutation which serves to offset, partly, if not entirely, the lack of commutating-pole density on high load. The combined effect is to produce perfect commutation at all loads.

Since the commutation is automatically taken care of for variations in speed and current, it is possible to change the voltage impressed on the motor through quite a range without sparking. This is thoroughly borne out by motors of 50 to 250 horsepower recently constructed in this country.

The only limitations in raising the voltage are:

1. Armature speed and strength of binding wire.
2. Volts between bars.
3. Insulation.

This brings us naturally to the question: What effect will this commutating pole have on designs for voltages higher than are now general for railway service?

Railway-motor commutators, before being connected to the armature winding, are tested from bar to bar with 400 to 500 volts, alternating current, which means a maximum of 40 per cent. more, so that actual jumping of current from bar to bar on a clean commutator would not occur at less than 500 volts per segment. An ordinary commutator of 111 segments and four poles would, under these conditions, be good for 13,000 volts between brushes. The actual jumping of current across side micas of a clean commutator is not the limiting condition.

Our limiting condition is the voltage per bar which will maintain an arc already established. The allowable voltage per segment is largely dependent upon the condition of the commutator. The condition of commutator depends upon the deteriorating tendencies, such as sparking and other causes, like poor carbon brushes, hard side micas, etc.

If the sparking be eliminated, the etching of the commutator bars is largely reduced. The carbon brushes are required to carry only the line current, instead of the line and a large amount of local current; therefore the brushes are not disintegrated so rapidly. The carbon brush has less mica to wear off, because the bars are not burned away. The result is that the carbon brushes work better, and the commutator stays in a very much better condition. The conclusion from the above is that much higher average volts per segment may be used with commutating-pole motors than with motors not having commutating poles.

The usual non-commutating-pole railway motor, 40 to 50 horsepower, has a commutator about 9.5 inches in diameter, with 111 to 125 segments. The average potential between segments is approximately 18 volts. Large motors, operating on 650 volts normal, have 155 to 165 segments, and the average potential between segments is approximately 17 volts. If the average volts between segments on commutating-pole motors be assumed as 24, and the number of commutator bars per inch of circumference as 5, we have the following possible voltages on various sizes of motors and commutator diameters:

Horsepower	Diameter of Commutator.	Maximum Volts Motor.
40	9	850
75	11	1,040
100	13	1,230
150	14.5	1,370
200	16	1,510
250	18	1,700

The above may be said to apply only as far as tendencies are concerned. Not all these various voltages would be practical. It would be better, for various reasons, to adopt 1,200 volts as the higher standard.

The propositions requiring higher potentials than 600 volts, are usually 30 to 50-ton cars with speeds of 40 to 60 miles per hour. These call for a motor of 75 horsepower or larger, so the sizes naturally fall where 1,200 volts can be made with reasonable cost.

The commutating-pole motor, on 600 volts, makes possible commutation and general operation in service many times better than that of the non-commutating-pole motor. On 1,200 volts the commutation is decidedly better than with a non-commutating-pole-type motor on 600 volts.

The 1,200-volt motor requires proportionally more insulation than the present 600-volt motor. This extra insulation requires more diameter and more external dimension.

Theoretical Possibilities of Voltage.—We have the possibility of 1,200 volts per motor, the motor having four poles. Should the motor be bipolar and the speeds high enough to make the design possible we may have 2,500 volts per motor. Then again, if there should be two windings on one core, a commutator on each, and these windings connected in series, we have the possibility of a 5,000-volt motor. Then again, should we have a double-track railway and the rail neutral we might have 10,000 volt direct current between the two trolley wires.

It will be appreciated that more voltage means more insulation, more space and more cost. It will also be seen that the control, car lighting and operation of auxiliary apparatus require special consideration.

Service Capacity.—The non-commutating pole motor has inherently a higher iron density, which serves as a compensating feature, improving commutation. The commutator pole compensates for armature reaction and takes care of troubles due to lack of compensating features; a lower iron density may therefore be utilized and lower iron losses obtained.

The absence of sparking makes the commutating losses very much less. The rating on the hourly basis may not be much greater than with the non-commutating pole motor. On account of core loss and commutator loss being considerably less, and these prominent features in heating, the commutating-pole motor has naturally a higher continuous rating; it is not only capable of taking large fluctuations of voltage and current, but will have a greater all-day service capacity. This latter feature becomes more pronounced as the distance between stops is greater.

There are several ways of making use of higher direct-current potentials. The most prominent of these are the following:

1. (a) City service, 600-volt trolley.
   Maximum speed 25 to 30 miles per hour.
   Stops and schedules incident to city service.
   (b) Interurban service, 1,200-volt trolley.
   Maximum speed 50 to 60 miles per hour.
   Few stops and high schedules.

The motors would be wound and insulated for 1,200 volts.

Two motors would be connected in multiple, and the two groups of a four-motor equipment handled in series and in parallel.

2. (a) City service, 600-volt trolley.
   Maximum speed 25 to 30 miles per hour.
   Stops and schedules incident to city service.
   (b) Suburban service, 600-volt trolley.
   Maximum speed 30 to 60 miles per hour.
   Stops and schedules incident to suburban business.
   (c) Interurban service, 1,200-volt trolley.
   Maximum speed 50 to 60 miles per hour.
   Few stops and high-schedule speed.

The motors would be wound for 600 volts with a relatively low armature speed and insulated for 1,200 volts.

On a 600-volt trolley two motors are connected in multiple, and the two groups handled in series and parallel.

On a 1,200-volt trolley, two motors are connected in series, and the two groups of four-motor equipment handled in series and parallel.

The armature speed and commutating features should be so designed that if one wheel slips and one motor has 1,200 volts or so across its terminal, its armature speed will be reasonable and the commutation good.

Interurban cars with four axles and four motors usually accelerate at 1 to 1.5 miles per hour per second: this requires about 100 to 150 pounds per ton, which is 5 to 7.5 per cent. coefficient of traction. These are low coefficient values for interurban roads and are seldom met with; however, should slipping occur the motor design should be such that no damage to equipment will result. In the city the dirty street may give a low condition of traction, but under these conditions the motors may be used in multiple or operated as any four-motor equipment is now handled.

Advantages of Commutating-pole Railway Motors as Compared with Non-commutating Pole Type.

1. Sparkless commutation even on heavy overloads.
2. Flashing at commutator largely reduced and probably eliminated.
3. Less wear on commutator.
4. Cleaner and safer motor because of reduced carbon and copper dust from brushes and commutator.
5. Marked reduction in heating of commutator.
6. Great current density in brushes.
7. Increased life of brushes.
8. Increased efficiency and free running capacity because of lower core and commutator losses.
9. Possibility of successfully using higher voltages.
10. Greater facility in design of large motors, especially as regards commutation.
11. Possibility of increasing service capacity of motors by blowing.

Wireless Service Aids Central American Fruit Plantations

The United Fruit Company, which operates fruit steamers from its plantations in Central America and the West Indies to United States ports, having its corporation headquarters in Boston, has received a license from the United States War Department to establish a wireless telegraph station at Point San Antonio on the extreme westerly end of Cuba. The company has about 100 vessels in its service and the perishable nature of its cargoes makes communication with the company officials exceedingly desirable while at sea. The company has wireless stations already along the Gulf of Mexico and Caribbean Sea. A relay was desired at the Cuban point named.

Indiana Telephone Items.

The Home Telephone Company of Goshen has just contracted for $35,000 worth of improvements, including a new switchboard. A few other contracts are yet to be awarded.

A question of who shall pay the cost where it becomes necessary to remove wires in order to permit the moving of a house across the street or public highway has been raised in Indiana. The usual custom where it is desired to move a building through the path of telephone wires, is for the mover to pay the expense and for the telephone company to move its wires and poles. Where the mover is not financially responsible, it is customary to estimate the expense of changing the wires and require the mover to pay it in advance, or give the company an indemnifying bond covering any expense or loss which the company may suffer. House movers are objecting to this custom, and the matter is likely to be settled by the courts.

The executive committee of the Indiana Independent Telephone Association has arranged for the beginning of district meetings during the month of September. The question of the association's attitude toward the consolidation of the Independent and the Bell exchanges in certain localities, having been settled at the last annual meeting of the association, the questions to be discussed and considered during the coming district meetings will be that of economical operating, construction and maintenance of telephone plants.

The Central Union and American Telephone and Telegraph companies operating in this state have sent out notices that the discounts that have been allowed large customers of the toll lines will be discontinued, on account of the large increase in the cost of labor, materials and other expenses.

The Madison Telephone Company of Madison is erecting a new building and is preparing to install a new system complete. It has decided to discontinue a sub-licensee contract with the Bell company and to return the transmitters and receivers. It is in the market for a complete Independent outfit of its own. S.

New England Telephone News

The American Telephone and Telegraph Company has decided to change the monthly statement of output which has been a feature of its publicity department for about 25 years, and present hereafter a summary that will show the amount of gain each month in the number of stations.

Arlington, Mass., has opened a new and up-to-date telephone exchange. The office is in a fireproof brick structure erected by the New England Telephone and Telegraph Company in a central location in the town and is equipped to operate 1,500 telephones.

There exists for Boston and vicinity an organization called the Suburban Telephone Reform Association. Through its secretary, Stoughton Bell, the association has requested the State Highway Commission, which exercises supervision over the telephone business in the state in certain particulars that have been defined by the statutes, to consider five specified matters looking to a more satisfactory service. The methods of the association are likely to secure important concessions, because it is prepared to prove its case whenever it submits its desires to a competent tribunal. B.

Telephone News from the Northwest.

The Great Western Telephone Company seeks a franchise at Pierre, S. D., for a competing exchange. The Dakota Central Telephone Company is already in the field.

The Central Telephone Company of Carlos, Minn., has been incorporated with $25,000 capital stock.

The Independent Telephone Company has been incorporated at Lexington, Neb., with a capitalization of $12,500. C. F. Wiggins is interested.

The University Place (Neb.) Telephone Company has let the contract to the Lincoln Telephone Company for the construction of a $25,000 plant. Work will be started at once.

An underground telephone system is being installed at Pomeroy, Iowa. R.

GENERAL TELEPHONE NEWS.

The Rocky Mountain Bell Telephone Company has gone into court to restrain a number of labor organizations and individuals of Livingston, Mont., from conducting a boycott or in any manner interfering with its business. The entire system has been placed on the "unfair" list.

The San Francisco Home Telephone Company is making rapid headway in the laying of its underground conduits throughout the down-town business district. Two exchanges will be erected at present and plans have been prepared for five exchanges to cover the entire city. A cable will be laid across the bay to Oakland, and it is proposed to establish several stations for the receipt and sending of interurban telephone messages before the central offices in San Francisco are ready for operation.

CORRESPONDENCE.

Continental Europe.

Paris, August 13. The French government decided some time ago to assume control of all the radio-telegraphic operations which are to take place in this country in the future, and will henceforth allow no such stations to be erected by private companies. This is in line with the policy which has been adopted as regards the telephone and telegraph service, which are under the control of the state. Although this may somewhat hinder the development of radio-telegraphy in France, it is considered essential in time of war that all such operations should be in the hands of the state. A more recent decree, which appeared not long since, relates to the character of the stations which are to be erected on the coast or inland. Such posts are divided into four classes: First, coast stations or posts located in the interior of the country for the commercial service; second, coast stations specially used for the navy department; third, special military posts for the land army; fourth, lighthouses which are equipped with the apparatus. These systems in general are to be controlled by the departments of war, navy and public works. That the government expects to take up the question of radio-telegraphic stations on a somewhat larger scale than at present is seen by the fact that a special commission has been appointed to act with the public works department in order to examine the question and find the best technical conditions for operating the stations and also to take measures for making a series of experiments.

An international exposition of considerable importance will be held at Brussels in 1910 under the patronage of King Leopold and it is to rank among the great expositions of recent years.

Among the new hydro-electric plants which it is proposed to erect in Spain may be mentioned a large plant in the province of Seville. The plant will be about 75 miles distant from Seville and is to be located on the Carchado River, which will give a considerable amount of power. In the station will be erected a number of turbine-alternator groups of 1,500 horsepower each. These machines are of the three-phase type and operate at 5,000 volts. A bank of transformers will provide a voltage of 50,000 volts for the power line.

The Royal Academy of Sciences of Turin has lately published the conditions of the prize which Senator Vallauri founded in his recent legacy. Five thousand six hundred dollars is to be awarded to the Italian or foreign scientist who publishes the most important and best-known work in the domain of physical science within the period lying between June 1, 1907, and December 31, 1910. Manuscript works will not be considered in the present case.

According to recent figures it appears that the copper mines of Japan are now yielding an output of 40,000 tons annually. This places them in line with the mines of the United States, Mexico and Spain. It is to be noticed that Japan will be a competitor in the foreign market, seeing that it is able to undersell the other countries. This is brought out by the following case which I may cite as an example: In the Hamburg market American copper was quoted at 2,820 francs per ton not long since, while Japanese copper delivered at the spot was quoted at 2,700 francs. A. DE C.

Great Britain.

London, August 17.—The annual return relating to the working of the Pacific cable is again a somewhat sorry affair, there being a deficit of nearly $270,000. This amount will have to be provided on certain arranged proportions by what are called the contributing governments, viz., Great Britain, Canada, Australia and New Zealand. The biggest share falls to Australia; Canada and Great Britain pay equal proportions and New Zealand makes the smallest contribution. Minus interest and sinking fund charges there was a credit balance of $120,000. The revenue showed a fairly substantial increase, but it was due to an abnormal cause in the main, viz., the breakdown for several months of the eastern extension, Australasia and China Telegraph Company's cable between Australia and New Zealand for nearly two months. The total traffic receipts amounted to $582,500, representing 96,783 messages, totaling 1,126,940 words.

A company has been formed called the Calcium Carbide Factories, Ltd., for the purpose of building a factory in Yorkshire on the site of the power station of the Yorkshire Electric Power Company, with which it will work in conjunction. The idea is that the new works will take power from the electric company between a minimum and maximum of 250 horsepower and 2,500 horsepower, respectively, and so help to maintain a steady output from the power house. In other words, the generating station will be at liberty to supply just as much energy within these limits as the other demands will permit, a valuable position for any power station.

The Swansea municipal telephone service has been handed over to the National Telephone Company and the sole survivors of the municipal telephone idea are Hull and Portsmouth. In this connection may be mentioned the decision of the National Telephone Company in concert with the postmaster general to abolish the unlimited service rate in the provinces and to establish universally the message rate system. Up and down the country great opposition has been offered to this by chambers of commerce and big merchants on the ground and it is not disputed that their telephone charges for the same number of calls that they now make on the average per annum will be just about doubled. Instead of an unlimited service for $85 per annum the charge is to be $25, for which a subscriber is entitled to 500 calls. For the next 1,000 calls the charge will be four cents per call; above 1,000 calls the charge will be three cents, then two cents. At a certain point to prevent overloading of the subscriber's line and presumably to induce him to have another instrument the charge is again four cents per call. A few simple calculations will show that an average large business house will very soon reach a number of calls which will increase the annual bill to considerably beyond $85 (the present unlimited service rate); hence this inevitable outburst, which is natural. Of course the main object of the change is to encourage and develop the small user, who, although a very large potential source of profit on any telephone undertaking, has hitherto been sadly neglected in Great Britain.

A Franco-British exhibition is to be held in London from May till October next year. I notice that the Institution of Electrical Engineers is giving its support to the engineering section. There is also a tacit understanding that a representative electrical exhibition will be held in Manchester in the autumn of next year, and if this is so it rather has the appearance that the two exhibitions will be incompatible with one another. Once it is definitely decided to hold the Manchester exhibition it may be taken for granted that there will not be a great response to the invitation of the Institution of Electrical Engineers to exhibit at the Franco-British.

Railway fares in London and tramway and omnibus fares in and out of London continue to call for much attention. Just recently many half-yearly meetings have been held at which the subject has been the one topic upon which the shareholders have been addressed. I have already mentioned the fact that a sort of standing committee has been formed of the various transport authorities in London, and there are strong hopes that some sensible arrangement will be come to to prevent the present absurd cutting of fares. So far as the railways are concerned, electrical working has proved little, if any, cheaper than steam working, and yet the fares have had to be reduced by a very large percentage. The common view now taken by railway, tramway and omnibus managers is that the public should be imbued with the spirit that quicker and more comfortable traveling must be paid more for—not less—presumably on the maxim that time is money. One real grievance stands out, however. The companies have had it put upon them by Parliament to run workmen's trains at certain fares. These fares, which are unremunerative, cannot be altered. Consequently the whole brunt of the increase will fall upon those who have the good or bad fortune to travel at other hours than those prescribed by the cheap trains acts.

The accounts of the Glasgow municipal electricity undertaking are always interesting and those just issued for the year ended May 31, 1907, are no less so than usual. The total capital expenditure upon the undertaking (which, by the way, is quite distinct from the tramway undertaking) now stands at $8,300,000. There are 15,500 consumers connected and they took 24,677,993 units, an increase of about 24 per cent. over the figure for the previous year. The motors connected number 3,302, the output being 11,954 horsepower. Nearly 10,000,000 units were sold for power purposes. After providing for interest, sinking fund and depreciation there is a balance of $15,000, and this sum has been added to the reserve fund. The gross revenue amounted to $1,225,000, an increase of $150,000. G.

New England.

Boston, August 24.—Stone & Webster, railway engineers, builders and owners of many important street traction properties over the country, have purchased a building at 147 Milk Street, this city, and will have the entire structure refitted for their own occupancy.

The telegraphers' strike has not seriously incommoded the business interests of Boston, for quite a number of operators kept at work here, and the Western Union and Postal companies have both claimed to be handling messages easily.

Moody Boynton, inventor of what he terms the bicycle railway system, has been trying to finance his project for a road from Brookton to Boston since his charter was reissued, and requires, it is said, $2,000,000 for the purpose.

The Yetman Typewriter Transmitter Company, it is announced, has purchased an idle factory in North Adams, this state, and will occupy it shortly, giving employment to 200 hands.

The Massachusetts Railroad Commission has received a petition asking for approval of the construction of a new electric railway from Marlboro, Mass., to connect for Boston via Waltham, and run through Weston, Wayland, Sudbury and Maynard. Atherton W. Rogers heads the directors of the new company. B.

New York.

New York City, August 24.—W. J. K. Kenny, a receiver for the New York Electrical Workers Union, has presented a report on the condition of affairs and declares that "thousands of dollars have been taken by certain officers and members of the union in disregard of the laws of the state." No system whatever was employed, it is said, in keeping up the books of the union or in the establishment of a duplicate set. The treasurer has disappeared and so have the books, so it is a pretty difficult matter to close up the union. A meeting of the union is to be called for the second Wednesday in September for the election of a new set of directors and other officers.

The new high-pressure salt-water fire service which is being installed in the city to prevent the great waste of water from the commercial mains and which will be maintained at a pressure of approximately 250 pounds is now nearing completion, and already bids have been received for furnishing the requisite power to the stations in Manhattan as well as in Brooklyn. It has been decided to give the contract to the Edison companies, the New York Edison Company in Manhattan and the Edison Electric Illuminating Company in Brooklyn, they being the only companies which have the proper facilities for supplying the power. The illuminating company bid $3,850 per month and 1½ cents per kilowatt-hour for electricity. After the failure of the municipal plant which lighted the Williamsburgh Bridge and which lighting has been turned over to the New York Edison, the city has been more reticent as to the matter of municipal operation.

The Public Service Commission in the Second district announced today that it had denied the application of the Newburg Light, Heat and Power Company for leave to increase its capital stock from $500,000 to $750,000.

Preparatory to taking up the question of railroad car service and demurrage charges the Public Service Commission in the Second district is requiring all steam and street railroads in its district to furnish to the commission information of its schedules, rates, rules and regulations, distribution of rolling stock, amount of freight handled and the number and quality of its equipment, so that a study may be made and if possible a remedy found for the delay in handling coal and other commodities and tending to greatly assist in improving the general service.

An order has been adopted by the Public Service Commission and is to be served on all electric-lighting companies which are within its territory. The order requires the companies to furnish copies of all documents relative to incorporation, legislative grants, consolidation or merger agreements, franchise rights, mortgages, leases, deeds, contracts, etc., and to furnish a detailed description and location of all property owned, together with a map showing all pipes, conduits and other structures maintained in the streets. E. H. S.

Indiana.

Indianapolis, August 24.—General Manager Harry Dickey of the Winona Interurban Company announces that a temporary power plant will be installed at Akron, so that cars can be run from Peru to Fulton County in a short time. The work of distributing ties on this line is progressing rapidly. At one point the company is up against an expensive proposition in the nature of a sink-hole which gave no indication of trouble until recently, when it swallowed a $2,500 concrete bridge. There is no way to rescue the old arch, and a new one will have to be built.

The first car was run over the St. Joe Valley Railroad into Angolia on the 21st inst. The car came into the Wayne Street crossing, where it was met by President Bucklen, Mayor Carver and a large crowd of waiting people.

Perry A. Randall, president of the Fort Wayne and South Bend Traction Company, has arranged with the American Trust Company of Chicago, as trustee, to finance his enterprise.

The City Council of Richmond has given the McGowan syndicate two weeks in which to accept a franchise providing for transfers between interurban and local cars, or cease using the streets for operating through interurban cars. In defense of this action the companies have joined in a petition to the Wayne County Circuit Court for an injunction against the council's enforcement of the ordinance. The companies are preparing to establish freight stations on the east and the west sides of the city, and propose to transfer freight by drays in case the courts decide that they have no right to operate freight cars upon the streets of Richmond.

The inspectors sent out under authority of the Indiana Railway Commission to inspect railroad tracks, devices, crossings, bridges, stations, equipments, etc., of both steam and traction lines, are making lengthy reports to the commission, advising a large number of changes and improvements in order to make travel more safe and also lessen the hazard of railroad employes. The commission immediately sends notices that the improvements recommended by the commission must be made at once.

The Central Station Engineering Company of Frankfort has incorporated with a capital of $25,000. It proposes to do a general construction business, making a specialty of constructing and equipping central-station plants with water, heat, light, power, etc.

The $200,000 plant of the Indiana Creosoting Company in Bloomington has been put in operation. Twenty-five thousand cross-ties, and many telegraph, telephone, trolley poles and bridge timbers are now on hand to be treated. The company has a complete electric-car system covering its 10 acres of ground, to carry its timbers into and out of the plant. The plant is the third of the kind to be established in this state, the others being at Evansville and Shirley.

The Moore Fare Register Company of Indianapolis, recently incorporated, will establish and equip a plant for the manufacture of fare registers and other supplies for interurban and street railroads. The directors are C. L. Davis, Albert Deprez and Enos Porter. S. S.

Ohio.

Toledo, August 24.—Announcement is made that hereafter all purchasing for the Lake Shore Electric Railway Company will be done in the office of the general manager at Norwalk, Ohio, instead of at Cleveland as heretofore. All purchases are to be made over the signature of F. J. Stout.

The People's Telephone Company at Wharton, Ohio have adopted a plan of giving daily weather reports to their farm patrons. At 10:30 each morning a weather report ring is given and the report read from the central office.

About $25,000 worth of electrical work was recently awarded to the Erner & Hopkins Company of Columbus by the Hocking Valley Railroad at Logan. M. A. Pixley will be in charge. The work will not be commenced for some time, as the various buildings are not yet complete.

After a long and vigorous fight between those in favor of a second telephone system for Napoleon and Henry County and those desiring only the Home telephone, the Home telephone people won out before the council, which refused to grant a franchise to another telephone company. The Home company has agreed to take over the old mutual lines at a reasonable figure.

A new interurban electric line is being planned to extend between Norwalk and Sandusky, Ohio. The venture is being projected by Sherman Culp, vice-president of the Sandusky, Norwalk and Mansfield Railway Company, with a party of eastern capitalists.

To avoid all misunderstandings as to responsibility the Lake Shore Electric Railway Company is installing the Egry dispatching machine in all offices and in the booths where orders are received by conductors. The dispatcher gives the order by telephone, the conductor writes it down, turns the crank and has a copy for himself, one for the motorman and one left in the machine for permanent record.

A 16-mile addition to the Sandusky, Fremont and Southern Electric will be built from Fremont to Tiffin, Ohio. The estimated cost of construction is $25,000 per mile.

A large car barn and repair shop will be erected at Dayton, Ohio, by the People's Railway Company on a new site just purchased. The present car barns will be tore down and a power house erected on the ground.

The Valley Transit and Power Company was recently incorporated at Columbus, Ohio, with a capital stock of $100,000, for the stated purpose of building a line from Canton to Columbus. It has been intimated that the real purpose is to close the gap between New Philadelphia and Coshocton, giving direct electric service between Cleveland and the capital city. H. L. S.

Illinois.

Peoria, August 24.—The City Council has ordered the Western Union Telegraph Company to put all its wires underground for a mile and a half on Washington Street as well as the wires to the Weather Bureau, a distance of more than two miles.

General Manager Fischer of the Illinois Traction Company, who was a visitor to the city this week, said that as soon as the schedule could be arranged limited trains would be put on between here and Bloomington.

The Nernst Lamp Company has established a branch office here. A store has been secured on Main Street and fitted up to show the various types of lamps sold by the company. Mr. Soldinger who is in charge, is pleased with the outlook.

The Peoria Railway Terminal is still buying land to use for switching facilities, having recorded a tract of 18 acres at South Bartonville this week. Work on the yards is progressing nicely and the steel is expected to arrive this week.

According to the last report of the Illinois Traction Company the outstanding bond issue of the system was $13,817,500 for the completed lines and $6,213,000 for the roads under construction. The amounts for the completed lines all bear interest at 5 per cent. except the Danville property, the Danville and Champaign Railway and the Jacksonville Railway Company, which bear 6 per cent. interest. The report also gives in detail the amount of bonds outstanding on each piece of property owned by the system.

The Peoria, Streator and Ottawa Railway Company, which proposed to build a road between those cities, has certified an assignment of all its rights and franchises to the Chicago, Peoria and Ottawa Railway Company.

The Danville Car Company has certified to the secretary of state of an increase of capital from $250,000 to $750,000.

The Illinois Traction Company is now running a sleeper out of Springfield to St. Louis every night at 12:30. The car formerly ran through from Decatur, but the business failed to justify its continuation, so the passengers desiring to take the sleeper must now board it at Springfield.

Authority for the construction of electric block signals between Murrayville and Roodhouse has been granted and work will be commenced at once.

A professional nurse living in Chicago has sued the Peoria Railway Company for $5,000 damages for alleged injuries. She was a passenger on the cars from a park up the river when the car stopped to uncouple a trailer. At this the end of the car on which she was standing, released from the weight of the trailer, suddenly shot into the air and she "soared like a bird" into the air, alighting with great force and violence upon the ground. V. N.

Pacific Slope.

San Francisco, August 21.—There are many reports to the effect that the street-car strike is to be settled speedily, and that an agreement with the leaders of the Carmens' Union to call off the strike has been decided upon by President Patrick Calhoun of the United Railroads, on a basis of $3 per day of nine hours. The service is still being improved and a number of additional cars have been placed in operation.

It is announced that the San Francisco Gas and Electric Company has closed a contract with the Union Oil Company to deliver 2,500,000 barrels of fuel oil a year at $1 per barrel on the wharf in San Francisco, to be used for firing the boilers at the lighting company's electric generating stations. The oil will be taken from wells in Southern California.

The Presidio and Ferries Railroad Company has modified its plans with a view to dispensing with the use of a cable, which it was supposed would be required to transport loaded cars over the Union Street Hill, since it has been found, by actual demonstration, that with motors, it is possible to surmount grades of 14 per cent. with little difficulty. At the only place where the grade exceeds this figure and amounts to 18¾ per cent., it is proposed to install a combination cable and clutch to draw the cars up the incline. This method can be employed, it is said, without materially delaying the movement of traffic. The tracks of the road are now completed for 32 blocks from Polk Street to the Presidio and Harbor View, and from Montgomery to East Street on Jackson Street. Twenty-four blocks remain to be laid.

The San Francisco Board of Supervisors has denied the United Railroads an overhead-trolley permit, and has taken the first step looking to the abolition, 18 months hence, of all overhead electric wires in the district eastward from Devisadero Street.

Vallejo and Northern Railroad officials have denied the report that the company has sold out to the Northern Electric Company. Franchises applied for by both roads are pending before the city trustees of Sacramento, Cal. The Vallejo and Northern, which has projected an electric road 105 miles long connecting Vallejo and Sacramento, has acquired rights-of-way, and it is said that actual construction will soon be commenced. A line of fast steamers is to be established to connect Vallejo with San Francisco.

The Sonoma and Lake County Railroad Company is about to build an electric line from Lakeport to Cloverdale, which will pass through Adams Springs, Highland Springs, Saratoga and Bartlett. The company will commence the construction of the line as soon as arrangements are completed for a connection with San Francisco.

President H. P. O'Reilly, local manager of the American Telegraphone Company, announces that a factory will be established in Seattle, Wash., to manufacture instruments for the Pacific coast supply.

More than $100,000 has been subscribed by the citizens of Valdez at a mass meeting for organizing the Alaska Home Railway Company to build an electric road from Valdez to the interior of Alaska. Construction has been commenced on wharves and terminals in the heart of the town. H. D. Reynolds, owner of the Alaska Coast Company, headed the project.

A. E. Dickinson, J. E. Fulton, vice-president and general manager, and Engineer D. F. McIntyre, who recently visited San Francisco, are seeking to establish communication through the California and Northwestern Railroad or one of the other lines tapping their territory. The total outlay is estimated at $750,000, and the line will cover a distance of 27 miles, the highest point traversed being the 1,800-foot altitude between Highland Springs and Pieta Creek, about 11 miles from Lakeport. The line will handle passenger and freight traffic and will cater to tourist business.

Preparations for the commencement of work on the Los Angeles Pacific Railway Company's subway have been begun. The tunnel strikes out in a diagonal direction from the south side of Temple and Hill streets in Los Angeles, going northwest toward Hollywood.

J. C. Stevens, president of the Willamette Valley Company, and Howard Butcher, director, both of Philadelphia, have been in Portland, Ore., holding a conference with A. Welch, vice-president and general manager, to outline plans for the development of the various projects being carried out by the company, which owns a large number of gas and electric plants throughout the Pacific Northwest, and plans building some electric lines. The latest project is an interurban road between Portland and Salem, with a branch running to Eugene.

The Northwest Electric Company will in a short time begin the erection of a large plant for the manufacture of all kinds of electrical appliances, somewhere in the south end of the city of Seattle, Wash. The new company will absorb the Seattle Electric Heating and Manufacturing Company. A. E. Ransom will have general supervision of the plant. A.

PERSONAL.

James W. Moore, a prominent man of Richmond, Ind., and secretary of the Richmond Home Telephone Company, died at his home in Richmond during last week.

President Coffin of the General Electric Company has gone abroad for an automobile trip through France and England, to be absent until the middle of October.

Walter A. Murphy, superintendent of the Carbaras-Boone Traction Company, Boone, Iowa, is dead as the result of an electric shock obtained while handling a car controller.

George Dyer, superintendent of the Sandusky division of the Lake Erie and Western Railroad, with headquarters in Lima, Ohio, has resigned his position to become general manager of the South Bend and Indiana Interurban Railway system, commonly known as the Murdock lines.

Edward W. Barrows, secretary-treasurer of the American Engineering Company of Indianapolis, has returned from Texas, where in the interests of his company he closed a contract to build and equip an electric traction line from Fort Worth, Tex., to Mineral Wells, a distance of 60 miles.

John S. Speer, general manager of the Speer Carbon Company, St. Marys, Pa., passed through Chicago last week en route to St. Marys. Mr. Speer has been enjoying a well-earned vacation and spent the last five weeks on a tour of the Western States, accompanied by Mrs. Speer and a party of friends.

Mr. Avery P. Eckert will become general sales manager of the Duplex Metals Company, with his new headquarters at 208 Fifth Avenue, New York. Mr. Eckert's long and well-known electrical career began with the New York Telephone Company. Following three years with the Kerite Company, for 14 years he has been associated with the Safety Insulated Wire and Cable Company. For some time he was secretary of the Electrical Trades Society of New York. His company is engaged in introducing Monnot wire, which consists of an iron strand clad with copper, so that tensile strength, elasticity and durability of both metals are combined. The company controls patents for welding metals and the Westinghouse company will use material thus treated for making steam-turbine blades.

F. B. Maltby, who has been connected with the Panama Canal work as principal assistant engineer to J. F. Stevens, has resigned to go with Dodge & Day, engineers and constructors, of Philadelphia, in the capacity of chief engineer. Mr. Maltby is a graduate of the University of Illinois, receiving an honorary degree from the same institution. He has had a long experience in railroad construction work, municipal engineering and irrigation work, and has had charge, for the United States government, of all the dredging operations in the lower Mississippi River, and designed and built the lock and movable dam on the Osage River in Missouri for the government. Mr. Maltby has been connected with the Panama Canal for the last 2½ years, having had charge of the construction of railroads, docks and wharves, shops and dredging. He constructed a cold-storage plant, laundry and bakery in Panama. He has designed over $1,250,000 worth of dredging plant for the canal work, and the preliminary plans and construction work for the Great Gatun lock and dam were done under his direction.

ELECTRIC LIGHTING.

The Prentice (Wis.) Light, Water and Power Company has been incorporated with a capital stock of $3,000.

The Lawton (Okla.) Lighting Company has been incorporated with a capital of $100,000 by C. S. Stephenson and others.

George I. Watters of Victor, Mont., proposes to develop waterpower and establish an electric-light plant in Stevensville, Mont.

The Waurika (Okla.) Public Service Corporation has been incorporated with a capital of $200,000 and will furnish electric light and gas.

A. B. Hulit has applied for a franchise for an electric-light plant to compete with the present plant at Oklahoma City, Okla.

ELECTRIC RAILWAYS.

The Arkansas Valley Traction Company has been incorporated by H. W. Potter, J. E. Gauger and Eugene S. Alnutt with a capital of $150,000.

The Russellville and Ozark Mountain Traction, Light and Power Company has been chartered with a capital stock of $200,000. The incorporators are prominent business men of Pine Bluff, Atkins, Ozark and Russellville, whose object is to build interurban lines between Russellville and neighboring towns. Adam J. Robins is president.

It is expected that an electric line will be built from Clarkston through Lewiston, Idaho, and across the Clearwater into the bench land district, where eventually a connection will be made with the Spokane and Inland Empire, which is building into Moscow. Another part of the great scheme is to use power developed at Grande Ronde to lift the water from the river and distribute it over the bench land for irrigation purposes.

RADIO-TELEGRAPHY.

M. A. Vivien, chief engineer of the Marconi wireless system, arrived on the liner La Touraine, from Havre, last week. He said the French line was to be equipped with powerful wireless apparatus that would keep the big ships of the fleet constantly in touch with either the American or European coasts.

The Dutch Indian government has granted to a syndicate a concession for establishing a radio-telegraph system between Java, Celebes, Borneo and the neighboring islands. The company, with a capital of 2,650,000 florins (florin equals 40.2 cents American) is now in the course of flotation, but there will be no public issue.

PUBLICATIONS.

Thomson polyphase induction wattmeters measure the energy in any two-phase, three-phase or monocyclic circuit, and consist of two single-phase motor elements, each acting upon its own disk with both disks mounted upon a single shaft actuating the regiser. The meters may be applied to a circuit carrying a mixed load of lamps, motors or other devices and record accurately, irrespective of load conditions. Bulletin No. 4527, issued by the General Electric Company, Schenectady, N. Y., describes the latest form of these meters which are made in three types; one for house service with metal cover and two for switchboard use, one having a metal cover and the other a glass cover. The bulletin gives catalogue numbers and capacities, etc., of the various sizes and a large number of connection diagrams showing the method of installation on different classes of circuits.

Helios flaming-arc lamps are described in a handsome and interesting bulletin, No. 40, issued by the manufacturers in Philadelphia. The properties and illumination data of flaming arc lamps are fully explained and illustrated by curves and diagrams. Most of the pages are taken up with the description and operation of the Helios lamps, and a comparison table for incandescent, enclosed arc and the Helios lights gives the cost for 600 hours of burning as $356, $265 and $78, respectively.

The Cutler-Hammer Manufacturing Company of Milwaukee, maker of electric controlling devices, has just issued a booklet—pigeonhole size—descriptive of its line of electric crane controllers. In addition to full descriptions and illustrations of five types of crane and hoist controllers, the booklet contains connection and dimension diagrams, repair part charts, prices, net weight and shipping weight of apparatus, etc. An improved form of contactor for handling heavy currents is also described.

The Excello Arc Lamp Company, 24-26 East Twenty-third Street, New York, has issued a list of the principal spare parts for Excello flaming arc lamps. A complete "exploded" view of replacement parts has each detail numbered so that by reference to an accompanying list the prices may be learned. Recent improvements in the construction of the lamps are noted in order to enable customers to order differing parts intelligibly. The publication is to be looked upon as another proof of the manufacturers' desire to give the users of their lamps every satisfaction.

SOCIETIES AND SCHOOLS.

The Navy Department will soon erect at the Mare Island Navy Yard at Vallejo, Cal., a building costing $25,000 for use as an electrical school for the enlisted men of the navy. A small school is now maintained where wireless telegraphy is taught and where all of the electrical apparatus for the various wireless stations established on the coast is tested. All but one of the operators in charge of the Pacific coast stations are graduates of the Mare Island school.

The American Street and Interurban Railway Engineering Association has sent to the general managers and engineers of member companies the list of questions which will constitute the question box to be presented at the Engineering Association convention held at Atlantic City during October. Each recipient is asked to make a point of answering at least five questions. The question box is to be placed in printed pamphlet form, together with the replies received from the various companies and will be distributed in advance of the convention.

The American Street and Interurban Railway Association has asked for another report from its committee on municipal ownership, to be presented at the convention to be held in October next. In order that the report should cover all progress made either for or against the movement as well as some statement in regard to general conditions here and abroad a sheet has been enclosed with a letter to the general manager of street and interurban properties in America covering a few questions designed to ascertain the condition of affairs with respect to municipal ownership in the immediate vicinity of the addressee.

MISCELLANEOUS.

The short ends of old carbons may be cemented together to form rods which burn quite well and are no more brittle than ordinary carbons. The cement required is of potassium silicate and carbon dust. The rods have their ends faced off square and, after application of the adhesive which as used is of a pasty consistency, are pressed together by hand.

The United States Civil Service Commission announces an examination on September 11-12, 1907, to be held at various cities throughout the country, to secure eligibles for three vacancies in the position of miscellaneous computer at the Naval Observatory, Washington, D. C., and similar vacancies as they may occur in that observatory. The department states that miscellaneous computers are paid by the hour and earn from $800 to $1,000 per annum. Promotions are made from this grade without further examination to the grade of computer, at $1,200 per annum, as vacancies occur. As an insufficient number of eligibles to meet the needs of the service were secured from previous examinations held for this position, qualified persons are urged to enter this examination.

TRADE NEWS.

Mr. Colby has succeeded to the electrical supply business of Colby & Vredenburg of Trinidad, Colo.

In Little Rock, Ark., the Electric Construction Company has been incorporated with a capital of $25,000 and proposes to sell electrical supplies and apparatus.

The last semi-annual report of the Chicago Pneumatic Tool Company shows the profits for the half year ended June 30th to have been $507,528.12. Deducting amounts set aside for depreciation and repair of plant, development of new tools, interest, sinking fund and dividends a balance of $190,818.88 has been added to the previous surplus, making $1,069,228.32 surplus to be carried forward.

An American consular officer in South America has sent the names of prospective purchasers of electric engines to the United States Bureau of Manufactures. He also writes of the proposed electrification of a street-car line, the installation of an electric-lighting plant and the proposed improvement of the electric-lighting plant now in operation. Particulars may be learned by addressing the bureau at Washington and referring to the file number, 1346.

BUSINESS.

Mr. William W. Merrill has resigned as president of the Appleton Electric Company of Chicago and disposed of his entire stock holdings to Mr. Albert I. Appleton and Mr. John V. Painter. Mr. Appleton assumes the presidency of the company, of which he is also treasurer, and Mr. Painter becomes secretary.

The new firm of George H. Erich & Co., dealers in electrical supplies, has taken over all the business interests formerly conducted by George H. Erich at 358 Dearborn Street. The new concern will retain the same offices, and Mr. Erich hopes to continue to receive the favors of his friends under his new business arrangement.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) August 20, 1907.

863,609. Electrically Signaling from Moving Trains. Alva D. Jones, Louisville, Ky., assignor of parts to T. Harris, W. O. Bradley, J. Gayle, F. A. Fuller, E. D. Martin, A. G. Martin and J. C. Strother. Application filed December 3, 1906.

A vertically swinging arm is provided to be raised and lowered from the locomotive cab and ends in a supplemental bifurcated extensible arm, each fork of which carries a metallic brush to make contact with the line conductor.

863,613. Means for Operating the Controlling Switches of Electric Vehicles. Louis Krieger, Paris, France. Application filed January 10, 1906.

The switch control is arranged inside of the tubular steering pillar.

863,617. Combined Telephone Receiver and Transmitter. Rodney F. Ludlow, Philadelphia, Pa. Application filed April 6, 1904.

One diaphragm serves for both functions, being located in the field of the receiver magnets and also having connection through levers with a transmitter capsule.

863,643. Grinding Machine. George P. Ransom, Oshkosh, Wis. Application filed May 29, 1907.

In order to maintain a constant surface speed of the grindstone, a gauge fitted against its periphery is mechanically connected to the motor controller so that as the stone's diameter decreases from use, the motor speed is correspondingly increased.

863,656. Safety Fuse. Joseph Sachs and Frank D. Reynolds, Hartford, Conn., assignors to the Sachs Company, Hartford, Conn. Application filed March 22, 1906.

The fuse comprises a tube with end caps and the fuse strip electrically connected between them. An indicator wire inside the tube is visible through a flap in the casing.

863,667. Relay. Jacob B. Struble, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed February 18, 1907.

The relay consists of a core affording two magnetic paths with a winding for each. By increasing the reluctance of one magnetic path over the other, a pivoted armature will be moved in response to the strongest magnetic circuit.

863,674. Joint for Carbon Electrodes. Frank J. Tone, Niagara Falls, N. Y. Application filed September 25, 1906.

One carbon has a tapered threaded end and the other a tapered threaded socket.

863,683. Brush Holder for Electric Motors or the Like. Thomas S. Watson, Milwaukee, Wis. Application filed September 1, 1906.

The brush-holder comprises jaws having oppositely disposed parallel ways that are tapered in cross-section to form guides.

863,690. Trolley Device. Samuel E. Belcher, Los Angeles, Cal. Application filed January 10, 1906.

The trolley pole is controlled by a compressed-air cylinder.

863,692. System of Electrical Distribution. William L. Bliss, New York, N. Y. Application filed July 20, 1904.

This distribution system for governing the supply of a storage battery into the generator circuit has a regulator with two windings, one of which is connected in the supply circuit and the other in the translating circuit. The regulator is rendered inoperative whenever the generator and battery combine to furnish current to the translating devices.

863,705. Telephone Signal System. Howard M. Eldred, Milwaukee, Wis. Application filed March 19, 1906.

For a magneto-signaling telephone system, the drop is connected to one side of line through a cut-off contact in the jack. The other terminal of the winding is led to a grounded generator. The subscriber signals the operator by simply pressing a button which establishes a ground at his station. (See cut.)

863,720. Telephone Call-bell or Ringer. William Kaisling, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Application filed March 2, 1906.

Details of construction of a ringer are given.

863,755. Controlling Apparatus for Railroad Signaling. Petrus J. Portman, Amsterdam, Netherlands. Application filed June 8, 1906.

A dial has a number of long and short contact strips to which the circuit is closed by contacts carried by the pointer.

863,773. Lightning Arrester. Ernst J. Berg, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 8, 1907.

The circuit shown has a translating device electrically connected with the line through a reactance, condensers connected in series across the reactance and forming a discharge path for high frequency oscillations, and a discharge path including a spark-gap connected to the line.

863,774. Parallel Connected Generators. Ernst J. Berg, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 17, 1907.

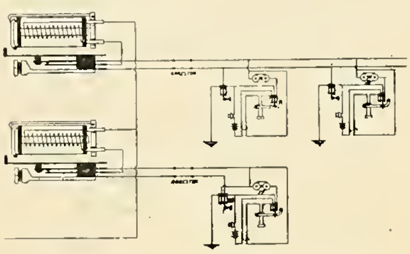
When several generators are connected in parallel and driven by prime movers having different speed-regulation characteristics, the plan is to produce automatically a relative decrease in the field-strength of the generator having the best speed regulation upon a sudden increase of load on the generators.

863,791. Protective Device. Loren Emery, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 10, 1907.

The device is operative to open the circuit upon an overload and upon a reversal of energy.

863,793. Forming Filaments Out of Viscose or Similar Viscous Material. Charles A. Ernst, Lansdowne, Pa., assignor to Silas W. Pettit, Philadelphia, Pa. Application filed April 27, 1907.

To form viscose for producing cellulose filaments, soda-cellulose is treated with carbon bi-sulphide to form cellulose xanthate and the xanthate is then dissolved in an alkaline solution containing sodium sulphite to prevent the further action of the carbon bisulphide on the cellulose.



NO. 863,705.—TELEPHONE SIGNAL SYSTEM.

863,799. Electric Meter. Charles E. Holmes, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 23, 1904.

The feature of the meter casing is a spring which when depressed permits of removing the entire operating mechanism.

863,807. Snap Switch. Frank W. Sanford, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 1, 1905.

Details of construction of a snap switch having "off" and "on" buttons, are given.

863,808. Dial Plate for Switches. Howard R. Sargent, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed August 24, 1905.

The dial plate is carried by the rotatable switch contacts.

863,810. Telegraph Key. Henry Smith, Raleigh, N. C. Application filed July 17, 1906.

This key is one of a kind designed to relieve the operator of making dots which are in this instrument formed by contacts, made by a vibrating reed. One key is used to send dashes and a second key transmits dots as long as it is depressed.

863,814. Dynamo-electric Machine. Louis E. Underwood, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 9, 1904.

The machine is fitted with the usual polar projections from the frame, and has a piping system through which a cooling fluid may flow, detachably secured in the spaces between the windings. (See cut.)

863,818. Rail-bond. Ben Willard, New Orleans, La., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 31, 1899.

The terminals of the flexible conducting cable make contact with a number of rail connections which are serially connected by flexible conductors.

863,847. Electrical Socket Seal. Llewellyn T. Hatfield, Sacramento, Cal. Application filed August 3, 1906.

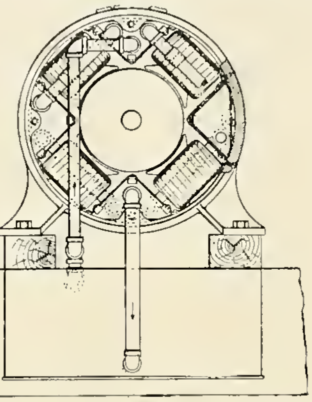
A non-conducting plug is arranged to be fitted in the socket and sealed.

863,852. Transmission of Intelligence by Electric Means. Isidor Kitsee, Philadelphia, Pa. Application filed February 5, 1904.

[illegible] telephonic communication between two distant [illegible] over a single line without earth connection, artificial local circuits at each station are provided, each of local circuits having a value at least equal to the value of the line-proper.

863,853. Telegraphy. Isador Kitsee, Philadelphia, Pa. Application filed April 24, 1907.

In a system of duplex telegraphy in which two sources of current are connected in opposition, there are means for making the home instrument immune to the home transmission.



NO. 865,814.—COOLING SYSTEM FOR DYNAMO-ELECTRIC MACHINES.

863,875. System of Selective Electric Signaling. Sylvanus A. Reed, New York, N. Y. Application filed August 4, 1906.

In a circuit having condensers, oppositely biased ringers with a predetermined tension in their biasing springs, a low and a high resistance, there are also means for operating the ringers adapted for alternately charging and discharging the condensers respectively through the low and high resistance or vice versa, the high resistance being sufficient so to reduce the current that it will be insufficient to overcome the tension of the biasing spring.

863,913. Block-signaling Apparatus. Walter E. Foster, Chicago, Ill., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed April 25, 1907.

By an arrangement of electromagnets and polarized relays the lock of a controller at one station may be released from the next station or may be controlled by a passing train which reverses the line polarity.

863,924. Selective Signaling System. William W. Kidney, Buffalo, N. Y., assignor to the Century Telephone Construction Company, Buffalo, N. Y. Application filed May 28, 1907.

Current of requisite polarity is applied to a line on which a number of sub-stations are connected, each equipped with polarized signaling apparatus, a condenser and a contact on the ringer armature for opening and closing the circuit to the condenser.

863,955. Interrupter Apparatus. Reinhold H. Wappler, New York, N. Y. Application filed October 30, 1906.

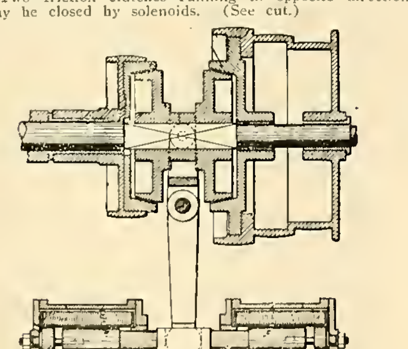
An auxiliary interrupter-electromagnet attracts the pole of an armature mounted on an axle, which carries a cam opening the circuit in this position. The now deenergized magnet allows the armature to move past, permitting the closure of the circuit, so that the operation is continuous.

863,956. Electric Cloth-cutting Machine. Edward M. Waring, New York, N. Y. Application filed July 11, 1906. Renewed July 26, 1907.

An electric motor in the body of the machine drives the cutting knife.

863,966. Electromagnetically Operated Mechanism for Reversing the Motion of Machine Tools. Julius Billeter, Aschersleben, Germany. Application filed October 25, 1906.

Two friction clutches running in opposite directions may be closed by solenoids. (See cut.)



NO 863,966.—ELECTROMAGNETICALLY OPERATED REVERSE.

863,969. Telegraph and Telephone Cable Core. William Dieselhorst, Old Charlton, and Arthur W. Martin, London, England. Application filed March 29, 1904.

A method of making cable cores, consists in twisting together pairs of individual conductors with a constant length of lay from end to end of each twisted pair, and again twisting the twin conductors in pairs but with a different length of lay.

863,984. Trolley. Nelson J. Greenison, New York, N. Y. Application filed January 28, 1907.

The trolley harp extends vertically from an extension to the trolley pole.

864,027. Automatic Circuit Closer. Henry A. Pearson and Harry Adams, U. S. Navy. Application filed October 22, 1906.

When the circuit is opened by a circuit-breaking device the movement of the controller shaft automatically restores the connection as the controller is moved to its "off" position.

864,048. Electric Time Switch. Bernhard Tropp, New York, N. Y., assignor of one-half to William Henry Laird, New York, N. Y. Application filed February 1, 1906.

Power to operate the switch is supplied through a spring by an electric motor which is automatically started and stopped after a predetermined period.

864,102. Luminometer. John T. Marshall, Metuchen, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 26, 1906.

On the base of the photometer an electric lamp is mounted and covered by an opaque box in one of whose faces is a photometer screen. The lamp, with resistances in the box, forms the arms of a Wheatstone bridge, whose balance is secured by an adjustable resistance and galvanometer.

864,129. Controlling Mechanism for Electric Signaling Systems. Willard H. Gilman, Medford, Mass., assignor to the International Telemeter Company. Application filed October 31, 1906.

In brief this may be explained to be a controlling apparatus comprising an electromagnet and its armature, a contact device made and broken by successive reverse movements of the armature, a second contact device made and broken upon each movement of the armature, and locking means for preventing the operation of one of the contact devices.

864,135. Spark Plug. Charles A. Mezger, New York, N. Y. Application filed December 26, 1906.

NO. 864,135—SPARK PLUG.

A non-rotative annulus of relatively soft metal surrounds the insulation member at an enlarged portion and is engaged and partly inclosed by the bushing. (See cut.)

REISSUE.

12,681. Floor Surfacer, Cleaner and Polisher. Aaron T. Spence, Alameda, and Samuel B. Zimmer and John H. Prugh, Oakland, Cal., assignors to the American Floor Surfacing Machine Company. Application filed April 8, 1905. Original No. 728,423 dated May 19, 1903.

An electrically driven floor surfacer has the details of its construction described.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired August 26, 1907:

434,943. Electric Connector. E. L. Orcutt, Somerville, Mass.
434,949. Gearing for Electrically Propelled Vehicles. N. B. Possons, Cleveland, Ohio.
434,961. Section Insulator for Overhead Electric Conductors. E. Thomson, Lynn, Mass.
435,015. Dynamo-electric Machine. W. F. Collins, New York, N. Y.
435,084. Electric-lighting System. A. H. Bauer, Chicago, Ill.
435,093. Electric Switch. C. H. Herrick, Winchester, Mass.
435,097. Electric Signal for Cable Railways. S. J. Jacobs, New York, N. Y.
435,105. System for Electric Circuits. F. Stitzel, Louisville, Ky.
435,110. Electric Forging Machine. G. D. Burton, Boston, Mass.
435,111. Electric Car Heating and Feeding Apparatus for Forging Machines. G. D. Burton, Boston, Mass.
435,114. Means for Distributing Electric Energy. S. De Ferranti, London, England.
435,116. Guard for Electric-light Globes. R. M. Gardiner, Hamilton, Canada.
435,185. Electrical Watchman's Clock. H. S. Park, Chicago, Ill.
435,213. Electric Alarm for Clocks. W. H. Deane, Brooklyn, N. Y.
435,223. Electric Cut Out. C. Heisler, St. Louis, Mo.
435,259. Electric Device for Preventing Accidents on Railways. G. Thew, Peru, N. Y.
435,261. Generator for Electric Engine Circuits. C. J. Van Depoele, Lynn, Mass.
435,262. Structure for Supporting and Insulating Suspended Bare Conductors. C. J. Van Depoele, Lynn, Mass.
435,263. Electric Railway Conduit with Tubular Conductors. C. J. Van Depoele, Lynn, Mass.
435,264. Reciprocating Electric Hammer. C. J. Van Depoele, Lynn, Mass.
435,283. Method of and Apparatus for Welding by Electricity. C. L. Coffin, Detroit, Mich.
435,284. Process of Heating Metals by Electricity. C. L. Coffin, Detroit, Mich.
435,292. Autographic Telegraph. H. Etheridge, Pittsburg, Pa.
435,295. Automatic Telephone Connector. W. H. Ford, St. Louis, Mo.
435,340. Automatic Electric Train Signal and Controlling Device. W. H. Wilson, New York, N. Y.
435,343. Articulate Electromagnet. F. H. Brown, Chicago, Ill.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, SEPTEMBER 7, 1907 No. 10

The Lockport-Chicago (Drainage Canal) High-tension Transmission Line.

A high-tension transmission pole-line whose construction has been the subject of considerable interest among electrical engineers and others is nearing completion along the banks of the Chicago Drainage Canal between Lockport and Chicago. Near Lockport, as readers of the Western Electrician know, the water of the Chicago Sanitary District's drainage canal, fed by the reversed Chicago River from Lake Michigan, has a considerable drop to the Desplaines River, from which it finds its way to the Gulf. By the extension of the canal two miles beyond Lockport between great concrete retaining walls, which rise above the level of the surrounding country as the land slopes away, a power-house site has been obtained which insures a 40-foot fall for the ultimate flow of 600,000 cubic feet of lake water.

The 32,000-kilowatt generating station at the site thus secured is now near completion and the primary installation of 20,000 horsepower will soon be available for use. A complete and illustrated description of this station appeared in the Western Electrician of April 20th. A considerable portion of the electric power from this plant will be transmitted to Chicago over one of the most substantial pole lines ever constructed.

The present article will be directed to a description of the unusually interesting construction of the pole line which follows the canal into Chicago and which includes some features that make it one of the most unique as to size and modern in design in the world. The difficulties in erecting the massive steel poles were heightened by the changing characteristics of the country along the 40 miles of the transmission line, which runs on the bank of the canal between the water and the spoil pile. The channel has been cut through solid rock from Willow Springs, Ill., to the Lockport power house, a distance of about 16½ miles. This rock has been piled along the shore in great mounds, and at one place the derrick wagon had to be placed on a mound of rock 12 feet high to set a pole in a hole which had been blasted in the solid rock below. Aside from this there were several difficult railroad crossings to be made.

As will be gained from inspection of the accompanying illustrations, the poles are intended to accommodate two three-phase transmission circuits and a ground wire carried on the peaks of the poles which will extend the whole length of the line. The transmission voltage will be 44,000.

The erecting of the poles is shown in Figs. 1, 2 and 3. Some idea of their great size will be obtained from a glance at Fig. 4, where the height of the pole, almost 60 feet, may be compared with the man at the base.

The poles are of steel, square in plan section, of bridge construction, and weigh complete 4,000 pounds. On a side they measure 42 inches at the base and 20 inches at the top. The cross-arms are similarly of bridge construction, the lower arm being 18 feet long and weighing 600 pounds, while the top arm is 12 feet long and weighs 300 pounds. The material used in the diagonal braces is 2 by 2 by 3-16 inch angle. The size of the material in the corner posts varies from 3½ by 3½ by ¼ inch at the base to 3 by 3 by 3-16 inch at the top of the pole. The rivets in the body of the pole are all three-quarters inch and in the cross-arms five-eighths inch.

Fig. 6 is a detail drawing of the pole construction, giving dimensions.

The Aermotor Company of Chicago, manufacturer of windmill machinery and towers, made the lowest bid for the construction of the poles and received $130 apiece for the 500 furnished.

The poles are placed 350 feet apart. They are set into the ground 5½ feet and the hole filled in with concrete which is brought up six inches above the surrounding earth and rounded off at the edges so that no water will lodge about the base. Fig. 5 shows a straight stretch of the line just out of Chicago and illustrates the accurate alignment which has been maintained in the setting. The view is typical of the upper end of the drainage canal and shows the water course itself and the high spoil banks flanking it on either side. The other poles shown in the picture are 40-foot telephone poles, which are, it may be seen, effectually dwarfed by the large steel structures.

Setting of the poles was undertaken by the Brennan Electric Construction Company of Chicago, which company also contracted for the wiring of the power house and the stringing of the high-tension wires. The bid made by this concern was much lower than others submitted, which is accounted for by the fact that the company had devised and figured on an economical method of construction which, while considered unique, has proved itself perfectly successful and equal to the various difficulties encountered.

The holes are dug perfectly square, are accurately lined, and are four feet on a side. This leaves three inches outside the pole on the four sides for the concrete into which the poles are set.

The derrick wagon seen in Fig. 2 was especially designed by the constructing company. It consists of a stone wagon with the platform extending one foot behind the rear axle; on this is set a 40-foot gin pole, to the top of which are attached guy lines which hold it in a perpendicular position. While setting a pole these lines are fastened to stakes driven in the clay or to bars inserted in the crevices in the rock. Moving from pole to pole the gin pole is kept in an upright position by the men who walk alongside and hold on to the guy lines.

In raising the steel poles (see Fig. 1) a three-quarter-inch wire cable is used, which is threaded through two 14-inch iron double-sheave blocks, then through the top of the pole over a sheave wheel, and finally down to the base of the gin pole on the derrick wagon, where it is attached to a crab hoist. Four men can raise the pole with this hoist. After the pole is set, lined and graded, it is securely guyed, and the derrick wagon proceeds to the next.

Concrete is placed in the following manner: A canal boat (shown in Fig. 3) loaded with stone and cement is towed up from the quarry and landed at the first pole to be concreted. On this boat is placed a Smith concrete mixer of one-half-yard capacity. The concrete is mixed on the boat and wheeled out and dumped around the pole. When the proper quantity has been placed about the pole the gangplanks are pulled aboard, the line untied and the boat floats down to the next pole.

By this method one gang has set as many as

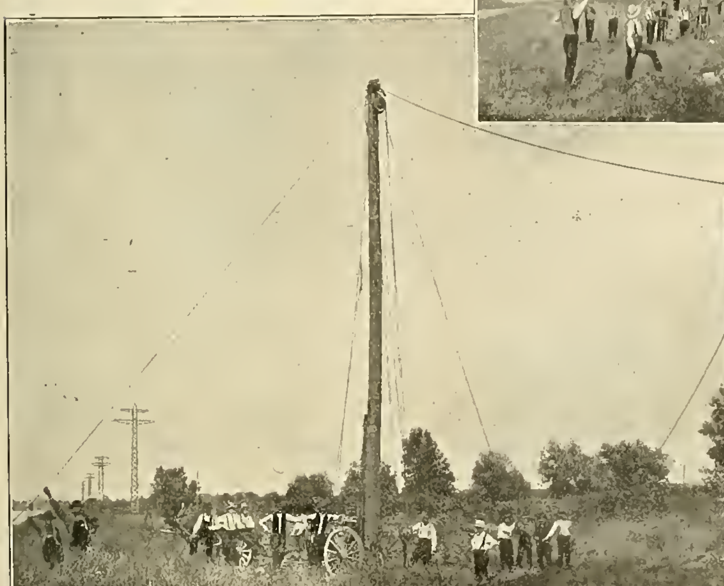


Fig. 1. Raising One of the 60-foot, 4,000-pound Steel Poles into Position.
Fig. 2. Derrick Wagon with its 40-foot Gin Pole for raising the Steel Poles. Fig. 3. Concrete Mixer on Boat which Floats down the Canal from Pole to Pole.
THE LOCKPORT-CHICAGO (DRAINAGE CANAL) HIGH-TENSION TRANSMISSION LINE.

12 poles in a day, though difficulties are sometimes encountered which do not allow such progress. Three hundred and seventy-five of the poles are now set, beginning at the Chicago end, and the work of placing the balance and stringing the wires it is expected will be completed by October 15th.

The poles were designed to carry the transmission wires on the lower arms 47 feet above the ground. The insulators of each three-phase circuit will be arranged at the apexes of an equilateral triangle six feet on a side, so that distance will be maintained between wires. The wires are carried 16 inches above the metal arms. The insulators, furnished by the Locke Insulator Manufacturing Company, are of the type shown in Fig. 7. They have a diameter of 14 inches and are 12 inches high, and were tested assembled ready for use at 120,000 volts. Each of the four shells tested at 60,000 volts before assembly. This insulater, mounted on a suitable metal pin, is guaranteed for a maximum horizontal strain of 4,000 to 5,000 pounds and is ordinarily rated for 60,000 volts.

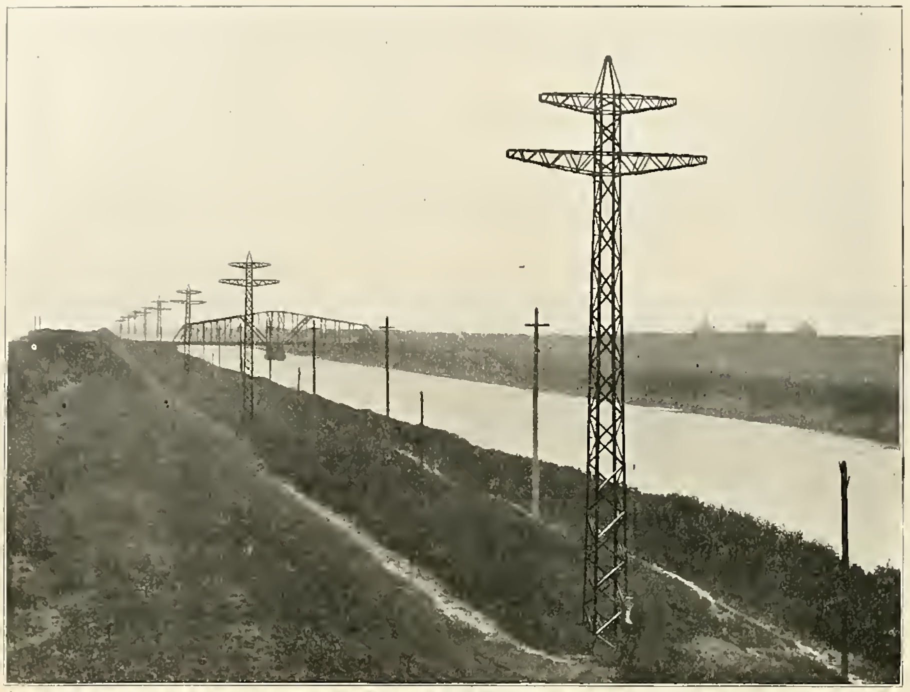

FIG. 4. VIEW ON CHICAGO DRAINAGE CANAL, SHOWING LOCKPORT-CHICAGO TRANSMISSION LINE.

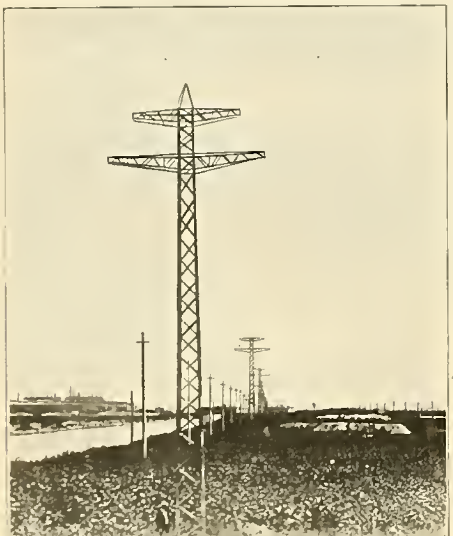

FIG. 5. VIEW OF LOCKPORT-CHICAGO TRANSMISSION LINE, WITH SUB-STATION IN THE DISTANCE.

At the top of the pole the four corner posts end in a cap which is fitted with a socketed clamp to be tightened down on the one-half-inch iron ground wire which will be carried the whole length of the line. This cable will connect all the poles electrically and on account of its position above the transmission wires is expected to receive any lightning which may strike the line and carry it off to the excellent grounds afforded by the concrete-[illegible] poles.

Electric Illumination of Niagara Falls.

Various schemes have been proposed to illuminate Niagara Falls. The latest proposition for illuminating the great waterfalls is quite in keeping with their natural grandeur and beauty and illustrates one of the most interesting developments in illuminating engineering.

The city of Niagara Falls has contracted with the General Electric Company of Schenectady, N. Y., for the necessary apparatus to illuminate the cataract, and the work of installation is expected to be completed early this month, when the falls will be artificially lighted for the first time. Two batteries of searchlights of the naval type will be used. One battery of not less than five 60-inch projectors will be mounted on the highest available point on the Canadian side and so placed as to catch the crest of the falls and plunge the light into the broken water as it rushes down between the bridge and the brink on the American side. The color attachments will be used so as to tinge the water various shades of carmine, crimson, orange, yellow, green, violet and purple. These various colors will be combined in different ways so as to introduce innumerable pleasing tints and shades in various combinations.

The second battery will consist of not less than 25 36-inch projectors mounted in the form of a crescent at the base of the gorge on the Canadian side. These will also be provided with color attachments and the projectors will be so placed that they can be concentrated on either the American or Canadian falls, or subdivided so as to cover the Canadian or American falls as well as the "Bridal Veil" falls. Along the edge of the water opposite the battery the scintillator head, which discharges clouds of steam to augment the mists in producing cloud effects, will also be placed.

The two batteries of searchlights are powerful enough to bathe the falling water in a flood of dazzling light, and with the color scintillators the effect will be beautiful indeed. All the projectors will be controlled from a single vantage point by one operator manipulating a keyboard. In this way it will be possible to obtain a thoroughly artistic interpretation of the color scheme.

The scintillating apparatus consists of three parts, namely, the scintillator-head, the color disks and the boiler. The scintillator head consists of the steam pipes, nozzles and valves by which the various cloud effects are produced. The color disks are carried in a frame in front of the projectors. The construction of these color screens is such that sheets of various colored gelatine can be attached therein. Upon revolving these screens colors can be brought in front of the arc with the result that a beautiful color is imparted to the beam.

The scintillator-head will be located close to the water and at intervals masses of steam will be emitted from the nozzles. Upon this bank of rising steam the searchlights will play their colored beams, producing a sunset effect of startling beauty. Steam will be supplied from a concealed boiler. Other novelties will be bombs filled with black powder which will be thrown above the falls to burst with heavy clouds of smoke or a shower of confetti.

The apparatus with which the falls will be

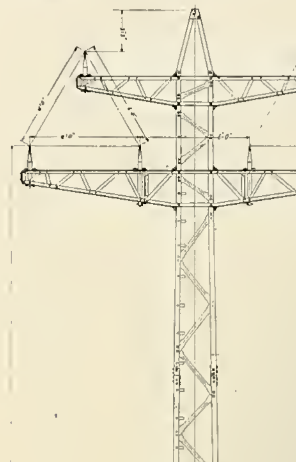

FIG. 6. DETAIL DRAWING OF THE LOCKPORT-CHICAGO TRANSMISSION POLE.

lighted was thoroughly tested at Nahant, Mass., last fall. Several of the searchlights to be used will be the largest and most powerful types made, and with the two batteries it will be possible to produce an artificial aurora-borealis in the heavens which, under proper atmospheric conditions, will be visible at Rochester or Toronto.

The illumination of the mighty torrent by night will be an added attraction to the sightseeing tourists who annually visit Niagara. The apparatus permits of so much originality that the programme will be changed every night, and in the

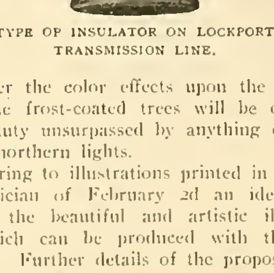

FIG. 7. TYPE OF INSULATOR ON LOCKPORT-CHICAGO TRANSMISSION LINE.

early winter the color effects upon the snow, the ice and the frost-coated trees will be of a spectacular beauty unsurpassed by anything other than the great northern lights.

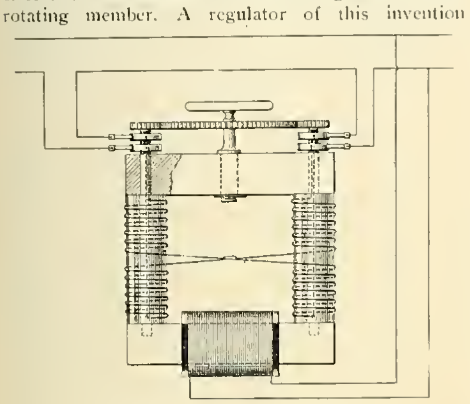
By referring to illustrations printed in the Western Electrician of February 2d an idea may be gained of the beautiful and artistic illuminating effects which can be produced with the electric scintillator. Further details of the proposed illumination of the falls were given in the issue of June 22d.

An Ingenious Voltage Regulator.

This invention, which secures a transformer that may be made to furnish a variable potential at the secondary terminals, will certainly strike the practical electrician or the laboratory worker as being ingenious in principle. As such, the idea is applicable to many allied purposes, and various transformers, regulators and auto-transformers might be made on this principle.

One of the forms which will serve to illustrate the scheme involved is shown in the accompanying drawing. Broadly, the device consists of a magnetic circuit formed by rotatable iron spools yoked by iron keepers. On one of the latter what may be considered the primary winding is placed. The secondary winding is of a flexible conductor, which is carried by the spools, and so arranged that on turning the spools, which are controlled from one hand-wheel, it will unwind from one spool onto the other, resulting in subtractive or cumulative inductive relations. The ends of the secondary windings are led out through slip-rings and brushes. The variation is gradual and without interruption of the circuit.

With the generic idea in mind, many useful applications will at once suggest themselves. Potential regulators, as generally constructed, consist either of transformers having spaced leads to which one side of a circuit is successively connected to vary the voltage, or depend for operation upon the position of a winding on a rotatable core with respect to a stationary winding. The first requires circuit interruption, while the latter involves a considerable air-gap in the magnetic circuit and necessitates a careful alignment of the rotating member. A regulator of this invention



THOMPSON'S VOLTAGE REGULATOR.

may be constructed with an inexpensive core and may effect a wide regulation without circuit interruptions. In case the flexible winding is in two portions, they may be wound upon parallel spools or bobbins, as illustrated.

Another scheme the inventor suggests is the provision of a non-magnetic auxiliary spool to reel up the conductor unwound from the spool included in the core. The principal advantage in providing two flexible portions, the turns of which may be interchanged in position, lies in the fact that the available space on the core is completely occupied at all times.

As then arranged the turns of both portions of the flexible winding are in such relation that the electromotive forces induced in all the turns of both portions may be added together and act in one direction, or by simultaneously rotating the core spools, the turns of one portion of the flexible winding may partially or wholly neutralize the turns of the other portion, or the electromotive forces generated may be added together in the opposite direction. Thus, the voltage delivered from the line may be varied from a maximum obtained when all the turns are acting in the same direction, corresponding to that of the line voltage, to a minimum value obtained when all the turns act in opposition to the line voltage.

When collector rings are mounted in such a position that the magnetic flux in the core passes through them, it is advisable to provide an opening in the ring in which insulation may be inserted to prevent the induction of a short-circuited current in the ring, and, in regulation, where such short-circuited currents would be excessive, a pair of narrow brushes, which are connected by an inductive resistance, may be advantageously employed to engage the ring at different points, the circuit connection being made to the middle point of the interposed resistance instead of to a single brush, which would in some instances short-circuit the ring or break the circuit.

The invention has been patented by William D. Thompson and is assigned to the Westinghouse Electric and Manufacturing Company.

Underground Work at Peoria.

The Peoria Gas and Electric Company of Peoria, Ill., is putting its wires underground in the down town district within the fire limits. The accom

UNDERGROUND WORK IN LIBERTY STREET, PEORIA.

panying illustrations show the work in progress, the pictures being taken in Liberty Street, at the foot of which the company's plant is located. There are 54 ducts running up Liberty Street, arranged six wide and nine high. The top layer of ducts will be used for the distribution, and at various points service boxes will be built and the services to the buildings taken direct to the basements, the intention being to make one service box take care of three customers. When a tap is made for a service and there is no other customer ready for service who can be taken care of from the same box, the taps will be made and the stub ends sealed up so that in future when the service is desired the main cable will not have to be opened.

In the picture looking down Liberty Street the stacks of the company's plant are shown at the right, also the pole line and wires which are to be removed. At the bottom of the trench is first laid a concrete foundation varying in thickness according to the number of ducts, usually four inches. On this is laid the ducts, all well placed in cement. Owing to the sandy nature of the soil, the trenches require sheeting in most places to prevent the slipping of the pavement. Nearly all of the downtown district has a brick pavement, laid on a concrete foundation, with a

UNDERGROUND WORK IN PEORIA —ARRANGEMENT OF DUCTS.

sand cushion of two inches between the bricks and the concrete. One picture shows the ducts in place and the arrangement of them.

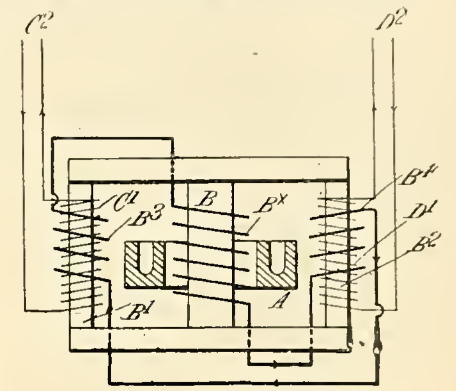
The contract for the entire installation of the work was let to G. M. Gest of New York. The work is under the direct charge of H. J. Hawkshaw as superintendent for Mr. Gest.

Through electric trains between Evanston and Milwaukee will be in operation by the middle of October, according to Mr. A. C. Frost, president of the Chicago and Milwaukee Electric Railroad Company. Buffet dining cars will be attached to all through trains, but the report that sleeping cars would also be run is denied by Mr. Frost, as he expects to make a schedule time of 2½ hours.

Polyphase Induction Furnace.

There is a class of induction furnaces, known as the Kjellin type, which are constructed upon the principle of a transformer, and in which the charge to be melted forms the secondary. These furnaces have been operated successfully with single-phase alternating current, but various attempts have been made to utilize polyphase currents, such as two or three phase currents, providing one annular bath or fusion chamber for each phase, either separate or in conjunction. But the losses caused by heat radiation were found very high, in fact, about nine kilowatts per square foot of the bath surface, and where only the polyphase current was available it was found necessary to convert it into single-phase by motor generators, thus greatly increasing the original cost of the installation. Moreover, as the fusion chambers or secondaries have to be placed at a considerable distance from the primary coil, an arrangement of two or three fusion chambers will greatly increase the magnetic leakage in the transformer, causing a low power factor and inefficient operation of the generating plant.

According to an invention designed to overcome these difficulties, and upon which J. Harden of London, England, has secured a United States patent, polyphase alternating currents are employed in the working of induction furnaces by combining transformers to convert the polyphase currents of the supply mains into single-phase currents in the induction furnace. For this purpose the primary windings of the induction furnace are connected to the secondaries of transformers whose primaries are connected to the different phase windings of a polyphase system, so that the currents induced in the secondaries are all in the same direction,



A POLYPHASE INDUCTION FURNACE.

but possess phase differences corresponding to the phases of the polyphase system.

Herewith is given a diagram showing the transformers for a two-phase system, combined with the induction furnace itself. (A) is the annular fusion chamber surrounding the middle member (B) of the furnace, the side members of which are indicated by the letters (B^1) (B^2).

The primary windings (C^1) (D^1) and also the secondary windings (B^3) (B^4) are wound upon the outer members (B^1) (B^2) of the induction furnace. In this case, the windings (B^3) (B^4), which are secondary windings with respect to the windings (C^1) (D^1), are the primary windings with respect to the charge contained in the annular chamber or bath (A).

The advantage of this construction is the economy of material occasioned by employing the furnace core (B) as the middle member of the transformer, while as well serving as means for positioning the magnetic flux.

Tantalum Stronger Than Steel.

The following physical properties of the metal tantalum are of interest, since the recent extensive application of tantalum high-efficiency lamps: The melting point of tantalum is said to be between 2,250 and 2,300° C. Its resistance increases with rise of temperature, just as in the case of osmium or other metals. At ordinary temperatures the resistance of a wire one meter long and one square millimeter in section is 0.165 ohm. At the temperature of the incandescent lamp this figure becomes 0.85 ohm. The breaking strength of tantalum, when cold, is very great, being 93 kilos per square millimeter, as compared with from 70 to 80 kilos, for good steel. When heated, however, it becomes soft like osmium, and a filament, after burning for some time, is easily broken. The material is for incandescent filaments, the diameter being from 0.035 to 0.05 millimeter.

Some Hydraulic Features of Kern River Plant No. 1.

Several references have already been made in the Western Electrician to the recently completed Kern River Station No. 1 of the Edison Electric Company of Los Angeles. But a number of accounts will hardly exhaust the interesting features of this unusual installation. This plant, from which is developed enough power to double the capacity of all the Edison Company's other plants combined, is located far up in the lower Sierras of California, almost at the headwaters of the Kern River, whence through a wonderful channel, comprising 20 tunnels in all, water is led down 12 miles from the mountains for a fall of nearly a thousand feet and hurled against the four great Allis-Chalmers impulse wheels, aggregating over 40,000 horsepower and direct-connected to General Electric generators.

DISCHARGE WATER FROM FIRST WHEEL AT KERN RIVER PLANT NO. 1.

The engineering problems involved in building tunnels, flumes, penstocks and power houses to endure the heavy strains put upon them, were no more difficult to solve than the transmission of the electrical output from the new station under a pressure of 75,000 volts over a distance of 117 miles to Los Angeles. The route of transmission lies through the canyon in a direct line, thence over the hills, plains and divide, to follow the course of the Piru River and its tributaries. Large galvanized-iron towers carry the heavy wire cables of the transmission line.

In many respects the Kern River development is unique. It is said to be the largest hydraulic electric plant west of Niagara. The transmission line is one of the longest in the world. The pressure of 75,000 volts over such a length of cable is the highest ever attempted. The conduit which leads to the pressure main is the longest underground tunnel system in use for this purpose. The concrete-encased penstock, tapering so as to accelerate the force of the water at the power house, is said to be the first of its kind ever placed in service.

The four big wheels which convert hydraulic to mechanical energy have each a capacity of 10,750 horsepower at full gate and a speed of 250 revolutions per minute, when operating under a net effective head of 865 feet. In addition to the main turbines, there are two exciter turbines, also of Allis-Chalmers design, each with a capacity of 450 horsepower, and a speed of 430 revolutions per minute.

The large waterwheel units are of the impulse type, with hand-adjustable needles and governor-operated deflecting nozzles. Each unit has two runners, one on either end of the generator shaft. The interchangeable buckets are made of non-corrosive phosphor bronze of special mixture for the high head and are attached to the cast-steel disks bolted to the flnaged ends of the generator shaft. These disks of cast steel furnish sufficient flywheel effect to supplement the amount contained in the generator, in order to meet the guarantee of speed regulation. (For sudden changes of load amounting to 25 per cent., 50 per cent. and 100 per cent. it is guaranteed that the speed variations will not exceed 1.7 per cent., 3.5 per cent. and 7.8 per cent., respectively.)

The nozzles are provided with hand-adjustable needle and arranged to be deflected by the governor automatically, or by the latter's hand-regulating device. By deflecting the jet instead of regulating its discharge by adjusting the needle with the governor it is possible to secure a constant velocity of water in the pipe line as well as a constant discharge of water into the tail race, even when the plant is operating with heavy fluctuations of the commercial load.

The nozzles are of the best quality of cast steel. Special attention may be called to the design which has a number of new features. The nozzles consist of two "Y" pipes, flanged together in such a way that the whole nozzle has a diamond shape. The upstream end of the nozzles forms the movable part of the knuckle joint and the downstream end carries the nozzle tip. It is declared that by making the nozzles diamond-shape these advantages are obtained:

1. The center of the jet corresponds to the center of inlet pipe; therefore any reaction from the jet upon the needle and nozzle is not eccentric. This is of importance with deflecting nozzles, where any variable reaction upon the governor should be avoided.

2. As the two branches of the "Y" join at ample distance from nozzle tip the water has time to gather concentrically around the needle under an absolutely uniform pressure. The result is that the jet leaves the nozzle tip at a high velocity and without disturbance.

3. Due to the fact that the jet leaves the nozzle tip uniformly, the needle is axially balanced and not subject to any vibration.

4. The needle stem not being subject to any bending, it need not be made slender and flexible, but is made very substantial. The end of the stem projecting through the front "Y" pipe is of smaller diameter than the stem. The differential room thus formed can be put under adjustable water pressure. This pressure tends to close the needle and puts all pins and links of the connection in a position for hand adjustment under slight pressure in the closing direction. By this any rattling of the needle is prevented.

The upstream end of the nozzle forming the movable part of the knuckle joint is hooked into the stationary part or swivel-head. The swivel-head is heavily bolted to the foundation, as it has to take up the full pressure of 375,000 pounds, tending to pull the nozzle away downstream. This pressure is taken up by two steel pins carefully fitted into their bearings and provided with suitable lubrication.

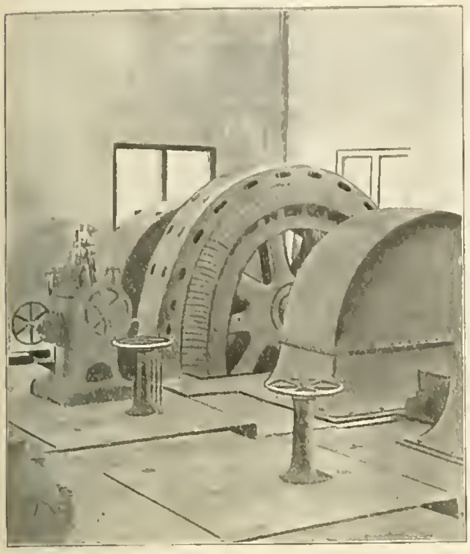
A 28-inch gate valve is connected to the swivel-head and controlled either by hand or electrically by a motor operated from the switchboard. All parts of this gate subject to the operating pressure are made of the best quality of cast steel. The gate is single-seated and bronze-lined.

The needle consists of a hollow stem of cast steel, into which is screwed and secured the steel needle tip. A heavy cast-iron base plate grouted and rigidly bolted to each side of the generator base frame forms the solid foundation for the cast-iron wheel housing. These housings are made very substantial in order to avoid resounding. They are divided horizontally along the center line of shaft, thus allowing easy removal for inspection or for replacing of the buckets. The sides of the housing have extensions of removable steel plates which protect the concrete against the impact of the discharging water. The pits in which the deflecting nozzles are located are of sufficient width to allow passage on either side. They are covered with substantial cast-iron floor plates made in sections of such size as to permit of easy removal.

Another feature of these impulse wheels deserves comment on account of its novelty. As already mentioned, the regulation of the wheels is effected by a governor which deflects the jets of the two nozzles. The needles are adjusted by hand and are usually set to that maximum size of jet which will be sufficient to develop the maximum peak load expected for that period of setting of the needles. In other words, there is always a maximum amount of water leaving the nozzles. The governor adjusts the deflecting nozzle in such a way that only as much water is directed upon the buckets as is needed for the load for the time being. The balance discharges below the buckets into the tail race. It is evident that at times when all load is thrown off the wheels the governor will deflect the jets entirely. Each jet has a maximum diameter of 7⅜ inches and leaves the nozzle tip at a velocity exceeding 225 feet per second. It was, therefore, necessary to provide means of receiving this tremendous power and deflect the jet into the tail race in such a way that its impact would not be detrimental to the parts against which it is directed.

DISCHARGE OPENINGS AT KERN RIVER PLANT NO. 1, SHOWING DEFLECTORS IN PLACE.

This has been successfully accomplished by the present arrangement of deflectors. It consists of an upper channel heavily ribbed and bolted to the concrete foundation and of a lower bottom plate. The channel at its upper end is slightly more inclined than the deflected jet. Thus the jet will strike the bottom of the channel under a small angle and therefore tend to spread and fill the section of the channel. The channel gradually widens and consequently the jet is offered a larger resistance area. The lower part of the channel is curved and at its end the jet discharges almost perpendicularly. The bottom plate is "S" shaped, its upper



ONE OF THE GENERATING UNITS IN KERN RIVER PLANT NO. 1.

end being flush with the bottom of the wheel pit, the lower end being practically level. The jet strikes the bottom plate almost in the turn of the "S" and under a small angle. Thus the jet is again forced to spread and follow the base of the bottom plate. In due consideration of the unavoidable wear and tear of these deflectors, they are lined with removable steel plates wherever the surfaces are exposed to the flow of the deflected jet.

The exciter units are also of the impulse type, with hand-adjustable needles and governor-operated deflecting hoods. Each unit has one runner overhung on one end of the exciter shaft, the other end carrying a flywheel. The interchangeable buckets are bolted to a cast-steel disk which is keyed upon the exciter shaft. This disk and the flywheel furnish sufficient flywheel effect for the speed regulation guaranteed. The nozzle is stationary and "S" shaped in the horizontal plan and carries the stand and handwheel for hand operation of the needle. The needle has a removable tip. A hand-operated gate valve is connected to the upstream flange of the nozzle. The base of the wheel housing is cast in one piece with the exciter base frame. The cast-iron wheel housing is split horizontally along center line of the shaft. The sides of the base have extensions of removable steel plates which protect the concrete against the impact of the discharging water. The pits of the nozzles are covered with removable cast-iron floor plates.

The automatic regulation is effected by a governor which deflects the jet from the buckets, this, however, not being accomplished by deflecting the whole nozzle but simply by inserting a hood, which cuts into the jet from underneath and directs this part of it directly into the tail race. That part of the hood which deflects the jet is made of steel and is removable. Care is taken in designing this arrangement so that the knife edge of the hood does not disturb the working portion of the jet.

When the governor arrangement was designed the leading idea was to have each turbine with its respective governor form an independent unit. Although the available operating water pressure of 370 pounds from the force main is ample to operate governors, it was preferred to substitute oil pressure. It was also preferable not to feed the governors with oil pressure from a control system, but to make each governor absolutely self-contained.

Special attention was paid to the safe operation of the units, avoiding from the beginning any runaway. For this purpose the arrangement of the generator as well as the exciter governor was made in such a manner that the jets will be automatically deflected from the buckets should the oil pressure in the governor fail.

The weight of each generator deflecting nozzle is partly carried by an hydraulic balancing piston, which receives water pressure directly from the force main. As soon as the oil pressure in the governor fails the nozzle will lower on account of the unbalanced weight, and thus deflect the jet from the buckets. The same result is accomplished with the deflecting hood of the exciter wheels, which is connected to a hydraulic water piston, tending always to insert the hood and thus deflect the jet.

The governors are driven by a silent chain from their respective wheel shafts. The connections between the operating pistons and the deflecting nozzles or hoods consist of levers, pins, links and shafts, and the use of gears or racks has been avoided, thereby preventing the jars that result in lost motion and wear and tear.

The oil pump is attached to the casing and immersed in the oil reservoir. It is of the rotary type, having no valves, which are often the cause of failure of oil pressure. The main pump shaft also carries the bevel gear which drives the flyballs operating the pilot valve over the regulating lever. The pilot valve is self-contained between opposing pressures and any reaction upon the flyballs is eliminated. It is evident that this is a condition of prime importance for exact regulation. The pilot valve distributes the oil pressure in the regulating cylinder. The motion of the regulating piston is reversedly transmitted to the regulating valve by means of a combined compensation. The leverage of this compensation is adjustable, so that the governor may be set to any change of speed between no load and full load, from 16 per cent. to absolutely constant speed.

The governors are equipped with four regulating devices which can be used at any time, viz.:

1. Mechanical hand regulation (without oil pressure).

2. Automatic regulation with flyballs.

3. Hand regulation with oil pressure (flyballs disconnected by a clutch coupling inserted between pump shaft and flyball shaft).

4. Hand regulation with oil pressure and electric motor operated from the switchboard. (Synchronizing attachment.)

The exciter governors are of similar design, except that they are not provided for electric hand regulation.

The Kern River installation of the Edison Company is but one of three waterpower developments owned by this company in addition to six or seven steam plants located within a radius of 200 miles, all of which will operate in synchronism. A portion of the output of this plant will be disposed of along the line to Los Angeles. A very considerable amount of power will be utilized in the city of Santa Barbara. The demand for power in Los Angeles, Santa Barbara and San Luis Obispo counties far exceeds the supply, and the output from this station will help to satisfy the general requirements rather than be devoted to any specific purpose. The Edison Company contemplates the building of plants Nos. 2, 3 and 4 on the Kern River, which will aggregate over 100,000 horsepower in addition to the output of the present station.

Milling Head Used as Ice Cutter for Third Rail.

Sleet and ice are sources of great annoyance to third-rail systems of railways for the reason that the coating on the third rail which they form acts practically as an insulator to prevent the current from reaching the shoe or contact device on the

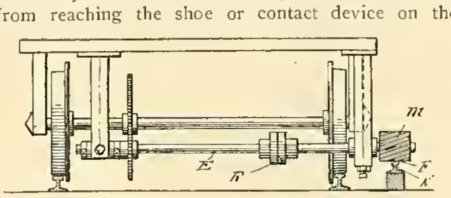


FIG. 1. MILLING-HEAD ICE CUTTER FOR THIRD RAIL.

car. Various methods have been proposed to cope with the difficulty, including the use of chemical solutions or mechanical rail cleaners, and several are in use. An interesting example of the mechanical type is that recently invented by George A. Spice of Chicago and covered by a United States patent. Here a milling-head or cutter is used as shown at (F) in Fig. 1 of the accompanying drawings, which shows the manner of attachment to the car truck, the third rail being at (N). Fig. 2 is a vertical section of the cutter employed, and Fig.

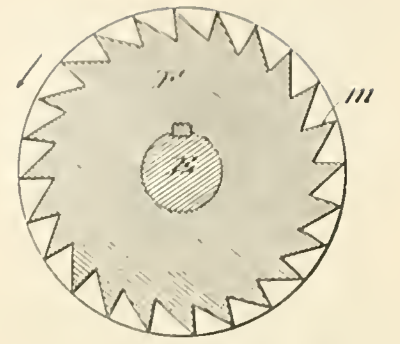

FIG. 2. VERTICAL SECTION OF THIRD-RAIL ROTARY ICE CUTTER.

3 is a partial, horizontally developed bottom plan view of the same cutter.

The drawings show the general arrangement of Mr. Spice's invention with sufficient clearness. The cutter-head is practically cylindrical and provided peripherally with teeth (m) disposed spirally and parallel with each other. It is so disposed relatively to the car wheels as to normally ride upon the third-rail of the system, being normally maintained under pressure in contact with the upper surface of the third rail by means of springs, the latter serving also to cushion vertical movements imparted to the cutter-head by inequalities in the height of the third rail at various points along the route.

Gearing is provided so that a higher surface speed is imparted to the cutter than the surface speed of the car wheels. The cutter revolves in the same direction as the wheels.

The teeth of the cutter (F) are disposed so that one face is practically radial, and this face is presented in the direction of motion of the cutter, so that the sharp cutting edges will during the revolution of the cutter-head act in practically the same way as the cutter-head of a planer to cut away any coating of ice or sleet on the rail. The angle of disposition of the teeth is also such relatively to the direction of motion as to throw the ice and

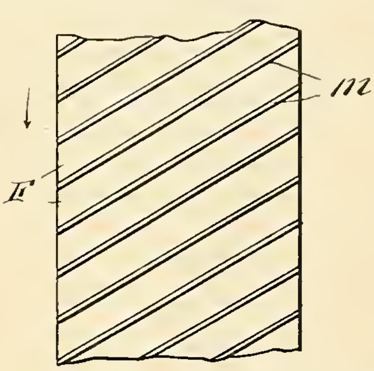

FIG. 3. PLAN VIEW OF THIRD-RAIL ROTARY ICE CUTTER.

sleet removed away from the car instead of toward it.

An insulating coupling (R) is provided on the shaft (E) of the milling-head cutter. The device is simple, and during warm weather it may be readily removed from the truck.

Hydro-electric Power for the Alamo Mining District.

A hydro-electric development attended by extraordinary conditions as to character of country and difficulty of construction is being completed on Congo Creek, 20 miles west of Sumpter, Ore., by the Fremont Power Company, of which Mr. John Thomsen is manager. The company has expended about $500,000 thus far and proposes to furnish power for operating the quartz mills in the Sumpter district, driving the machinery of the Sumpter smelter, and furnishing light for the city of Sumpter. The plant is installed, the transmission line is nearly completed to Bourne, and current is about to be turned on to that point. Bourne is a mining town, five miles from Sumpter, and is the center of the Alamo mining district, including the Alamo, Quebec, Strasburg, Belcher, I. X. L., Hicks, Phœnix, Psyche, Snow Creek and other quartz mines where stamp mills are being erected. The line will be extended south to the Quartzburg district, where are the Standard, Copperopolis, Present Need and Gem mines.

DEPARTMENTS.

DATES AHEAD.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

New York Electrical Show, Madison Square Garden, September 30th to October 9th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

TYPOGRAPHICAL ERRORS are seemingly destined to cause annoyance, profanity or hilarity, as it may be, so long as the art of printing continues to exist. A curious example of these thorns in the flesh occurred recently in an esteemed English electrical journal. Speaking of the recent American specifications for street lighting, this journal remarked that "the committee consisted of Messrs. Dudley Tarrand, A. E. Kenelly, C. P. Steinmentz, L. A. Furguson and P. Spencer." In this list every surname is misspelled except the last.

TO ENCOURAGE the wiring of old buildings the monthly-payment plan is adopted by central-station companies with gratifying results. Mr. F. H. Golding of Dayton recommended this plan "where conditions seem to warrant" in his paper, "How to Get the Old Buildings Wired," read on June 7th last at the Washington convention of the National Electric Light Association, and the subject also attracted much attention at the recent Ohio convention. The Chicago Edison Company has now adopted the plan and extended it to make the cost of the wiring of the old building payable in 24 monthly installments. This makes the cost of even quite a considerable job of wiring scarcely felt, and the plan is proving remarkably successful. Many customers are by this means secured who would not otherwise feel able to meet the installation expense.

THE DISCHARGE of electricity at high potentials through gases has been the subject of some attractive laboratory experiments in the production of artificial fogs on the small scale of a bell-jar, whose results have led to beautiful and accurate determinations of the absolute size and number of the molecules of the gas. Reversing the process there has been proposed the artificial dispersion of fogs by similar apparatus working on a larger scale. The proposed station will require a large induction coil or transformer capable of giving a spark about 40 inches. Its primary will be energized by a source of direct current, the circuit being rapidly broken by a rotating interrupter. A condenser may be bridged across the interrupter to absorb the heavy arc which would follow the breaking of the large current required to operate the coil. The current from the secondary windings is led through mercury-vapor rectifiers which change it from alternating into a pulsating unidirectional flow. Large Leyden jars are connected in the circuit to secure the proper capacity. The positive wire is carried to the top of an aerial mast, where it ends in a crown of points. It is said that with such apparatus clear spaces 300 to 400 feet across have been found in very thick fogs. While clear regions even of this size would be very useful in harbors or on railways, it is to be remembered that such a space extending at least for a quarter of a mile in every direction from a vessel at sea would be necessary for safety if bare steerage headway were to be maintained. But the proposition is an attractive one and seems endowed with potentialities, when developed on a still larger scale, of avoiding collisions with other vessels, derelicts and icebergs which are the dread of mariners.

PRESENT PROSPECTS are that the time is near at hand when Chicago will be connected with Detroit, Indianapolis and St. Louis by diverging lines of electric railway on the east, southeast and southwest as it already is with Milwaukee on the north. The line to Kankakee, 54 miles south, will be in operation in a few months, no doubt, while the nearby cities of Elgin, Aurora and Joliet have been linked to Chicago by electric bonds for several years. The constant extension of the interurban electric railway and its ever-increasing popularity constitute one of the most significant economic tendencies of the present day. The electric lines link town and town and city more closely together. People like to ride on them, particularly in summer; they afford frequent trains and convenient stopping places. They are home-like and neighborly, while the comparatively infrequent steam trains are more alien and strange. At first the retail merchants in villages and small cities feared that the interurbans would tempt the country people to go to the larger cities to do their shopping to a greater extent than before; but it is found that the country merchant can also take advantage of the interurban to secure quick shipments, to keep himself as well as his stock up-to-date by frequent visits to the city. The electric railway is popular with all classes, with the women and children as well as with the men, and it needs only a trip into the country in almost any direction to see how rapidly it is being extended.

This popularity is not likely to be endangered unless a false economy in men or material results in a disproportionate number of accidents. Some accidents seem to be bound to happen in railroading—to be beyond human foresight—but many that do occur could be prevented; and the responsible managers of the electric railways, profiting by the painful record of the steam railroads in this country, will do well to make safety of travel an aim of such great importance as not even to be eclipsed by the very natural and laudable desire to return large dividends. Let the electric railway be synonymous with the most careful regard for human life, and let the electric-railway accidents that have already happened—would that there were less of them!—serve as warnings or severe lessons which may make like disasters less frequent in the future.

MAYOR BUSSE is to be thanked and congratulated for his first message to the Chicago City Council, in which he advocates the "electrification" of the steam railroads within the city. This reform is needed and inevitable, and the Western Electrician has pleaded for it for several years. The mayor's action was indorsed by the Council, and accordingly the local transportation committee of that body, with expert assistance, will "make such investigations and prepare such reports as may be necessary, to advise this Council fully as to the possibility of installing the necessary electrical equipment for use on the railway terminals of Chicago to do away with the steam engines and eliminate the smoke nuisance from that source." The mayor's message is a temperate document, and indeed it is to be expected that anyone who has given careful attention to the subject will appreciate the magnitude of the problem and the expense and effort which it will impose upon the railroad companies. Nevertheless, the improvement is bound to come, and the mayor's action will doubtless prove to be the entering wedge which will result, in a few years, in the electrical operation of the railroad terminals in Chicago.

In his message the mayor calls attention to the example of New York city in electrifying railroad terminals, and he remarks that if similar action be taken in Chicago the smoke nuisance would be thereby greatly abated. The mayor investigated the situation in New York, and in his report continues:

"Our observations, while satisfying us as to the advisability of substituting electrical motive power for steam power on railroad terminals in the city, have no definite bearing, of course, upon the difficulties to be surmounted and the practical details involved in the working out of such a change. As Chicago is the greatest railroad center in the world, this problem of doing away with the common type of soft-coal-burning steam engines inside the city is, of course, a tremendous one, but it is a problem which I think the railroads realize must be faced some time in the near future, and it is one which the city must help to solve, to the end that the smoke nuisance may be eliminated."

The mayor advocates the change on the single ground of abating the smoke nuisance, but there are also other advantages, as the marked decrease in the noise of train operation—and the noises of city life constitute a serious detriment to health and comfort—and the greater ease of riding for the many thousands who use the trains daily, to say nothing of the enhancement of property values in neighborhoods adjacent to the railroad lines. Chicago will be greatly benefited by the change, and although the undertaking is a large one, it should be entered upon with a confident and resolute spirit.

Insurance Report on Motor and Generator Accidents in England.

The British Engine, Boiler and General Insurance Company issues annually an instructive report upon the electrical and other machinery which is confided to its care. The following results of the inspections in connection with breakdowns and other accidents are furnished by the London correspondent of the Western Electrician, who says:

It is satisfactory to note that whereas a considerable increase took place in the number of dynamos and motors insured, the breakdowns increased in a lower ratio. Dynamos failed in the proportion of one in 16 of those insured, and motors, one in 8.2. Direct-current machines failed twice as often as alternating-current machines, but the cost of repair per breakdown for direct-current machines was only about one-half that of alternating-current machines. The company has also now a large number of starting resistances insured, but the breakdowns of these have increased far more rapidly than in the case of dynamos and motors.

A warning is uttered against the use of foreign-made commutators, which invariably seem to have the insulating washers of "made-up" mica of poor quality material, instead of the soft, green mica, for small motors, as frequently recommended.

The following figures show the percentage proportion of the various parts of machines which have failed: 50 per cent. of armatures and rotors in dynamos and 44 per cent. in the case of motors; 11 per cent. of magnet coils and starters in dynamos and 14 per cent. in motors; 20 per cent. of commutators and brush gear in dynamos and 28 per cent. in motors. The remaining 19 per cent. and 14 per cent., respectively, are attributed to miscellaneous.

In connection with starting switches and controllers, it is stated that 48 per cent. of the resistance coils have failed; 10 per cent. of contacts and switch arms, and 17 per cent. of the automatic apparatus. In attributing the breakdowns to various causes, it appears that the largest percentage in the case of dynamos is due to bad workmanship and design, while in connection with motors and starters age and deterioration are responsible for the greater proportion of mishaps.

This report is quite an unofficial one, issued by the insurance company in the interests of its clients, and is quite distinct from the Home Office electrical inspector's report. Nevertheless, although the present document is not of such a far-reaching character in importance, it contains information, gained from actual experience, of value to all manufacturers of electrical and other plants.

Canadian Electrical Convention.

Plans for the seventeenth annual convention of the Canadian Electrical Association have progressed most satisfactorily with the result that a programme of unusual interest has been prepared. The convention will be in Montreal on September 11th, 12th and 13th and the meetings will be held in the assembly hall of the Canadian Society of Civil Engineers. Exhibits will be in the government drill hall on Craig Street. The local committee has prepared an excellent programme of entertainment features.

The usual arrangements have been made with the Eastern Canadian Passenger Association, including points in the United States in its territory, for reduced fares on the certificate plan for both rail and water. Persons should purchase a first-class full fare one-way ticket to Montreal and obtain from the ticket agent a standard certificate. If 50 certificates are presented the return fare will be one-third; if 300 or more certificates, free return.

After the usual opening exercises, including the president's address and committee reports, the following papers appear on the programme: "Electric Heating and Cooking Devices," by A. B. Lambe; "Trials of the Operating Man," by M. A. Sammett; "Three-wire Generators," by B. T. McCormick; "High-tension Insulators from an Engineering and Commercial Standpoint," by Clarence E. Delafield; "The Value of the Nernst Lamp to the Central Station," by A. E. Fleming; "Incandescent Lamps," by J. M. Robertson; "Frazil and Anchor Ice—the Difficulties They Cause at Hydraulic Plants—Some Remedies," by John Murphy; "The Load Factor," by R. M. Wilson; "Modern Lighting Transformers," by G. P. Cole; "The Responsibility of Electric Companies for Accidents," by George H. Montgomery.

Parts of each session will be devoted to the Question Box. Elaborate preparations have been made for entertaining the guests, including several special features for the ladies.

Mr. R. G. Black of Toronto is president of the association and Mr. T. S. Young is secretary.

Luminous Arc Lamps from the Standpoint of Central-station Operation.[1]

By Howard Grabill.

The Ashland Gas and Electric Light Company was one of the first central stations in Ohio to adopt magnetite or luminous arc lamps. This installation, made in December, 1905, consisted of 90 type 2 lamps, the rate for energy on a midnight moonlight schedule being $68 per lamp per year.

During the present summer we have been replacing this lamp with the type 3, which corrects about the only defects we have found the magnetite lamp to have. In the place of a swinging upper electrode a stationary one is substituted. The latter gives better service and is also reversible, thus practically doubling its life. A heavier and closed globe is also used instead of the former one with an open bottom, to which a rather heavy ash-pan was attached.

As T-H open arc lamps were formerly used for lighting the streets of Ashland, what we have to say is in the nature of a contrast between that lamp and the magnetite lamp. Our experience proves the latter to have many decided advantages. These points of superiority may be placed under two heads:

(1) Advantages to the public.

(2) Advantages to the central station.

The advantages to the public are (1) improved distribution of light; (2) better quality of light, and (3) fewer outages. For the central station we find the following points of superiority: (1) Economy of energy. (2) Lower cost of maintenance. (3) Ease of adjustment. (4) Ease of trimming, and (5) lower cost of repair and renewal.

The open carbon arc lamp will be remembered as having a large shadow just beneath it, a wide variation of illumination due to the wandering arc, and as giving a good light for a short distance, beyond which point the amount of light falls off abruptly. With the magnetite lamp the distribution is much more uniform. A globe with a frosted or sand-blasted bottom is used and there is almost no shadow beneath the lamp. As one walks from one toward the next, one notices that the illumination midway is much better. This is because there is more light reflected there, and also because of the absence of that sharp contrast between the amount of illumination under each open carbon lamp and that midway between them. As we made no readings with a luminometer while operating the open carbon lamp, we can make no comparison on this basis with the magnetite lamp. However, we did make some readings in a neighboring city where alternating-current enclosed series lamps are used, and find that the amount of illumination there at a distance of 165 feet is equal to that at the distance of 205 feet from a magnetite lamp.

Two things make possible the better distribution of the magnetite lamp. First, the positive electrode does not form a crater as does the positive carbon of an open arc lamp, resulting in the axis of maximum distribution being at an angle of about 45 degrees. Second, since the arc in the magnetite or luminous arc lamp always has the same relative position, it is possible to use a reflector. This reflector is placed in a horizontal position just above the arc, but being enameled iron it is unaffected by the heat and so is not a part that would need to be renewed during the life of the lamp. The result is that the axis of maximum distribution of this lamp is at an angle of about 90 degrees, or almost horizontal.

The quality of the light is excellent, being whiter than that from alternating-current lamps and steadier than from open carbon lamps. Another advantage which this lamp has is that of fewer outages. When a lamp is found not to be burning it can usually be started by jerking the rope by which it is raised and lowered. It is caused by a small particle of the burnt electrodes getting between them and acting as an insulator. We have found it necessary to replace broken globes at once, as this lamp will not burn unprotected from the air. This is no serious defect, as the long-burning feature of the lamp makes frequent trimming or handling unnecessary; hence the chances for broken globes are reduced. In our experience the ratio of outages as compared with the carbon lamp is one to three in favor of the magnetite lamp.

The low wattage of the magnetite lamp is one of its most distinguishing characteristics. It is designed to operate on direct-current series circuits with 70 to 85 volts at the lamp terminals or by mercury arc rectifiers connected to alternating-current circuits. We are using the direct-current system, energy being furnished by a Brush arc machine. To replace a 480-watt lamp with one consuming 320 watts we have found to be a great benefit to our company.

Because of the long-burning feature of this lamp the maintenance cost, as compared with open carbon lamps, is very low. The upper or positive electrode, a heavy piece of copper, is reversible and has a life of about 4,000 hours. The lower electrode, an iron tube five-eighths inch in diameter and eight inches long, and filled with black magnetite oxide of iron, has a life of 175 hours. It is thus necessary for us to trim our lamps only nine times a year. The cost of maintaining these electrodes on a schedule such as ours is about 60 cents per lamp per year.

The two adjustments—the length of the arc and the feed contact magnet—are easily made. The length of the arc is controlled by an adjustable stop which is fastened by a set screw to the left-hand guide rod. To increase the arc voltage, raise this stop; to decrease the voltage, lower it. After an adjustment has been made the lower electrode rod should be tripped and then pushed up as in trimming. The feed contact magnet is adjusted by lowering or raising the armature disc and checknut placed just below it. If the lamp feeds too often the disk should be turned to the left. If not often enough it should be turned to the right. This magnet is in shunt with the arc and should close the contacts, causing the lamp to feed, when the arc voltage rises to about 110 volts. As we have said, these two adjustments are easily made.

In trimming the lamp the first thing to do after the globe has been unlatched and swung over to the side is to clean the center tube. It serves as a chimney through which the fumes of the arc pass out of the lamp, and unless kept clean there is danger of these reddish-brown fumes accumulating in it, clogging it up and then settling on the inside of the globe, shutting off the light. A small brush run through this tube a few times readily cleans it. Next the globe should be cleaned. The accumulation of this reddish-brown dust on the globes from one trimming to the next, while slight, is sufficient to cut off considerable light. It is, however, easily removed with a cloth dampened with coal oil. To replace the burned-out electrode the tripping rod should be pushed up until the clutch in the lamp is disengaged. The lower electrode holder will then drop into a position where the change is quickly made. To those who have had the experience of trimming of the open carbon lamps, the ease with which the magnetite lamp is trimmed is at once apparent.

Repairs and renewals cost us last year 54 cents per lamp. With the type 3 lamp we do not think this item will be as large, since it has a heavier globe and does away with a large copper ash-pan, and these were the only two parts it was necessary for us to replace during the year. For the present year, however, this item will be larger on account of our changing to the new type lamp.

As a whole, the system comes fully up to our expectations and we regard it as the best in operation at the present day. In fact the magnetite lamp, with its improved distribution of light, economy of energy and low cost of maintenance, represents a distinct advance in the art of illumination and cannot but appeal to any central station contemplating a change.

1. A paper read at the Toledo convention of the Ohio Electric Light Association, August 20. Mr. Grabill is connected with the Ashland (Ohio) Gas and Electric Company.

The Easy-payment Plan of Wiring.

The Chicago Edison Company and the Commonwealth Electric Company have recently adopted a new plan for the wiring of residences and high-class apartments that has yielded excellent results. The scheme, in a nutshell, is to extend payment for this class of work into 24 equal monthly installments. By this policy a great deal of new business is being secured that otherwise could not be obtained, for the installation and wiring charges are spread out so that the consumer scarcely notices them.

A large part of the public has been eager for the use of electric light, especially since the recent further reduction of rates, but has hesitated on account of the cost of wiring. This problem has now been solved by the installment plan. The plan is confined to completed buildings and does not apply to new structures. The wiring of old buildings has been much more difficult to secure than that of new ones. Mr. Cregier of the contract department has charge of this line of work and reports that he can scarcely get men enough to handle it. This latest plan is but another move of the company in its campaign to make the use of electricity practically universal in Chicago and vicinity. The plan is also being tried in other cities.

Conventions at the Madison Square Electrical Show.

During the electrical show to be held at Madison Square Garden, New York city, September 30th to October 9th, two important conventions will be held in the concert hall at the garden. At recent meeting of officers of the Street Railway Association of the State of New York and of the state Gas and Electric Association it was decided to hold the annual gathering at Madison Square Garden during the show.

ELEMENTS OF ELECTRICAL ENGINEERING.

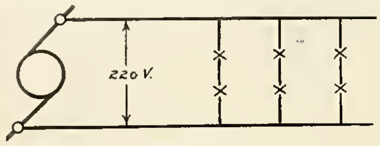
By Geo. R. Metcalfe.

XXXII.—Electric Lighting.

Balancing in Three-Wire Systems.

In order that the three-wire system of distribution described in the previous chapter shall operate satisfactorily, a careful study of the load should be made with a view to having it divided at all times as evenly as possible between the two sides of the system. The difference in the load between the two sides of the system is known as the unbalanced load, and it is important to keep the unbalanced load as small as possible, as any large amount of unbalancing seriously affects the regulation of the whole system.

If a much larger number of lamps are connected to one side than there are connected to the other side, the voltage of the light-load side will be too high, while that of the heavily loaded side will drop. For example, on a three-wire lighting

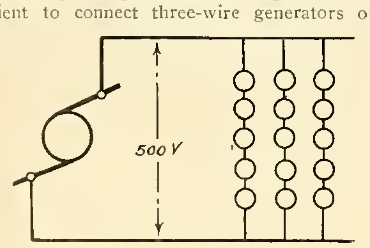


CONNECTIONS OF SERIES-MULTIPLE ARC LAMPS.

circuit with a normal voltage of 220 volts between the outside wires and 110 volts on either side, the unbalanced load may be sufficient to cause one side to drop to 108 volts, and the voltage on the opposite side will be 112 volts. If this condition exists in a central-station distribution, all the customers' lamps connected on the low-voltage side will burn below their normal candlepower and have a dim appearance, while those lamps on the high-voltage side will burn too brightly, which will considerably shorten their lives. In connecting the lamps on a three-wire system, therefore, great care must be taken so to arrange them that the load on both sides will be very nearly even.

In connecting up a small number of lamps, such as would be used ordinarily in a small private house, a two-wire service is usually supplied, which is connected on either side of the system, which will tend to produce the best balance. In larger installations a three-wire service is generally carried into the building, and the entire wiring of the building is on the three-wire system. Where any device is used which requires a large amount of current, such as a very high candlepower lamp or a large motor, it should be connected across the outside wires, where it cannot affect the balance of the system when thrown in or out.

From what has been said, it is evident that if the system were perfectly balanced there would be no necessity for carrying the middle or neutral wire back to the generators, as the neutral wire only carries the unbalanced load. In large stations, therefore, operating a number of generators, it is sufficient to connect three-wire generators of the



SERIES-MULTIPLE DISTRIBUTION —FIVE 110-VOLT LAMPS IN SERIES ON 550-VOLT CIRCUIT.

proper voltage to the outside lines only, and to install only a sufficient number of three-wire generators to carry the difference between the loads on the two sides of the system.

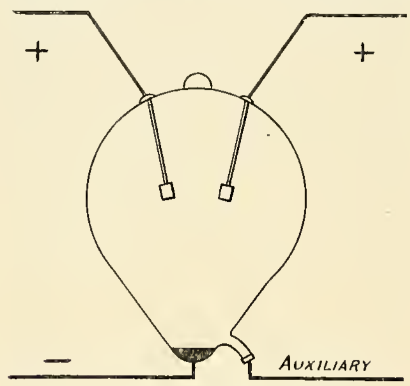
Series Parallel Distribution.

This system of distribution is used only to a limited extent for both arc and incandescent lighting. It consists of connecting groups of lamps in series and arranging several such groups in parallel. This connection is explained in the accompanying diagrams, and is principally used for operating two arc lamps in series on 220-volt distributing systems, or for operating series of five incandescent lamps from 550-volt railway circuits. The incandescent lamps used on electric-railway cars are generally connected in this manner, as are also many arc lamps which are used upon 220-volt constant-potential distributing systems.

Mercury Rectifiers.

Within the last three years mercury rectifiers have been used to some extent for the operation of arc lights. By means of the mercury rectifier direct-current arc lamps may be operated from alternating-current circuits without the intervention of moving machinery. Previous to this the only way to obtain direct current from an alternating-current supply was by the use of a rotary-converter or a motor-generator set, either of which consume considerable power and are impracticable for use where only small amounts of current are required, on account of their size and the expense of installation and attendance. The mercury rectifier changes an alternating current into a pulsating direct current without the use of any moving machinery, and is well adapted for the conversion of small amounts of current, as it occupies but little space and when once started operates continuously without further attention.

A diagram of the mercury rectifier is shown herewith. The rectifier consists of a glass bulb somewhat similar in outline to the ordinary pear-shaped incandescent lamp, and is about nine inches in diameter by one foot high. It contains four electrodes, the upper two of which are of graphite and the lower two of mercury. Each of these electrodes is provided with leads and terminals and the bulb is thoroughly exhausted of air. The two upper electrodes are called positive electrodes, and



OUTLINE DIAGRAM OF MERCURY RECTIFIER.

the large lower electrode in the center of the bulb is called the negative electrode. The small auxiliary lower electrode is used only for the purpose of starting the rectifier into operation.

The operation of the rectifier is based on the rather peculiar conditions which exist in relation to the conductivity of mercury vapor. When mercury vapor is in contact with solid metallic electrodes, current will flow very readily from the solid electrode to the mercury vapor, but if the current is flowing in the opposite direction, that is, from the mercury vapor to the solid electrode, the resistance is so high that it practically prevents all flow of current. In other words, the current flows readily from the solid to the vapor, and does not flow at all from the vapor to the solid. When alternating current, therefore, is supplied to the two positive electrodes of the rectifier, these electrodes pass the current in one direction only, and oppose all current flowing in the opposite direction, so that the pulsations of alternating current flow alternately between the positive electrodes through the mercury vapor to the negative electrode, which, therefore, gives off a direct or unidirectional current which is pulsating in character.

There is but little resistance to the flow of current between the mercury vapor and the mercury after the rectifier has started into operation, but there is a high resistance at the negative electrode which must be overcome before it is possible to start the rectifier into operation. The accompanying diagram of current waves will serve to explain the operation of the rectifier more clearly. Curves (A) and (B) show the current waves in the two positive electrodes, and the resultant curve (C) shows the rectified current which passes out from the negative electrode. The lower curve (D) shows the alternating-current electromotive force supplied to the rectifier, and it is apparent that if the part of the wave below the zero line were reversed there would result a direct current of very large pulsations which would vary from zero to the maximum value. While this would be a true unidirectional current, such a current could not be produced by the rectifier, for the reason that as soon as the value of the electromotive force reached zero the resistance of the negative electrode would be established, which would break the circuit.

It therefore becomes necessary to provide some means for bridging over this zero point of the electromotive force, and this is done by inserting a reactance in the circuit which changes the wave form of the current to the shapes shown in curves

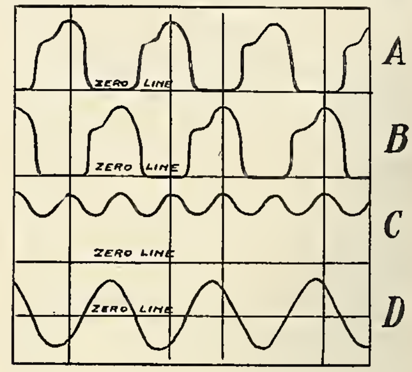


DIAGRAM OF CURRENT WAVES AND ELECTROMOTIVE FORCE.

(A) and (B). The reactance absorbs some of the energy from the peak of the wave and gives out this energy again at the lower part of the wave, so that the curve does not reach the zero point, and the two waves overlap, the resultant curve being shown at (C) in the diagram. It will be seen, therefore, that the whole of the alternating-current wave, both above and below the zero line, is utilized by the rectifier.

In order to start the rectifier into operation, the bulb is mounted so that it can be tilted, permitting the mercury to flow between the auxiliary and the negative electrode. The short space between the two electrodes is thus bridged by a little stream of mercury which becomes vaporized as soon as the current passes, after which the bulb is set vertical, and the positive electrodes come into operation. A resistance is inserted in series with the auxiliary electrode, through which the current is started. After the negative resistance is broken down and the positive electrodes become active, this starting resistance is automatically cut out.

The accompanying diagram shows one of the methods of connecting the rectifier to an alternating-current source of supply. In this method of connection the alternating-current circuit is con-

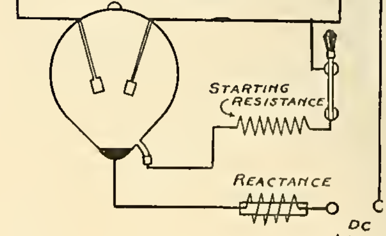

DIAGRAM OF CONNECTIONS FOR MERCURY-RECTIFIER CIRCUIT.

nected to two taps on an auto-transformer, which is a transformer with only a single winding, the location of these taps being determined by the voltage of the supply circuit. The two outside ends of the auto-transformer winding are connected to the two positive electrodes of the rectifier, and from the middle point of the auto-transformer a connection is brought out which completes a circuit through the load and the reactance coil in series to the negative electrode. The starting resistance is connected between the starting electrode and one

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

of the positive electrodes. The supply circuit may be either 110 or 220 volts alternating current, and by inserting a suitable regulating reactance in the circuit the rectified current may have a range of from 40 to 125 volts. A single rectifier bulb has a capacity of about 30 amperes, and where larger currents are required, two or more bulbs may be operated in multiple. The efficiency of the rectifier varies but little from light load to full load and is in the neighborhood of 80 per cent. for its entire range of load.

[*To be continued.*]

What Is the Best Form of Power for Stations of Five Hundred Kilowatts Capacity or Less?[1]

By Prof. F. C. Caldwell.

Ten years ago this association would hardly have considered it profitable to give much time to a discussion of this subject, but so remarkable have been the developments in central-station apparatus in the last few years that now the question is far from being an easy one to answer. Like most questions of this form, it is quite incapable of a complete and satisfactory solution within the limits of a paper of this character, and what follows can only be regarded as a framework which the members of the society may perhaps develop into a valuable structure in the course of their discussion. "Power" will be taken in the broad sense of the term, and the best form for the supply of electrical energy will be first considered.

There are now available to choose from the following types of apparatus: Direct current two-wire 220-volt and three-wire 110-volt; also alternating current, single-phase or polyphase. The choice between these will depend, first, on the character of the load to be supplied; second, upon the size of the plant, and third, upon the conditions under which it will be operated. A few years ago the two-wire 220-volt direct-current system seemed likely to take an important position for the smaller central-station supply. But two factors have recently been introduced into the problem, which are both unfavorable to its growth. The first of these is the development of metallic-filament incandescent lamps. The low resistivity of metals as compared with carbons makes the extension of these to voltages as high as 220 seem improbable, while the great saving in current, resulting from their use, must not be overlooked. The other factor is the placing on the market of successful three-wire generators at a cost not greatly in excess of the standard types. The 220-volt system has never been much used in this country outside of the smallest plants, though its simplicity and comparative economy in distribution were strong arguments in its favor. It will doubtless continue to be employed in cases where transmission for power purposes is the main business; but where lighting is an important element it is probable that it has passed its period of greatest usefulness. The problem may therefore be narrowed down to a question of three-wire direct current versus alternating current, single-phase or polyphase.

As between the direct and alternating current the question of distribution of load is the most important factor. Wherever more than one town is to be supplied from the same plant, or where the character of the farming population is such as to make the sale of power and light among them a matter of importance, the decision must be in favor of alternating current. On the other hand, where the conditions seem to set definite and comparatively narrow limits to the area which the plant will supply, the greater simplicity, higher economy in distribution and superior regulation usually obtained from direct-current plants may determine in favor of this form of supply. The amount and character of the motor load must be given careful consideration. If this is large in the immediate vicinity of the power plant, and especially if variable speed is important, the direct current will have the preference. If, on the other hand, the demand is more widely scattered, or is of such a nature that the simplicity and brushless character of the induction motor recommend themselves, the decision may be favorable to alternating current. The use of the storage battery in connection with the direct-current system gives it an advantage. In some cases, for instance, it may be possible to supply direct current for 24 hours with the use of but one 10 or 12-hour shift, at the same time obtaining the great advantages in the matter of regulation and storage against an emergency shut-down which are provided by the battery. Such a use of the battery, however, would only be possible in cases where the motor load was negligible—a condition which is in itself unfortunate. In general also the small plant is unable to supply the same quality of expert attention for the battery as is possible in a larger station, and this would often make its use questionable. In the case of quite small stations, such as are now being installed to a considerable extent in the villages of the country, the use of an alternating current system with a frequency of 25 cycles should receive careful consideration. This would often be advantageous on account of the possibility, actual or prospective, of joining up such a plant with the 25 cycle distribution system of some interurban electric railway. Ample experience has demonstrated the satisfactory operation of incandescent lamps with 25-cycle current, and in almost every case it would be more economical to purchase power from railway systems during a considerable part of the 24 hours rather than to keep the generating plant operating continuously. In many cases the whole output of the station could be most advantageously obtained in this manner. This suggests the supplying of current from one plant to a number of small towns throuhout a given district—a field which deserves more energetic cultivation than it has yet received.

The question of the use of single or polyphase alternating current is also an interesting one. Single-phase motors are obtainable in small sizes running up to about 30 horsepower, so that where the supply of power in large units is not to be anticipated, as, for instance, in the case of a strictly farming community, much is to be said in favor of the greater simplicity of the single-phase. Especially is this true in the case of the smaller plants where it is not practicable to employ a superintendent who has had much training or experience. In the case, however, of the larger plants within the range which we are considering, especially if connection with an electric-railway supply circuit is considered, the polyphase system should probably be used. With a little more care in the distribution, just as good results can be obtained as with the single-phase, and the possibility of the use of larger motors is always present.

Turning next to the question of prime movers, the following classification will be useful:

1. Waterpower.
2. Gaspower—Natural gas, producer gas.
3. Steam power—Reciprocating engines, turbines.

With regard to waterpower nothing need be said, further than to predict that before many years much more electrical energy will be developed in Ohio by waterpower than is now done. It is a very interesting problem, but of course peculiar to special localities only.

Where natural gas is available there is hardly room for any further discussion of this subject, so far is the gas engine thus operated superior to all other forms of heat engines. With a thermal efficiency approximately double that of reciprocating steam engines, with the entire absence of loss when the engine is not running and with the great rapidity with which it can be brought into operation, no form of steam engine is to be compared with it for small plants. The complication and liability to accident and shut-down which have been in the past attributed, with more or less justice, to the gas engine, have of late been rapidly losing weight by virtue of improvements in design and greater familiarity on the part of engineers. In the case of small plants for lighting and power purposes the defect of the gas engine in not having a considerable overload capacity is not so serious as in other lines, although it must be taken into account in the design of the plant.

In the absence of either water or natural gas the producer and gas-engine plant is in free competition with the various forms of steam engine, with a strong indication that the odds are coming to be more and more favorable to the former. Here success depends entirely upon the producer, which seems satisfactory in the case of the harder coals. In Ohio, however, the producer must demonstrate its ability to handle the bituminous coals of the state before it can be generally accepted as a substitute for the steam boiler. Its friends already claim the victory, and when account is taken of the relative time that has been spent in the development of the producer and the boiler, those who have been devoting themselves to the former certainly deserve congratulation. With a producer working successfully with soft coal, the steam engine will indeed have to look to its laurels, for the possibility of getting nearly twice as much energy from a ton of coal, together with the small standby losses and the quick service, give the gas engine enormous advantages, against which the somewhat lower first cost and the long-standing reputation of the steam plant cannot long prevail. Steam is, however, still with us, and doubtless will be for some time to come.

So far, the great development which the turbine has induced in the case of the larger stations has not been much felt by the smaller. Although at present turbines in a variety of smaller sizes are available, their use does not show as great an advantage over the reciprocating engine as in the large sizes. Generally speaking, also, in the case of the small station, economy of space is not so vital a matter as with the large city plant. On the other hand, the simplicity of the turbine should be a matter of even greater consequence, so that the question of relative first cost would probably be a determining factor in most cases.

Of course, wherever condensing water is available in ample quantity, anything but the very smallest plant should be operated with compound condensing machines. The availability of condensing water would also be important in determining the use of turbines.

The use of artificial means for the cooling of the condensing water, such as towers or reservoirs, is a financial one, and depends largely upon the price of coal, the cheapness of which in Ohio would seldom permit of the use of this system.

Another factor which should always receive consideration, and which may at times determine the character of the steam plant, is the sale of exhaust steam for heating purposes. The jacket-cooling water in a gas-engine plant may be similarly used.

In the case of small lighting and power plants, their combination with some other form of industrial activity should be given consideration. In many cases, a power plant may be made to pay if, during the daytime, the energy of the plant can be consumed in the operation of some productive industry. This works out especially well where the industry is of such character that a part at least of its machinery can be closed down an hour or two earlier during the winter months without seriously interfering with its success. A combined electric and pumping plant is a similar case. This is an especially desirable arrangement, if water storage is available, so that the pumps can be entirely shut down during the period of peak load. In this connection the electrically driven centrifugal pump, which has recently come before the public, ought to prove useful.

The above will serve to point out the wide range of choice with which the central-station designer of the present day is confronted, and to indicate in some measure the lines along which his decision must be made. It must never be forgotten, however, that here, as in most other engineering works, every case is a problem by itself and should be carefully studied in order to obtain the bearing of all accompanying conditions before deciding as to the best form of power.

1. Paper read before Ohio Electric Light Association at its thirteenth annual convention, held in Toledo, Ohio, August 20, 1907. The author is professor of electrical engineering in the Ohio State University.

QUESTIONS AND ANSWERS.

Resonance.

C. F. W., New York, referring to the formula for resonance, $2\pi nL - \frac{1}{2\pi nC} = 0$, states that at University College, London, some recent experiments with circuits having resistance, inductance and capacity showed $2\frac{1}{2}$ complete vibrations per second when C was 7 microfarads, L 31.5 millihenrys, and the resistance 7 ohms, and wants to know how 2.5 can be the proper value for n.

Answer.

The values given by C. F. W. do not show that $n = 2.5$ is the proper frequency for a condition of resonance; in other words, if n is 2.5, resonance could not exist. A derived formula obtained from the one above shows that $n = \frac{1}{2\pi\sqrt{LC}}$ is the critical frequency for particular values of L and C. With the values given above n must equal about $33\frac{1}{3}$ cycles per second.

Taper of Starting-box Resistances.

G. A. R., Chicago: Please give a formula for determining the resistance of the different steps of direct-current motor-starting boxes. Also kindly explain how to design solenoids for operating switches.

Answer.

The "taper" of the resistance in the different steps of a starting box depends upon the size of the motor and the purpose for which it is to be used. For small motors, the resistance steps are usually all equal. For a five-horsepower machine, under ordinary conditions, the steps might be tapered down until the last is only about half of the value of the first step; that is, resistance is cut out more rapidly during the first period of starting. For larger machines the ratio may run as high as one to six, but is so dependent on the starting behavior of the motor and many features of its design that no more definite statement can be made.

Formulas which will give data for the design of solenoids to exert a given effort will be found in practically all electrical textbooks, but the actual results depend so much on the length of the sucker armature and the air-gap around it that the best determination for the purpose will possibly be obtained from a simple experiment under the desired conditions.

Holland, Mich., is undecided whether to give a trial this winter to the Grand Rapids-Muskegon Power Company, buying current from that company instead of operating the municipal plant, and retailing it in the city.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

Best Ways to Meet Gas and Gasoline Competition.[1]

By F. H. Golding.

As a preliminary a list of present and prospective gas users should be obtained by a house-to-house canvass if necessary, ascertaining at the same time whether the premises are wired for electricity or not.

From the information thus obtained a working list should be prepared and the solicitor is then in a position to go after the business in a systematic and thorough manner, assisted by mailings of pertinent literature at regular intervals. In conjunction with the efforts of the solicitor and with personal mail matter, judicious and varied newspaper advertising will be found effective.

Possibly the gas or gasoline gas is proportionately a little cheaper per thousand feet than your electricity is per kilowatt, but the solicitor has a variety of arguments with which to meet this situation.

As a majority of central stations now furnish free lamp renewals and free maintenance of fuses and other slight repairs, the expense and maintenance of mantles are good talking points for the solicitor, and in many cases will make the cost of gas lighting higher than that of electric lighting. As additional arguments in favor of electricity the solicitor has cleanliness, coolness, convenience, freedom from danger of fire or asphyxiation, the elimination of redecorating at frequent intervals due to discoloration from burning gas, ability to use an electric fan, iron, sewing-machine motor or other convenient appliance when electricity is available, and many other points which suggest themselves.

The mail matter should be carefully selected with a view of aiding the solicitor in impressing the prospective customer with the general desirability of electricity, and should be so alternated with the solicitor's visits as to prevent the prospect's interest from waning in the slightest degree.

The central station should pursue a liberal policy relative to the connected load for which it will set a meter and furnish service, as frequently a very small current consumer, possibly a heating pad, fan, porch light or something practically as negligible as a revenue producer will lead to the extension of electric service over the entire premises. The electric flatiron is particularly effective in this direction, and a number of stations within the writer's observation have secured gratifying increases in their old-house business by pushing the iron where other arguments have failed.

Probably the most serious obstacle met with in gas competition is the expense of installing the electrical work, particularly in old houses, but a judicious handling of the subject on the part of the central station will overcome it. One plan which is productive of good results is the installation of a certain number of outlets at slightly above cost, furnishing everything complete and ready for use, to introduce the use of electricity on the premises. First ascertain the cost of installing the proposed number of outlets in ten or a dozen houses, selecting various types and sizes, so that an average will be a fair indication of what the average cost will be; decide on a line or set of fixtures, add the price of the fixtures to the average cost of wiring, and add 10 per cent. to the total, which will give you a flat price per house to submit to your prospects.

Another plan which is used very successfully by some of our Ohio companies is an arrangement whereby the prospective customer may pay for the work in six, 12 or 18 monthly payments, as the customer may desire.

In some cases the company contracts directly with the prospect as agent for the electrical contractor, and in others the contractor deals directly with the customer, submitting the proposition upon notification from the solicitor that the customer will entertain it, the central station guaranteeing the contractor against loss as a consideration for carrying the long-term account.

In using the partial-payment plan it may be entirely feasible to add, say, 10 per cent. for the incidental expense of carrying the account, but this will be governed by local conditions.

A room equipped with gas and electricity for purposes of comparison will greatly aid the central station in competing for store and factory lighting. In one 15 by 24 "comparison" room belonging to an Ohio company one-half the room is equipped with an open flame burner, a Welsbach burner, an inverted mantle burner and a gas arc, all so arranged that any one fixture will give its maximum light without shadows from the others. The electrical half of the room is equipped with incandescent high-efficiency and Nernst lamps so arranged that any desired combination of lights can be obtained by manipulating switches. At one end of the room indicating wattmeters and gas meters are installed, so that the comparative lighting and cost values may be readily demonstrated.

1. Abstract from suggestion offered to the Ohio Electric Light Association at the Toledo convention, August 22d. The gentlemen quoted are connected with Ohio central stations.

In competing with gasoline the added insurance hazard makes a very good argument, and a statistical compilation of fires and explosions resulting from the use of gasoline is an excellent thing for the solicitor to have with him.

By Samuel Rust.

This is a subject that every central-station man in the smaller towns and cities has to contend with and is, to my mind, a very hard one to overcome. Our business men in the smaller towns have much time to figure on expenses and count the time which they or their employes waste in cleaning and repairing gasoline or other apparatus for lighting as nothing.

A great many feel that they have that time, they are paying for it and might just as well be doing that as nothing, and the writer's experience has been when a man gets it into his head to put in a lighting outfit of this kind he will not listen to any argument you may produce. He simply compares cost of gasoline with watts consumed for a given amount of light. I have found the best thing to do is to go to your man and make a plain statement of what you know as to the cost of the installation, maintenance, depreciation and trouble. This statement may not bring results at the time, but he will remember what you have said, and if he puts in his system every time there is anything wrong it will call to his mind your talk with him. When his system begins to clog and give poor light, together with the repairing cost, constant care and expense, he will again think of your statement and wonder after all if you were not right. In the meantime you should make a special effort to be friendly and courteous to him, dropping in his place of business as often as convenient, and endeavoring to get just as near him as possible. The result will be that in time you will find that he will acknowledge his plant is not a success, and he will consent to figure with you for electric light. This is the time to get in your work, and if you have any inducements to offer, give them to him, and you will have a customer who will stay with you.

The most important and effective time to prevent this competition is before your customer gets dissatisfied. Your efforts should never cease along the lines of good service; see your customer as often as possible; study his conditions; if his place could be fitted up to get better service for less money, make suggestions to him and show him the result he might obtain.

The time has come when the central-station man must study and work for the interest of the customer as well as for that of the company, and he must use every effort to make the public feel that he is not only working for his own interest but for their interests as well.

In a small town or city cost is a big item to the business man. We have found that the installation of some high-efficiency lighting units, even though at a sacrifice to the company, will go a long way in warding off competition. A new style cluster, the addition of a reflector or the installation of an attractive lamp often is all that is needed to continue profitable business relations between the company and the customer.

In our city we are in competition with artificial gas at $1.30 per thousand and natural gas at 25 cents per thousand. The artificial gas arcs have been a very strong competitor of ours for some time, due to the gas company furnishing gas arcs free to any one that would allow them to be installed. This plan took with the people for a short time, because it appeared that they were getting something for nothing, but the reaction is coming now. It started when the customers found that their bills were not materially reduced; in fact many found that their expense for light was even higher for gas than with the electric light.

The dangerous character of gasoline and acetylene outfits is always a strong factor against their use, and the complicated nature of the apparatus and the inexperience of the users give a constant opportunity to urge the substitution of electricity. Friendly relations and frequent talks with the users finally bring results.

To recapitulate, I would suggest the best way to meet gas and gasoline competition is: Good service; prompt attention to complaints; maintain friendly relations with the non-user of your product; frequent calls and talks on his method of lighting; furnish best appliances for his use and reduce his lighting cost as much as possible consistent with good service.

By W. E. Russell.

During the 1905 convention one of the members suggested that he had been having some competition with acetylene gas plants and that he had gotten the idea to subscribe to a clipping bureau for all correct accounts of accidents therewith. The writer had occasion a short time later to forestall the first efforts of a salesman of acetylene plants by an advertisement which was run for a time in the local papers.

If the clipping bureau could furnish ammunition to fight acetylene, how much more effective it would be if one should get the clippings as to natural-gas accidents, because natural gas is in far more general use. In the fall when the long evenings had begun and people began to use the gas for heat and light the accounts of explosions and other fatalities began to flow to us through the mail with such regularity that we had enough accounts to publish a different one about every day in our local papers. The paper and date of issue which furnished the clipping were given credit in each case, and at the end was added some unsigned comment like: "Use coal for heat, electricity for light and be safe, healthy and happy." This scheme is effective, beginning regularly every fall and continuing through the winter. It is a mighty good way to combat gas, and it is not expensive. There are a number of clipping bureaus which will furnish all references to one subject for from $3 to $5 per month. Try it.

Examine your rates with a view to lowering them. Figure out cost of production first and then readjust. Go to the hotels, restaurants, drug stores, barber shops, in fact all the long-hour burners, and notify them that the gas company has now had the long-hour consumers of light long enough and that you are now making a rate that will force a swap of the short-hour burners for the long ones. In Massillon we have made a saloon, barber shop and drug-store rate of $5 per kilowatt of lamps installed as a "readiness-to-serve" charge and two cents per kilowatt for all current use. For example, a man has lamps installed that will consume 900 watts in an hour if all are burning; we make him a "readiness-to-serve" charge of $4.50 net per month and he pays two cents net per kilowatt for all current consumed, making out the bill at $5 per month for "readiness to serve" and three cents per kilowatt for all current consumed, with a discount of 10 per cent. of the "readiness to serve" and also of one cent per kilowatt for payment of the bill on or before the 10th of the month following use. We give free renewals of all clear lamps under this contract.

After more than a superficial examination through several years of competition with natural gas, the writer is forced to the conclusion that free lamp renewal giving is one of the most effectual ways to combat natural gas if combined with several others. Where the electric-light plant has no artificial light competition it may not be necessary to furnish free renewals; but with sharp gas competition there is mighty little to be said against such policy. Supply the customer with free lamps, and it not only insures you against the empty socket here and there, but it permits you to give the very best light service of which your plant is capable and at a minimum consumption of current.

Assuming that you are giving 24-hour service, go after the day user. Make a separate contract with each daylight off-your-peak user after you get him and do not try to keep rates uniform. Every different power user will present different conditions and justify rates to fit. When you make a power rate do not fail to make a minimum rate per horsepower per month.

Contract for a little space in the local paper. The electrical journals, trade publications and larger central-station monthlies will give you a lot of material from which you can crib. For a small amount you can be furnished with a monthly periodical issued in the name of your company with an ad on the back to fit local conditions. Do not say it will not pay in your town. It will. Buy a Neostyle or some other efficient duplicator of hand or typewriting and send out letter talks on what you have to sell. Do not fail in these talks to point out the defects and dangers of natural gas use. Put up an electric sign, no matter how modest its size, so that those who pass your office nights will see your good work. Impress it on your customers that you are doing all in your power to be accommodating and give a service unequaled by anybody's plant anywhere.

In order to cope with natural gas, the wiring up of new and old houses must be done at a minimum rate. The central-station man will be glad to give up the wiring business, but with natural-gas competition in smaller towns he is forced to do such work under present conditions, else he will not get all the business that he otherwise might.

If you have not waged an electric flatiron campaign your have not done your opportunities justice. Because we are, generally speaking, in the "juice" making and furnishing business, rather than apparatus vending, I believe it policy to put out irons, etc., at the lowest price possible.

By Arthur Pomeroy.

Of those who employ the gas engine for power purposes there are but few who include the full details in computing the cost of operation. The central-station representative, therefore, in endeavoring to advance the cause of the electric motor, is confronted at the outset with considerable misplaced confidence in the economy of a gas engine.

When an estimate is made on the cost of central-station purchased electric power, practically all expenses are included in the electricity cost, whereas the expense usually given for operating a gas engine includes gas alone, which, of course, is but a small portion of the total expense. To the cost of gas should be added the expense for oil, water, repairs and labor; depreciation, interest, taxes, insurance and value of space occupied.

For engines of 30 horsepower and under, running 10 hours a day, the water consumed will approximate 3,000 cubic feet per horsepower-year; lubricating oil, about 12 gallons, and this must be of a better grade, owing to the high temperature, than that used in a steam engine.

The repair bill on a gas engine is governed mainly by the design and workmanship in the engine, its age, the operator, and the character of the load on the engine. In general practice the average annual amount of repairs during the useful life of a small single-cylinder gas engine has been found to vary from eight to 15 per cent. of its first cost.

One of the most widely disputed items of expense is the salary of an operator. Almost every gas-engine salesman claims that anyone possessing a reasonable amount of mechanical intelligence is competent to operate the engine, all that is necessary being to start and stop it and keep the oil cups filled. It has, on the other hand, been demonstrated that a gas engine requires an operator of more than ordinary mechanical experience and ability to care for it, and in the long run needs more attention than a steam engine.

The stopping of a gas engine may be caused by premature ignition causing back firing; by the mechanical derangement of valves, igniters, governor mechanism, mixer, etc., due to wear and tear, poor design or cheap construction; by sudden variations in load and other causes. Likewise, the starting often causes much trouble, due to inability to secure proper mixture and ignition, and especially there may be trouble when the engine has to start under nearly full load. Accordingly, to insure good service, an experienced man in gas-engine operation should be employed, which obviously means an adequate salary.

Depreciation varies between 10 and 35 per cent. It is the consensus of opinion among users of gas engines that only in rare instances the useful life of a gas engine is as high as eight years, and many instances are known where gas engines have been scrapped at the end of three years. Twenty per cent., therefore, represents a low estimate for interest and depreciation.

Taxes and insurance should be added to the expense of gas-engine cost, and also the value of the space occupied by the engine. A motor can be hung on a wall or a ceiling, while a gas engine requires a good foundation and plenty of floor space, which latter perhaps could be used for manufacturing purposes.

It is conceded by those familiar with the relative load-carrying ability between gas engines and electric motors that the size of the engine must be nearly twice that of the motor to carry a given average load. For example, satisfactorily to take care of an average load of 10 horsepower a 20-horsepower gas engine should be installed, while a 10-horsepower motor would be sufficient. One reason for this is the natural loss in the engine itself, which includes its friction load. Another reason is that it has no overload ability. Its indicated load is its rated load.

The first investment, therefore, is greatly affected, which suggests a point too important to be overlooked—this is the earning power of invested capital. Money invested in almost any manufacturing business ought to earn at least 15 per cent., so that every $1,000 invested in motive power represents a loss of income of at least $150 a year, which amount should be charged to operating expense.

Under perfect conditions and on natural gas of 1,000 B. T. U., small gas engines consume about 15 cubic feet per indicated horsepower-hour, but under ordinary operating conditions an engine will consume about 30 cubic feet per indicated horsepower-hour. This is due to ill-fitting valves and shortage in B. T. U. of gas used and other causes. Running the engine while no machinery is actually in use rather than stop and start again increases the amount of gas for the power required. In many instances where a gas engine has been displaced by electric power it has been found that the engine has used over 50 cubic feet of gas, including gas consumed in overcoming engine friction, for each kilowatt delivered.

Fifteen cubic feet is the figure usually used in selling gas engines, but experience shows that an estimate based on 30 to 40 cubic feet is more nearly correct. When artificial gas is used the consumption will be from 20 to 28 cubic feet per indicated horsepower-hour, or from 53 to 75 cubic feet per kilowatt delivered, the variation being due to the different qualities of gas, which depends upon the method of manufacture.

In endeavoring to contract for electric power in competition with gas it is often advisable for the central-station man to confine himself at first to questions, as in this way he will be able to determine whether the prospective customer is fully acquainted with all the expenses and the accuracy of gas-engine operation. After making sure that such is the case, an excellent opportunity is afforded to bring up convincing facts that electric power supplied by the central station is ultimately the most economical and advantageous power to be obtained.

The perfect cleanliness of electric power and the small amount of attention required by electric motors recommends this power to many manufacturers. The comparatively noiseless operation of a motor adds greatly to its favor.

Electrical transmission is especially advantageous from the view of future enlargement, due to growth of business. As the business grows, motors may be added in proportion. An isolated plant has not this flexibility; its investment increases unduly with plant enlargement. This fact will appeal to a man starting a manufacturing business, for he has great faith in the future growth of his industry.

When the central-station man encounters a case where a gas engine is already installed and running smoothly he should thoroughly acquaint the owner with the advantages of electric power and see to it that he charges all the items of expense against his power cost. Then keep close watch on the performance of the engine. At the first sign of trouble be on hand with renewed activity in behalf of electricity.

By W. C. Anderson.

We believe the following to be a few of the best ways to meet natural-gas competition:

1. Make rates giving the long-hour burners prices in proportion to the cost of long-hour service.

2. Develop decorative lighting to the fullest possible extent to which this can be developed.

3. Give the customer the greatest possible amount of useful light with the smallest possible cost for current and maintenance.

4. Go after business like the sewing-machine agent goes after business. There is no reason why the electric companies should take a back seat for any one in commercial enterprise. Our profits depend greatly on the quantity sold, and we can afford to spend four times the money in getting the second $3 per capita of business than we can afford to spend in getting the first $3.

Do the street lighting. There is no reasonable excuse for a municipal street-lighting plant. Where there is a municipal street-lighting plant some one is to blame. Probably the city authorities are the principal offenders, but if they compel you to go with them one mile, go with them twain. The street-lighting contract helps to get business otherwise unobtainable. Every consumer should understand that the street-lighting contract helps the company to improve and cheapen his service and that he not only has a personal interest in this as a taxpayer but as a consumer of electricity.

By E. T. Selig.

Believing that one of the first things necessary in order to successfully meet natural-gas competition is ability to give good, reliable service, we started in at our power house, which was equipped with antiquated machinery, determined what should be done to make the operation of each department most reliable and efficient, and then made the necessary changes and additions all along the line from the fuel supply to the consumer's premises.

With service conditions satisfactory we next took up the rate question and adopted the following scale, to wit:

For the first kilowatt-hour consumed each month for each light or equivalent of maximum demand, 15 cents per kilowatt-hour.

For the second kilowatt-hour, 10 cents per kilowatt-hour.

For all over two kilowatt hours per light, six cents per kilowatt-hour.

A minimum bill equal to 15 cents for each light of maximum demand, but in no case less than $1.11 was charged.

A discount of 10 per cent. was allowed on all bills at the above rates if paid by the 10th of the month.

We established a system of free renewal of lamps growing dim or burning out in service, making a charge of 25 cents, however, for the first installation of lamps and for all renewals of broken lamps. We renew only lamps obtained from us, and in this way prevent contractors and others from furnishing a low-grade lamp.

With improved service, reasonable rates and free lamp renewals our old consumers soon lined up on our side, and through newspaper advertising, letters and personal soliciting we went after new business.

We, of course, used all the usual arguments, such as the convenience, safety and cleanliness of electric light, but perhaps the most effective of all were those regarding free renewals. We showed that, except in rare cases where a lamp might be accidentally broken, the consumer's only cost for lighting was his current bill, while in some instances the cost of gas, together with the cost of mantle and chimney renewals, amounted to more than the cost of electric light.

By using gas under our boilers we were enabled to cut our fuel cost to half that of coal, besides dispensing with the services of several firemen; therefore we rather regard natural gas as an advantage than a detriment to our electric lighting business.

Report on Electric Heating Devices.[1]

By Mathias E. Turner.

Electric Heating in Homes.

Electric heating is now bidding for favor in all departments of household heating, heating for the laundry, for the cooking, for hot water; in the sick room, and in all manner of step-saving ways about the house.

It is the custom generally for electricity-supply companies to advertise and sell these appliances, but the time should not be so far distant when electric heating devices will be so well advertised and their uses so well understood that they will be sold in large quantities, as other household utensils are sold, by department and other stores. It will, however, before that time, be necessary for the manufacturers to build a much more durable and operative economical line of goods. And your reporter has thought best to refer to those defects in detail in the apparatus with which he has had experience during the present year.

The first general criticism is that most electric heating devices are too slow in heating. What is needed is higher temperature during the first few minutes, and, if necessary to get it, more current used for a shorter space of time.

The second general criticism is that the methods used for attaching the appliances to the electric circuit must be improved. It is desirable that the attachment be a removable (both from the heating appliance and the circuit) flexible cord with a simple, durable plug, for making the connection and disconnection to the heating appliance, that does not require the burning of hands or upsetting of the vessel's contents, and that will not continually open or short-circuit.

Electricity in the Laundry.

In the laundry immersion coils are practical for boiling clothes in a clothes boiler, and are conveniently connected to a receptacle by a fixed flexible cord to the coil, and a three-heat push plug in the length of the cord. In fact, a push plug designed by one manufacturing company offers an admirable method for obtaining three heats where the appliance is not intended for use in connection with a cooking table. It is made in appropriate sizes to accommodate the small current required in a heating pad and the larger current of an immersion coil. The chief objection in the use of an immersion coil is the danger of severe shocks where the laundry floor is wet.

Laundry irons of six pounds weight and single heat are perhaps best adapted to general household use. A switch located on the iron is a simple and effective improvement over the former methods of heat regulation for ironing different materials. Favorable comment that has reached your reporter through users of electric irons is that the blunt nose and side flange found in one particular make of iron commends itself in the ease with which pleats and corners are ironed.

Electric Cooking Outfits.

Criticizing electric coooking outfits, your reporter in this report limits himself to his own experience in catering to the wants of a number of purchasers of complete cooking sets. In these cases the type of outfit advised was an oak table with a slate switchboard at the back and an oak raised shelf at the side for the oven. The table legs were equipped with well-adjusted casters. On the back of the switchboard was an asbestos-lined cabinet containing the fuses. In front three base receptacles for single-heat appliances and four three-point plug attachments were set in flush with the slate. Above these connecting points were placed three snap switches, indicating "off" and "on," and four three-heat snap switches indicating "off," "low," "medium," "high." Flexible cords 18 inches long were provided, having at the circuit-connecting end plugs for single-heat cords and three-pronged plugs with handles for three-heat cords.

This description is detail, but the practicability of electric cooking is very much detail, and it is for us who are in touch with the users of electric appliances to indicate to the manufacturers as far as we may at this time the requirements to be met in electric heating development.

Manufacturers are developing two distinct types of cooking outfits—one in which portable appliances are connected to a table similar to that described, and one in which stationary heating disks are designed much like the ordinary gas range, the difference only being that disks are used in place of flame burners. It may be that neither of these types is best. Possibly sectional shelves mounted with switches, connectors and disks, and capable of easy connection end to end or above and below each other, may offer a much more flexible method, adaptable to extension from

1. Abstract of a report made at the Toledo convention of the Ohio Electric Light Association, August 20th. Mr. Turner, the reporter, is a central-station man of Cleveland.

a very small cooking outfit, as the need for a larger outfit increases in any family.

The electric oven, with heaters top and bottom, is a superior baker, but decidedly wasteful of heat. A chef proficient in electric cooking stated that it was the best baker he had ever used. But this one piece of apparatus wastes so much heat that, because of its expensive operation, electric cooking development is somewhat retarded. The oven should be very much better heat-insulated; it should be deeper; its doors should be at the narrower end and fitted practically air tight when closed; it should be easy to clean; it should heat to a sufficiently high temperature in about 10 minutes and maintain a temperature suitable for most baking purposes for several hours, consuming not more than 250 watts per hour—which it will do if properly constructed.

In a particularly well-equipped kitchen, an electric cooking outfit replaced a gas range, excepting only a vertical gas broiler. Later a vertical electric broiler (so-called restaurant size) was tried. A voluntary testimonial, here reproduced, indicates how successfully:

"This is the first time I have found to write and tell you about the electric broiler. I have tried fish, chops and steaks, and in each experience success was the word. No smoke, no smell, no flame. I think it quite the best of all the electric utensils that I have tried for you. I intend to keep it, and would ask you to get me one extra wire broiler, as in steady cooking two are needed."

This particular type of vertical broiler is one of the best-designed cooking appliances of any kind that has come to the notice of your reporter.

Other kitchen utensils, such as fry pans, sauce pans, cereal cookers, grids, etc., compare very favorably with such appliances heated by means other than electricity. Electric waffle irons and milk warmers are unique in their comparative efficiency and convenience.

Water Heaters.

Hot water always available is requisite in all households. Until recently it has only been possible to obtain a sufficient quantity of hot water for washing purposes by means of immersion coils or similar devices which are bothersome to use, and this has made it necessary for would-be exclusive users of electricity to obtain hot water by other means. Lately there has been put on the market an instantaneous electric water heater. This device, together with all the other electrical heating appliances—more or less perfected—now makes it perfectly feasible for us to specify in the house building plans (where we are permitted by prospective customers) special heating circuits and single-pipe water systems for the exclusive use of electricity in all the duties usually performed by other illuminants and fuels, excepting winter interior heating, which we must still allow the furnace to do.

In the sick room electricity is now almost indispensable. It offers a ready means for quickly and safely boiling small quantities of liquids in portable vessels, in sterilizing articles, in vaporizing medicines under tents, as is often done for children in certain illnesses.

The heating pad has won many friends for electricity. In fact there have been several cases in which houses have been wired for electric light in order to get service to use the heating pad. Its virtues are so well known and its many applications so well advertised it scarcely needs elaboration here. In one particular make the details of construction have been admirably worked out. Its method of heat regulation and connection or disconnection to the electric circuit is convenient. It is light in weight, flexible and well adapted to many uses in the sick room and it shows good workmanship in its construction.

Now some inventive mind brings out an inexpensive device consuming little current to insert in a hot water bottle to keep the water hot.

And so we could go on, if time permitted, through many pages, describing numerous electrical devices tending to make electricity the universal light, heat and power in homes.

Before closing these general remarks on electric-heating appliances it is pertinent for your reporter to say that in so far as his experience goes it is at the present writing inadvisable for central stations to accept manufacturers' "complete cooking and heating outfits," but rather to build up their own sets, each piece being selected from the manufacturer who may be making the best article for the particular work it will be called upon to perform.

It is very necessary to the rapid development of electric cooking and heating that these pioneer electric outfits give as little trouble as possible to the users of them.

Current for Cooking in Eleven Cleveland Homes.

At the time of writing this report it was not possible to obtain from all the users of electrical cooking outfits data relative to the average number of persons in each household, etc., by reason of many families using these outfits being away from the city on a vacation. Reliable data were, however, collected from 11 homes using complete cooking outfits and are given in the following:

No	Full Months of Use.	Average No People Cooked for	Average Units Used Per Month	Average Per Month Per Person	All or Partly Electric Cooking
1...	11	7	237	*34	All.

*Includes laundry ironing and water heating.
†Includes laundry ironing.

The above number of families using electric cooking outfits exclusively is too small to draw any definite conclusions, yet it would indicate that we might expect with the growth of this branch of the business an increased current consumption of from 100 to 200 units per residence per month.

In Cleveland a two-rate method is used for billing residences. The result is that electric heating generally receives the benefit of the secondary or lower rate. In fact, the cooking in all the 11 residences cited was done at a five-cent rate. The expense under these conditions compares favorably with artificial gas.

To illustrate how popular electrical current consuming devices are becoming in the home there was sold in Cleveland by the illuminating company during the 12 months preceding last June over 1,100 electrical heating devices. This was done through the efforts of one salesman and newspaper advertising. There are now being sold over 100 such devices a month without the aid of any direct solicitation. In addition to this, supply dealers have been selling their quota in the city.

New Developments in Arc Lamps and High-efficiency Electrodes.[1]

By George M. Little.

Arcs for lighting may be formed between electrodes of many different kinds. This paper deals with the development of the so-called magnetite electrodes and of a lamp suitable for burning them. A few points of comparison between these metallic-oxide electrodes and carbon electrodes will be considered, and some of the many interesting advantages possessed by the metallic-oxide electrodes and lamp will be touched on. Among these are the long life, high efficiency and good distribution and color of light.

The magnetite electrodes were so named because magnetite is usually one of the constituents of the negative or cathode, but it would be more satisfactory to call them metallic-oxide electrodes, as in addition to the magnetite there are always at least two other oxides present, namely, oxide of titanium and oxide of chromium.

These electrodes are made in a very different manner from the carbon electrodes. As is well known, the latter are squirted or molded from a plastic mixture and are baked, the carbon furnishing sufficient mechanical strength and electrical conductivity. A metallic-oxide electrode cannot be made this way, for it is a familiar fact that a fine powder is a poor conductor, no matter of what it

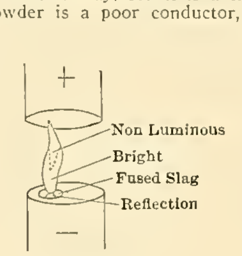

FIG. 1. METALLIC ARC WITH NEGATIVE BELOW.

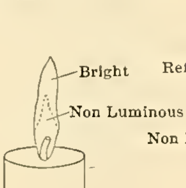

FIG. 2. CANDLE FLAME.

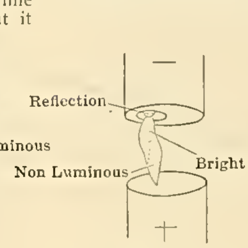

FIG. 3. METALLIC ARC WITH NEGATIVE ABOVE.

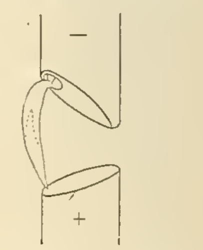

FIG. 4. SHOWING WASTING AWAY OF CARBONS TO A BEVEL BEFORE USE OF DOWN-DRAFT.

is composed, and as these electrodes are made for the most part from finely powdered oxides, it is evident that a conducting binder or a conducting case would have to be used. In practice, the mixture of oxides is tamped into a thin iron tube and the end sealed in an arc.

The oxides have distinct and separate reasons for their presence. The titanium oxide has the property of rendering the arc luminous; and it may be here noted that the metallic-oxide arc is a flame arc, the light not coming from a crater, as with carbons. The oxide of iron gives conductivity to the fused mixture when cold, the other oxides being conductors only when hot. The oxide of chromium prevents a too-rapid consumption, so that by its use an electrode may be given a very long life.

The positive, or anode, used with these metallic-oxide negatives is generally a metal and is consumed much more slowly than the negative. This is contrary to what would be expected, judging by the action of carbon electrodes.

There are a number of advantages possessed by the metallic arc over the carbon arc. In the first place, the efficiency is much better; that is, a metallic arc lamp operating on a four-ampere current, with approximately 65 to 70 volts at the arc, will give a light equal or superior to that of a 6.6-ampere, 75-volt, direct-current, enclosed-carbon arc lamp.

The distribution of light is far better. This is owing to the fact that in the enclosed-carbon arc practically all the light comes from the crater on the flat under surface of the upper electrode, most of it being thrown down and not serving to illuminate the street between lamps. The light from the carbon arc itself is weak and of a blue color. This is very pronounced at times, especially if the flat under surface of the upper electrode is somewhat inclined, thus hiding the crater. In the case of the metallic-oxide electrodes, the arc is itself the source of light, practically none coming from the crater, except by reflection. The metallic arc is much like a candle flame, having its luminous and non-luminous zones. The light is brightest near that end of the arc which is next to the negative electrode, and comes from a hollow cone-shaped mantle of volatilized oxide of titanium rendered incandescent by the heat of the arc, just as in the candle flame the light comes from a hollow cone-shaped mantle of carbon particles made white hot by the heat of the flame.

The voltage required to maintain a metallic arc is less than that of an enclosed-carbon arc. It is a familiar fact that an enclosed-carbon lamp will not burn properly with the arc voltage down to 65, while a metallic arc will burn well at less than 55. Metallic arcs are adjusted to burn at from 65 volts to 75 volts in different cases, while the carbon arcs are all set at 80. This is a very evident advantage in favor of the metallic arc, as more lamps may be put on a circuit without raising the voltage on the line.

The life of carbon electrodes, as a rule, is not over 150 hours, while the metallic-oxide electrodes can go considerably longer.

The uniform white color of the metallic arc is in marked contrast to the changeable blue and white of the enclosed-carbon arc.

As the metallic-oxide electrodes are not burned "enclosed," there is no inner globe required on the lamp.

While it looked easy to secure all of these advantages, many difficulties appeared, but they have now practically all been overcome. In the first experiments the electrodes were trimmed with the anode or positive above and the negative or metallic-oxide electrode below, just as carbon lamps are trimmed, but a number of troubles presented themselves.

First—The bright portion of the arc was near the surface of the lower electrode, which cast a large shadow.

Second—The light reflected from the brilliant surface of the fused slag on the lower electrode was thrown upward and could only be partly saved by using a reflector.

Third—An under-feed mechanism was seen to be necessary, as, contrary to the action of carbon electrodes, the negative metallic-oxide electrode is the more rapidly consumed.

Fourth—Only a comparatively short metallic-oxide electrode could be used, as a long one would necessitate the use of an unwieldy long glass globe. This would limit the life and could only be met by adopting a negative electrode of large diameter, which it is evident would be undesirable.

Fifth—A particularly undesirable feature was the gathering of a large amount of reddish soot that would collect in spongy masses around the electrodes, obscuring the light. This had to be removed by some mechanical means, such as scraping or shaking it off, and some receptacle other than the glass globe had to be provided to catch it.

Sixth—The negative or metallic electrode was seen to burn to a blunt taper point, causing the arc to be very unsteady, as it tended to leave the end and run up the side in the manner of the carbon arc when flaming.

As noted above, the bright portion of the metallic arc is located near the surface of the negative electrode, and it was seen to be very desirable to burn the electrodes with the negative above, thus getting the bright portion of the arc in such a

1. A paper read before the National Electric Light Association at Washington, D. C., June 5, 1907. The new Westinghouse metallic flame-arc lamp is described.

position that the shadow thrown down would be less, and that the light reflected from the brilliant surface of the fused pool of slag on the negative electrode would be thrown down and utilized instead of being thrown upward and wasted. The other advantages, noted above, possessed by the carbon lamp would be retained if this inverted position of the electrodes could be made practical.

The first attempt to burn the metallic-oxide electrode above and the metallic electrode below showed that there were serious obstacles to be overcome before it could become a practical method. In the first place, the electrode would not keep a square

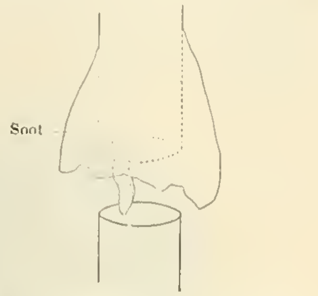

FIG. 5. SHOWING ACCUMULATION OF MASSES OF SOOT BEFORE USING THE DOWN-DRAFT

end, but would waste away on one side, and the arc would run up this bevel, or slope, giving a very unsteady light. In the second place, the volatilized oxides of iron, chromium, titanium, and so forth, would condense on the sides of the electrodes and hang down as a fringe or curtain, hiding the light.

The first means taken to overcome these troubles was the introduction of a rotating draft of air around the arc. This had the effect of forcing the arc to hold a central position, stopped the crooked burning, and steadied the light, but did not take care of the fumes. Attempts to blow the fumes away sidewise gave only partial success. Finally, a current of air was directed down around the arc, and this gave excellent results. The electrode burned perfectly square, and the clean layer of air prevented any gathering of fumes. This was a very marked advance, as this did away with any need for a mechanical scraper or shaker, the soot practically all passing out of the chimney and not requiring to be caught in any receptacle, the globe remaining clean.

When burning metallic-oxide electrodes with the metallic-oxide stick below, copper was used as an anode, with fair results. On reversing the position of the electrodes, it was found that the new conditions made it possible to improve on the action of a pure copper anode, and a number of changes were accordingly made. In the first place, if the arc plays for a time on pure copper, it will oxidize

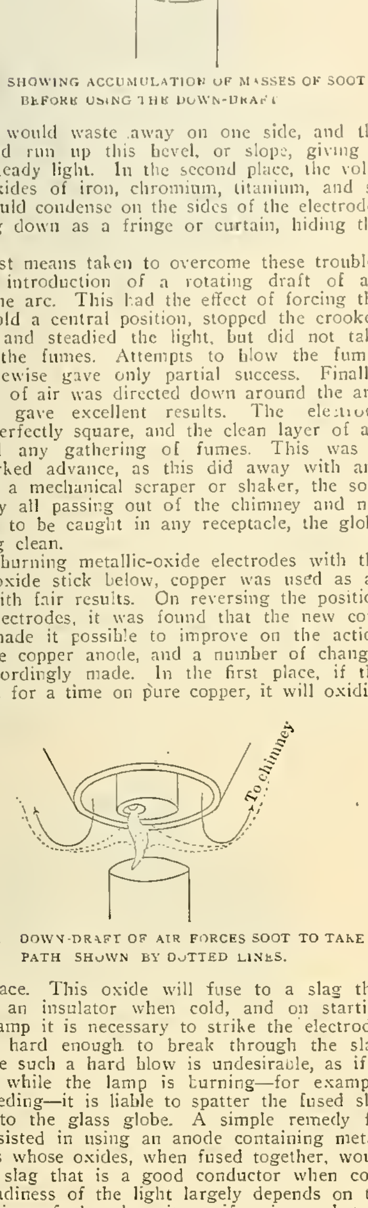

FIG. 6. DOWN-DRAFT OF AIR FORCES SOOT TO TAKE PATH SHOWN BY DOTTED LINES.

the surface. This oxide will fuse to a slag that becomes an insulator when cold, and on starting a cold lamp it is necessary to strike the electrodes together hard enough to break through the slag. To strike such a hard blow is undesirable, as if it is done while the lamp is burning—for example, when feeding—it is liable to spatter the fused slag out on to the glass globe. A simple remedy for this consisted in using an anode containing metals or alloys whose oxides, when fused together, would make a slag that is a good conductor when cold. The steadiness of the light largely depends on the composition of the slag, its uniformity and temperature. The anode surface is at all times covered with this slag, which slowly dissolves the metal and is itself slowly volatilized. If the arc plays on bare metal it consumes it rapidly, and it was found desirable to secure this slag cover from being knocked off. This was accomplished by providing a rough surface for it to cling to, and by running the entire anode tip very hot.

A characteristic property of the metallic arc has been a very noticeable dying down or dimming of the light, which would occur at irregular intervals, especially after the electrodes had burned for 20 hours or more. These dim spells would last from a few seconds to two or three minutes, when the normal brilliancy would return. This is explained as follows: In the metallic arc the brilliancy is largely due to the presence of volatilized oxide of titanium, and anything that interferes with the uniform evolution of vapors of titanium will cause the light to dim—for example, the presence of a high percentage of highly infusible oxide of chromium. This oxide of chromium is volatilized at a slower rate than the oxides of titanium and iron, and after the electrode has been burning some 20 hours the slag on the end of the cathode has become very rich in oxide of chromium, which forms a film on the surface of the fused pool of oxides. When the film is not present there is a plentiful evolution of oxides of iron and titanium, and there is a bright arc. The oxide of chromium can be seen to gather on and finally entirely cover the surface of the pool. This stops the evaporation of titanium and iron, and the light turns to a bluish color and dies down until the chromium film is burned away again. This trouble was met by modifying the mixture in such a way that the oxide of chromium could not separate from the oxides of iron and titanium, thus doing away with the film on the surface and entirely doing away with the dim spells.

In carbon lamps, there was very little done to keep the impurities volatilized from the carbons from depositing on the globe. This trouble had to be met by the carbon manufacturers, who were prodded up to produce carbons containing less than 0.2 per cent. of impurities, but this means was not to be considered in the case of the metallic-arc lamp. The metallic-arc electrodes, being chiefly composed of oxides of iron, titanium and chromium, do not burn away to an invisible gas, as does a carbon stick, but are volatilized bodily, and the vapors instantly condense, on leaving the arc, to a fluffy reddish soot that settles on everything it touches, so that a chimney is a very necessary feature in the lamp. This soot, if it comes in contact with the reflector or globe, will smudge them badly in 10 minutes. As was noted before, a current of air flowing down around the electrode served admirably to keep it clean, so it was applied to the reflector and globe, with gratifying results. A thin layer of air is introduced at the top of the reflector and forms a shield through which the soot-

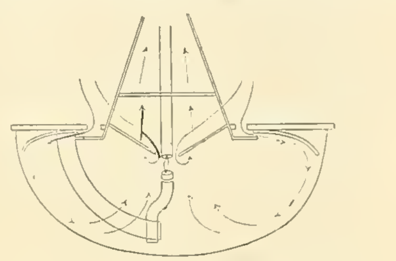

FIG. 7. PATH TAKEN BY AIR CURRENTS IN LAMP.

laden air cannot penetrate, so that the reflector and globe will keep clean for a long time.

As the air currents play such an important part in this lamp, it became necessary to do a large amount of experimental work on the design of an air intake and of a chimney top. The chimney could not be made long enough to cause a very powerful draft, as the wind was very apt to blow down it; but by persistent effort the openings have been so designed that the wind may blow from any direction (up, down or sidewise), and the only effect is to increase the natural draft in the lamp. Incidentally, the increasing of this draft actually centers the arc and holds it remarkably quiet.

It was found advisable to run the lamp at four amperes and 65 to 68 volts at the arc with a cut-out set at 85. This low cut-out was made possible by the inverted position of the electrodes and by the peculiar arrangement of the air draft, which prevented any tendency of the arc to flame or to run up the side of the electrode. Without these features, a cut-out of 100 to 110 volts would be necessary. As the power factor at which the lamps operate depends largely on the amount of variation of voltage in the arc, this 85-volt cut-out is seen to be very desirable. In actual service, the lamps,

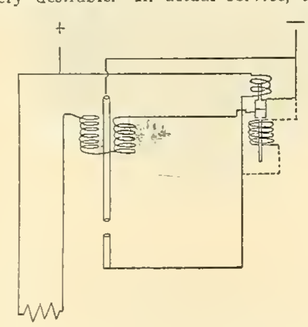

FIG. 8. DIAGRAM OF CONNECTIONS.

including a mercury arc rectifier, run very well at from 65 to 70 per cent. power factor.

In several places above we have described special conditions that must be obtained for getting the best results with these electrodes, and these conditions, of course, must be supplied by the lamp in which they are burned. An example of a lamp well adapted for this service is here shown. [It was on exhibition at the convention.] A study of its design and construction will show that it is simple and rugged, as no float feed is used, it being necessary only to strike an arc and hold the electrode in a permanent position until, due to change in voltage, the cut-out causes the restriking of the arc. The lamp consists essentially of a base and top, connected by a chimney, a set of magnets for striking the arc, a shunt cut-out for causing the lamp to feed, due to rise in voltage, and a series cut-out for disconnecting the striking magnets after the arc has been formed.

The special conditions described with regard to drafts are obtained by the down-draft tube, which directs the current of air down around the electrode, another current of air over the reflector and circling around the globe, forming a means of protection to them, and a special construction of top and case for giving proper draft conditions when under all conditions of wind.

BOOK TABLE.

Of the series of little volumes covering the general subjects of technology published by Dr. Jänecke of Hanover, Germany, brief reviews of four which relate more particularly to electrical subjects follow. The volumes are the work of reputable continental engineers, and the explanations are very clear, many phenomena being aptly illustrated by familiar analogies. While the practical instructions given in many cases apply rather to European models of machinery, the essentials of operations are given with characteristic German thoroughness. The prices of the books (in Germany) range from 34 to 67 cents.

Die Montage Elektrischer Licht und Kraftanlagen (The Arrangement of Electric-light and Power Plants). By H. Pohl. A new and revised edition. Pp. 165, with 230 illustrations and diagrams.

This is a pocket-book for engineers, electricians, installers and owners of electric plants. It is practically written and gives a review of the elementary ideas as well as more advanced excursions into special departments of electro-technology. In the latter direction the list of subjects is very complete, and the book will be found instructive to the operator as well as interesting reading for the layman.

Die Krankheiten Elektrischer Maschinen (Diseases of Electrical Machinery). By Ernst Schultz. Pp. 86, with 42 illustrations.

Carrying out the idea of the title, the book gives a list of symptoms and specific prescriptions for the treatment of generators, motors and transformers and other apparatus for direct-current and single-phase and multiphase alternating currents. Remedies for a great number of troubles, with full explanations, are given under the headings of the various faults.

Der Schalttafelwärter (The Switchboard Operator). By Emanuel Stadelmann. Pp. 160 and 106 illustrations.

After perusal of the book, the switchboard operator will surely have grasped a more accurate idea of the forces he handles and the principles of the apparatus which he uses. Following the elementary explanations, the author has taken pains to explain and illustrate by diagrams all the usual switchboard devices, measuring instruments, systems of connection and distribution, etc. The care and operation of storage batteries and lightning arresters are treated fully. The material is well ordered, and the little work will furnish good advice to those interested.

Prufung Elektrischer Maschinen und Tranformatoren (Testing of Electrical Machinery and Transformers). By Friedrich Weickert. Pp. 116 and 64 illustrations.

The little volume is quite a complete treatise on general electrical testing, but perhaps it will not be so useful to the average reader as some of the others. Measuring instruments and methods are described, with their application to the testing of direct-current machines, storage batteries, alternating-current generators, synchronous motors, polyphase motors and transformers.

Direct Current at 1,200 Volts on an Indiana Railway.

The Indianapolis and Louisville Traction Company commenced the running of cars over the 50-mile stretch between Scottsburg and Seymour, Ind., on August 25th. The feature of this new line is the use of direct current at 1,200 volts, said to be the first time direct current has been used at this high voltage in the history of electric railroading.

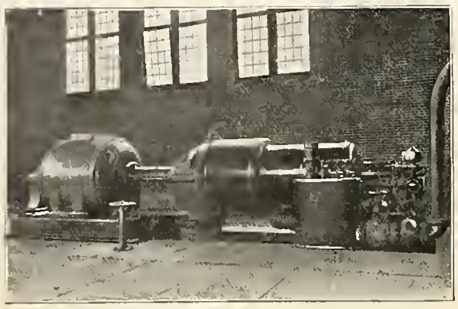
James Brown of Pittsburg, consulting engineer for the traction company, specified the 1,200-volt installation and says that he is the originator of the idea. On the trial trip Mr. Brown was enthusiastic about the new installation and is quoted as saying that the adoption of 1,200 volts direct current for trolley roads would revolutionize electric railroading, principally on account of the possibility afforded of abandoning many sub-stations.

A. A. Anderson, general manager of the Indianapolis, Columbus and Southern Traction Company, was with the party on the trial run, and it is said his company will now adopt the new system as soon as the change can be made.

Test of a 1,000-kilowatt Steam Turbine and Alternator at Kokomo, Ind.

An interesting test was recently made of the turbine-generator unit installed at Kokomo, Ind., in the power house of the Kokomo, Marion and Western Traction Company for the purpose of determining the steam consumption of the turbine when operated under normal load. Through an arrangement with the officers of the traction company, Mr. Paul Diserens of Purdue University, working in consultation with Mr. Phil H. Palmer, superintendent, represented the traction company's interests, and Mr. F. C. Purcell represented Allis-Chalmers Company. The unit tested is shown in the accompanying illustration.

The steam turbine is an Allis-Chalmers-Parsons standard horizontal turbine. The generator is a



NEW TURBO-ALTERNATOR UNIT AT KOKOMO, IND.

standard Allis-Chalmers turbo-alternator direct coupled to the steam turbine. The condensing apparatus is of the Allis-Chalmers standard turbo-jet type. The characteristics of the unit are as follows: Rated capacity, 1,000 kilowatts; speed, 1,800 revolutions per minute; frequency, 60 cycles; winding, two-phase; electromotive force, 2,300 volts; current per phase (normal), 218 amperes.

The turbine was built to operate normally with steam pressure of 140 pounds per square inch gauge pressure at turbine throttle, dry saturated, and a vacuum of 28 inches of mercury, referred to 30-inch barometer at the exhaust nozzle. The unit is calculated to carry an overload of 50 per cent. when operating under the above steam conditions and at 100 per cent. power factor.

The auxiliary machinery provided consists of a motor-driven exciter, a steam-driven exciter, the jet condenser and pump mentioned above and two small circulating pumps. There are five boilers supplying steam to a loop header. The turbine, two Russell engines and an auxiliary header are supplied from this main header.

During this test boilers 3, 4 and 5 were made to supply steam to the turbine being tested. Both sets of boilers were operated at as nearly the same steam pressure as possible. The water delivered to boilers Nos. 3, 4 and 5 was weighed in calibrated barrels. The drip from the steam header and from separators at the Russell engines and at the throttle of the machine was collected and weighed.

At the conclusion of this efficiency test boilers 3, 4 and 5 were cut out of service and the entire load of the station was thrown on boilers 1 and 2. With the plant thus operated enough fire was allowed to remain under boilers Nos. 3, 4 and 5 to maintain a steam pressure equal to that carried by boilers Nos. 1 and 2. The weight of water fed to boilers 3, 4 and 5 during this test was assumed to establish a rate of leakage and radiation from boilers and piping which would apply to the efficiency test.

In determining the steam consumed by the turbine the drip caught at the Russell engines at the trap in the steam header, at the separator, at the turbine throttle, and the amount due to leakage and radiation in the boiler, as shown by the leakage test, was subtracted from the water fed to the boilers. This result corrected for the quality of the steam was assumed to equal the dry steam supplied to the turbine.

The electrical output was measured by carefully calibrated instruments.

All the load possible given to the turbine aggregated only a little over half its normal capacity.

Following are the results of the tests:

1. Average load ....553.3 kilowatts
2. Per cent. of rated load..........55.33 per cent.
3. Duration of test ....4 hours
4. Steam pressure at turbine throttle..136.4 gauge
5. Steam pressure at turbine inlet....:. 61.9 gauge
6. Vacuum turbine exhaust ....26.59 inches
7. Barometer 28.93
8. Vacuum at turbine referred to 30-inch barometer 27.66
9. Revolutions per minute 1,800
10. Total water used ....55,662 pounds
11. Total drip 450.6
12. Boiler leakage ....5,344.6 pounds
13. Moisture in steam by calorimeter..2.82 per cent
14. Dry steam supplied to turbine per hour ....12,115 pounds
15. Actual consumption of dry steam for kilowatt-hour .... 21.90 pounds

The guaranteed steam consumption for one-half load, 28 inches vacuum, was 24 pounds per kilowatt-hour, and the result of the test showed that the actual steam consumption was 2.1 pounds less than the guarantee.

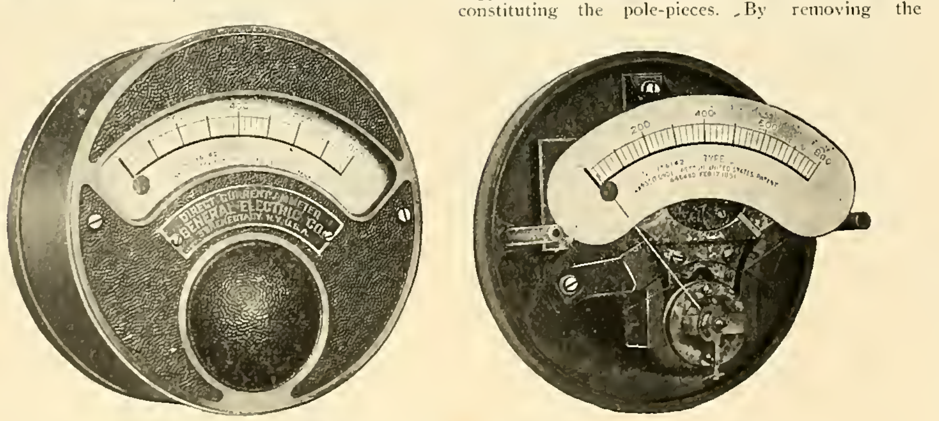
A New Line of Instruments.

A new line of ammeters and voltmeters for direct-current switchboard use has just been placed in production by the General Electric Company. These instruments, which are to be known as type D, are constructed on the D'Arsonval principle. A small coil of wire mounted on a light cylindrical aluminum frame is pivoted in jeweled bearings, so as to move freely in a small annular space between a soft iron core and the pole-pieces of a permanent magnet.

The operation of these instruments is rendered dead-beat by the foucault currents generated in the aluminum frame as it passes through the field of the permanent magnet. This damping quality prevents injury to the pointer from violent load fluctuations and permits rapid and accurate readings, as the pointer comes quickly to rest after each change in current value.

Continued accuracy of type D instruments is assured by the unusually high torque, light moving elements and the very small air gap between magnet pole-faces and the iron core, combined with the permanency of the magnets, which are made from the best obtainable grade of magnet steel and subjected to special processes of hardening and aging, which fixes its magnetic characteristics.

The round cast-iron case which encloses the instruments protects it from the effects of stray fields and makes it dustproof. Inspection or repair of type D instruments is easily made. The soft iron core, together with the armature and jewel supports, are assembled within the soft steel shell constituting the pole-pieces. By removing the screws which hold the shell to the magnet pole faces, the entire mechanism may be removed.



A NEW LINE OF INSTRUMENTS.

The scales of type D instruments are uniform throughout their entire range and very legible. The standard finish is dull black with raised portions polished copper, making a very pleasing and durable surface.

Type D voltmeters are made self-contained in capacities up to and including 750 volts. The ammeters are self-contained up to 60 amperes capacity. Larger capacities are furnished with external shunts, which are made of a special alloy having practically a zero temperature coefficient. All instrument shunts above 1,000-ampere capacity are now provided with a thermo-electric attachment. This attachment consists of a metal strip having one end electrically connected with one end of the shunt, with the other end in close thermal contact with the other end of the shunt, but insulated from it electrically. The ammeter leads are connected to the shunt and to the metal strip at the two insulated points. This prevents the superimposing of secondary thermo-electric currents upon the primary current, which is due to the fall of potential in the shunt and the amount of which fixes the value of the indication of the instrument. Ammeter shunts with this attachment will be found free from temperature errors due to generation of thermo-electric current.

"Combat Igniter" Sparking Battery.

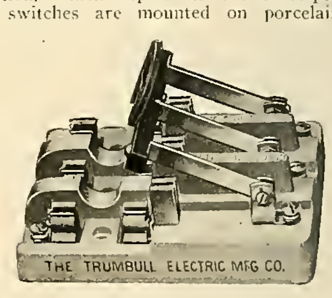
The accompanying illustration shows the six-volt 60-ampere-hour "Combat Igniter," especially designed as a sparking battery for automobiles. It is made by the Commercial Battery Company, 204-206 Michigan Street, Chicago. The cover is made of heavy hard rubber, constructed so as to form

"COMBAT IGNITER" SPARKING BATTERY.

a well to hold any of the electrolyte that may get on the top when replenishing or charging. The handle is made of spring wire and is detachable. All the connections inside are very strong, being cast and completed at the factory. The cell is enclosed in a very neat quartered-oak box, with instructions printed on a "transfer" just underneath terminals in front. There is no metal about the battery that acid can reach or corrode. The makers report that it is proving very efficient and most satisfactory, and assert they are producing not the cheapest but the best sparking storage battery at the lowest price.

New Trumbull Combination Switches.

The Trumbull Electric Manufacturing Company, Plainville, Conn., has brought out the convenient combination switch shown in the accompanying illustration, which represents the three-pole type. These switches are mounted on porcelain bases



A NEW COMBINATION SWITCH.

and are available up to 30 amperes and 250 volts. They are arranged for National Electrical Code fuses. Catalogue numbers and descriptions follow:

No. 704, double-pole, 3½ inches by 6 inches, for wires entering from top; No. 705, three-pole, 4½ inches by 6 inches, for wires entering from top; No. 724, double-pole, 3½ by 6 inches, for wires entering from bottom; No. 725, three-pole, 4½ inches by 6 inches, for wires entering from bottom.

Fatal Electric Railway Wreck in Illinois.

One of the worst interurban railway wrecks in Illinois took place on the morning of August 30th about a mile west of Charleston, Ill., on the Mattoon and Charleston Electric Railway. The accident occurred on a sharp curve and was between a passenger car crowded with travelers going to Charleston, and an express car and trailer. The impact was so hard that the motor car and trailer were telescoped. Of the ninety passengers that were on the car, fifteen were killed and all the rest were more or less injured. The wreck is said to have been caused by a misunderstanding of orders. The telephone is used to dispatch trains on this road, and according to late reports the cars should have met on a switch nearer Charleston than where the wreck occurred.

CORRESPONDENCE.

Continental Europe.

Paris, August 10.—Casablanca, on the Mediterranean, which is the scene of the recent trouble in Morocco, is now in communication with Paris by radio-telegraphy, and messages are exchanged constantly between the two stations. On the cupola of the French consulate at Casablanca is mounted a mast which is connected with high-power radio-telegraph apparatus located within the building. At Paris the station is erected on the flat ground of the Champ de Mars and the aerial wire is placed on the Eiffel Tower. Owing to the great height of the tower the signals can be sent and received over long distances. For some time past the tower has been used as the base of operations of this kind, and signals were exchanged with the port of Bizerta on the Mediterranean coast near Tunis with very good results. Messages were also sent to Brest on the channel coast and to Belfort on the eastern frontier. London and Berlin are among the other points with which messages can be exchanged at present. The apparatus of the station is lodged in a shed at the foot of the tower. An iron rod supported like a lightning rod runs down the side of the tower and is used for the antenna. Wire connection from the transmitting station on the ground to the war and marine department headquarters in the city enables messages to be now constantly exchanged from these offices with Casablanca so as to transmit orders for the troops and receive news from the seat of operations. It is curious to note that in spite of the greater distance and the fact that the Pyrenese Mountains lie in the way, it is easier to send messages to Casablanca than to Bizerta. The exact reason for this is not as yet explained.

A considerable increase has been made lately in the large hydro-electric station of Italy, known as the Ferrari Gallieri hydraulic plant. This station was started some years ago upon the high-tension direct-current system and 16 generators of the Thury type were erected, these machines being all connected in series and giving a total of 16,000 volts and a constant current of 50 amperes, each generator delivering 1,000 volts. Since then it has been decided to increase the plant and to add three-phase 5,000-volt alternators. At present there are 10 turbine alternators mounted in the station. These machines are rated at 500 kilowatts each. In the plant have been erected two separate switchboards, one for the 5,000-volt current and the second for the 25,000-volt lines. Step-up transformers of the water-cooled type are used. The three-phase power line runs through the surrounding district for the light and motor supply.

The new laboratory for the production of radium salts which has been annexed to the imperial establishment for the prepartion of uranium salts at Joachinsthal is now undertaking to treat large quantities of radiferous residues so as to secure large quantities of radium salts in the future.

Not long since the Swiss Federal Council ratified the agreement which was made between the postal and telegraph department and the administration of the federal railroads by which the railroad stations can be used for public telegraph messages. In this case an additional rate of 10 cents per message is charged. Before this many of the railroad stations did not take public messages.

The government of French Indo-China has recently opened a new telegraph line which connects Indo-China with Siam. This line runs between the towns of Bassac and Oubone.

According to recent figures it appears that the imports of rubber into France have increased considerably within the last few years. Bordeaux especially receives large shipments and holds a prominent place on the market. The cargoes of rubber come from the African regions of the Soudan, Conaky, Gambia and others. The figures given are as follows: For 1904, imports in long tons, 1,183 tons; for 1905, 1,330 tons, and for 1906, 1,716 tons.

A. DE C.

Great Britain.

London, August 23.—It is evident that the directors of the Metropolitan Railway Company and the Great Western Railway Company of London are still exercised in their minds as to how to deal with the surplus rolling stock which they have from their steam-working days. The District company is not in the same plight, for practically all its steam stock should have been scrapped years ago. But the other two companies have a fair quantity in first-class condition. The Great Western Company already runs some of its old stock upon the city lines by means of electric locomotives. Similarly the Metropolitan company runs electric locomotives upon its outer city lines and is also converting some new ordinary stock into electric working. That the locomotive working is to be extended is evident by an additional order for 10 electric locomotives which has been placed by the Metropolitan company with the British Thomson-Houston company, three of which have just been delivered. These for the first time have a box-wagon-shape cab, are of the double-truck type and weigh 47 tons. The control is of the Sprague-Thomson-Houston multiple-unit system, similar to that used on the trains. Each of the four axles is fitted with a 200 horsepower G. E. motor, of the one turn armature type. The length over cab and head stocks is 30 feet, the width over all eight feet seven inches and the height from rails to top of cab 12 feet 3 inches. The equipment is in all respects similar to the motor cars already in use. Each locomotive on a 600-volt circuit is capable of handling a 120-ton passenger train on the level at 35 miles per hour and of starting with this load on a one-in-44 grade. They are also said to be capable of hauling a 250-ton freight train up a similar gradient.

The Home Office has just issued a draft set of regulations in connection with the use of electrical energy upon premises coming within the workshops and factory acts. These are intended to apply to all pressures above 130 volts continuous and 65 volts alternating. In an official communication accompanying the regulations the secretary of state for home affairs stated that while realizing the possibility of danger at lower pressures he has been guided by the fact that the serious accidents which have come to his notice have been at pressures exceeding those named. The effectiveness of the regulations may be measured by the conviction on the part of those responsible for them, that the dividing line between the conditions which will render a shock merely trifling and those which will render it fatal is so narrow that it becomes necessary to provide, so far as is practicable, that no shock shall be received at all. The regulations, however, are open to criticism and suggestion for 40 days. A few of the regulations may be briefly mentioned. Every circuit arranged to carry more than 750 watts must be separately protected. Where one point of a system is connected to earth no single pole switch other than a link for testing purposes shall be placed in any cable connection thereto. At the working platform of every switchboard and switchboard passage way, if there be bare conductors, there is to be an unobstructed passage way seven feet high and three feet wide for low and medium-pressure cables and eight feet high and four feet wide for high and extra high pressures. Generally speaking, the rules hardly enter into technical questions, being designed primarily for the safety of the employes. Many of the proposed regulations are obviously necessary ones, and in the large majority of cases will have been put into effect voluntarily, but the effect of giving them the importance of official regulations will have a salutary effect in cases by no means rare, where poor work is likely to be permitted. The wiring rules of the Institution of Electrical Engineers and other official rules have been consulted in relation to the compilation of the new regulations.

It has now been definitely decided to hold a representative electrical exhibition either in Manchester or Salford during the autumn of next year. The idea originally came from Manchester, but was somewhat strongly opposed by a number of leading manufacturing firms on the ground that 1908 was too soon to hold another electrical exhibition after the one held in London in 1905. The firms in question were members of the National Electrical Contractors' Association. Manchester, however, is fast becoming such an important manufacturing center that the hint was plainly given that the district felt powerful enough to carry an exhibition unaided, especially in view of the boom in Lancaster trade at the present time. Consequently the Manufacturers' association has, fortunately, taken the matter up officially and will take a leading part in the organization of the 1908 show. The city electrical engineers at Manchester and Salford, respectively, will act as consulting electrical engineers to the scheme, the full details of which have yet to be worked out.

Apparently as a counterblast to the announcement that the Marconi Wireless Telegraph Company will inaugurate a transatlantic wireless telegraph service very shortly comes a communication from the company owning the Poulsen patents that its arrangements for a similar service are in a very forward state and that communication is expected to be made between a permanent station on the west coast of Ireland and a temporary station in Canada by the end of the present year.

G.

New York.

New York City, August 31.—The Public Service Commission has designated Marvyn Scudder to inspect and examine the accounts, records and memoranda kept by the Interborough-Metropolitan Company, and all books of original entry, all ledgers, all balance sheets, and any and all books showing or purporting to show the assets and liabilities of the corporation. The company has already refused to produce its books, and it is expected that the matter will be taken to the courts and the constitutionality of the act under which the commission was appointed will be determined.

In 1886, when the New York Central greatly increased its terminal facilities, it was decided to use the left-hand method of operating trains. For several weeks past arrangements have been in progress to reverse this method, so as to allow of greater flexibility in handling the baggage. Sunday, August 25th, was the day when the change was to be made, and at 4 a. m. the first train went through on the new system sucessfully. The suburban service was crippled for a time by the change.

The New York and Queens County Railroad proposes to develop a large tract of meadowland near Flushing Creek, where the company will erect one of the largest car barns and repair shops in Queens County.

An opportunity to subscribe at par to an issue of $1,500,000 six per cent. collateral trust notes payable after two, three or five years, has been offered to stockholders of the American Light and Traction Company.

Herman Barth, a young electrician of 521 Sixth Avenue, Manhattan, has been arrested and charged with the installing of a device which will make the meters of the New York Edison Company run backward. The device has been sold mostly to saloonkeepers, and it was the practice to place the device over the meter late Saturday night, as there is no danger of an inspector getting into the saloon over Sunday. The device was guaranteed to reduce the electric-light bills 50 per cent. The device consists of a large electromagnet, which is placed over the case of the meter so that the north pole of the meter's motor will be under the south pole of the electromagnet and likewise with the south pole of the meter's motor. Reversal of the field produces a corresponding reversal of the motor of the meter and its dial train. The strength of the electromagnet can be set either to retard the motion of the meter or to reverse its direction. There is a legitimate device used to regulate the pressure of gas, preventing it from blowing out more than is actually needed to supply a particular jet, and some people have been fooled into thinking that electricity blows the same way. This device was called a "regulator" to "save electricity" and consequently its inventor had little trouble in finding a market for his invention, the price of which was $200.

E. H. S.

Ohio.

Toledo, August 31.—The F. Bissell Company has completed some improvements which have added materially to the comfort and convenience of its store. The offices have been removed upstairs and room made for the proper display of wares on the first floor. This step was deemed necessary because of a determination to push the retail business, which has heretofore been a secondary consideration with the concern. The new offices will be model when completed. The store when the finishing details are done will be one of the finest in the state.

An application has been made by G. D. Ridenour and J. C. Gillett to the state board of public works for a lease of the abandoned Hocking Canal, or the outer slope of the towpath between Carroll and Nelsonville, for use for electric-railway purposes.

The capital stock of the Ohio Electric Railway Company has been increased from $100,000 to $25,000,000. It is understood that the properties of the Indiana, Columbus and Eastern Traction Company, the Cincinnati Northern Traction Company and the Lima and Toledo Traction Company will be taken over by this company.

Grading on the road that is to connect Toledo with St. Louis will probably reach Napoleon this fall. Work is progressing rapidly.

The standpipe valves of the Fremont (Ohio) waterworks will be operated by electrical devices. It is probable that the Yaryan service will be installed.

Scarcity of teams has caused the Bucyrus-Marion electric-railway people to increase the pay of teamsters to $4 per day.

The advisability of installing radio-telegraphy on the lakes was discussed at a meeting of the Pittsburg Steamship Company this week. Boats have been greatly discommoded by the telegraph strike.

H. L. S.

Indiana.

Indianapolis, August 31.—A new interurban road is being promoted to connect Logansport with Rochester and Lake Wanatau. It is proposed to secure power for the new road from the Rochester light and power plant. In addition to the passenger traffic, it is proposed to ship immense quantities of ice from the lake.

H. E. Huntington, one of the chief promoters of the Grand Central Traction Company, announces that all the right-of-way through the several counties for an interurban line from Indianapolis to Evansville has been secured and the deals closed up. He says that construction work will begin about the first of October.

The Chicago, South Bend and Indiana Railway Company has ordered plans for the construction of a modern interurban station at Front and Main streets in Mishawaka.

Action has been begun by the city authorities of Hammond to annul the 50-year franchise, granted some three years ago to the Hammond, Whiting and East Chicago Street Railway Company. Better cars and service are demanded.

The town of Bicknell, with a population of 3,000 people, is in darkness owing to the inability of the Town Board and the Bicknell Light and Power Company to agree on terms of a franchise. The company has furnished incandescent street lights for the last 18 months under individual contract with property owners, where lights were desired, operating under a franchise granted by the county commissioners two years ago. Two weeks ago the company turned off the street lights, and left the town in darkness till a franchise from the Town Council could be procured, permitting the company to extend its service to all parts of the town, and requiring the town to pay for street lights. It is understood that a new company is being organized to apply for a franchise in the immediate future. This movement will be opposed by the old company.

The City Council of Washington, Ind., has ordered a special election to be held on October 2d to vote on a proposition of repairing and improving the city electric-light plant, which is estimated to cost $50,000. A considerable number of the taxpayers advocate selling the property to a private company for whatever can be obtained for it.

Because of disagreement among small and large creditors of the Converse Electric Light Company, the concern has been placed in the hands of a receiver. Bonds were recently issued for the purpose of paying off all small creditors, but they were not sold. L. O. Arnold has been named as receiver.

The Lowell Light and Power Company has incorporated for the purpose of constructing and equipping electric-light and power plants throughout this and adjoining states. The directors are Edgar L. Shank, J. M. Jones and Clifford Wiley.

S. S.

Illinois.

Peoria, August 31.—The Harter Electric Company has been incorporated with a capital of $50,000 to manufacture electrical appliances and devices. The principal office is in Chicago and the incorporators are Fred W. Uppatel, George A. Schmidt and Ralph J. Taylor.

The Illinois Traction Company has contracted for a new 3,000-kilowatt turbine generator for the power house at Riverton. The power house now has a capacity of 6,500, and the new generator will increase it to 9,500. The General Electric Company will install the new unit. The traction company will also erect at Buffalo a new substation, making four in use between Springfield and Decatur.

During the severe storm of this week the telephone exchange at Kilbourne was struck by lightning and totally destroyed by fire.

The Illinois Traction Company has secured a 100-year lease of the ground now occupied by the Springfield Consolidated Railway Company as car barns. Large barns and a large passenger station will be erected on the property, which is only three blocks from the business center.

Net earnings of the Illinois Traction Company for the year ended July 31st show an increase of $20,275.95 over the previous year.

A rumor was in circulation that the Illinois Traction Company would trade off the city car lines here for the car lines in the city of Springfield. The same persons who own the utilities in the city of Springfield control the Peoria Gas and Electric Company here, and the traction company runs its cars over the lines there under a lease. The rumor has since been denied by those in charge of the companies' properties.

V. N.

Southeastern States.

Charlotte, N. C., August 31.—The Bowman Transfer and Storage Warehouse Company, a local concern recently chartered in Richmond, Va., will make use of electric omnibuses, cabs and trucks for the handling of passengers and freight in the city of Richmond. Samuel H. Bowman is president.

Two shifts of men, 1,000 for day work and 500 for night work, are employed at the Whitney electric plant on the Yadkin River, near Salisbury, N. C. The power will be on about January 1st, and from the rapids and waterfall in the company's 14,000 acres of land a total of 100,000 horsepower is expected to be derived. The present development will afford about half the total available power.

The Southern Cotton Oil Company is making some important tests at Gastonia, N. C., to determine the relative cost of ginning cotton by electricity and by the old steam methods. E. R. Camp of the Charlotte division of the company is interested in the work. The company may make a general substitution of electricity for steam in its numerous plants south.

The South Carolina Public Service Corporation, a $10,000,000 company, has applied for a perpetual franchise in the town of Greenwood.

The Carolina Light and Power Company is developing a large waterpower at Anderson's Falls, near Langley, S. C.

A report has gained currency that all attempts at a merger of the lighting and heating plants in Louisville, Ky., have been abandoned for the present. This is said to be a direct result of money stringency. The merger will not be abandoned permanently, it is said.

Seven transformers weighing 20,000 pounds are being installed in the transformer station of the Cape Fear Electric Power Company at Fayetteville, N. C. This development at Buckhorn Falls will furnish light and power for a number of the largest cotton mills in the state.

A. F. Hart & Co., Hickory, N. C., have been awarded the contract for the building of the plant of the Hickory Power and Electric Company, including the dam, which will be built to supply 5,000 horsepower. The work will be completed by January 1, 1908. The Horseford Shoals property, three miles from Hickory, which was sold recently for $25,000, is to be offered for sale again, a local company having raised the bid 10 per cent.

J. D. Pitts and associates are planning a cotton mill at Glen Alpine, N. C., to be operated by electricity from the Catawaba.

L.

Northwestern States.

Minneapolis, August 31.—The new Selby Avenue tunnel in St. Paul has been thrown open to the traffic of the Twin City Transit Company. The work has been going on for nine months and is an important engineering feat for the Northwest. The slope in the tunnel is seven per cent., and is a reduction from 16 per cent., which was the incline of the surface line.

The Rockwell City (Iowa) Electric Light and Power Company has sold its plant to F. S. Moore.

A new company will be organized to push the project of building an electric line from Sidney, Iowa, to Council Bluffs.

Bonds for $15,000 have been voted at Washburn, Wis., for the purpose of purchasing the local lighting system.

The Northwestern Interurban Railway Company will be incorporated by J. L. Lambrecht of Minneapolis and associates for the purpose of building several trolley lines in Northern Minnesota and North Dakota, including one from Grand Forks, N. D., to Crookston, Minn.

The Dakota Power Company has been organized to develop the power of Rapid Creek, near Rapid City, S. D. About 10,000 horsepower will be generated.

A waterpower plant may be constructed for furnishing power for the municipal electric-light plant at Gary, S. D.

Harry Hoffman has resigned as superintendent of the electric-light plant at Valley City, N. D. About $12,000 worth of new machinery is to be purchased for the plant.

R. A. Roberts of St. Louis has begun surveying for an interurban line which he proposes constructing from Muscatine to Davenport, Iowa.

Messrs. Lambrech and Murray of Minneapolis, who are planning to build a third-rail line from Crookston, Minn., to Grand Forks, N. D., have enlarged their plans and now propose to extend it as far west as Carrington.

The entire street-railway system at Des Moines, Iowa, is to be double tracked. It is estimated that the work will cost close to half a million dollars. Of the 80 miles of line in the city only about a quarter consists of double tracks.

Plans have been completed for an addition to and a remodeling of the plant of the Union Light, Heat and Power Company's plant at Fargo, N. D. The improvement will cost about $30,000.

The Western Supply Company received the contract for new machinery for the electric-light plant at Valley City, N. D. The cost will be about $10,000.

The Davenport (Iowa) and Manchester Railway Company has incorporated with George T. Baker as president and F. E. Rank, secretary; capital, $15,000.

The Prentice (Wis.) Light, Power and Water Company has filed articles of incorporation, with a capitalization of $3,000. A. F. Zeigler heads the list of incorporators.

R.

Pacific Slope.

San Francisco, August 28.—The local street-car service has been further improved by the operation of additional lines and more night cars. It is thought that the small semblance of a car strike that is still remaining will be abandoned, although a few of the leaders of the carmen still assert that they are in the fight to stay.

The Board of Supervisors of San Francisco will defend the city in the suits brought to restrain the supervisors from proceeding with the construction of a municipal street railway on Geary Street, using the $720,000 specially appropriated for the purpose.

The Board of Supervisors has awarded the contract for furnishing light to the municipality to the San Francisco Gas and Electric Company for the ensuing fiscal year. The company is to light the streets with no less than 4,210 gas lamps and 1,616 electric arc lights. Of the arc lamps 1,366 are to burn all night and 250 may be extinguished at midnight. The rates are as follows: For each separate arc light per night, $0.20713. For electric current for public buildings and for power purposes, per kilowatt-hour, $0.04. Each separate gas lamp per night, $0.087. For gas for public buildings, per 1,000 cubic feet, $0.60. The total payments made to the company must not exceed the amount of the appropriation, $275,000.

The new system of the City Electric Company in San Francisco will be in operation in October, and many contracts have been signed for commercial lighting. The two 2,500-kilowatt turbo-generator sets have been installed at the new reinforced concrete power station on the corner of Beach and Mason streets. The boilers and switchboard are being erected and the salt-water condensing system installed.

At the last meeting of the directors of the San Jose-Los Gatos Interurban Railroad Company and of the Peninsula Railroad Company J. T. Burke of the Southern Pacific was chosen to fill the vacant directorship, and he was unanimously elected to the presidency of both companies. F. E. Chapin was re-elected to the vice-presidency and the remaining directors are W. C. Andrews, A. E. Wilder and Gus Lion.

The Great Western Power Company, which is spending several millions of dollars in the construction of a great electric power generating plant on the Feather River in Plumas County, Cal., is also engaged actively in work near Antioch.

It is announced from Willows, Cal., that the Snow Mountain Power Company has made excellent progress on the hydraulic work for its electric plant. The big sawmill of the company is running night and day cutting lumber for the flume to be built. The line of this flume is now being surveyed.

The City Council of Pasadena, Cal., has passed an ordinance calling for bids for a double-track electric-railway franchise on Colorado and other streets.

The electrical smelter at Heroult-on-the-Pitt, near Redding, Cal., has begun operations. Pig iron is produced by the Heroult process. Ten men to a shift are required at the smelter in addition, of course, to the force of miners. The plant will not operate commercially until a short railroad has been built.

The Noble Electric Steel Company has been incorporated with a capital stock of $1,000,000. H. H. Noble is president; E. V. D. Johnson, vice-president; C. B. Morgan, secretary.

The Fresno Home Light and Power Company, recently incorporated with $250,000 capital stock, will erect a $280,000 plant. The principal place of business is Fresno, Cal.

The Colt Automatic Air Brake and Trolley Company has filed articles with a capital stock of $300,000.

Work has commenced on a big dam at Gold Lake for the Sierra Mercantile Mining and Power Company, a corporation that proposes to furnish power to operate a short line of electric railroad between Marysville and Reno through the Yuba Pass. A similar dam is to be constructed at Long Lake in Plumas County, and the pipe laid down Gray Eagle Creek, which will converge at the power plant with a similar pipe line down Fraser Creek from Gold Lake, where all the waters will be combined and utilized. The contour of the ground permits of this being done with facility.

The Nevada-California Power Company is rapidly constructing its high-tension transmission line from Palmetto to Rhyolite, Nev. Current is to be transmitted for light and power purposes at 100,000 volts. F. G. Baum, who is connected with the company, has brought out a new style of high-tension insulator which will be tried out on this line.

A.

PERSONAL.

W. B. Vot, has been appointed superintendent of the Sheboygan (Wis.) Light, Power and Railway Company.

Abraham White's successor as president of the United Wireless Telegraph Company, the concern operating the De Forest system, is Col. C. C. Wilson of Denver.

C. H. Edwards, manager of the Northwestern Telephone Exchange Company's system at St. Paul, Minn., has resigned his position, and C. W. Reese of Omaha, Neb., has been promoted to fill the vacancy.

Cleveland papers announce the engagement of Mr. Leroy P. Sawyer and Miss Jessamine A. Pike, both of Cleveland, Ohio. Mr. Sawyer is treasurer of the Buckeye Electric Company of Cleveland and is popular in the electrical field. His fiancee is a vocalist and musician of considerable note and belongs to the leading society circles of Cleveland.

Mr. A. C. Bell, until recently in charge of the patent department of the Stromberg-Carlson Telephone Manufacturing Company, at Rochester, N. Y., has resigned that position and will enter the patent-law offices of Mr. Charles A. Brown, 1550 Monadnock Building, Chicago. Mr. Bell's scientific training was secured at Cornell University, of which institution he is a graduate. He has had experience both as a patent solicitor and as an engineer since leaving college. Mr. Bell will be engaged principally in the work of soliciting patents in Mr. Brown's office.

Prof. F. B. Crocker of Columbia University, New York city, has been appointed secretary of the American local committee of the International Electrotechnical Commission. A meeting of the committee will no doubt be held soon and a plan of action decided upon.

R. W. Bailey has been appointed general superintendent of the Peoria (Ill.) Railway Company. Mr. Bailey came from Alton, where he was superintendent of the Alton division of the East St. Louis and Suburban system for the last year and a half. The position is a new one, and Mr. Bailey will have charge of the detail work in connection with both the interurban and the city lines.

Charles J. Haines, father of J. Allen Haines, vice-president of the Western Wire Sales Company of Chicago, died suddenly of heart disease in a downtown Chicago store on August 29th. Mr. Haines was a pioneer resident of Chicago and a prominent business man of the city. He was 61 years of age. The younger Mr. Haines is well known in the electrical fraternity and has many sympathizing friends.

William O. Tague, professor of experimental electrical engineering at Purdue University, Lafayette, Ind., has resigned his position to accept the general management of the Brookline Motor Car Company of Brookline, Mass. Professor Tague has been at Purdue for several years in charge of the engineering laboratory and has done special work in connection with automobiles and electric power. His successor has not been named.

ELECTRIC LIGHTING.

Stanton, Neb., has voted $5,500 in bonds for a lighting plant.

Contracts have been awarded for the construction of an electric-light and water plant at Dawson, Minn.

The Hico (Tex.) Electric Light and Power Company has been incorporated with a capital stock of $10,000.

Atwood Benton is about to begin the construction of a $135,000 electric power plant at Hot Springs, Ark.

An election is to be held at St. Paul, Neb., on the proposition to vote bonds for the construction of an electric-light plant.

The City Council at Aberdeen, S. D., has granted a franchise to C. F. Freehauf for 25 years for an electric-light system.

The Union Central Light and Ice Company has secured a franchise at Hubbard City, Tex. A $50,000 plant will be installed.

The Union Light, Heat and Power Company is planning on $30,000 worth of improvements to its power plant at Moorhead, Minn.

In Terrell, Tex., the City Council has passed an ordinance authorizing the issuance of bonds to the amount of $15,000 for an electric-light plant.

The City Council of Tacoma, Wash., has decided to construct an electric power plant to furnish 10,000 horsepower. The product is to be sold at one-half cent per kilowatt-hour.

Low water in the Grand River, Michigan, the lowest in years, is handicapping many lighting and power plants temporarily. At Ionia the lighting wires are connected with the Commonwealth Power Company's line to Jackson, where current is generated by a steam plant, the city plant being entirely out of business because of the low water.

ELECTRIC RAILWAYS.

The Oklahoma City Street Railway Company will build a $180,000 power house at Belle Isle.

According to statements by officials of the New Haven rapid progress is being made in the installation of electricity on the New York division. If present plans are carried out all trains west of Stamford that run into the Grand Central Station will be operated by electricity. This means both local trains and the fast Boston trains, except the Colonial express and the Federal express, which do not use that station. The change from steam to electric locomotives at Stamford, it is estimated, will not take more than two minutes.

The Russellville and Ozark Mountain Traction, Light and Power Company is planning a power plant to be erected between Russellville and Dover, Ark.

The Harvard (Wis.) and Lake Geneva electric railway has been sold to the Elgin, Belvidere and Rockford Company. About $60,000 will be expended in additions to the power plant at Walworth.

POWER TRANSMISSION.

In the state of Washington W. H. Lewis has filed a water-right location notice in the county auditor's office for power in eastern Lewis County at the junction of the Cispus River with the Cowlitz, proposing to flume 4,000 cubic feet of water per second to the place of use, 15 miles from the river junction.

Announcement is made of the completion of the 900-foot dam for the Whitney Reduction Company on the Yadkin River, eight miles from Salisbury, N. C. The dam is 46 feet in height and 45,000 horsepower will be developed for transmission to mills and factories and for lighting a dozen towns, the power to be available before the end of the year.

Reports from Eugene, Ore., say that engineers at the head of the McKenzie River are making surveys for some unknown corporation for a big electric plant. It is said that water will be taken from Clear Lake and will be tunneled through a mountain to a great generating station, where a 900-foot fall will be secured with a capacity to generate 50,000 horsepower.

The Commonwealth Power Company of Battle Creek, Mich., is troubled by a scarcity of water at its plants at Allegan, Otsego and Plainwell. The streams supplying these plants are very low, and further difficulty is expected unless several inches of rainfall bring relief soon. The cities most affected are Battle Creek and Jackson. Auxiliary steam plants may be called into use.

PUBLICATIONS.

Rossiter, MacGovern & Co. of New York city have issued a new list of electrical machinery, boilers, engines, dynamos and motors dated August 1st, which supersedes all previous lists.

Catalogue No. A12 of the Ward Leonard Electric Company, Bronxville, N. Y., describes and illustrates self-starters for electric motors. The motor is stopped or started by simply pressing a button—"it does the rest." Wiring diagrams are added. The reversing motor-starters, shown in Catalogue A10, can be used to start in either direction of rotation. A renewable spring switch is supplied to open the circuit with a quick break, and magnetic blowouts are used in sizes above 10 horsepower.

The N. E. L. A. Bulletin, Vol. I., No. 1, published by the National Electric Light Association, has made its appearance, dated August. The new publication, besides serving as a bulletin of current events of interest to members of the association, will also be a question box. Matters of timely interest upon which members wish prompt information will be given attention. The bulletin will be published regularly about the fifteenth of each month, and all members of the association and other central-station men are at liberty to contribute to its columns. Communications should be addressed to the secretary, Engineering Societies Building, 29 West Thirty-ninth Street, New York.

SOCIETIES AND SCHOOLS.

Additional electrical machinery and switchboards are being installed in the electrical engineering department of the Louisiana State University. These improvements will afford the university one of the best and largest laboratories and engineering schools in the South. One board will be for a polyphase generator for one, two and three-phase currents while another is a plug distributing board for single and polyphase currents, and the third is a similar board for direct current. This arrangement affords the students any desired kind of current for experiment and tests.

MISCELLANEOUS.

Zinc electrodes in the form of pencils, about six inches long, placed in the suction chamber of a surface condenser employing sea water for cooling, have done away with the galvanic action between the iron base and the other metals in the condensers, which led to the rapid corrosion of the iron. This has apparently ceased entirely since the zinc pencils were introduced, although the latter are eaten away rapidly.

TRADE NEWS.

The General Electric Company is erecting a number of large factory buildings on land purchased by the company at Erie, Pa.

The Northwestern Electrical Company of Seattle, Wash., which has been incorporated with a capital stock of $250,000, will build a plant for the manufacture of electrical appliances.

D. C. & William B. Jackson, engineering experts, announce the removal of their western office from Madison, Wis., to the Commercial National Bank Building, Chicago. An eastern office will be opened in Boston this month. Mr. William J. Crumpton will be in immediate charge of the Chicago office. These gentlemen are prepared to do consulting engineering for electric and allied properties and include in their line of work plans, specifications, supervision or construction, examination and reports.

The Sarco Fuel Saving and Engineering Company of New York is finding a large demand for its Sarco CO_2 recorder. In addition to indicating at sight the amount of carbon dioxide (CO_2) in the flue gases, this machine records the information on a chart, so that the engineer can read at his leisure from the daily record just what furnace economy the fireman has practiced at any particular time. The company is also getting out the Caldwell automatic mechanical coal shovel, which differs from mechanical stokers in that it is independent from and can be applied to any grate. The shovel periodically projects a predetermined amount of coal over different parts of the grate surface and produces a very uniform distribution of the fuel. This company also makes a number of other devices tending toward boiler-room economy. Its officers are: President, H. Sanders; vice-president, C. O. Mailloux; general manager, John A. Caldwell.

BUSINESS.

Type K Allis-Chalmers direct-current motor has been designed to meet the mechanical and electrical requirements of an individual drive for machinery. It is explained to be equally well adapted to belt drive at constant speed and continuous service, or geared drive, variable speed aind intermittent service. The machine is very compact, the construction is rigid, and every detail has been worked out to the exacting requirements of modern service.

The July business of the Westinghouse Electric and Manufacturing Company was considerably above the average. The last information from East Pittsburg stated that the railway department alone showed a record for orders booked approximating about $2,500,000. Among these were two of more than ordinary importance. The Brooklyn Rapid Transit Company contracted for 400 electric-railway motors, 200 of which, of 200 horsepower each, are for the elevated railroad cars, while the balance, of 60 horsepower each, will be surface-car equipment. In connection with the elevated-car equipment the company will also furnish the Westinghouse multiple-unit control. The other large order comes from the Schoepf interests of Cincinnati, which control one of the largest urban and interurban electric-railway systems in this country, operating cars in Eastern and Central Ohio and Southern Indiana. This order includes a complete equipment of electrical apparatus for 24 sub-stations, consisting of rotary transformers, transformers and switchboard appliances as well as four Westinghouse turbo-generators aggregating 26,000 horsepower.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) August 27, 1907.

864,154. Device for Alarm and Detecting Burglary. Paul Brauer, Wittenberge, Germany. Application filed June 8, 1906.

The various parts of this device to cause alarm and secure photographs of burglars are set in operation by the intruder completing an electric circuit.

864,167. Insulating Conduit for Electric Wires. Anthony P. Hinsky, Hoboken, N. J. Application filed December 3, 1906.

A tubular conduit of fibrous material is provided in its outer surface with corrugations or ribs. The tube and covering are saturated with an insulating and preservative material.

864,228. Trolley Harp. Frank H. Brueggeman, Norwood, Ohio, assignor of one-half to the Acme Automatic Street Indicating Company, Cleveland, Ohio. Application filed April 23, 1906.

The sections of the harp have hollow heads.

864,232. Railway Switch. James D. Downes, Detroit, Mich., assignor of one-half to Charles R. Burke, Detroit, Mich. Application filed April 1, 1907.

The switch is fitted with electric contacts which close circuits, lighting signal lamps to show the position of the switch.

864,236. Automatic Gas Cut-off. James G. Fairbanks and William O. Rice, Marion, Ohio. Application filed March 7, 1907.

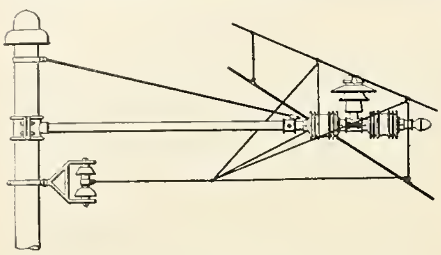
On failure of the gas supply, a pressure-maintained piston sinks, releasing a spring-actuated cut-off valve. Meanwhile an electric alarm bell is sounded.

864,251. Catenary Suspension Bracket for Curves. Elmer P. Morris, East Orange, N. J. Application filed October 20, 1906.

A brace is secured at one end to the cable and at the other end to the trolley wire, so that the lateral strains thrown upon it by the cable and wire respectively are in the same direction.

864,252. Catenary Suspension Bracket. Elmer P. Morris, East Orange, N. J. Application filed October 20, 1906.

Secondary insulators are arranged to trap the cable and prevent its making contact with uninsulated portions of its support. The working conductor is supported from the messenger in substantially a horizontal plane. (See cut.)



NO. 864,252.—CATENARY SUSPENSION BRACKET.

864,259. Electric Reciprocatory Device. John B. Rathbun, Hammond, Ind., assignor to Charles G. Kingwill, Hammond, Ind. Application filed May 9, 1906.

A number of coils arranged so that their fields are coincident are arranged for sending a direct current of electricity through one of them and an alternating current through another, so that the coils first reinforce each other in their magnetic effect upon the core, and then neutralize each other.

864,261. Electrical Cut-out Switch. William H. Ringwood, East Pittsburg, Pa. Application filed November 22, 1906.

A detachable cam connection for electrical poles has engaging projecting lugs on its walls, so that when one section is turned upon the other engagement of contact plates will occur. A fuse connects the contact plates of one section.

864,272. Space Telegraphy. John S. Stone, Boston, Mass., assignor to William W. Swan, trustee, Brookline, Mass. Application filed January 4, 1907.

As shown in the circuit diagram, a resonant circuit includes a condenser with a local receiving circuit connected across its terminals, and has in series an audion, a source of unidirectional electromotive force and a circuit of low resistance and high inductance connected in shunt to said rectifier. (See cut.)

864,297. Storage Battery. William Gardiner, Chicago, Ill., assignor to Cornelius P. Stringfield, Chicago, Ill. Application filed December 23, 1905.

The plate consists of a series of trough-like juxtaposed sections, each open at one side, and with its other sides provided with apertures covered by a porous strip, against which the active material bears.

NO. 864,344 —FLUID-PRESSURE SYSTEM.

864,306. Electric Switch-operating Device. Frank A. Johnson and David A. Robbins, Danville, Ill. Application filed October 22, 1906.

Swinging contacts carried by the trolley span-wires may be engaged by a movable contact carried on the car, to close a circuit to operate the track switch.

864,332. Telephone Attachment. Albert S. Perry, Yukon, Okla. Application filed March 2, 1907.

Auxiliary contacts in the telephone box are controlled by a push rod.

864,341. Annunciator. Frederic Sidler, West Pullman, Ill. Application filed November 14, 1904.

A pawl extending from an armature actuated by an electromagnet in the call-bell circuit advances a ratchet wheel.

864,344. Fluid-pressure System. Samuel B. Stewart, Jr., Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 20, 1903.

The rheostat arm is advanced by a pilot motor to start the pump motor when the line pressure falls below a set value. (See cut.)

864,348. Electric Welding Clamp. William E. Williams, Chicago, Ill. Application filed July 21, 1905.

Two electrode blocks, carrying contact pieces, are mounted to move in a line toward each other. The contact pieces move so as to grip the work at the welding point. (See cut.)

864,362. Burglar Alarm. Nelson L. B. Doull, Los Angeles, Cal. Application filed December 11, 1905.

This burglar alarm is a combination of a lock, a battery, an electric bell and casings inserted in the door frame opposite the lock and latch bolts, carrying plungers which normally complete a circuit with the bolts through the lock mechanism.

864,382. Support for Telephone Receivers. John S. Mills, New Grenada, Pa. Application filed January 21, 1907.

Attached under the transmitter-arm bolt is an angle arm ending in a telescoping bracket which holds the receiver in clips.

864,422. Trolley Guard. Charles Harkness, Providence, R. I., assignor to the Harkness Trolley System Company. Original application filed February 16, 1905. Divided and this application filed March 8, 1906.

A lever, weighted at one end, is provided at the other with upwardly diverging arms pivotally mounted on the bracket arm, on which it is movable both vertically and transversely.

864,427. Lamp Receptacle. Harry W. Lawrence, Denver, Colo., assignor to the New England Electric Company. Application filed January 5, 1907.

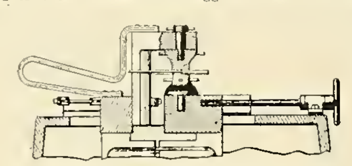
The socket comprises a porcelain base or block having an annular groove therein, which has a number of outward extensions. A threaded shell having outwardly bent ears is inset in the groove.

864,446. Controlling Mechanism. Herbert W. Cheney, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed June 30, 1906.

The controller drum has "off," starting and running positions, and a spring which tends to move it to "off" position when in starting position, but exerts no influence when in running position.

864,454. Testing System for Telephone Lines. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed June 29, 1903.

An operator's busy-test system capable of being applied to the well-known Kellogg cord circuit is detailed.



NO. 864,348.—ELECTRIC WELDING CLAMP.

864,519. Apparatus for the Electric Operation of Type-setting Machines. Heinrich Drewell, Hanover, Germany. Application filed August 25, 1906.

The characters are controlled by the combination of brushes making contact with a conducting roller through perforations in non-conducting strip.

864,520. Trolley Wire Hanger or Ear. Harry G. Dyer, Gloucester City, N. J., assignor of one-half to William J. Van Meter, Gloucester, N. J. Application filed September 7, 1906.

The trolley wire is carried up in a curved path, while a part of the hanger presents a straight under-run for the trolley.

864,530. Device for Pulling Electric Cable and Wire. Daniel H. Garber, Indianapolis, Ind. Application filed January 25, 1907.

Two clamping shoes which grip the cable are forced together by a bell-crank lever, to which the pull rope is attached.

864,535. Electric Lamp Adjuster. Wilson S. Hawker, Dayton, Ohio. Application filed December 1, 1905.

An extendible tubular arm ends in hinged clips which clasp the lamp sockets.

864,542. Bracket for Electric Headlights. Charles E. Jones, New York, N. Y., assignor to the Dressel Railway Lamp Works, New York, N. Y. Application filed May 7, 1907.

The bracket holds the lamp with its center in the focus of the reflector.

864,571. Trolley Harp. Thomas W. Small, Cleveland, Ohio, assignor to the Acme Automatic Street Indicating Company, Cleveland, Ohio. Application filed December 5, 1906.

A contact-boss is carried at the side of and insulated from the harp, and connects with the car through a wire insulated from the trolley pole.

864,576. Alarm. Thomas H. Troland, New London, Conn. Application filed March 8, 1905.

Water escaping from an automatic sprinkling nozzle throws a contact lever over its center, completing an alarm circuit.

864,599. Insulator Tie for Electric Wires. James W. Beckett, Little Rock, and William R. Beckett, Rose Bud, Ark. Application filed May 21, 1906.

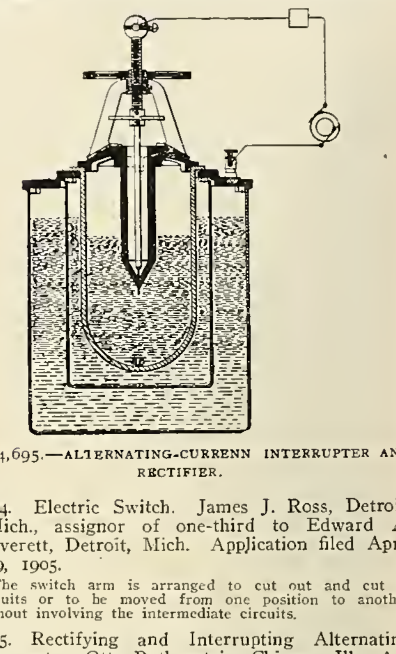
The wire is gripped by a clamping screw carried by a strap which encircles the insulator.

864,623. Driving Gear for Motor Vehicles. William H. Douglas, Belleville, N. J., assignor to Healey & Co., New York, N. Y. Application filed September 26, 1906.

The motor is supported on the axle and is connected to the pinions by double universal joints.

864,653. Electric Railroading. Isidor Kitsee, Philadelphia, Pa. Application filed April 15, 1907.

A system of four tracks has five overhead wires, the outside of the outside tracks being provided each with one wire connected to a common terminal of a generator, the inside of the outside tracks being provided each with one wire connected to the opposite terminal of the generator and the inside of the two inside tracks provided with a common wire connected to the first terminal of the generator.



NO. 864,695.—ALTERNATING-CURRENN INTERRUPTER AND RECTIFIER.

864,694. Electric Switch. James J. Ross, Detroit, Mich., assignor of one-third to Edward A. Everett, Detroit, Mich. Application filed April 19, 1905.

The switch arm is arranged to cut out and cut in circuits or to be moved from one position to another without involving the intermediate circuits.

864,695. Rectifying and Interrupting Alternating Currents. Otto Rothenstein, Chicago, Ill. Application filed November 1, 1906.

To prevent heating during operation, which would greatly diminish the "valve" effect of the aluminum, the outside vessel contains a refrigerating fluid; a second vessel of rectifying material, as aluminum, is provided with a binding or terminal post and contains a suitable electrolyte; a third vessel of inert material, containing a suitable electrolyte, is suspended in the second vessel. Annular rings of insulating material separate the vessels electrically.

864,713. Telephone Repeater System. Nathaniel G. Warth, Columbus, Ohio. Application filed January 25, 1907.

The principle is that of reproducing the incoming currents through a receiver in mechanical connection with a transmitter capsule, but a novel arrangement of circuits renders the receiver operative only to the received currents and not to the locally reproduced currents.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired September 2, 1907:

435,424. Electric Switch. C. W. Huntington, Baltimore, Md.
435,438. Telephony. T. D. Lockwood, Melrose, Mass.
435,440. Automatic Electric Annunciator. J. W. Luthe and A. E. Jeavous, Cleveland, Ohio.
435,447. Electric Conductor for Street Railways. L. M. Perkins, St. Louis, Mo.
435,471. Electric-railway Closed-circuit System. M. Wheless, Nashville, Tenn.
435,486. Conduit for Electric Railways. W. R. Elliott, Kansas City, Mo.
435,487. Electric Conduit. W. R. Elliott, Kansas City, Mo.
435,490. Automatic Electric Switch. T. M. Foote, Boston, Mass.
435,516. Electric Signaling Apparatus for Preventing Collisions Between Railway Trains. T. Perls, Wurzburg, Germany.
435,525. Regulator for Dynamo-electric machines. C. E. Scribner, Chicago, Ill.
435,526. Regulator for Dynamo-electric machines. C. E. Scribner, Chicago, Ill.
435,527. Regulator for Dynamo-electric Machines. C. E. Scribner, Chicago, Ill.
435,536. Electric Conduit. H. N. Curtis, New York, N. Y.
435,545. Automatic Regulation of Electric Circuits. G. B. Prescott, Jr., Newark, N. J.
435,550. Electrical Measuring Instrument. G. W. Walker, New York, N. Y.
435,559. Upward-pressure Contact for Electric Railways. J. A. Duggan, Quincy, Mass.
435,639. Electric Motor. H. H. Blades, Detroit, Mich.
435,640. Means for Supporting Storage-batteries on Railway Cars. H. H. Blades, Detroit, Mich.
435,641. Electric Railway Car. H. H. Blades, Detroit, Mich.
435,642. Electric Railway Car. M. W. Dewey, Syracuse, N. Y.
435,643. Method of Electric Welding. M. W. Dewey, Syracuse, N. Y.
435,662. Electric Railway. R. M. Hunter, Philadelphia, Pa.
435,679. Method of and Apparatus for Producing Musical Sounds by Electricity. G. Breed, United States Navy.
435,687. Means for Charging and Using Secondary Batteries. T. A. Edison, Menlo Park, N. J.
435,688. Process of and Apparatus for Generating Electricity. T. A. Edison, Menlo Park, N. J.
435,689. Telegraphy. T. A. Edison, Menlo Park, N. J.
435,690. Method of Making Armatures for Dynamo-electric Machines. T. A. Edison, Menlo Park, N. J.
435,700. Device for Controlling the Current of Electric Generators. H. W. Leonard, Chicago, Ill.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, SEPTEMBER 14, 1907. No. 10

Combined Working of Electric Power Stations and Gas Works.

By Dr. Alfred Gradenwitz.

In spite of the indifference shown in the beginning by gas works to the rapidly increasing number of electric power stations, it may be said that gas works and electric power stations may very well continue prospering side by side. In fact, the development of the former has hardly ever been hampered by the subsequent erection of an electric power station at the same locality, while in many cases a mutual assistance between these two kinds of power stations has been found extremely profitable. While the managing cost of both works can thus be reduced to some extent, the gas works will be able to supply the prime energy for the electric station at far cheaper rates.

An interesting instance of a combination of these two kinds of power plant is afforded by the community of Lichtenburg, near Berlin. The community had possessed for some time a gas works operated on a rather satisfactory basis, when in 1904 the construction of an electric power station was decided upon and carried out immediately. In this case the consumption of gas, so far from decreasing after the electric station had been opened, was even found to increase in the first year, while the electric power station showed so satisfactory a development as to require an extension after a short time.

As shown in Fig. 1, the electric station was erected immediately beside the gas works, suction gas generated from the coke of the works being chosen as prime energy. This gas at present operates two engines of 200 and two of 500 horsepower each, all of which have been supplied by the Maschinenbau-Gesellschaft, Nurnberg.

In Fig. 2 is shown a general view of the engine room of the power house at Lichtenberg. Each of the two smaller gas engines and one of the 500-horsepower engines is direct-coupled to a direct-current dynamo, the power station having been planned at the outset as an exclusive direct-current station. Shortly after its completion, however, the necessity of supplying more distant districts with large amounts of energy was felt, resulting in an alternating-current extension. For this reason the 500-horsepower gas engine last installed was directly coupled to an alternating-current generator, while a suitable converter was provided as mutual reserve for both kinds of current. The direct-current output of the works is assisted by two accumulator batteries of considerable capacity.

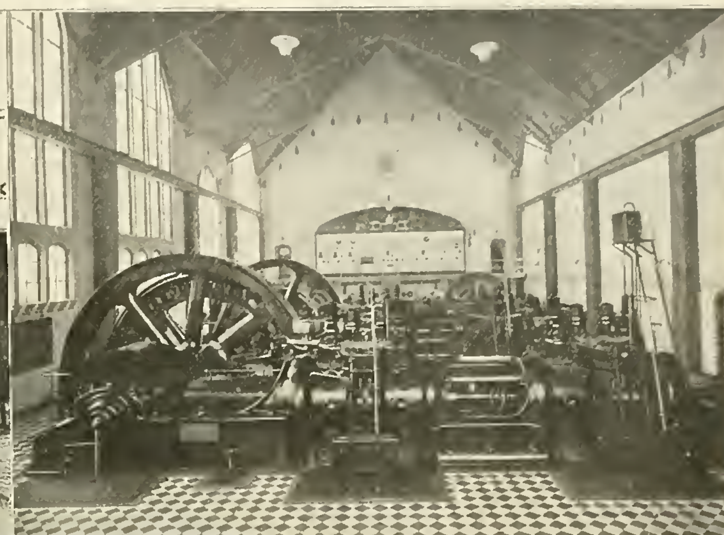
On the ground of a former estate situated in the neighborhood of the central station a converter station was erected at the same time the extension mentioned was carried out. This comprises provisionally two converters (Fig. 3) and an accumulator battery. This arrangement allows both of yielding alternating current to the outlying district and of feeding the existing direct-current system by the aid of converters.

The electrical energy generated at the electric power house was utilized in the recent extension of the gas works for operating, by means of electric motors, any machinery required for the operation of an up-to-date gas works. A total of eight direct-current motors (of the enclosed type on account of the great amounts of dust) was installed.

Fig. 4 shows a coal crusher operated through belt transmission by a 15-horsepower motor. Fig. 5 shows a discharging machine with electric traveling mechanism, in the gas works. The machine itself is actuated through belt transmission by a motor. A similar equipment was chosen for the charging machine in the same room.

Operation of the De Brower chute, shown in Fig. 6, is by means of a 3½-horsepower electric motor provided with gearing, reducing its number of turns at a ratio of 5 to 1, while the drive itself is effected from the intermediary shaft through belt transmission. There is further an elevator operated by a five-horsepower motor and a Bamag chute actuated by a three-horsepower motor, both through belt transmission.

All the above-mentioned plants have given satisfactory results in practice, illustrating the mutual benefit to be derived from a combination of gas works and electric power stations.



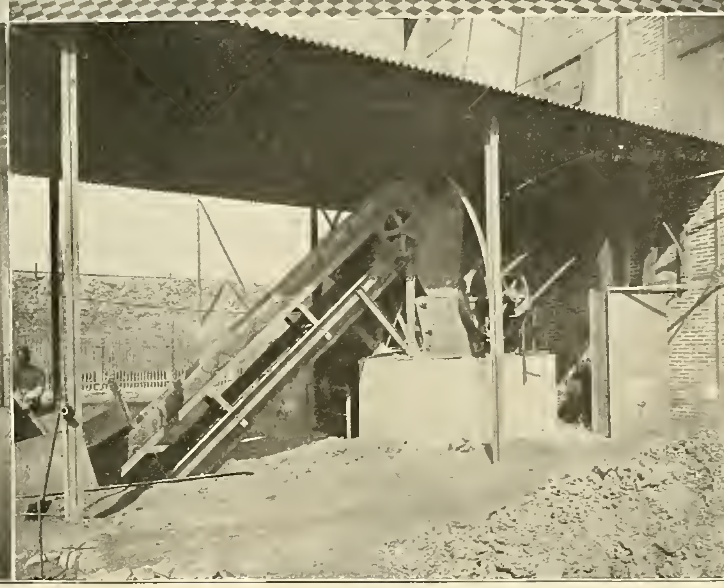


Fig. 1. Electric Power House directly beside the Gas Works.
Fig. 2. General View of direct-connected Gas Engines and Generators.
Fig. 3. Converter Station in connection with Lichtenberg Power House.
Fig. 4. Coal Crusher operated by 15-horsepower Motor.

COMBINED WORKING OF AN ELECTRIC POWER STATION AND GAS WORKS AT LICHTENBERG, GERMANY.

Advices from Tacoma, Wash., say that Pacific Avenue will follow the example of C Street and place cluster lights 100 feet apart along the curbs. Business men will beautify the thoroughfare. R. F. Anderson has assumed charge of the enterprise.

Electrical Progress in New Zealand.

Reporting to the governor of New Zealand on the Post and Telegraph Department of that country for the year 1906, Mr. J. G. Ward of Wellington, postmaster-general and minister of telegraphs, says that the year has been one of uninterrupted

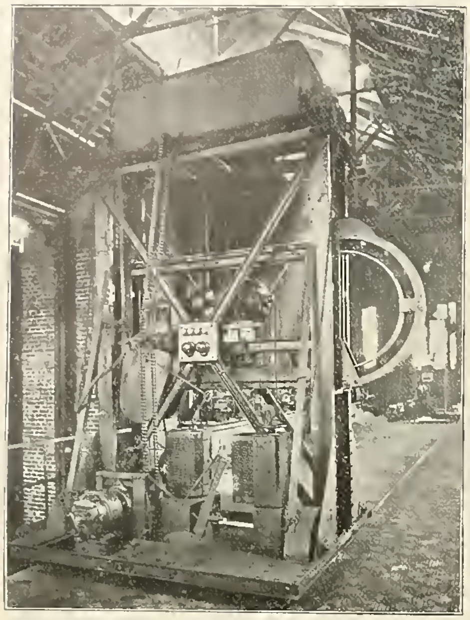

FIG. 5. ELECTRICALLY OPERATED DISCHARGING MACHINE IN LICHTENBERG GAS WORKS.

prosperity. The revenue of the department and the excess of revenue over expenditure were the highest yet attained. For the first time the revenue of the telegraph branch has exceeded the expenditure, and this by the substantial sum of £16,161.

The charges for continuous attendance at telephone exchanges having over 150 paying subscribers have been altered to permit of alternative rates being charged—viz., £7 per annum for business establishments and £5 for private residences, or £6 a year for each business and private connection.

The total value of the telegraph and telephone business for the year ended March 31st last, including miscellaneous telegraph receipts and government telegrams, was £325,007 15s. 7½d., as compared with £298,079 17s. 11d. for the previous year.

The working of the Pacific cable has been satisfactory. Delays due to weather conditions occurred occasionally on the Canadian land lines.

In the public-works' estimates for 1906-7, Parliament voted £2,000 for wireless telegraphy. Negotiations which had been proceeding with the commonwealth toward establishing wireless-telegraph communication between Australia and New Zealand and some of the outlying islands did not result in any decision to prosecute this work. It will probably be found the best policy, says Mr. Ward, to withhold any considerable outlay in connection with wireless telegraphy until something more definite is known as to what is likely to result from scientific research now proceeding.

Several orders in council for tramway extension

FIG. 6. DE BROWER CHUTE IN LICHTENBERG PLANT.

have been dealt with during the year on behalf of the Board of Control, and supervision maintained over the several tramway undertakings in the colony. A few applications for licenses for the electric lighting of boroughs have been received.

Alternating-current Coal Mining Installation of the McKell Coal and Coke Company.

After operating its Kilsyth (W. Va.) mine for a number of years, using electric haulage of the rack-rail type and employing electric power for various purposes in and about the mines, generating the current at 275 volts close by the bank mouth, the McKell Coal and Coke Company, which was a pioneer in the New River field of West Virginia, realized the necessity of supplying electric power for its new operations farther up Loup Creek.

The first plan considered was the placing of other power plants at each operation. Lack of water during a portion of the year was, however, an obstacle in the way of this plan, and further, it means a large increase in operating expense, each plant requiring its own engineers and firemen. Moreover the distance between the new operations and from the existing plant to the new operations is too great to allow of direct-current or low-voltage transmission. Further than this, the installation of such individual low-tension power plants would meet the requirements temporarily. The extent of the coal to be eventually mined and handled over the tipples is so great that the cost of distributing electric power over the entire territory from these stations in the form of direct current would largely offset the economy of its use.

The establishment of a central station from which power could be distributed to the many points needed was the logical solution of the problem, and naturally the location of this station, other things permitting, should be, as its name indicates, in the center of the entire property. This, as has already been said, was not feasible, owing to lack of suitable water supply, and that requirement led to the final choice of Kilsyth for the new generating apparatus. Besides being the nearest point to the power center where a water supply was available, it further offered the advantage of combining the new with the already existing power plant, which it is necessary, or at least advisable, to maintain in its existing shape for the present.

The power requirements of the McKell properties, like all mining operations, are steadily and constantly increasing, and this fact, with the present needs, fixed the size of the first unit to be installed for the transmission work at 500 kilowatts, with a station proportioned for a second unit within the same building, and space available for an extension of the building to accommodate a third unit, should it be found necessary. The main power house with its first unit is shown in Fig. 1.

The existing boiler plant, consisting of four horizontal tubular boilers, was increased by the addition of four 72-inch by 18-feet boilers of the same general type, having four-inch charcoal iron tubes. The engine is of the Allis-Chalmers Corliss type, 26 by 42 inches, running at 120 revolutions per minute, with a normal steam pressure of 115 pounds. This is direct-connected to a 500-kilowatt 24-cycle 6,600-volt three-phase Allis-Chalmers generator, revolving-field type, with 24 poles. It is separately excited by a 20-kilowatt Allis-Chalmers generator wound for 230 volts, direct-connected to a high-speed engine.

The switchboard consists of three panels of Vermont marble. A swinging bracket attached to the board carries an arc voltmeter with illuminated dial and a Lincoln synchronizer.

Lightning arresters are placed where the line wires leave the power house, though ventilating cupolas and disconnecting switches at the same point allow the cutting out of the entire equipment from the line wires when shut down.

The transmission line from Kilsyth to Sydney sub-station consists of three No. 00 copper wires carried on high-tension porcelain insulators, supported by iron pins. The three wires are placed in the form of a triangle, in cross-section, about 28 inches on a side. The top wire insulator is carried on an iron ridge pin and the other two are held by iron pins supported by a southern pine cross-arm three feet long, 26 inches from the top of the pole. The poles are largely second growth chestnut 35 feet in length.

From the Oswald sub-station to the Graham sub-station the same form of construction is used, but the size of wire is onl No. 4. The amount of copper installed is sufficient to supply double the present capacity of the sub-station with a line drop of 10 per cent. At each sub-station are located transformers reducing the alternating current to a voltage of 160 for conversion to direct current at 250 volts through rotary converters, all of Allis-Chalmers Company's manufacture.

At Oswald the sub-station is equipped with a 300-kilowatt rotary with equivalent transformer capacity. This sub-station supplies direct current for locomotive haulage, coal cutting and other minor

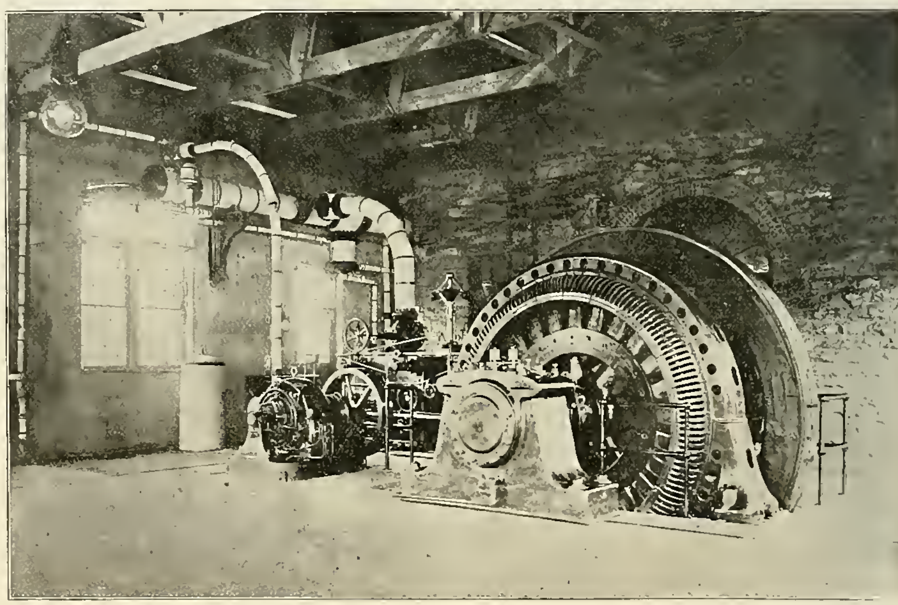

FIG. 1. KILSYTH POWER HOUSE OF THE M'KELL COAL AND COKE COMPANY.

uses in the Sydney mine close by the station, and also for the same uses in the Oswald mine, the bank mouth of which is across the stream from the sub-station. Fig. 2 shows the interior of the Sydney sub-station.

At Graham a 200-kilowatt rotary supplies the Graham mine. Each sub-station is designed for an increase in capacity to double the present installation, and each contains a four-panel switchboard. The alternating-current 6,600-volt current first passes through an automatic oil switch placed in a concrete cell at the rear walls of the building and controlled from the switchboard. The same panel carries three alternating-current ammeters and voltmeters on a swinging panel. The second panel carries an ammeter for low-tension alternating current and three single-pole double-throw main switches for the rotary. In operation these switches are thrown down for starting, connecting thus the rotary to half-voltage taps in the transformers, and the regular running position is up. Field break-up switches are placed on the frames of the rotaries themselves, as are also the equalizer switches for future equipment. The direct-current panels carry their usual direct-current generator and feeder equipment for two main circuits and an auxiliary direct-current lighting circuit. The main circuit and each feeder circuit are protected by circuit-breakers, and both alternating-current and direct-current lines are provided with complete lightning-arrester equipments. The incoming and outgoing lines pass through tiled openings in the rear walls and the alternating-current lines are provided with disconnecting switches. The sub-stations, like the main station, are of stone, with concrete floors and foundations.

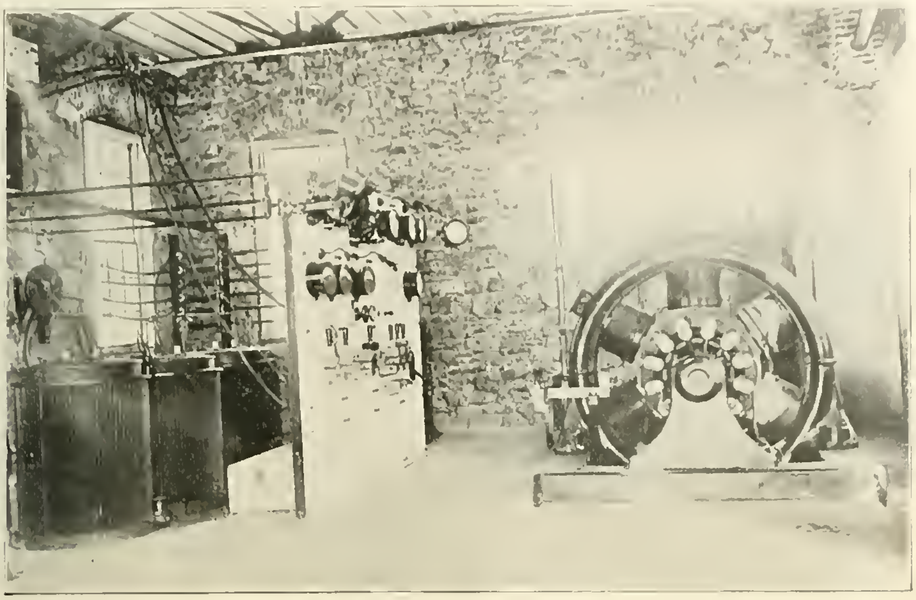

FIG. 2. SYDNEY SUB-STATION OF THE M'KELL COAL AND COKE COMPANY.

The sub-stations are located to reduce the direct-current distributing distance as much as possible and at the same time place them where the small attention required may be conveniently given by employes at the tipples, or on other portions of the outside works. The main circuit-breakers (direct-current) in each station are provided with a contact device by which a bell, located at any point where some employe is within sound, is rung and also lamps lighted when the circuit-breaker is out, giving both a visible and audible alarm.

The three mines are provided with Clifford-Capell fans, and owing to the heavy demand for power which these fans, when run at their full capacity, will make, they are operated by alternating-current motors entirely independent of the sub-stations. The Sydney and Oswald fans located at No. 4 and No. 5, respectively, are 11 feet in diameter, four feet four inches in width, with nine-inch shaft, and are rated to deliver 100,000 cubic feet of air each per minute against a three-inch water-gauge pressure. Under these conditions the fans would run at 230 revolutions per minute and require about 80 horsepower each. The Graham fan requires about 40 horsepower for driving. The fans are belted to the motors, which are standard three-phase induction type, controlled by compensators. Each motor is provided with large and small pulleys, allowing a variation in speed. Banks of lamps on the secondary of the transformers, normally burning, will show an interruption of the current by their darkness, and a visible signal will also be arrayed to show an interruption of the fan itself through the same cause or trouble with the motor or belt connection.

Induction or synchronous motors for various purposes, such as the operation of mine pumps, etc., may be placed practically at any points needed in the entire territory at a nominal copper cost, the voltage of 6,600 reducing the size of conductors so that the principal items of expense in such distribution is very materially cut down. Fig. 3 shows a set of motor-driven pumps in one of the mines.

It is equally feasible to place other rotary transformer stations at distant points on the property for direct-current distribution underground, and if such distribution is needed at points in the workings midway between the outcrops on the main creek and its branches and those on the head waters of Mill Creek the high-tension current may be carried overhead to a point above the center of such a needed distribution and thence down a bore hole to an underground transformer station similar to the sub-station already described.

The details of the electrical installation in these mines were furnished by Timothy W. Sprague and Charles K. Stearns, consulting engineers. The Allis-Chalmers Company furnished the principal power and electrical equipment.

Canadian Electrical Exhibition.

The Canadian electrical show was opened in the old Drill Hall, Montreal, on September 2d and will continue until September 14th. The exhibits were arranged very artistically and the illumination is brilliant. There are over sixty exhibitors, and nearly everything electrical is on exhibition, many of the devices, especially in the line of household heating and cooking utensils, being new to the general public. All the exhibits are contained in uniformly built booths, giving a systematic appearance. Each booth is painted white and there is a uniform arrangement of signs. Each sign and each railing separating the booths is made to conform to the standard.

So far the attendance has been good, and public interest is increasing. Many of the largest electrical concerns in Canada and the United States are exhibiting, and the large staff of experts gives interesting demonstrations of the various devices. Of special interest to the ladies is the large electric kitchen exhibited by the Canadian General Electric Company. Here electrical devices for the household are shown and their uses demonstrated.

Many prominent men of the Dominion are taking a lively interest in the show. On the evening of September 5th the visit of Hon. Lomer Gouin, provincial prime minister, was made a special feature. The premier and his party were escorted through the various exhibits by W. McLea Walbank, president of the exhibition company; R. S.

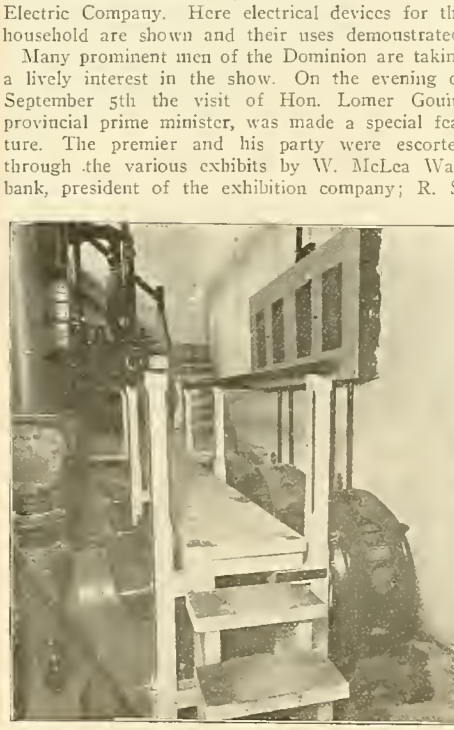

FIG. 3. INDUCTION MOTORS DRIVING PUMPS IN M'KELL COAL PLANT.

Kelch, managing director; J. W. Pilcher, secretary and treasurer; H. D. Bayne and J. A. Milne, directors.

Music is furnished in the exhibition hall by the band of the Sixty-fifth Mount Royal Carabineers. During the show several conventions will be held in Montreal, including the Canadian Electrical Association, the Canadian Street Railway Association and the Maritime Electrical Association.

Aside from the brilliant illumination, artistic decoration and numerous entertainment features, which make the show a success from the popular viewpoint, there is much to interest the electrical student and engineer, as the latest developments in the field are shown.

Following is a nearly complete list of the exhibitors:

Adams-Bagnall Electric Manufacturing Company, enclosed arc lamps.

Allis-Chalmers-Bullock, Limited, electrical and hydraulic machinery and appliances.

Aluminum Company of America, aluminum cables and joints.

American Conduit Company, conduit construction.

American Instrument Company, electrical measuring instruments. The Packard Electric Company, Ltd., agents.

Babcock & Wilcox, Limited, water-tube boilers and fittings.

Bell Telephone Company of Canada, telephone exchange.

Canadian Buffalo Forge Company, electric blowers, etc.

Canada Electric Company, electric and gas fixtures.

Canadian Fairbanks Company, Limited, electrically driven machinery.

Canadian General Electric Company, Limited, electrical machinery and apparatus of all kinds.

Canadian Pneumatic Tool Co., Limited, electric drills.

Canadian Rand Company, Limited, motor-driven air compressor.

Canadian Westinghouse Company, Limited, electrical machinery and apparatus of all kinds.

Crocker-Wheeler Company, motors, generators, A. C. and D. C. The Packard Electric Company, Ltd., agents.

Dominion Electric Manufacturing Company, Ltd., electrical specialties, conduit fittings, switches, switchboards, fixtures.

Dawson & Co., J. A., electric-light, power and railway supplies.

Dossert & Company, solderless connectors and terminals for wires and cables.

Economical Electric Lamp Company, turn-down lamps.

Fibre Conduit Company, fibre conduit.

Forman, John, electrical supplies.

Gest, G. M., conduit construction.

Garth Company, fixtures and fittings.

Jandus Electric Company, enclosed arc lamps. The Packard Electric Company, Ltd., agents.

Munderloh and Company, general electrical supplies.

National Electric Lamp Association, Canadian Member, Sunbeam Lamp Company.

Northern Electric and Manufacturing Company, Limited, telephone and fire-alarm apparatus and supplies.

O'Leary, W. J. & Company, auto electric switches, telephones, etc.

Pringle, R. E. T. Company, Limited, electrical supplies.

Phillips, Eugene F., Electrical Works, Limited, wires and cables.

Packard Electric Company, Limited, electrical machinery, instruments.

Reynolds-Dull Flasher Company, carbon gravity flashers.

Robb Engineering Company, Limited, direct-connected lighting plant engines and parts thereof.

Sayer Electric Company, electrical supplies and novelties.

Shawinigan Water and Power Company, photographs and drawings.

Stratton Rotating Engine Company, rotary engine connected to dynamo.

Sunbeam Lamp Company, incandescent lamps of all kinds.

Thomson, Fred, & Company, electrical apparatus and demonstrations of electrical phenomena.

Wire and Cable Company, electrical wires and cables.

Concrete Poles for Transmission Line.

W. D. Boyce, owner of the Marseilles Land and Water Power Company of Marseilles, Ill., has decided on the use of concrete poles for his transmission line from Joliet to Peru. This fall only part of the line will be built as a test. The concrete, after being well mixed, is placed in long molds made of seasoned lumber and is then properly tamped and allowed to dry. In each mold are placed from eight to ten half-inch steel rods for reinforcement that extend from bottom to top of pole. After the concrete is thoroughly set the poles are each tested before being used. In testing each pole is subjected to a load of 700 to 2,000 pounds, according to its size and length. These loads are much in excess of what the poles will carry in service.

The poles are made in several sizes. The smaller ones are 30 feet long, and nine inches square at base and six inches at top. These weigh about 2,000 pounds. The larger ones are 45 feet long and 14 inches square at base and six inches at the top, weighing about 7,000 pounds each, and support a load of 3,000 pounds. All the poles taper gradually and have an obelisk appearance. The cost of the poles is estimated at from $8 for the smaller to not exceeding $25 for the larger sizes. The poles will be set 150 feet apart.

Large Draw Spans Electrically Operated.

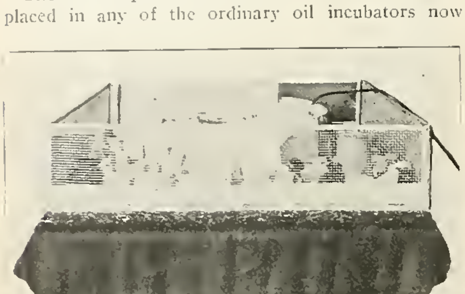
The Illinois Central Railroad bridge between Omaha and Council Bluffs over the Missouri River is said to have the two longest draw spans in the world. The draw mechanism on this large bridge is electrically operated, and there is a complete electrical signaling and interlocking equipment. The length of each draw span is 520 feet and the weight of each is 5,500,000 pounds. The time consumed in bringing the spans to right angles is one minute and 30 seconds. The electric draw, signal and interlocking equipment was designed by Weeks, Kendall & Newkirk of Kansas City, Mo.

Chickens Incubated by Electric Heat.

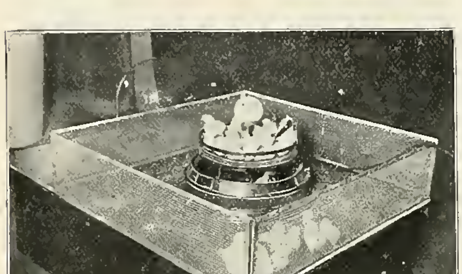
By Frank C. Perkins.

During the recent annual convention of the American Poultry Association at Niagara Falls there was an interesting display of electric incubators showing chickens being hatched by means of current supplied from the Niagara power plants. In these novel electric incubating devices the necessary heat for hatching the chickens was provided by incandescent lamps controlled by thermostats and by electric diaphragms or heating disks with german-silver wires embedded in asbestos base, these conductors also being operated in series with thermostat.

The "electroplane" is so arranged as to be easily placed in any of the ordinary oil incubators now



Electric Brooder.



"Electrehen" for Nature Study

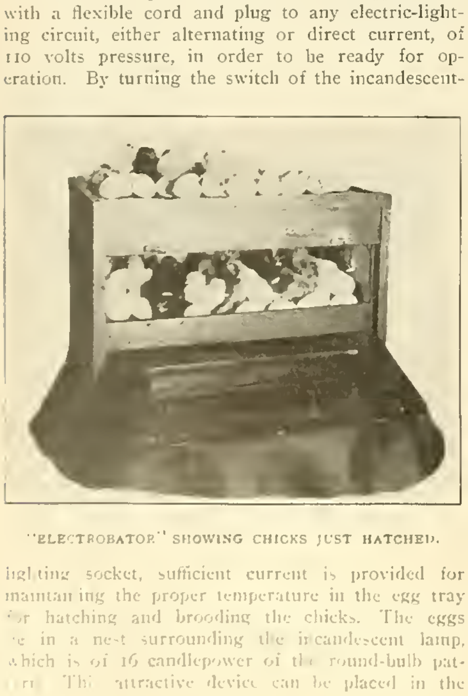
CHICKENS INCUBATED BY ELECTRIC HEAT.

in use throughout the country, its purpose being to supply electric heat in place of the oil heat usually used, at the same time not in any way interfering with the use of the incubator should oil fuel be desired.

By means of this device all of the disagreeable features of oil incubators are avoided, there being no fumes, smoke or offensive odors, and the device is made safe and attractive for use in the home.

The "electrobator" is a purely electrical incubating device, and therefore differs from the attachment above described for use in oil machines. In the upper part of the "electrobator" is located an electroplane, similar to that above mentioned, equipped with a thermostat for controlling the temperature and maintaining the heat constant at 103 degrees Fahrenheit. This thermostat is very sensitive and delicate in adjustment, there being a variation of only a fraction of a degree at any time in the electrobator. An electric condenser is provided on the electroplane, placed in parallel with the terminals of the thermostat, so as to avoid sparking at the contacts, which are of platinum.

The "electrehen" was designed and constructed by the writer for use in nature study in schools and kindergartens, the electric lamp providing all of the necessary heat for incubating the eggs and for brooding the chicks after they have been hatched. It is only necessary to connect the machine, which is contained in an oval glass case mounted on a gun-metal or oxidized-copper base, with a flexible cord and plug to any electric-lighting circuit, either alternating or direct current, of 110 volts pressure, in order to be ready for operation. By turning the switch of the incandescent-



"ELECTROBATOR" SHOWING CHICKS JUST HATCHED.

lighting socket, sufficient current is provided for maintaining the proper temperature in the egg tray for hatching and brooding the chicks. The eggs are in a nest surrounding the incandescent lamp, which is of 16 candlepower of the round-bulb pattern. This attractive device can be placed in the furnished parlor or library of an electrically equipped home, in the window of a store or in the display rooms of a department store, working day and night without attention, as the current maintains practically a constant temperature with but slight action on the part of the thermostat.

A drawer is provided, which is partly drawn from the base, and the electric chicks run about in the fenced enclosure, about three or four feet square, making an attractive feature for a window display to hold the attetnion of the passerby. Electric incubation, even on a large scale, is thoroughly practical, and undoubtedly will be utilized to advantage in the country as well as the city where current is available.

This form of load is very attractive for the electric-lighting companies, and the rates obtainable are as low as for power and heating purposes. The service being for 24 hours per day and for 21 days' continuous run for each hatch, it is a most desirable and constant load from the central-station point of view.

The electric brooder shown in the accompanying illustration was designed to take care of chicks after hatching. The temperature is maintained at 90 degrees to 95 degrees for the first week, and after the chicks are older the regulator is adjusted to from 80 degrees to 85 degrees, and finally the artificial heat is dispensed with entirely.

OBITUARY.

William J. Phelps.

William Joshua Phelps died at Grace Hospital, Detroit, Mich., on September 3d. He had had some trouble with one of his ears and went to the hospital to get relief by a mastoid operation. This was apparently successful, and he seemed to be recovering when he suddenly fell into a condition of coma. The doctors attributed it to a pressure on the brain and opened the wound again to remove this, but found nothing to justify the condition.

Mr. Phelps was born in Elmwood, Ill., November 19, 1866. He was a graduate of Knox College, Galesburg, Ill., and became an electrical engineer and inventor. The best known and most useful of his inventions is the Hylo lamp, and he was the pioneer of the turn-down lamp art, which has grown to be an extensive business. He also invented the motorless flasher, which has been a great help in the electrical advertising field. He was a member of the American Institute of Electrical Engineers, the American Society for the Advancement of Science, the Society of Illuminating Engineers and the Detroit Engineering Society. He leaves a wife and two children, a brother and sister and both his parents as well as a large circle of admiring friends and acquaintances in the electrical trades.

H. W. Hill.

Mr. H. W. Hill died a few days ago at his home in Lakewood, near Cleveland, Ohio. Too close attention to business without sufficient relaxation brought on his physical collapse. Mr. Hill was founder and president of the Hill Clutch Company, which manufactured many of the devices invented by him. Before coming to Cleveland in 1886 he was engaged in large engineering enterprises, one of the most noted being the building of the lighthouse at Key West, Fla. His age was 54.

E. R. Coffin.

Edward R. Coffin, son of Mr. C. A. Coffin, president of the General Electric Company, died in Omaha, Neb., last week. He was suddenly taken ill while traveling from San Francisco to New York and was removed to a hospital at Omaha, where he died after an operation for hernia. He was only 34 years old and was a man of great ability and seemed to be destined for an important place in the affairs of the business world. He was vice-president of the Electric Securities Corporation and was a director and officer of many other companies.

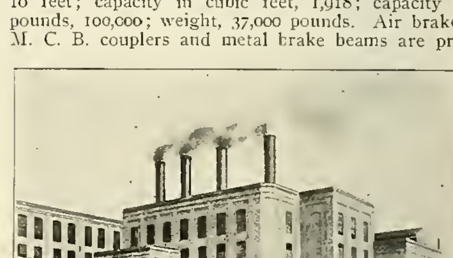
Coal-handling Facilities for the West Allis Works

A group of buildings belonging to a great industrial plant in which no detail of modern shop equipment has been neglected is that of the West Allis Works of the Allis-Chalmers Company, located on the outskirts of Milwaukee. The power house, containing every known improved apparatus and labor-saving device, has only recently been built and will supplant the original station used before the works were extended. The power to be supplied to the works from this central station is mainly electrical, but the boiler plant will at times be utilized to furnish live steam directly to the erecting shop for use in connection with the testing of steam turbines. The station has a capacity of 12,000 horsepower.

A power-house equipment like that described necessarily demands every facility in the supply and handling of fuel. The accompanying illustration shows an exterior view of the new power house with a train of special Allis-Chalmers gondola type coal cars backed into the boiler house ready for unloading. These cars form the latest feature of the handling system provided at West Allis. The coal is dumped directly from the cars into the coal pocket below the track and thence fed to a coal crusher, which delivers directly to an elevator of the bucket and link type. The elevator empties into a rubber belt conveyor, which discharges over the entire length of the coal bunker.

This coal bunker is of the Berquist suspension type, with a capacity of 700 tons. The down spouts are operated from the floor and feed the coal directly into the stoker hoppers. They are 72 inches in diameter and have bifurcated ends, each spout feeding two stokers.

The cars shown in the picture are provided with hopper bottoms to facilitate rapid dumping. They are similar in type to those recently purchased by the Grand Trunk Railway and form part of a line designed and built for Allis-Chalmers Company by the Pressed Steel Car Company, Pittsburg. This type of car is used to convey coal from the docks on the lake shore at Milwaukee to the works at West Allis, thus insuring constant service at all times. Following are their characteristics: Length, 31 feet 5 inches; width, 10 feet 1½ inches; height, 10 feet; capacity in cubic feet, 1,918; capacity in pounds, 100,000; weight, 37,000 pounds. Air brakes, M. C. B. couplers and metal brake beams are pro-



STEEL COAL CARS AT WEST ALLIS POWER HOUSE.

vided. The wheels are made of 33-inch stock; pressed steel beams and open-hearth axles are used.

The method used in removal of ashes is also carefully worked out so that the operation may be accomplished with the least possible expense. The ashes are raked forward into the ash hoppers in front of the stokers below the floor. The hoppers each have a capacity for a day's run at full load and are equipped with double cut-off gates, emptying directly into cars traveling on a narrow-gauge track under the boilers. The ash cars are of the side-dumping type, delivering into a narrow hopper from which the ashes are fed to an elevator discharging at the top of the boiler house into an ash-bin having a capacity of 100 tons. From this bin the ashes are dropped into standard-gauge cars which are provided with side discharge and have capacities each of 50,000 pounds. These cars are also a part of the Allis-Chalmers Company's rolling stock and used exclusively for conveying ashes from the works to places along the railroad track where they can be used for filling.

Electric Drive in Southern Cotton Mills.

Within a radius of about 35 miles, with Charlotte, N. C., as a center, just 67 cotton mills have contracted for electric power to be supplied by the Southern Power Company's plants along the Catawba River. Many of these mills are already using electricity with excellent results, while the others will use it as soon as the transmission lines are completed. On the other hand not a few mills have their own electric generating plants, utilizing the power of some river or small stream wherever a sufficient fall is available. The cotton mills, it is said, are saving several million dollars annually in the immediate section by the change of motive power.

Lectures on Illumination.

Members of the engineering department of the Holophane Company will be open this year, as last, to a limited number of engagements for lectures on "Illumination." These illustrated lectures have created wide interest among the electric-light and gas companies, for the benefit of whose solicitors and customers they are generally given. They are in no sense lectures on the prismatic system of lighting, but treat the fundamental principles of illumination broadly, combining primary instruction in the practical engineering of light with non-technical expositions of good and bad practice of the art.

A. J. MARSHALL.

Last season Mr. Lansingh gave 21 lectures, Mr. Lauritzen eight, and Mr. Marshall 69, the last-named speaking in all of the principal cities of the central and western states in a tour which lasted over nine months. Mr. Marshall's work in this department was particularly notable. In his nine months' tour he traveled over 28,000 miles, gave 69 lectures and addressed approximately 17,000 people. Each lecture was given under the auspices of the local gas or electric company of the city visited and was widely advertised in the newspapers by reading notices and display advertising, the latter not infrequently running from one-quarter to a full page and continuing several days previous to Mr. Marshall's arrival. Announcements or special invitations also were sent to technical societies, architects, gas and electrical engineers, merchants, window trimmers and others whom the lighting company deemed interested.

The lectures were without exception successful in focusing popular attention upon the importance of this subject. They were invariably well attended by people whom it was desirable to interest. The greatest practical result of the lectures, however, lay in the more or less informal after-meetings with the commercial men and solicitors of the several companies, who displayed an eagerness and desire for additional information which was eloquent testimony of the deep interest they felt. Not infrequently arrangements were made for private talks with the solicitors, these talks being in the nature of practical lessons in illuminating engineering, continuing several days. On a number of occasions also Mr. Marshall was called upon to act in his capacity of consulting illuminating engineer for the lighting company.

This branch of the Holophane Company's activities is a distinct departure in educational work along the lines of illuminating engineering. It is undertaken not as a source of revenue, but to assist those most vitally interested—the lighting companies—in bringing forcibly to the attention of their customers and salesmen the importance and mutual advantage of good illumination.

Improved Motor-driven Planing and Polishing Device.

A patent was recently issued to Vinzenz Spietschka of Cleveland, Ohio, for a motor-driven dressing device adapted to be held to its work by hand and particularly suited for planing, polishing and cleaning the curved walls of tanks or vats,

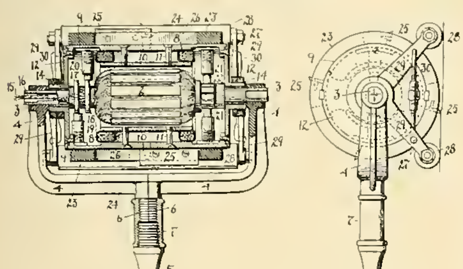


Fig. 1. Longitudinal Section. Fig. 2. End View.
MOTOR-DRIVEN PLANING DEVICE.

although it also is suitable for similar work on floors and other flat surfaces. The device is illustrated in the accompanying diagrams, of which Fig. 1 is a longitudinal section through the center and Fig. 2 is an end view.

A feature of the device is a direct-current motor with stationary armature and revolving fields. The armature (2) has its ends fastened into the arms (4) of the handle. The field-coils (8) are mounted upon the poles (10), and these are fastened to the cylindrical casing (9), which has end plates (12) provided with bushed hubs (14), so as to be capable of rotating about the ends (3) of the armature. The connections (15) for the motor extend through the bore (16), shown at the left end of the armature shaft and connect with the collector rings (17) and (18), upon which bear the carbon brushes (19) and (20) supplying current to the field coils. The wires (15) also connect to the brushes (21), bearing on the commutator (22) at the other end of the armature shaft, thus completing the armature circuit. The casing (9), which is the yoke of the field circuit, and its attached poles rotate about the armature when the current is applied to the motor.

Upon the outside of the casing can be fastened the various dressing tools, such as cutters, buffers or sandpaper. These are mounted upon a removable skeleton casing (23) provided with ribs (26), to which the cutters (25) are screwed so as to be readily replaced by other tools. The depth of cut is controlled by a guide frame (27) consisting of a pair of parallel rollers (28) supported by sets of diverging arms (29). These are placed at each end of the casing (9) and mounted free upon hubs (14). The angle between the arms (29) is adjustable by turnbuckles (30). The handle (5), its supporting arms (4) and the guide frame (27) can be easily removed to permit changes of tools or removal of the casings (9) and (23) for inspection of the motor or other parts. Sandpaper can readily be fastened to the surface of the casing (9) directly.

Novel Electric Portable Stove.

A new addition to the growing line of electrical household cooking devices has been brought out by Albert L. Marsh of Lake Bluff, Ill., who has secured a patent on his invention. The object of the invention is to provide a novel construction of portable electric stove or heater for table use in preparing food, especially as a toaster.

In the accompanying drawing, Fig. 1 is a plan

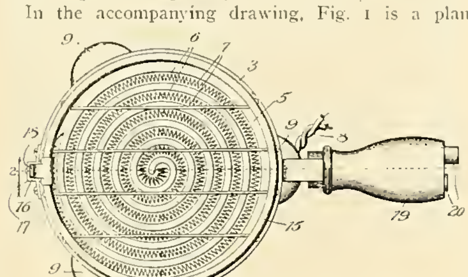

FIG. 1. PLAN VIEW OF MARSH ELECTRIC STOVE.

view, and Fig. 2 a section taken at the line (2) on Fig. 1 and viewed in the direction of the arrow.

The body of the stove, which is preferably of the circular form illustrated, consists of a metal ring (3) having inturned flanges (4) at intervals about its lower edge and a disk-shaped block (5) of fireclay or other suitable refractory material, having a spiral groove (6) formed in its upper surface and fitting inside the ring (3), in which it seats upon the flanges (4). Electrical resistance wire (7) is laid in the groove and tacked at intervals in its base, with the ends of the wire passing through the block (5) and connected with a flexible conductor (8), carrying on its free end the usual plug adapted to be inserted into the socket of an incandescent electric lamp for furnishing the current to heat the wire (7). This wire is shown in helical form to resist warping and tendency to fracture under the strains of expansion and contraction to which it is subjected.

The body is supported on legs fastened to the flanges (4), with interposed strips (10) of insulating material, these legs rising from a base (11), the preferred construction of which is that of a metal ring (12) having an inturned annular flange (13) through which the foot-portions of the legs are fastened to the base, with a disk (14) of non-heat-conducting material seating against the under side of the annular flange and secured by the fastening means for the legs. Thus the base affords an air-space underneath it, which, with the disk (14), renders it non-conducting of heat to a degree that enables the stove to be used on the polished surface of a table without danger of injury to the latter from the heat radiating from the body.

A circular grid (15) is removably and adjustably supported over the top of the stove body at a depending arm (16) fitting in a socket (17) provided on the outer side of the ring (3) and containing a spring (18) to permit the grid to be raised and lowered, and held in adjusted position by the pressure of the spring in the socket. The grid affords a support for any utensil adapted to be imposed on it for cooking its contents, and it also affords a toasting attachment.

On one of the legs is fastened a handle (19), of insulating material, containing an electrical switch, preferably of the common push button variety, represented at (20), connected with the conductor (8) for shutting off the current from the heater.

In use, with the current on, the wire (7) soon becomes highly heated, heating the walls of the spiral groove (6) to a glow, and the heat radiated from the wire and block (5) suffices for the cooking, heating and toasting purposes for which the heater is especially designed.

Charleston, S. C., Wan's Bids for Street Lighting.

Sealed proposals will be received at the office of the city electrician of Charleston, S. C., until 12 o'clock noon on November 15, 1907, for lighting the streets and public buildings of the city for a term of one, two or four years with electricity, gas or some other illuminating power equivalent thereto, or partly by one and partly by another.

The estimated requirements are 500 arc lights of the enclosed type to be supplied with alternating current of not less than 6.6 amperes under a pressure of not less than 70 volts, and the electric energy of each lamp 475 watts, with an illuminating capacity of 1,200 (normal) candlepower. Gas lamps to have 5-foot burners, gas to be delivered at pressure of not less than 13 inches, and to be of standard commercial quality. Detail specifications of lighting will be furnished all bidders upon application to the city electrician. Lights under the contract are to be ready for operation on June 30, 1908. A certified check for $350 is to accompany each bid, and every bidder must be prepared to furnish a bond satisfactory to the mayor to the penal amount of $25,000, conditioned for the performance of his part of the contract, provided his bid is accepted. Ion Simons is city electrician and R. M. Masters is chairman of the committee on lighting.

Safeguard Against Shipwreck from Shoals.

Mr. Albert F. Eells has been granted a patent of recent date on an electric device for sea-sounding. From the fact that sound produced within a vessel is indistinct in very deep waters but grows louder as the water becomes more shallow, the inventor makes use of this principle to determine the depth of water below the ship's keel.

Means are provided for making a continuous sound inside the vessel near the bottom plates, as by an electric hammer. This sound is transmitted through the walls of the ship to the surrounding water, and that which travels to the bottom of the sea is there reflected and echoed back to the walls of the vessel, where it actuates a telephone transmitter secured to the vessel walls. To the transmitter is connected a regular telephone circuit with

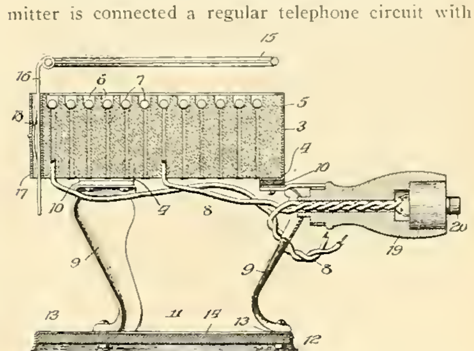

FIG. 2. SECTIONAL VIEW OF MARSH ELECTRIC STOVE.

the receiver in the pilot-house. In this circuit is also inserted a galvanometer with a scale indicating depths. The scale is provided with a contact so that as soon as the indicator reaches it and shows a dangerous shoal a local circuit is closed and an alarm sounded. The whole device is quite simple and is said to be a valuable safeguard against shipwrecks due to striking shoals, or at least to be a means of avoiding delay from becoming stranded.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies **10** cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

DEPARTMENTS.

DATES AHEAD.

Canadian Electrical Show, Power Building, Montreal, September 2d to 14th.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

New York Electrical Show, Madison Square Garden, September 30th to October 9th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

IN A TABULAR statement showing the number and characteristics of central stations in Germany the Elektrotechnische Zeitschrift of Berlin reports one, of 220 kilowatts capacity, operated by wind power. A number of private plants, with storage-battery auxiliary, are operated by windmills, but a public central station, even of small size, depending on wind power is certainly unusual. Further particulars would be of interest.

WHAT WITH the underground electric railway and the greatly increased use of the motor 'bus, it is reported that the hansom cab seems to be in a fair way to disappear from the streets of London, where for sixty years or more it has been such a conspicuous feature of city life. From Birmingham comes the news that a company which has been engaged in the manufacture of hansom cabs has decided to go out of business because of the great falling off in the demand for these vehicles. The extension of street-railway systems generally in Great Britain and the great number of automobiles in use throughout the kingdom are also assigned as reasons for the marked decline in the cab industry. When a Birmingham architect, Joseph Hansom, invented the vehicle that bears his name 70 years ago, it was considered very ingenious; as indeed it is. But apparently the hansom will ultimately follow the sedan-chair and the stage-coach into the dusty realm of transportation antiquities.

ONE USE of electric power which receives little attention but which nevertheless reaches considerable proportions in the aggregate, being withal of unusual interest, is in the construction of large buildings, bridges and other structures. A striking example is now at hand in Chicago, where a large mail-order house is erecting a building of mammoth proportions, being 900 feet long, 270 feet wide and nine stories high. With basement and subbasement the floor area is considerably over 2,000,000 square feet, or nearly 50 acres. The edifice is being constructed of reinforced concrete, manufactured on the spot, and in the various concrete-making and building operations no less than 1,500 horsepower in electric motors is employed. These motors are supplied with current from the central-station mains and they operate a tramway, the derricks for handling material, belt conveyors, cement mixers and the wood-working machinery of a lumber mill where the various molds for the concrete are made. It is one of the conspicuous advantages of electric power that it is particularly well adapted by its flexibility and comparative immunity from fire risk to extensive building operations of this character.

WHAT SHOULD be the clearance between street cars passing on double tracks in a city street? In the rehabilitation of the street railways of Chicago this question has received much attention, both from the Board of Supervising Engineers, which has the matter in charge, and from press and public. The question is whether the space between passing cars shall be so narrow that no one can stand in it, or whether it shall be wide enough to permit an adult to stand between passing cars in safety. If the latter solution is adopted, how wide a clearance shall be selected?

By official action taken on July 30th the Board decided that the distance between track centers be fixed at 9 feet 8½ inches. It is proposed that the new cars be nine feet wide, which would leave a clearance of but 8½ inches. If an adult person was caught in this space he would be severely injured and perhaps killed. The question excited so much attention that the action of the Board was brought up for reconsideration on August 22d, but after an interesting discussion the former action of the Board prevailed, and the distance between track centers remains fixed officially at 9 feet 8½ inches. Mr. C. V. Weston, representing the city, and Mr. H. B. Fleming, representing the Chicago City Railway Company, voted for this distance, and Mr. Bion J. Arnold, chairman of the Board, and Mr. J. Z. Murphy, representing the Chicago Union Traction Company, voted against it. But inasmuch as Mr. Murphy was not a formal member of the Board, his vote did not count, and the motion to reaffirm the previous action prevailed. Mr. Arnold was in favor of the 8½-inch clearance when the matter was first taken up, as related in the Western Electrician of August 17th, but on further consideration decided that a much wider distance, say 20 inches, should be adopted. The opposing views of the members of the Board were sustained by formal statements, and it will be of interest to glance briefly at the arguments presented.

Mr. Arnold explained that when he concurred in the first decision he thought that it was not practicable to establish a greater distance, owing to the posts of the elevated structure in the downtown district, the space required for teaming traffic and the width of the streets. But on further study he concluded that the arguments in favor of the narrow space were not sufficient to warrant a permanent decision in favor of a street-railway system having an unnecessary element of danger in it. By reducing the width of the cars to 8 feet 6 inches and increasing the distance between track centers to 10 feet 2 inches, a clearance of 20 inches could be secured without increasing the distance between curb and car. He advocated this standard as insuring greater safety. The distance between track centers is 10 feet 2 inches in New York city, and by adopting the "pay-as-you-enter" type of car, he thought that 8½-foot cars would be wide enough in Chicago. Mr. Arnold also called attention to the fact that the street-railway company in St. Louis, after using the narrow clearance, is widening the distance between passing cars to 20 inches on all new track.

Mr. Weston's contention was that to insure a width ample for safety the clearance should be three or 3½ feet. But this is impracticable. A lesser clearance might do for a clear-headed person, but a nervous or excited person or one of large size would be quite certain to meet with injury. Better meet the issue squarely and have the public understand that it is just as dangerous to get between the tracks as to stand upon them. There should be no invitation to persons to take doubtful refuge between the cars. "Unless we can provide ample space between passing cars to make it entirely safe for all persons to stand between them, we should contract the space sufficiently to make it prohibitive for anybody to attempt to stand between tracks at a point where two cars are passing." Mr. Weston cited minimum clearances of 12 inches in Detroit, 3 inches in Buffalo, 7 inches in Cleveland and 6½ inches in Philadelphia. Narrow clearances seem to be accepted street-railway practice.

Mr. Fleming agreed with Mr. Weston. He believes that there will be fewer accidents and safer operation by running the cars with a minimum possible distance between them. It is not possible to get a really safe clearance without widening the streets. If the width of the car is reduced as proposed, and the cross-seat type called for in the ordinance is adhered to, the width of the car aisle will be reduced to such an extent as to be impracticable.

Mr. Murphy said that no man measures 60 inches in circumference, and that a clearance of 20 inches would save life. Although a large man, he has stood between freight cars when switching at 20 inches clearance. The law calls for 30 inches on steam railroads. No man who keeps his head will be killed or sustain broken bones by a 20-inch clearance. Mr. Murphy added that he believed in reasonably small cars for city work.

The above is a fair summary of the arguments presented, and it will be seen that a good case can be made out for either side. The Board in its wisdom has decided for the small clearance, but there remains in the minds of many persons a feeling of uneasiness—a feeling that something else should be sacrificed if necessary in order to retain sufficient space between passing cars for a human being to stand with reasonable safety.

Organization and Administration of Board of Supervising Engineers.

On August 30th the Board of Supervising Engineers, Chicago Traction, adopted a plan of organization for engineering, inspecting and auditing during the work of rehabilitating the street railways of Chicago. This plan was drawn up by Mr. Bion J. Arnold, chairman of the board, in his capacity as chief engineer, and is of interest as showing the care bestowed upon the organization of a great engineering work of this character. The main features of the plan are as follows:

The chief engineer is responsible for the preparation of the plans and specifications, under Section 34 of the Traction Ordinance, and is given the requisite authority and assistance to prepare them, subject to the approval of the Board. He is also to inspect the work, or cause it to be inspected, during its progress, and cause to be kept a complete record of construction and expenditures.

The organization for this purpose is as follows:

Chief engineer—B. J. Arnold.

Assistant chief engineer—George Weston.

Division engineer in charge of track and roadway—R. F. Kelker, Jr.

Division engineer in charge of electrical transmission and distribution—E. N. Lake.

Division engineer in charge of power stations, sub-stations and buildings—Not yet assigned; special engineer in this division, R. A. Sanborn.

Division engineer in charge of cars and car routing.—W. Thorn.

Division engineer in charge of tunnels—Not yet assigned.

Chief draftsman, in charge of drafting department—F. W. Steeg.

Auditor, in charge of division of accounts—L. R. Acton.

The chief engineer, should he deem it advisable, may call in suitable outside talent from time to time, or he may direct that certain plans and specifications be prepared in the offices of the railway companies or in other places, subject to the approval of the board.

It shall be a part of the work of the organization to collect data and compile information showing the requirements of the railway companies in order to enable them to provide facilities for properly taking care of their share of the local transportation of Chicago in a comprehensive manner. The chief engineer will work jointly with the chief engineers of the railway companies, so that the ideas of the companies can be harmonized and brought to one general plan before the work is finally presented by the chief engineer to the Board.

Complete information relating to material used and its cost and distribution, hours of labor and its cost and distribution, also relating to all bids for material, shall be furnished the chief engineer by the railway companies. Engineer-inspectors will be placed on the various jobs to inspect the work as to material and wormanship and to gather information necessary to verify the reports of the railway companies.

Electrical Exports for July.

Electrical exports from the United States in the month of July, 1907, amounted to a total value of $1,580,995, compared with $1,208,791 for July, 1906. There was a good increase both in electrical appliances and electrical machinery, comparative figures being as follows: Electrical appliances—July, 1907, $694,938; July, 1906, $577,086. Electrical machinery—July, 1907, $886,057; July, 1906, $631,705.

The following-named countries were the principal destinations of electrical exports from the United States for the month of July:

Appliances—Brazil, $165,918; British North America, $110,821; United Kingdom, $74,960; Japan, $67,417; Mexico, $67,203; Germany, $20,906; Cuba, $20,217; British Australasia, $19,931; Central American states and British Honduras, $17,358; Philippine Islands, $14,609; Belgium, $11,011; Argentina, $10,386; France, $8,017.

Machinery—Mexico, $159,279; United Kingdom, $150,016; France, $112,256; Japan, $105,941; British North America, $99,830; Brazil, $57,084; British East Indies, $46,273; British Australasia, $44,375; Argentina, $27,024; Central American states and British Honduras, $21,328; Cuba, $11,208; Germany, $5,495; Philippine Islands, $2,773; British Africa, $2,442.

Surveys have been begun for the interurban line to be built between Little Rock and Pine Bluff, Ark. Fourteen miles has already been laid out.

Factory Lighting.[1]

By J. T. Kermode.

The fact that many manufacturing concerns are vacating their old premises to enter buildings of more modern construction, with saw-tooth roof and windows on practically four sides, is evidence that better lighted workrooms are essential and that the demand for a higher standard of artificial illumination is rapidly increasing. The short hours' use and usually heavy demand on the station peak has brought about a condition where there is some question as to the advisability of factory lighting from a supply company's standpoint; it is, however, very important when combined with the supply of power. In conjunction with power business, considerable work has been done in Cleveland, where it has been the policy to make surveys, plans, specifications and to obtain bids for this class of wiring with special reference to the best and most economical method of illumination for the various kinds of work in different processes of manufacture.

The average factory requires artificial light during 10 to 20 per cent. of the working hours, not including overtime or night shifts; therefore, the illumination should be sufficient and the lamps so arranged that the quality and quantity of work accomplished during these hours can be as well and economically done as that which is performed by daylight. The amount of light required varies, first, with the size of room, relative position of machines and the general shop conditions, and, second, with the character of work to be done. The treatment that will effectively light a clothing factory cannot be efficiently applied to industrial plants, where the atmosphere is filled with smoke and dust.

Experience has taught us that no general rule can be laid down to govern the many different situations that present themselves, but each factory must be studied separately to determine the amount of light, style of illuminant and the method of its installation, to give the best results. For instance, large units cannot be successfully operated in roundhouses or car shops. The principal parts of locomotives that need special attention are so located that to be of value the source of light must be reflected from each side of the engine. Five 100-watt Gem lamps, spaced 15 feet apart, at an elevation of seven feet, will light in a very satisfactory manner one side of two engines. Oil torches, so commonly used in cabs, boiler and floor pits, can be conveniently substituted with portable incandescent lamps.

In foundries, forges, steel mills, structural-iron works and boiler shops, where the walls are dark and the work does not require concentrated light, a lamp is needed that will give good general illumination. Enclosed arc lamps, giving a white light, combined with shadows, are undesirable for this class of work, as the dark walls and dense atmosphere absorb a large percentage of their penetrating powers.

The color and brilliancy of light produced by the flaming arc has attracted the attention of many manufacturing concerns, and, notwithstanding the cost of lamps and carbons, they are being extensively used to light large areas.

In a large mill operating steel presses 16 enclosed arcs were installed. On account of the dense atmosphere these lamps were hung below the tops of the presses, resulting in heavy shadows being cast around each machine. The 16 enclosed arcs were recently substituted by six flaming arcs. With slight changes in the wiring these arcs were placed 22 feet from the floor, resulting in the entire shop being flooded with a warm, bright light. The use of flaming arcs reduced the connected load 4.5 kilowatts. Averaging two hours' use a day, these lamps would save 234 kilowatt-hours per month, which, at the usual prevailing lighting rate for current, would more than compensate for the cost of carbons, without considering the increased amount of illumination.

It is generally conceded that the best uniform illumination can be obtained by distributing small units over the space to be lighted, but this is not always practical, for one must consider the building construction, and purpose for which the space is to be used.

The use of higher candlepower arc lamps for factory lighting is rapidly increasing, and the advantage that can be obtained by their use and efficiency must be recognized. The efficiency with which the light is produced and utilized are two important factors with which a supply company is intimately concerned.

In machine shops it is common practice, together with large units for general illumination, to furnish each workman with a single incandescent lamp, which when new, and at average height from his work, usually gives a fair amount of light. Oil and dust soon reduces the illumination one-half. But it is not expected that the amount of work should reduce in the same proportion. Some reasons why this practice has become so popular are:

First—That up to a few years ago the majority of industrial shops were equipped with generating apparatus, but the cost of electric lighting was charged against the operation of the shop and not against the cost of electricity as it should have been. Invariably I have found that where light is obtained in this manner the generators, feeders and branch circuits are heavily loaded with inefficient apparatus and there is no incentive to economize on current.

Second—Wherever a large installation is necessary the manufacturer usually employs a man to look after the operation, repairs and additions to the electrical equipment. These men, as a rule, are not familiar with the improvements that are continually being made on the various devices that go to make up a modern electric installation. Consequently inefficient light facilities are unintelligently installed.

Third—Employes have been educated to believe their work cannot be successfully performed unless each individual is furnished with an incandescent lamp, and realizing the flexibility of electricity it seems comparatively easy for one to convince the foreman that an additional lamp should be added here or there, resulting in an overlamped room for the number of machines operated and a poorly lighted room at an excessive cost.

In machine shops where lathes, drill presses, planing machines, milling machines, screw machines, punches, etc., are used good general illumination of uniform intensity is required. Nernst or Gem lamps are well adapted for this class of lighting.

The size and number of lamps to be used depends upon the size of the room, height of ceiling, color of walls, location of machines, belts and shafting. In estimating the size and number of units it might be of service to consider 50 watts per operator, or machine, as an average amount for all ordinary machine work and general illumination. For special machines or work that needs bright light, individual incandescent lamps with reflectors should be used. Machines that are automatic in their operation are many times provided with unnecessary individual lamps. Appreciating that these machines do need good light for changing their adjustment, the use of portable lamps that can be connected to receptacles near each machine will, if intelligently used, save current.

The general evenness of illumination, with the absence of glare, together with the easy shadows and searching quality of the light produced by mercury-vapor lamps, makes them especially adaptable for factory lighting by direct current. Unfortunately the alternating-current lamp up to the present time has not been successful, due to its inability to start readily.

Manufacturers of clothing require an even, shadowless, well-diffused light of considerable brilliancy. Nernst lamps with prismatic reflectors can be utilized for this purpose with a comparatively low consumption per operator.

The difficulties that exist in factory lighting are familiar to all men engaged in the sale of electricity for power purposes, and it should be the duty of each central station to educate its men to successfully overcome these conditions by encouraging the use of lamps, shades and reflectors that have been produced for scientifically converting wasted energy into useful light. Recent discoveries in the production of electric lighting are of revolutionary nature, the same principles which have been utilized in the cheapening of gas light, that is, the use of the peculiar properties of rare earths and metals, have been appropriated by the electrical interest, and the recent developments indicate the efficiency of electric lamp will be doubled in the near future.

Recently I read an article in which a supply company recommends the use of gas for factory lighting that they might be successful in retaining power business.

Is there a more exaggerated case of false economy than that of requiring people to work by poor illumination? In comparison with the cost of labor the cost of lighting is trifling. Take, as an illustration, the case of a skilled workman receiving $3 or $4 a day (say, an average of 30 cents an hour, or one-half cent a minute), figure the cost of a 16-candlepower lamp burning 10 hours, and see how many minutes of the man's time it requires to pay for the light. Yet there are thousands of skilled mechanics handicapped with insufficient and ill-directed light.

In presenting this paper my idea has been to bring out the fact that industrial plants can be lighted by electricity in a satisfactory manner and at an expense that would compare favorably with any other form of illumination, provided the equipment consist of units of the highest efficiency, installed according to modern practices. Electricity supply companies should devote more time to practically demonstrating to manufacturers the benefits to be derived from the use of higher-efficiency units, with the idea of introducing a more intelligent mode of factory lighting as a valuable factor in assisting to secure and retain power business.

1. Paper read at the Toledo convention of the Ohio Electric Light Association on August 20th. The author is connected with the Cleveland (O.) Electric Illuminating Company.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXXIII.—Electric Railways.

The idea of applying electric motors to the propulsion of vehicles, such as street cars, etc., was suggested in the early part of the last century by a number of experimenters, but the first commercial electric-railway installation which approached anything like present practice was installed in Richmond, Va., in 1886. The growth of electric railways can be appreciated from the fact that in the 20 years following the establishment of the first electric road practically every street railway in the United States is electrically equipped. In addition, interurban railways have come into existence since the application of electric propulsion and now aggregate many thousands of miles in extent. At the present time the adoption of electricity upon main-line railroads is engaging the attention of electrical engineers, and considerable progress in this direction has been made, so that today electricity has invaded every branch of railway transportation.

Up to the last three or four years electric railways have invariably been equipped with direct-current apparatus, but more recently alternating-current systems have been devised which have proved very successful competitors of the direct-current system where long distances and heavy trains are involved. Electric railways may therefore be properly classified into direct-current and alternating-current systems, according to the kind of motors used on the cars, and may be further classified as overhead or underground trolley roads, or as third-rail roads, according to the kind of line construction adopted.

All electric railways operate upon constant-potential circuits and use series-wound motors. The standard direct-current potential for railways is 500 volts, although in some cases as high as 650 volts and even higher is used. In alternating-current generators no standard voltage has been adopted, and no special necessity for any standard exists, as any voltage desired can be adopted, according to the length of the line, etc., and the trolley voltage is reduced to the required voltage for the car motors by means of transformers carried on the car.

The direct-current overhead-trolley system, which is in most general use, will first be described. The accompanying diagram illustrates the elementary principles of a simple direct-current railway. Current from the positive pole of the generator is led out to the trolley line and from the trolley wire is taken off by the trolley and is thence carried to the motor. After passing through the motor the circuit is connected to some metallic part of the car truck and is led to the track through the car wheels. The negative pole of the generator is connected to the track, thus completing the circuit of the generator. The track is used for the return circuit on account of the saving in copper conductors, of which it takes the place, and in order to make the track a continuous conductor each joint in the rails is bridged by copper wire, known as a bond, which is securely riveted to the rails.

The simple system of distribution just described could only be applied to a road of very short length, and is, in fact, hardly ever used, as constant-potential distribution at 500 volts cannot be economically carried for more than five or six miles from the generating station. If this distance is exceeded the amount and cost of copper required for conductors becomes excessive. It would be cheaper to build a second generating station than to carry the 500-volt distributing system more than about six miles in either direction from the first station.

In order to provide for roads of greater length a mixed system of alternating and direct-current distribution was next devised. In this system, which is now the standard method of distribution for all direct-current roads, the power is generated at one or more central stations in the form of alternating current of comparatively high voltage. This alternating current is distributed to sub-stations located about 12 or 15 miles apart, and as voltages of from 16,000 to 32,000 are carried on this high-potential distribution, a large amount of energy can be transmitted to the sub-stations over very small wires. In each of the sub-stations the alternating current is converted into direct current by means of rotary converters, and this direct current, at 500 volts pressure, is distributed to the section of the road extending six or seven miles to either side of the sub-station.

This system, therefore, comprises two distributions, one high-tension distribution from the central station to the sub-stations, and a secondary 500-volt direct-current distribution from the sub-stations to the trolley line. This system of distribution has proved admirably adapted to street railways and interurban railways of considerable length where the traffic is handled in single cars which run only at considerable intervals. For very heavy service, however, where it is required to run a number of cars in trains at very high speed and at frequent intervals, the amount of current required is so large as to necessitate the use of very heavy copper conductors, and, moreover, the cost of the sub-stations increases rapidly with the amount of current handled.

To still further decrease the cost of distribution for high-speed long-distance roads, of heavy traffic, several systems using alternating current throughout, including alternating-current motors on the cars, have been devised. Both single-phase and three-phase railway systems are in use. The single-phase system requires only a single trolley, while the three-phase system requires double trolleys and double overhead wires. The latter conditions have probably been the chief reason why the three-phase system has not been adopted at all in this country. It has been successfully introduced on a number of European railways, especially on mountain roads, where steep grades are negotiated.

The single-phase alternating-current system which is being introduced in this country on a number of heavy railways includes very high voltage distribution to transformer sub-stations where the voltage is lowered by step-down transformers and fed directly into the trolley line. As these sub-stations contain merely a transformer, and have no moving machinery of any kind, their cost is very slight and they require no attendance whatever. Alternating-current trolley voltages of from 6,600 to 11,500 volts are in use, and a transformer carried on the car reduces the trolley voltage to whatever working voltage is required at the motors.

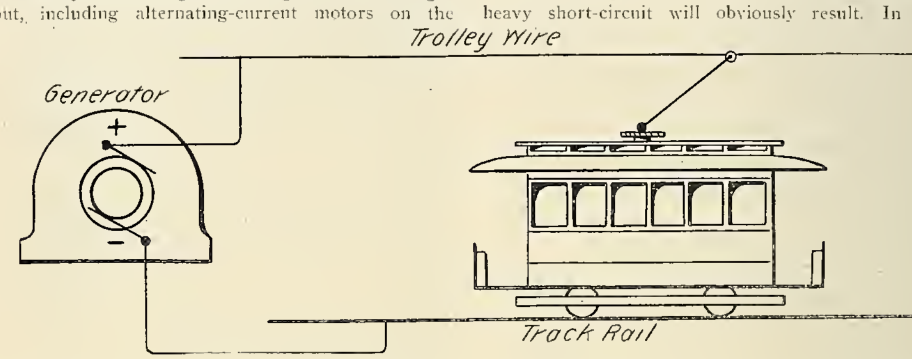
In special cases, where 500-volt direct current is employed in heavy railroad service, what is known as a third-rail system of distribution has been adopted. In the third-rail system the overhead trolley wire is replaced by a third rail located a little distance beyond the running rails and elevated slightly above them. This third rail is insulated from the ground and from the track, and current for the motors is taken from it by means of shoes supported by the car trucks and bearing upon the third rail. The shoes perform the same function as the overhead trolley, and the third rail the same as that of the overhead wire. The use of third-rail construction is sometimes adopted on account of the impracticability of using overhead conductors large enough to have sufficient current-carrying capacity, as well as on account of the difficulty of using on one train the large number of trolleys which would be required for such heavy currents. The third-rail system, however, is only suited to roads operating entirely upon private right-of-way, and even under this condition it involves some difficulties which, together with the high cost of construction, will probably preclude its use except in certain special cases.

Another system of distribution which is in very limited use is the underground-trolley system. This system was devised merely to meet the conditions where all overhead wires are absolutely prohibited. It is in use in but two or three of the largest cities in this country, and its cost of construction, which amounts to from $80,000 to $125,000 per mile, absolutely prohibits its use except where enormous traffic exists. In the underground-trolley system the tracks are not usually employed for the return circuit. Instead of this a positive and a negative trolley line are carried upon insulators and are situated in a conduit located entirely beneath the street surface. These underground lines are in the shape of flat copper bars, which are located on either side of a slot opening into the roadbed. This slot is about three-quarters of an inch wide and in it run the supports by which the underground trolley is suspended from the bottom of the car. The underground trolley runs between the two parallel conductors and carries shoes on either side, which press against them. The two sides of the trolley are thoroughly insulated from each other, as there is 500 volts difference of potential between them. One of the principal difficulties in connection with these open conduits is the liability of their filling up with surface water in case of heavy rains.

The bare conductors in the conduit are supported as high up as possible, but if water fills the conduit up to the level of the conductors a heavy short-circuit will obviously result. In designing a conduit for the underground-trolley system it is therefore essential to make the conduit of sufficient size not only to contain the necessary conductors but to act as a sewer to carry off the surface water of the street before it can reach the level of the conductors in the conduit.

A number of closed conduit systems have been invented, with a view to overcoming the difficulties of drainage and short-circuits to which the open conduit is liable. These have never proved commercially successful, however, and have never advanced beyond the experimental stage. The general arrangement of all the proposed closed-conduit systems is to have the conductor entirely buried in the ground and to have small blocks of metal inserted at intervals of a few feet on the surface of the street between the tracks. These contact blocks are connected to the buried cable through magnetically operated switches, which are normally open, so that ordinarily there is no current on the contact block. Beneath each of the cars electromagnets are located whose function it is to operate the underground switches connecting the contact switch with the underground cable. These contact plates are therefore alive only when the car is directly over them, and current is taken from them by means of a shoe extending under the length of the car and bearing upon the contact rods. The contact blocks must therefore be placed somewhat closer together than the length of the shoe under the car, in order that at least one block is constantly in contact with the shoe. Several systems similar to that just described have been tried experimentally, but, owing to the high cost of construction as well as the liability to derangement and inaccessibility of the underground moving parts, none of them has as yet been commercially adopted.

[*To be continued.*]



ELEMENTARY PRINCIPLES OF A SIMPLE DIRECT-CURRENT RAILWAY.

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Douglas & Co. of Cedar Rapids, Iowa, large manufacturers of corn products, including corn oil, cake, germ oil, meal, gluten feed and starch for laundry, domestic and manufacturing purposes, have equipped their plant for operation throughout by means of electric-motor (group and individual) drive. The latest addition to the equipment comprises approximately 650 horsepower in Allis-Chalmers induction motors, some of which are of the vertical type, specially adapted to the operation of corn-product mills. These machines are to operate at standard speeds for driving individual and grouped machines, according to the character of the work.

QUESTIONS AND ANSWERS.

Effect of Higher Voltage on Meter Registration.

[In answering, to the best of its ability, the questions put to it, the Western Electrician makes no pretense to infallibility, and is glad to print the views of others. Indeed, one object of this department is to stir up discussion; it is an "open court"—the more contributions the better. We therefore take pleasure in printing the following from Mr. William Bradshaw, detail engineer of the Westinghouse Electric and Manufacturing Company, who evidently refers to the answer to the following question printed in the Western Electrician of July 6th: "What effect will it have on a meter calibrated at 110 volts, 60 cycles, when put onto a 115-volt 60-cycle circuit? Will it make the meter run or register faster?"]

Mr. Bradshaw writes:

In reference to the above editorial which appeared in the July 9th [6th?] issue of the Western Electrician the writer wishes to take exception to a portion of the same as well as add the effect of changes of voltages on percentage registration under load.

As stated in the editorial, a meter will probably run slightly faster if subject to over-voltage if the increase in voltage is sufficient and the meter is operating at light load, such as four per cent. of full load or less. However, with a well-designed meter which has been calibrated at 110 volts there will be no tendency to run faster at 115 volts, and no tendency to "creep" with less than 140 or 150 volts. The tendency to "creep" is not dependent upon the torque of the meter, but upon the design of the magnetic circuit, especially the shunt portion. If the meter is of the type in which the greater portion of the magnetic lines created by the shunt circuit are shunted across the air-gap and do not pass through the disk, any normal change in voltage will not have any tendency to make the meter "creep." The reason of this is that a compensation for friction of the bearings is obtained by slightly unbalancing the shunt magnetic circuit so as to give a rotating field of small value which tends to drive the disk in the forward direction.

A meter using a shunt magnetic circuit of the above type will only increase this unbalancing in direct proportion to the increase in the total shunt field, and consequently the unbalancing will be the same percentage of the total shunt field as formerly, and the meter will not have any tendency to "creep" until the change in voltage is a very large percentage of the normal voltage. When this change has become sufficient to make the meter run faster on light loads its effect is such a small percentage of the driving torque of the meter under a load of any value that it is correct to say that it is felt at light loads only.

The editorial has entirely overlooked the most important effect of change in voltage on the percentage registration of a meter, and that is the damping due to the shunt field which cuts the disk. In a meter where a large percentage of the total shunt field cuts the disk this shunt damping is very marked, and in some meters will amount to as much as one per cent. in change of registration for a five per cent. change in the voltage of the circuit. This shunt dampening always increases with increase of voltage, and the meter will run slower with an increase in voltage and run faster with a decrease in voltage.

This shunt dampening is present in all makes of alternating-current integrating meters, but may be reduced to a negligible value in a well-designed meter. With a well-known standard meter when set for correct registration at normal voltage it will fall off in registration about 0.2 of one per cent. for an increase of 25 per cent. in the line voltage, and will increase one-half to one per cent. in registration for a decrease of 50 per cent. in line voltage.

The change in registration for the modern integrating wattmeter is so very slight between 80 per cent. to 125 per cent. of normal voltage, that it would be difficult to plot a curve showing the difference in performance of the meter when operating on either of these extremes.

It will be noted that the effect of a change in voltage, such as the values quoted in this editorial, is negligible, so far as registration is concerned.

The effect due to shunt dampening which shows up when the meter is under load and the voltage changes will be greater in percentage than the unbalancing effect which shows in tendency of meter creep at light load only under changes of voltage.

Current Required by Induction Motor.

H. M. C., Green Bay, Wis.: How much current or how many watts should a standard make 220-volt three-phase 60-cycle induction motor take at no load—a 15-horsepower motor? How many watts at 230 volts, at 240 volts and at 260 volts? Also, how many watts at full load at the above voltages?

ANSWER.

The information required can no doubt be obtained from the various manufacturers. It is to be remarked that the variation of current and watts with impressed voltages will depend largely on the particular type of induction motor. In general, at no load the variation would follow the magnetization curve very closely. At full load the conditions are slightly more complicated. In addition to the change in excitation there is a variation of the torque with the square of the voltage.

Electric Elevators.

F. F., St. Paul, Minn., wants to know the title of any books on the market dealing with the subject of operation and care of electric elevators.

ANSWER.

We have been unable to find such a book published in English and would appreciate a communication from any of our readers who may know of one. The bulletins published by manufacturers of this class of machinery are probably not comprehensive enough for F. F.

The following books in German treat of this subject: "Die Elektrischen Aufzüge zur Personen- und Warenbeförderung" (The Electric Elevators for the Use of Passengers and Freight), by Ed F. Walker, pp. 144, with 100 illustrations and six plates. Published by H. Buschmann, Leipzig: 1901.

"Elektrisch Betrübene Krane und Aufzüge" (Electrically Operated Cranes and Elevators), by Siegfried Herzog, pp. 463, with 981 diagrams. Published by A. Raustein, Zurich: 1905.

Secondary Connections of Transformers.

C. H. S., Southbridge, Mass.: I would like to ask if it is possible to connect up three transformers on a three-phase 2,300-volt circuit with secondaries designed to give 110, 220, 330, 440 volts, so as to result in a combination whereby I could obtain 250 volts from the secondaries, either single-phase or three-phase?

ANSWER.

The answer to this question is in the negative. The nearest three-phase delta pressure obtainable with the transformers mentioned is 220 volts. The Y connection of 110-volt coils gives 191 volts delta. The nearest single-phase pressure by combinations of the three transformers is about 290 volts.

Resistance of Telegraph Relays.

J. H. G., Harrisburg, Pa.: With reference to the query of W. T. H., Hammond, Ind., in your issue of August 31st, permit me to say that now and then one hears of railroad men who have charge of the telegraph but who really know very little about the electrical part of it, being promoted to that department on account of being excellent trainmasters. Such men may become impressed with the "superiority" of "low-resistance" relays and proceed to connect the two coils of the 150-ohm relay in multiple, reducing, of course, its resistance to 37.5 ohms. Perhaps this is what W. T. H. is driving at. The 150-ohm relay, as you point out, meets all requirements except on very short lines.

Battery-propelled Cars in Germany.

Accumulator cars have been running since February on three German railway lines. The arrangements have been made by the Prussian railway department, which controls the Hessian Railway. The new cars run four or six times a day, and the maximum speed is 28 miles an hour. The carriages are three-axle cars built for this purpose. The batteries consist of 180 cells of about 200 ampere-hours capacity, each weighing 121 pounds and containing four positive and five negative electrodes, a car battery weighing about 10 tons and yielding 68.5 kilowatt-hours; that is, seven watt-hours per kilo (two and one-fifth pounds) of all weight complete. Each car travels about 37 miles a day. The full car weighs 38 tons.

Guarantee Seal for Incandescent Lamps.

The purchaser of an incandescent lamp, unless he buys of the reliable dealers, has no guarantee except his own inspection of the appearance of the lamp, that it may not have already been in use and burned some hours, thereby decreasing its subsequent life. For the unwitting buyer's protection, Dr. Edward Schiff of Vienna has proposed a lamp seal like that shown in the sketch,

SEAL FOR INCANDESCENT LAMPS.

which may be put on at the factory and will assure the user that he is getting all the life of the lamp. As shown, through a hole in the lamp base is passed the seal-wire which carries an insulating plate covering the central contact stud. When the ends of the wire are sealed, the lamp cannot be used in an ordinary socket.

Central Electric Railway Association Plans Standardization.

At the meeting of the Central Electric Railway Association to be held in Columbus, Ohio, on September 26th it is planned to take up the question of standardization on all electric railways in Indiana and Ohio and to bring about as nearly as possibile uniform methods of operation.

In order to stir up interest in the meeting a number of Indiana electric-railway men made a trip to Detroit, Mich., last week in the private car Martha of the Indiana Union Traction Company. The car left Indianapolis on Wednesday and proceeded to Fort Wayne by way of Kokomo and Peru. From Fort Wayne the route was to Lima, Ohio, from Lima to Toledo and from Toledo to Detroit. The distance covered was 336 miles and was made in 11 hours, including stops. At each of the points named the car was switched to the tracks of a different road. In the party were Frank Norviel and C. C. Reynolds of the Indianapolis, Terre Haute and Eastern, H. A. Nicholl of the Indiana Union Traction Company, A. A. Anderson of the Indianapolis, Columbus and Southern, J. B. Crawford of the Fort Wayne and Wabash Valley, F. B. Carpenter of the Western Ohio and J. L. Smith and John Collins of the Toledo, Urban and Interurban Company.

Union Traction Reorganization Overthrown.

The plan of reorganizing the Chicago Union Traction Company as approved by Judge Grosscup has been overthrown by the United States Circuit Court of Appeals. The decision was rendered by Justice Brewer of the United States Supreme Court, with whom were sitting Judges Seaman and Baker of the Circuit Court. Justice Brewer said that however fair the reorganization plans might be, it was not the province of the courts to force the warring elements to agree. So the whole Grosscup plan was upset and the case was remanded.

The plan was to have the Union Traction Company and all its underlying companies consolidated into the Chicago Railways Company. This company was to accept the settlement ordinances and rehabilitate the properties, the security holders in the old companies to be taken care of according to terms named in the reorganization plan. Much of the holdings was deposited with a trust company to bring about the reorganization, but some of the security holders objected, and the hearing resulted in the overruling of Judge Grosscup's plan.

Unless the Union Traction interests can get together and agree upon some plan by which they can accept the settlement ordinance, the Chicago City Railway Company, according to the terms of the ordinances, is to take up the rehabilitation and operation of the North and West Side lines. At a special meeting of the City Council it is likely that the Union Traction interests will ask that the time for accepting the ordinances, which expires September 14th, be extended 30 days. Unless the Council has some assurance of agreement among the warring factions it is not likely that the time will be extended, in which case the situation will present a new phase.

Illumination Photometers and Their Use.[1]

By Preston S. Millar.

The illuminating engineer is concerned more particularly with instruments designed to aid the eye in determining the illuminating effect of light. These may be classified broadly as photometers dependent upon visual acuity, and those in which the

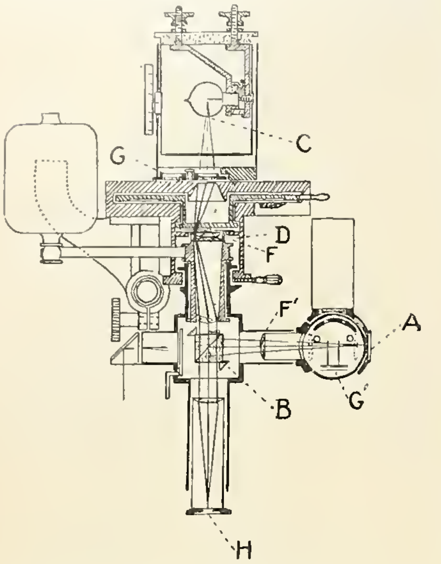


FIG. 1. BECKSTEIN PHOTOMETER, SECTOR TYPE.

illumination to be studied is compared to that produced by a standard light source.

Visual Acuity Photometer.

The principle of visual acuity, as generally applied, depends upon the detection of the vanishing point of an effect produced by the light to be studied. In some cases it is the disappearance of a figure or character; in others the disappearance of a contrast. Such instruments, being based upon the ability of the eye to see or distinguish objects, yield results which are proportional more nearly to those qualities of light which make for visibility than to its intensity. They are known as visual acuity photometers, or illuminometers.

There are fundamental difficulties with this extinction method which render it unsuitable for important work. These are the inability of the eye to judge of the point of disappearance with precision; the susceptibility of the eye to the influence of environments and conditions; the necessity for reducing the light to low intensities at which the "Purkinje effect" operates to distort results; and the errors encountered in effecting this reduction.

The decided advantages which this method can boast are simplicity, absence of expensive adjuncts, and minimum demand for technical knowledge and skill on the part of observers.

Illumination Photometers.

The only photometers which may be relied upon in engineering work to yield values are those in which a comparison light source is used, and reliance is placed upon the ability of the eye to judge equality of illumination. The essential features of such photometers are:

First, a photometric device.

Second, a comparison light source.

Third, a means of varying the intensity of the

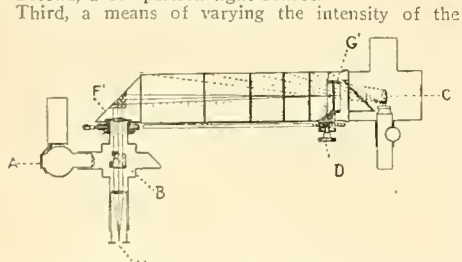

FIG. 2. BECKSTEIN'S FORM OF WEBER PHOTOMETER.

illumination produced upon the photometric device by the comparison light source.

Fourth, a test plate upon which the unknown light falls.

Photometric Devices.

These may be divided into three groups: First, arrangements of prisms whereby surfaces illuminated by the comparison and the test light sources may be viewed in one field with indistinguishable line of separation. Such devices are characterized by maximum sensibility and ease of comparison, but are generally difficult and expensive of construction. Particularly with low intensities they are superior, working with fair sensibility on intensities quite below the range of other devices. The Lummer-Brodhun photometer is a notable example of devices of this kind.

Second, screens of varying translucency, the opposite sides being illuminated by the comparison and test sources, respectively, and being viewed through prisms or mirrors in contiguous fields. The Bunsen photometer is the well-known example of this class of photometric devices. Various adaptations of the Bunsen photometer are used very largely in photometric work in this country. In general they fall but little short of the prismatic devices of the first class in respect to sensibility and ease of comparison and are simple and inexpensive of construction.

Third, the various devices whereby the illumination intensities produced by the comparison and test-light sources, respectively, are viewed in contiguous fields with well marked line of separation. In this class may be found the Bouguer screen, the Ritchie wedge, the translucent blocks of Elster and Joly and other means of comparing illumination intensities, all of which are simple and inexpensive of construction but lack in sensibility and ease of comparison.

Comparison Light Sources.

These are found in great variety in photometric work. They may be classified broadly as flame sources and incandescent electric lamps. Among the flame sources two deserve special mention. The pentane lamp, the legal standard of light in Great Britain, is used largely by gas companies in laboratory practice as a primary standard of light. The Hefner amyl-acetate lamp, the legal standard of light in Germany, is used largely in Germany as a primary standard of light and is used somewhat in this country in both laboratory and portable photometers. In addition kerosene, benzine and gas burners have been used in photometers as secondary standards of light. The pentane and Hefner lamps as primary light standards give results of considerable precision when used in the laboratory under carefully controlled conditions and manipulated by those who are expert in their use.

With the incandescent lamp used as a secondary standard of candlepower most favorable photometric conditions may be obtained. Its use, however, necessitates a source of current supply and a means of determining with fair precision the voltage at which it burns, or the current which it consumes. Under these conditions it may be relied upon to

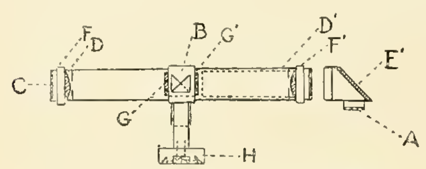

FIG. 3. BLONDEL AND BROCA'S PHOTOMETER.

remain constant for a limited period, during which time it constitutes the most reliable, accurate and satisfactory comparison light source.

Means of Varying the Intensity of Illumination Produced Upon the Photometric Device by the Comparison Light Source.

This has been accomplished by a variety of methods, some of considerable ingenuity. These may be classified as follows:

First, variation in distance, applying the inverse square law.

Second, rotating disks, relying upon Talbot's law.

Third, inclination of an illuminated surface, applying Lambert's law of the cosine.

Fourth, variation of the intensity of the comparison light source.

Fifth, the use of absorbing media.

Sixth, the use of variable diaphragms, generally with diffusing screens.

Seventh, dispersion lenses.

Eighth, polarization method.

Of the above the variable distance method is, in the opinion of the writer, superior in that it possesses accuracy, reliability, ease of verification, calibration according to a known law, simplicity, a wide range and universal applicability. No other one method possesses all of these advantages.

The rotating sectored disk is an excellent means of varying the intensity of light, but lacks somewhat in simplicity where it alone is relied upon.

The variation of the inclination of a plane with reference to the light incident upon it, or to the angle at which it is viewed, is an unsatisfactory method; first, because unless a perfect diffusing surface is obtained the cosine law will not apply; second, because any surface which approximates a perfect diffusing surface is likely to change in character, and third, because the scale calibration of an instrument in which this is used becomes very narrow with low intensities, so that the slightest displacement of the plane will produce a marked difference in the illumination.

Two methods of varying the intensity of the comparison light source have been used; in the one, adjustable opaque screens expose a greater or lesser portion of the luminous body. This method is particularly applicable when flame comparison sources are used. The other method consists in varying the intensity of the source itself—with flame sources, by wick adjustment and with electric lamps by varying the current flow. This method is unsuitable for use with flame sources, because it is necessary to wait some time after an adjustment is made before a constant luminous intensity is obtained. With electric lamps it is objectionable because the satisfactory range throughout which the method may be applied is of necessity small, since with very low intensities the color value becomes altogether objectionable, and with higher intensities the lamp must be operated at so high an efficiency as to endanger its constancy.

Absorbing media offer an excellent and very practicable means of varying the light intensity, but

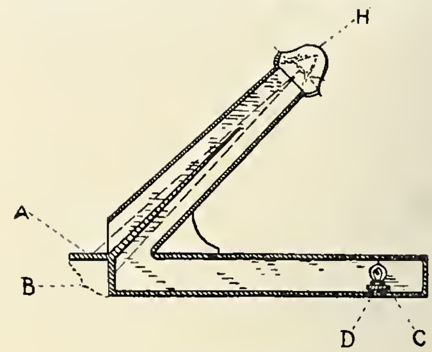

FIG. 4. BURNETT'S PHOTOMETER.

must be selected carefully in order to guard against errors due to selective absorption. While it is possible to construct absorbing screens which may constitute a complete device for varying the intensity, yet this method has found its best application in varying the intensity by large steps where supplementary means are provided for effecting finer variations.

The comments in the previous paragraph apply as well to the use of absorbing screens with variable diaphragms.

Dispersion and polarization methods are but little used in this country in photometry of the class now under discussion.

The Test Plate.

In general work the intensity of the light incident upon a given surface is the only quantity which it is practicable or even desirable to measure. This is not proportional necessarily to the illumination effect, which varies as well with the point from which the surface is viewed, with the color of the light and with the color and character of the surface.

Whether or not the light falling upon the photometric device varies only with that incident upon the test plate depends upon the design and location of that plate. The requirements for a theoretically correct test plate are:

First—A plane white surface, which when viewed from the point of photometric observation, obeys Lambert's law of the cosines with reference to intensity of illumination produced by light incident upon its surface at any inclination and from any direction.

Second—A material which will not introduce errors due to color differences.

Third—A plate which may be placed at any angle.

Fourth—A location such that neither the body of the observer nor instrument parts shall obstruct light which would otherwise fall upon the plate.

The character of the surface upon which the effect is studied, naturally influences the results materially. It is necessary to secure a plane surface which shall be as nearly as possible a perfect

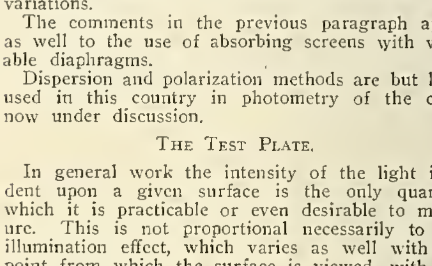

FIG. 5. MARSHALL'S PHOTOMETER.

diffuser of light, in order that light incident upon it at any angle may be credited with its true intensity, and only its true intensity. Unfortunately there is no available surface which accurately meets these requirements.

Until it shall be found possible to use a true diffusing surface, results must vary with the direction from which the test plate is viewed, unless it is studied by reflected light from a point directly above the center of the plate, or by transmitted light from a point directly beneath the center of the plate. The first is obviously impossible, because it would necessitate interference with light which would otherwise fall upon the test plate. It follows, therefore, that the correct method is

[1] A condensation of a paper presented at the convention of the Illuminating Engineering Society, Boston, July [illegible]. Mr. Millar is one of the engineers of the Electrical Testing Laboratories, New York city.

to consider transmitted light from a point directly beneath the test plate.

It is, of course, desirable to measure all of the light which would be incident upon an object at the point to be considered. In all interior lighting systems there is more or less diffused light, all of which has some illuminating value. In order to measure all of the effective light, there must be no objective interference with light incident upon the plate at any angle.

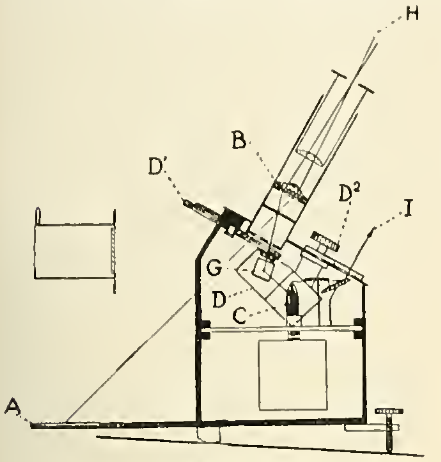

FIG. 6. MARTENS' PHOTOMETER.

The introduction of differences in color values complicate photometry seriously. If the light from the mercury-vapor lamp were to be studied upon a red surface, its illuminating effect would be no criterion of the light intensity. Hence the only color which is practicable is white, of as great purity as may be obtainable and as free as possible from selective absorption.

The Ideal Photometer.

It appears, therefore, talt in building a photometer, the designer has a choice of many photometric devices, comparison light sources and means of varying the light intensity and effecting the photometric comparison. With respect to the test plate, there should be no choice. It should have a plane white diffusing surface; it should be translucent and viewed from directly beneath its center; it should be capable of location at any angle, and should be so located that all instrument parts and the observer are beneath or behind it.

In the ideal photometer such a test plate would be found combined with the most sensitive photometric device, the most reliable comparison light source and the best means of varying the intensity. These features should receive first consideration, for reasonable precision ought to be the first desideratum. Next in importance come portability, simplicity of operation and reasonable cost. If there were any necessity for sacrificing reasonable precision in order to secure other desirable qualities, some compromise might seem advisable, but since this is not the case there can be no objection to adherence to the ideal, as set forth above.

Descriptions of Various Photometers.

As there is an insistent demand for an illumination photometer which shall be both reasonably accurate and thoroughly practicable, it is felt that a discussion of the instruments which have been designed with this end in view will be of interest. In the following paragraphs will be found brief descriptions of 11 photometers. Only the essential features of each are touched upon. The cuts are lettered similarly in order to facilitate comparison. Thus (A) indicates the test plate, (B) the photometric device, (C) the comparison lamp, and (D) the means of varying the intensity.

Fig. 1 shows a plan of the illumination photometer, designed by Walter Beckstein. The test plate (A) is placed at the point where it is desired to study the illumination. This plate may be rotated throughout a vertical plane about the photometric device (B) as an axis. (B) is a Lummer-Brodhun cube through which the lower

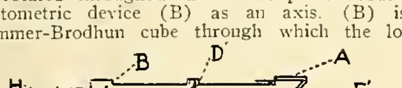

FIG. 7. MASCART'S PHOTOMETER.

surface of test plate (A) is viewed. Through the prisms (B) may be viewed also translucent plate (G), which is illuminated by the comparison lamp (C). Equality of illumination is obtained by viewing the plate (G) through a portion of lenses (F) which may be rotated. At (D) is placed a variable sector disk about the axis of which the beam of light is rotated by the lenses (F). The result of the photometric setting is obtained from the size of opening of sector disk (D), which is necessary in order to obtain equality of illumination. This device is in effect a rotating-sector disk, except that the beam of light, instead of the sector, is rotated, thereby facilitating precise adjustment of the sector disk.

Another illumination photometer, designed by Walter Beckstein, and of which a plan is shown in Fig. 2, is a modification of the Weber photometer and simpler in construction and less costly than that just described. The test plate and prism arrangement are similar, but the comparison lamp (C) is a benzine lamp, and equality of illumination is obtained by movement of translucent screen (G) by means of rack-and-pinion device (D) along a tube, its intensity of illumination varying inversely as the square of the distance from lamp (C). Results of photometric settings are read off directly from a scale along the tube through which plate (G') travels.

Fig. 3 shows a plan of the photometer designed by Profs. Andre Blondel and Broca. That portion of the light which is transmitted through test plate (A) is reflected from the 45-degree mirror (E') through lens (F') upon ground-glass plate (G') (which forms part of the photometric device). Before lens (F') is placed "cat's-eye" diaphragm (D'). A comparison light source (C) which is not described is placed to the left of the apparatus. Its light passes through lens (F) and falls upon ground glass (G). This is varied in intensity by the adjustable "cat's-eye" diaphragm (D). The photometric device (B) consists of crossed prisms through which ground-glass plates (G) and (G') are viewed from the binocular arrangement (H). Equality of illumination is produced by adjustment of variable diaphragms (D) and (D'), which are equipped with means for indicating the size of the aperture.

An illuminating power photometer, designed by Douglas Burnett, is shown in Fig. 4. The light which is to be studied falls upon test plate (A), which is one surface of a photometric wedge. The other surface of the wedge is illuminated by comparison lamp (C), which travels along the horizontal axis of the box. This lamp is moved by

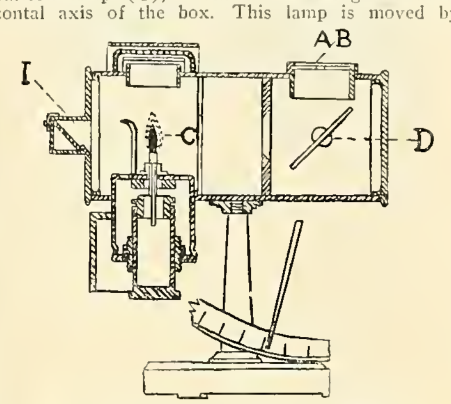

FIG 8. PREECE AND TROTTER'S PHOTOMETER.

means of a handle (D), which protrudes through the side of the box. The two surfaces of the wedge which constitutes the photometric device (B) are viewed from position (H) through a box which is divided by a partition which constitutes a well-defined line of separation between the two surfaces of the wedge. Results are indicated on a scale along the horizontal box which is calibrated directly in foot-candles.

Fig. 5 shows the arrangement of the "luminometer," designed by J. T. Marshall. The test plate (A) is also the upper surface of the photometric device (B). This consists of a screen of which the translucency is varied by different thicknesses of paper. It is illuminated from beneath by the comparison electric lamp (C), the intensity of whose light is varied by means of rheostat (D). Lamp (C) is operated from two dry cells within the instrument, a spring switch being placed in the circuit, so that the lamp is operated for a minimum time only. To effect a photometric setting, the flow of current through lamp (C) is varied until disappearance of contrast is obtained at screen (B) when viewed from above at an angle of about 45 degrees to its surface. The resistance of lamp (C) is then measured by a simple bridge method. The contact is moved along the exposed wire until the point of no deflection is obtained, and the foot-candles value is then obtained from the scale reading through an interpretation curve.

Fig. 6 shows a vertical section through the photometer designed by Martens. Test plate (A) which receives the light to be studied is observed through the photometric device (B), through which may be seen also the surface of plate (G), which is illuminated by comparison benzine lamp (C) through a pair of sliding mirrors (D). These mirrors vary the distance between lamp (C) and plate (G), being operated from rack-and-pinion device (D). Results are read directly from a scale over which plays a pointer attached to (D^2).

A modified design of the Mascart photometer is shown in Fig. 7, where the light to be studied falls upon a translucent paper (A), which constitutes the test plate. That which is transmitted passes through the 45-degree mirror (E'), a convex lens, and falls upon the upper half of a translucent screen (B). A comparison lamp (C) illuminates translucent screen (G). Light which is transmitted through this screen passes through a convex lens, the 45-degree mirror (E), the total reflecting prism immediately above (E), and falls upon the lower part of screen (B), where it is viewed from position (H). Both lenses mentioned have adjustable diaphragms (D) and (D), which are used to vary the intensity and effect quality of illumination upon screen (B). The adjustment of these diaphragms indicates the result of the photometric settings. Comparison lamp (C) is a flat-flame gas-

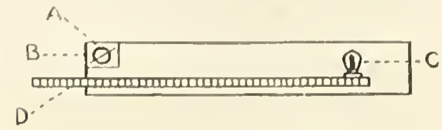

FIG. 9. RYAN'S PHOTOMETER.

oline lamp. The instrument is standardized by a Carcel lamp, whose light falls upon the test plate.

Fig. 8 shows a vertical section through the illuminating power photometer, designed by Sir William Preece and A. P. Trotter. The light to be studied falls upon surface (A), which is also a portion of the photometric device (B). The comparison lamp (C) illuminates bristol-board (D), which may be inclined at any desired angle. Through slits in surface (A), portions of screen (D) may be viewed. Photometric balance is made by equalizing the brightness of surfaces (A) and (D).

In the "candle-foot photometer," designed by W. D'A. Ryan, shown in Fig. 9, the light to be studied falls at A upon one surface of the photometric device (B), which consists of a translucent block, divided diagonally by a thin, opaque film. The comparison electric lamp (C) illuminates the other half of the block. The distance between this lamp and the block is varied by means of rod (D), upon which is calibrated a scale which indicates the results of photometric settings. The photometric device (B) is viewed through the side, equal portions of the two halves of the block being viewed.

In the Weber photometer, illustrated in Fig. 10, the light to be studied is received upon the portable test plate (A), which consists of white cardboard. This is viewed from eyepiece (H) through a simple Lummer-Brodhun cube (B). The light from the comparison benzine lamp (C) illuminates a traveling translucent screen (G), which is viewed from the eyepiece (H) through (B). A unique feature is the use of colored glasses in the ocular tube with a view to comparing illuminants of different color values with respect to those qualities upon which depends the ability of the eye to perceive objects which they illuminate. As has been stated, this is not necessarily proportional to the intensity of illumination.

The Weber photometer is now made in a more portable form and with some modifications.

Generally speaking, European instruments, as illustrated in the Beckstein, Blondel and Broca, Martens, Mascart, Preece-Trotter and Weber photometers, differ from American instruments as designed by Burnett, Marshall and Ryan, in that they are designed more particularly with regard to theoretical requirements than with regard to the utmost simplicity of operation and lowest cost. Many of the European instruments are relatively complicated, being combinations of a large number of parts, many of which would appear to the American mind to be unnecessary.

As respects the sensibility of the photometric de-

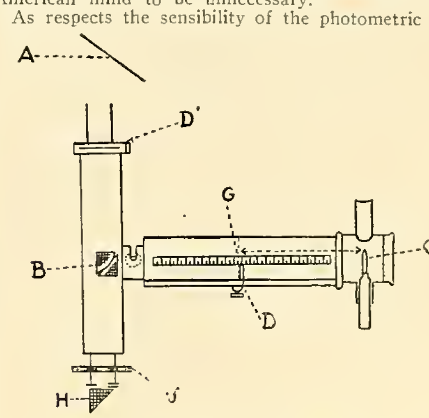

FIG. 10. WEBER PHOTOMETER.

vice, it was found from repeated settings with one of the instruments in which the photometric device is of low sensibility, that no higher accuracy than six per cent. could be obtained. The maximum variations in settings with this instrument were 15 per cent. below, and 10 per cent. above the average.

It was found that in one of the instruments in which a flame source was used, readings could not be relied upon within five per cent. because of flame variations due to drafts, changes in humidity, etc.

In measuring diffuse illumination, where much of the light comes from the ceiling and walls, it was found that with two of these instruments in which the design and location of the test plate were incorrect, results were obtained which were too low by 20 and 29 per cent. respectively. This was due to regular reflection and obstruction of light by the body of the observer or by instrument parts. With the same instruments, change from a black coat to a light coat on the observer, introduced differences amounting to 10 and 18 per cent.

As an illustration of the possibilities of errors entailed by reliance upon the direct comparison method in which a standard lamp is used directly in comparison with the test source, it was found that with one of the instruments, seven skilled observers, who, however, were not familiar with the particular instrument under test, obtained values which varied from 21 per cent. below to 34 per cent. above the value which was considered to be representative, namely, the mean of the results of the seven observers. The average variations of these observers from such mean was 13 per cent.

The Use of Illumination Photometers.

In the measurement of illumination, either of two general methods may be followed. The first is the direct comparison method, in which a primary standard of light is used, or a secondary standard of light is used as a primary standard, so far as the instrument is concerned. The Hefner lamp, more than any other light source, is used in this way. Or an incandescent electric lamp may be standardized to yield a certain candlepower and may be used, as is the Hefner lamp, for direct comparison purposes. Such a light source is located at a definite distance from the photometric device, and is calculated to produce a fixed intensity upon that device. This method has the great advantage that it permits an instrument to be more nearly self-contained, and to be used without reference to any other light sources. However, it is liable to serious objections in that all changes in reflecting surfaces or transmitting screens and changes in the comparison lamp, as well as any misplacement of parts, are likely to introduce errors for which no compensation is made. Furthermore, the method makes no allowance for the personal equation. The second, and superior, method is commonly known as the substitution method. This covers a multitude of photometric sins. Here the comparison light is strictly secondary, and is standardized and verified from time to time by other standards of light so placed as to produce upon the test plate illumination of known intensity. By this method changes which would introduce errors where the direct-comparison method is used, are compensated for either entirely or in part, since every effect which they produce upon the measurement of light from a test lamp will be proportional to the effects produced upon measurements of unknown intensities.

It is very important that instruments used in measuring light from any illuminants should be calibrated with reference to light of known intensity from illuminants of similar character.

One of the large difficulties in the practical use of an illumination photometer is to be found in the variability of light intensity in most commercial installations. If the installation consists of incandescent electric lamps, this can be dealt with best by operating the comparison electric lamp from the lighting circuit, when its variation will be similar in character, if not in degree, to that of the illumination to be studied. This is known as the "similar-circuit method." When an instrument is so designed that this cannot be done, or when the lighting installation consists of other than incandescent electric lamps, it is advisable to continue observations at each test point over a sufficient period to afford a fair average result.

With any of the photometers described in this paper it is probable that the skilled photometrist could approximate correct results, for he would locate the sources of error, determine their extent and apply such corrections as were possible. Most errors in photometry are occasioned by failure to recognize the limitations of instruments used. Instruments have been designed which apparently make so little demand for technical skill on the part of the observer as to give rise to the belief that photometry is as simple as is their operation. This has led to the publication of results which would appear to be utterly unreliable, judging from the instruments and methods employed in making the tests.

In closing, a few maxims are offered, which the illuminating engineer would do well to bring to bear upon photometric problems.

An instrument must be a good photometer before it can be a good illumination photometer.

Measurement of illumination is more difficult than the measurement of candlepower.

In obtaining a photometric setting one does not necessarily determine the value of the light studied.

Every photometer is to be regarded with suspicion until its accuracy is demonstrated. It is then to be regarded with suspicion until it is shown that no change has occurred since verification.

No photometric information is better than misleading photometric information.

Developments in Electric Incandescent Lamps.[1]

By Leon Gaster.

It is my object in this paper to give a short review of some of the most important improvements which have come before my notice during this year, and to exhibit the lamps mentioned in actual operation. I will start with the improvements of the carbon-filament, and bring before your notice the metallized, or, as it is also called, the graphitized carbon filament, by the aid of which lamps are made consuming on an average 2.5 watts per candle, with a useful life of about 600 hours. The lamps are manufactured for voltages varying between 100 and 130. I should also like to mention the use of the double-carbon-filament lamps, the two filaments being comprised in the same bulb, one large and one smaller filament, by the aid of which either the full candlepower or only a very small candlepower can be used, and the expenditure in lighting thereby reduced.

I will now pass on to the Nernst lamp. A recent improvement consists in fitting the lamps with a newly designed cut-out coil of high resistance, and it is claimed that by the use of this coil a great reduction of the premature failures of filaments will be secured. As regards the efficiency of the lamp, no very great further improvement has yet been secured.

Coming now to the metal-filament lamps proper, the osmium lamp, as produced by Dr. Auer von Welsbach, owing to the expensive nature of the metal used and partly to the difficulty in manufacture, and bearing in mind the improvements which have since been made by the same inventor by the use of tungsten, is now likely to be restricted to comparatively low voltages.

Tantalum is certainly the only metal-filament lamp which has proved to be successful commercially. There have not been, so far as I know, any particular developments made during this year which require to be recorded, except those in the direction of lengthening the life of the lamps when used on alternating-current circuits. It is as yet only made for voltages up to 125.

The next most important metal used in the manufacture of filaments, and with which much is expected to be accomplished, is certainly tungsten (wolfram). Several methods have been devised for preparing filaments by the use of this metal. One of the first methods was worked out by Dr. H. Kuzel of Vienna. By his process the metal is obtained in the colloidal state by means of an arc under water. The resulting paste of extremely fine metal is squirted into filaments, and afterward heated in order to make them better conductors. The lamps are manufactured in Vienna by Kremenetsky. From such tests as have been made it is ascertained that the lamps consume a little over one watt per candlepower, with a useful life of about 1,000 hours, with a loss of only 10 to 15 per cent. of the initial candlepower.

Another method of manufacturing tungsten filament is the joint invention of Dr. Alexander Yust and Franz Hannaman of Vienna. According to their process, the carbon filament is electrically raised to a high temperature in an atmosphere of gaseous tungsten or molybdenum compounds. The carbon then becomes coated with metal, and after burning out the carbon the filament appears quite homogeneous, even under the microscope. By another method the metallic powder is prepared by chemical means mixed with an agglutinant and squirted into the form of filaments, which are then freed from carbon as before. Messrs. Siemens & Halske have devised a process of stamning tungsten powder, sometimes mixed with another metallic powder, but without an agglutinant, in a tube of some metal which is easily drawn or rolled, such as tantalum or iron. Then, after electrically sealing the ends, they subject the tube to drawing or rolling processes. After the completion of the drawing process the outer skin can, if desired, be removed. This method obviates the necessity for the great care and treatment involved in the ordinary fusing process, but I have not heard whether the method is actually in use.

The next lamp using tungsten, and which is already used commercially, is the "osram" lamp, which is at present manufactured by the Deutsche Gasglühlicht Gesellschaft. The lamps burn with an efficiency of 1.2 watts per candle, having a useful life on an average of over 600 hours. The lamps are recommended to be burned for the present with the filament in a vertical plane, and can be equally well used on direct or alternating-current circuits. The Berlin Allgemeine Elektricitats Gesellschaft is also manufacturing some type of tungsten lamps, the process for the manufacture of which has not been divulged.

Turning now to the zircon wolfram lamp, I should like to draw attention to some of the improvements which have been made during the last few months. You will have an opportunity to see, for the first time, I believe, metal-filament lamps of voltages above 100 which burn satisfactorily in any position. The filaments are mounted on spring hooks made out of tungstenized carbon, the hooks having the effect of maintaining the filament rigid and in shape while in service, and of preventing the loops from touching, also of allowing of a greater number of filaments in the bulb, and, consequently, of reducing their length and that of the lamp. The lamps can be burned in any position, and the breakage of filaments is considerably reduced. On account of the elasticity of the spring hooks, the breakages of filaments have been reduced in transit and in service. Another improvement over the old type of lamp is the adoption of electrical soldering of the filament to the leading-in wires, thus doing away with the inconveniences caused by the use of graphite paste, which was a partial cause of the blackening, the giving off of gases and the defective contacts met with in the previous lamps. The improvement also avoids much extra labor, and also the danger of oxidation of the filament, if the paste is not very carefully burned away. The electrical soldering process takes place in the open, and an experienced operator can carry out the soldering of about 500 lamps daily. The firm of La Carriere in Paris is the inventor of this spring hook, and I understand that the filaments can now be mechanically mounted in such a manner that the operators do not have to touch them with their fingers, thus reducing the number of breakages in mounting the filaments. The latest type of 110-volt lamp contains only four filaments, of 0.025 millimeter diameter, giving out 24 hefner candles, or for 220-volt 48 hefner candles, necessitating only the use of eight filaments.

The helion lamp, of which very little information is as yet available, looks like an ordinary carbon incandescent lamp, mounted in the same sized bulb, and consumes 35 watts, giving out 30 candlepower. In the manufacture of the filament silicon is reduced from a gaseous form in combination with carbonaceous gases on the surface of a high-resistance carbon core. The inventors claim that this lamp operates at a high temperature without the carbon and silicon uniting to form carborundum, as might be supposed. The silicon shows no tendency to become molten or fluid at the temperature attained. The filament starts with a negative temperature coefficient less than carbon, but at about a red heat the coefficient changes distinctly to positive, and remains so as the temperature is further increased. The efficiency of the lamp is claimed to be 1.2 to 1 watt per candle, or it can run even at less. Although a useful life between 600 and 1,000 hours is claimed, a proper series of life tests could not be made, as there seems to be a difficulty in keeping the joints between the filament and the leading-in wires in good condition. For the proper working of the lamp, it is essential that mercury pumps be used for obtaining the vacuum, and great care must be taken in selecting the carbon core, so as to obtain homogeneity and purity, otherwise the results are considerably affected. Experiments are now being conducted by the inventors, using as a core the graphitized (metallized) carbon filament, and also with a special cement for the use of making the joints. One of the characteristic features of the lamp is that the length of the filament need not be increased over the ordinary carbon lamp. The filament is very pliable, and there will be no difficulty (if the present defects, which are chiefly of a mechanical character, have been overcome) in making lamps of low and high voltages and of reasonable candlepower. The lamp easily stands transport, and will be just as safe to handle as the ordinary carbon-filament lamp of today.

Iridium has also been used for the manufacture of lamp filaments. According to Gulcher's process, amorphous iridium is made up into a paste by the aid of an organic binding material. The filaments are squeezed from this paste and are made to glow in the air, and not in a receiver containing air in the diminished pressure or indifferent gases. The lamp is only produced for low voltages up to 24, and consumes between 1 and 1.5 watts per candle. Other metals, like vanadium, niobium, molybdenum, etc., may also be used in the future, but not much has been made public as yet regarding their use for filaments.

During a visit which I paid to W. J. Hammer of New York I saw a few sample lamps of Mr. Heany's invention, some using, I was given to understand, titanium for the filament, and others using a metallic alloy of tungsten and titanium in a dense, shining, coherent state.

Although we have seen that the metal-filament lamps can be made of relatively small candlepower at voltages above 100, and of high voltage up to 240, I am given to understand that it is not the intention of most of the manufacturers to sell for the present other lamps than those of high candlepower, above 30 candlepower, and intended for voltages varying between 100 and 130. This decision has a distinct commercial value, making the change from the carbon filament to the use of metal filaments gradual, so as to be properly appreciated and beneficial to the consumer, manufacturers and energy suppliers alike. It is well known that the carbon incandescent lamps are at present in many cases fixed at a low position, often

1. Abstract of a paper read before Section G of the British Association at Leicester, August, 1907.

situated in the direct angle of vision, and, therefore, detrimental to sight. The reason may be that, on account of the expense at which energy is supplied to the consumer, he could not well afford to enclose the lamps in properly diffusing globes, or to remove them a good distance away from the objects he wishes to be illuminated. With the advent of the new metal-filament lamps of relatively high candlepower, the lamp could easily be removed to above the level of the eyes, or enclosed in properly diffusing globes. We should thus obtain good illumination without additional increase of expenditure.

For those circuits where high voltage is used, and where it is advisable to introduce the metal filament, resort must be had to series wiring, which, as a whole, is not quite satisfactory, because as soon as one of the lamps breaks all the lamps in the circuit go out, and it is not so easy for the ordinary consumer to detect the broken lamp. Several devices have now been introduced to mitigate this drawback.

Speaking generally of the impressions which I received during my recent visit to America, I should like to inform the meeting that very great progress has been made in the recognition of illuminating engineering as a distinct branch of specialization in the engineering profession. I observed an extensive use of successful combinations of shades, lamps and lamp holders, by the aid of which combination the best and most efficient illumination is obtained. The Holophane shades and reflectors seemed to be very much used, enabling us to direct the light where it is mostly wanted, and producing any desired effect of illumination. I think that this combination of lamp, lamp holder and reflector, forming one suitable unit, is worthy of the careful consideration of the lamp makers in this country.

I should like to draw attention to the progress made in the use of vacuum tubes, and in particular wish to refer to the Moore vacuum-tube method of illumination. Two installations have already been erected in London, one outside the Savoy Hotel, and another at Salisbury House. The Savoy installation consists of a tube 176 feet in length, consuming 2,950 watts, using nitrogen gas for producing yellow light; power factor 70 per cent. The Salisbury House installation consists of a tube 85 feet in length, consuming 2,200 watts, with a power factor of 60 per cent. A white color is obtained by using CO_2. The use of CO_2 has enabled Mr. Moore to obtain with his tube the nearest approach to daylight yet attained, and I am given to understand that color can be matched in such a light with extreme accuracy. This is certainly a severe test for any method of lighting.

I should also like to draw attention to one fact in connection with illumination which seems to deserve greater consideration at the hands of manufacturers and large consumers of light, and that is the great value which ought to be attached to the adopting of proper methods of illumination. The advantages to be derived are: First, the sight of the workpeople will be improved and prolonged; second, the output will be quite appreciably increased, and third, which is very important, the quality of the work under proper illumination will be of the same high standard as when done in the daytime.

Before closing, I should like to refer to the work of the engineering department of the National Electric Lamp Association. Fifteen lamp makers in the United States have combined for the purpose, not of forming a trust, but with a determined object of improving the quality of the lamps they are manufacturing, and thereby maintaining a proper and high standard. Instead of each factory employing imperfectly trained chemists to analyze the chemicals which enter into the manufacture of lamp filaments, a well-paid and highly skilled chemist is employed in a thoroughly equipped laboratory to perform this work, and sufficient resources are put at his disposal to keep on making proper researches, and keep abreast with the latest discoveries. I may also mention in connection with the necessity of testing incandescent lamps the beautifully equipped electric testing laboratory which I visited in New York, which is so ably conducted by Dr. C. H. Sharp. In view of the fact that in this country a standard specification for carbon lamps has been framed, and has come into force on this July 1st, I hope before long that such a testing laboratory will also be established in this country, and will receive the proper support of the municipal authorities and companies supplying current for lighting purposes, enabling the consumers to get lamps of really good quality.

I should like to venture in indicating the lines upon which further researches might be conducted, and for that purpose I will refer once more to Mr. Hammer and his publications, and say with him that the ultimate solution of the problem of securing a satisfactory and efficient illumination may be obtained by means of the stimulation of phosphorescent and fluorescent substances in various ways, thus producing a cold light, a light, as he calls it, without flame and without heat. We must soon stop producing long and useless heat waves, and also, as far as possible, all radiation outside the visible spectrum, in the utilization of our illuminants.

"Helmet" Reflector for Window Lighting.

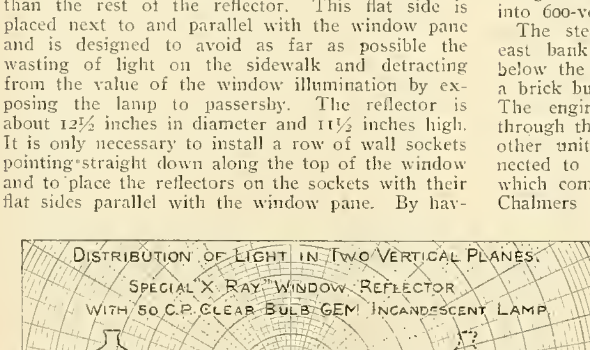
A reflector recently brought out by the National X-Ray Reflector Company of No. 247 East Jackson Boulevard, Chicago, is designated as the "Helmet" reflector. It is especially designed to meet the requirements of lighting high and shallow windows. It is suited to the lighting of all windows over 12 feet high whose depth is less than one half the height of the lamps above the bottom of the window, or where the lamps are as high above the level of the back of the window as the window is deep.

The reflector is intended to produce an approximately uniform illumination over the goods as ordinarily placed in show windows. It is designed to use a 125-watt Gem incandescent lamp, giving the user the advantage of a 25 per cent. increase in

EXTERNAL APPEARANCE OF "HELMET" REFLECTOR.

efficiency over the old-style carbon-filament lamp. It has the further advantage that it will also take a 105-watt tungsten lamp, so that the user can install these when they become more common. Future improvements in incandescent lamps have therefore been anticipated.

The illustration shows the external appearance of this reflector as viewed from one side. It has one side partially flattened and extended down lower than the rest of the reflector. This flat side is placed next to and parallel with the window pane and is designed to avoid as far as possible the wasting of light on the sidewalk and detracting from the value of the window illumination by exposing the lamp to passersby. The reflector is about 12½ inches in diameter and 11½ inches high. It is only necessary to install a row of wall sockets pointing straight down along the top of the window and to place the reflectors on the sockets with their flat sides parallel with the window pane. By having the lamps pendant, use can be made of the new tungsten lamp.



PHOTOMETRIC CURVES SHOWING EFFICIENCY OF THE "HELMET" REFLECTOR.

The high efficiency of this reflector for window illumination for the size of windows for which it is intended is shown in the accompanying photometric curves plotted from tests made by the Electrical Testing Laboratories of New York. In these tests the reflector was equipped with a 125-watt clear bulb Gem lamp, giving 50 mean horizontal candlepower. The reflector was held in position as used in practice with a standard 3¼ inch holder. The lamp was placed in such a position that the plane parallel to the loops of the filament made an angle of 45 degrees with the flat side of the reflector. One set of curves shows the apparent candlepower at various angles in a plane at right angles to the flat side of the reflector. The other shows the apparent candlepower at various angles in a plane parallel to the flat side of the reflector, or, in other words, the sideway distribution, as it would be installed in a window.

The first named curves would indicate that over 200 candlepower is given for a distance of 40 degrees to the left of vertical in the direction in which it is most useful in window lighting, while for a few degrees the candlepower is 436. The maximum candlepower is directed so as to give high illumination on the goods placed in the bottom and front of the window. As higher goods are usually placed farther back in the window a lower intensity is needed, and these requirements are met by the reflector. A very small amount of light is thrown outside the window on the sidewalk.

Besides window lighting a number of other useful applications of this reflector will suggest themselves to illuminating engineers—most notably the lighting of audience rooms of all kinds where the lamps themselves are concealed behind ground-glass skylights or beams, and where it is desired to throw the light sideway and forward and have as few rays directed back into the eyes of the audience as possible.

The makers are putting out this reflector with the claim that one 125-watt Gem lamp with this reflector will give the same results as three 55-watt common incandescent lamps used in the most efficient window reflectors for high, deep windows, while in the many cases where mirror troughs or other reflectors have been used one 125-watt Gem lamp is said to give the same results as four or five common 16-candlepower 55-watt lamps.

New Engines in the Twin City Rapid Transit Power House.

The Twin City Rapid Transit Company of Minneapolis, Minn., operates two power stations, one a hydro-electric plant with an output of 10,000 horsepower, and, operated in parallel with it in a station approximately 1,000 feet distant, a steam-driven electrical generating plant of 35,000 horsepower normal rated capacity. The output of these two plants furnishes power to 10 sub-stations in St. Paul, Minneapolis and adjacent towns, the maximum transmission distance being 25 miles, over which alternating current, three-phase, is carried at 13,200 volts, to be converted at the sub-stations into 600-volts direct current.

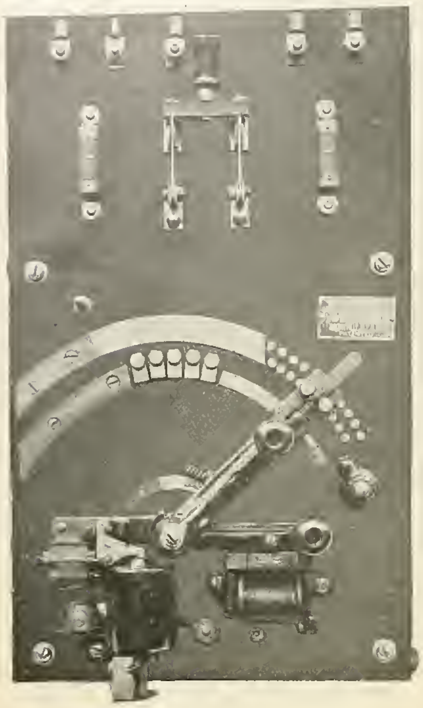
The steam-driven power plant, located on the east bank of the Mississippi River, stands just below the flour mills, in the center of the city, in a brick building 155 by 225 feet, and 93 feet high. The engine room, 67 feet wide and extending through the length of the building, contains, among other units, four reciprocating engines direct-connected to engine-type generators. These machines, which comprised the original installation, are Allis-Chalmers vertical cross-compound condensing engines 46 and 94 inches by 60-inch stroke. They have a normal capacity of 5,000 indicated horsepower. One of the four engines, the last to be installed, is equipped with an Allis-Chalmers barometric condenser, with the condenser chamber attached to the engine cylinder. This condenser has two barometric columns, one 16 inches in diameter for the removal of both air and water and one 20 inches, for an overflow. Cooling water is supplied by a 20-inch centrifugal pump.

Aside from its city lines, a portion of the Twin City Rapid Transit Company's output is utilized for the operation of the double-track electric line to Excelsior, on the southern shore of Lake Minnetonka, 19 miles west of Minneapolis. Two sub-stations of unusually large capacity for interurban lines have been built, and the feeding of these stations, together with the natural growth of the system into other extensions, necessary to meet the growing traffic, has rendered large generating capacity necessary in the main station.

The Nevada Consolidated Telephone Company, composed of Carson capitalists, has received the support of the board of City Trustees of Carson in the franchise matter, although a Salt Lake City company has been trying to secure a franchise. The Nevada Consolidated, which now has long-distance lines extending from Carson to a number of surrounding towns, will soon install a local system.

New Motor-controlling Devices.

The Ward Leonard Electric Company of Bronxville, N. Y., is continually increasing its line of "foolproof" motor-controlling devices. In its latest device, illustrated here, the resistance is entirely enclosed in a moisture-proof, fire-proof, sheet-iron casing. This controller is for use with variable-speed motors and is equipped with 20 steps of resistance for speed control by field regulation. The



NEW MOTOR CONTROLLING DEVICE.

no-voltage release magnet is independent of the shunt field current and the armature current.

It is in the overload device, however, that the rheostat is made "foolproof." The overload device is an independent, interlocking, overload circuit-breaker, giving protection against overload at all times and under all conditions, i. e., during ordinary running, during the act of starting or controlling the speed of the motor, or if the starting arm should become stuck on any starting point and the current then be switched on from the outside.

The National Electrical Code states, under rule 60, section G: "Overload release devices which are inoperative during the process of starting the motor will not be approved unless other circuit-breakers or fuses are installed in connection with them." The United States government specifications go further, for they positively state that an overload device which operates by short-circuiting or open-circuiting the retaining magnet of the no-voltage release will not be accepted.

The double-arm independent-throw circuit-breakers are universally specified because of the fact that after closing one side of the circuit-breaker, if the second side is closed and if overload exists, the side first closed will instantly open. The Ward Leonard Electric Company claims just such protection in the single-pole circuit-breaker which is part of this rheostat, for to close the circuit-breaker it is necessary to open the circuit upon the starting contacts, and in starting, if the lever is moved to the initial contact and short-circuit or overload exists, the circuit-breaker will instantly open upon its own independent contacts.

The circuit-breaker prevents the starting of the motor too rapidly and it teaches the operator just how to use a starter promptly.

Electric Heating and Cooking on Shipboard.

"Electric Heating and Cooking Devices for Marine Use" is the title of a handsome publication just issued by the General Electric Company as Bulletin No. 4523. The pamphlet is bound in a neat cover and contains illustrated descriptions of small apparatus particularly useful in ships' galleys, staterooms, smoking rooms, sick bays, etc.

A ship's lighting plant, usually of more than ample capacity for intermittent load, offers at once an available source of supply, which, utilized for cooking, heating, etc., would provide numerous real and profitable conveniences with small increase in cost.

The electric heater, on account of its compactness, neatness, easy regulation and simplicity, is ideal for stateroom use. The General Electric Company manufactures several forms, including luminous radiators and non-luminous air heaters. One or two-quart water heaters, electric wash bowls and electric shaving mugs are familiar conveniences, and electric flatirons in sizes from three to 24 pounds are supplied for the laundry. Among special devices particularly serviceable on shipboard may be mentioned electric soldering irons, glue pots, curling-iron heaters, surgeon-instrument sterilizers, heating pads, cigar lighters, etc.

Two distinct forms of heating elements are used by the General Electric Company, known as the cartridge and quartz enamel units. Both heating units are practically infusible and indestructible, but can be readily replaced if damaged by accident. The makers have taken great care in the design to insure the most efficient application of the heat and sufficient radiating surface so that nearly all the apparatus may be left in circuit indefinitely without fear of burnout.

Electrical Show at Madison Square Garden.

The electrical show at Madison Square Garden, New York city, takes place September 30th to October 9th. Plans are now formed for elaborate electrical decorations by the numerous large and small exhibitors. Among the exhibits will be nearly every invention or device used in a commercial or domestic way, and expert demonstrators will instruct the visitors.

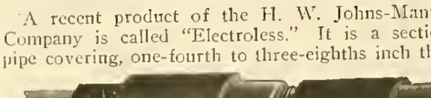
It is the intention of the Brooklyn Edison Company to fit up a perfect modern house, built in the Garden, with every appliance known at this date. It will be electrically equipped from cellar to garret. This includes electric stoves, electric flatirons and cooking apparatus of every kind. The Eastern Cahill Telharmonic Company will fit up the garden with wires and give to the visiting public electric music transmitted from a distance. Another exhibit will be the photophone. By attaching this instrument to any telephone one can see the person speaking on the other end of the wire. A demonstration of the efficacy of a recently invented burglar alarm will be given by a real live crook from Sing Sing, now reformed. The names of the directors are: George F. Parker, president; Walter Neumuller, treasurer; Dudley Farrand, Arthur Williams, W. W. Freeman, James R. Strong and James C. Young.

Resistance Devices up to 10-horsepower Capacity.

The National Rheostat Company, 115 Franklin Street, Chicago, has extended its line of resistance devices up to capacities able to take care of a 10-horsepower motor, securing a 50 per cent. range of speed. For some time the company has been making, in smaller sizes, a very compact form of rheostat available for use as a motor speed regulator, dimmer, field resistance, or for many purposes where a gradual control of the current is necessary. The resistance wire is wound on a ring of non-conducting fireproof material, and the contact arm bears directly upon the turns, insuring fine graduation and consequently a low potential difference, and no tendency to spark between adjacent coils. A very ingenious arrangement combines both overload and no-voltage release. A thumb-screw adjustment makes the former adjustable within wide limits. The overload break occurs in the presence of a strong magnetic field, serving to extinguish the arc quickly, and the arcing points are entirely different from the normal working contacts. In the 10-horsepower size the ring on which the resistance is wound is 18 inches in diameter, while the length of the cross-section of the ring is perhaps four inches. Complete with iron cover and steel base, the whole apparatus measures hardly 20 inches across and six inches high, and appears a veritable pygmy beside the usual resistance apparatus of such capacity.

A New Preventive of Electrolysis.

A recent product of the H. W. Johns-Manville Company is called "Electroless." It is a sectional pipe covering, one-fourth to three-eighths inch thick,



ELECTROLESS PIPE COVERING.

made of specially prepared asbestos paper in laminated form, thoroughly impregnated and coated with a high-grade waterproof insulating compound, which presents an effective barrier to the transmission of electric current. It is furnished in three-foot sections of various sizes to fit over underground lead and iron pipes. When used upon a system of pipes or lead-covered cables, "Electroless" protects them from the corrosion due to electrolysis, caused by extraneous currents, and also serves to guard them from rusting. The accompanying picture illustrates an application of Electroless.

Indiana Telephone Items.

The Home Telephone Company of Jeffersonville has petitioned the Board of Public Works for a franchise to construct and operate a telephone system in the city.

The Indiana Independent telephone companies have issued a bulletin saying that they have practically gained control of the local business in Indiana. The Independent companies in the state claim that the service is being given at too low a rate, and an effort will be made during the coming year to obtain more adequate rates for the service which is being given.

The Citizens' Telephone Company of Columbus has purchased and taken over the Grammar Telephone exchange, together with the telephone line in the Burnesville district. The Citizens' company recently purchased the Elizabethtown exchange, and is after other local lines and companies in the county, with a view of connecting up a large system.

A movement is on foot to organize a stock telephone company to take over the Hope Independent Telephone Company at Hope. The property is valued at $20,000. The movement is due to a recent increase in the rate, as well as poor service. If the new company is formed and obtains possession of the property the rates will be lowered.

Instructions have been sent out from the headquarters in Indianapolis by both the Central Union Telephone Company and the New Long-distance Telephone Company that rates from and after September 16th for night service will be the same as for day service on all the toll lines. The night rates heretofore charged by the Central Union were about two-thirds and that charged by the New Long-distance about one-half of the day rates. Overtime at the rate of one-third the initial period will be charged for each additional minute more than three.

The Central Union Telephone Company, which is moving into its elegant new building in Indianapolis, will add a new feature in the form of a typesetting machine. The machine will be used in composition for the numerous telephone directories of the company in Indiana. New directories will be issued every four months, and a list of the changes and additions will be printed every day. The typesetting of the directories for more than 300 cities and towns will be done on this machine, and the managers say the plan will effect a large saving and also furnish patrons with speedy information. S.

GENERAL TELEPHONE NEWS

The Arnett (Okla.) Telephone Company has been incorporated with a capital stock of $10,000 by C. O. Shaffer and others.

The Bagley Mutual Telephone Company, Bagley, Iowa, has been incorporated with $9,990 capital stock and is formed by six of the lines running into Bagley.

The annual convention of the New York State Independent Telephone Association will be held at Syracuse on Wednesday, September 25th. The convention headquarters will be at the Yates Hotel. R. Max Eaton, Niagara Falls, N. Y., is secretary.

Consideration of the Chicago Telephone Company's franchise extension ordinance was to be in order at a special meeting of the City Council on Thursday of this week. Numerous amendments to the ordinance as reported by the committee on Monday night were offered and further action was deferred until Thursday.

The New York Telephone Company announces that, beginning September 1, 1907, night rates on long-distance calls will be discontinued. It was found that long-distance traffic directly after 6 p. m. has become so heavy as to block the lines for several hours and thus give poor service to the patrons. The abolition of the night rates will distribute the traffic more evenly.

The Australian government contemplates inaugurating the automatic telephone, and all persons interested in the supplies needed may be put upon the mailing list of the telephone department and furnished copies of specifications, bid forms and other particulars by writing the postmaster-general, whose office is in Melbourne. It is said that the Australian government is about to ask for bids for 30 miles of telephone cables.

The Home Telephone Company of Alameda County, Cal., has its automatic system in successful operation in Oakland. About 1,000 subscribers' telephones have been connected with the two central offices in Oakland, where 3,000 subscribers have been secured and the service is being rapidly extended. A central office in Berkeley will be practically a part of the Oakland system. Nothing has been done as yet toward installing the new company's system in the city of Alameda.

CORRESPONDENCE.

Continental Europe.

Paris, August 26.—Carbons treated with metallic salts have been used in Germany with some success, especially for outside lighting. They are used either in the ordinary form of vertical lamp or in special lamps having the carbons placed at an angle at the bottom of the lamp. In all cases the voltage which is used is about 40 volts for the first kind and 45 volts for the second. Such lamps are used for public lighting. A considerable economy is claimed for these carbons and they consume from 0.23 to 0.28 watt per candle. As regards the color of the light, it is either yellow, white or pinkish, according to the nature of the metallic salts which are used. The yellow light is said to be the most economical. Such lamps have been made in 1,000 and 5,000-candlepower sizes. The carbons in this case will last from six to 20 hours. However, there is considerable smoke or fumes from the treated carbons which confines them to outside use.

Radio-telegraphy is found to be useful in determining the difference of longitude between two points where there is no telegraph circuit. Experiments have been carried on in this field by Albrecht in Germany and these proved to be quite successful. Potsdam and the Brocken were the points chosen in order to compare the results with the usual telegraphic method. The great radio-telegraph post of Nauen, lying at a distance of 19 miles from Potsdam and 110 miles from Berlin, was used as a source of the waves. The differences found between the new method and the usual one were of the order of one one-thousandth of a second of longitude. It is to be remarked, however, that atmospheric disturbances have a much greater effect upon the radio-telegraphic method.

One of the first memorial tablets to be erected to the memory of the late Professor Curie at Paris is a medallion which is placed on the wall of the laboratory of the Municipal School of Physics and Chemistry. It is the work of the sculptor Vernier, a personal friend of Professor Curie, and represents the latter in profile with the dates 1859-1906 and a short inscription.

The Academy of Science of Copenhagen has recently elected as foreign members Professors Gabriel Monod and Violle of Paris. Professor Violle of the Paris University is well known for his work in the field of photometry.

An interesting comparison of the different methods of lighting which are now in use commercially is made by M. Lockemann as regards the cost of lighting. For the price of one mark ($0.25) we obtain the candlepower which is given in the following figures for each of the usual methods of lighting: Wax candle, 29; stearic acid candle, 70; paraffine candle, 117; Schmitt gas burner, 418; Argand gas burner, 556; Edison lamp, 662; Nernst lamp, 1,064; alcohol lamp with incandescent mantle, 1,136; Argand oil burner, 1,205; tantalum lamp, 1,299; Bayen electric lamp, 1,818; Welsbach burner, 2,632; Lucas mantle, 3,704; Millenium mantle, 5,000. The result thus shows greatly in favor of the incandescent mantle lamp as regards economy. The life of the lamp is not considered in the above estimate.

Copper deposits have been discovered in the western part of South Africa in the Tsavo valley, and they appear to have considerable value, according to the reports of the prospectors connected with the Uganda Railroad. The principal deposit lies at 40 miles from the station of Tsavo, and here are found great quartz veins which run parallel with the railroad. Here the copper is nearly pure, or else contains sulphur. Gold is also found in the quartz veins. At Naivobi the ore which is taken from the recently discovered beds contains 30 per cent. of copper, and the prospectors state that it can easily be worked. A. DE. C.

Great Britain.

London, August 29.—In Aberdeen there exists a small mileage of underground conduits in which bare copper-strip cables are used. Since the early part of 1903 there have been periodical explosions, and investigations have followed as a natural course. Although the early explosions have been traced to the explosion of coal gas, due to a service cable failing in an end box, subsequent troubles have not been definitely traced. A series of tests was carried out in which a service cable, built into a manhole, was intentionally short-circuited. This demonstrated the possibility of an explosion in the absence of coal gas or any other explosive gas, for the manhole was lifted. The conclusion was arrived at from these experiments that the explosions could easily have been due to the sudden heating and consequent expansion of the air in the manhole. Experiments were next carried out with ventilated manholes, but it was found that a six-inch square hole cut in a 26 by 24-inch cover did not make any appreciable difference to the height to which the cover was lifted by the explosion. Fan ventilation, which has been found successful in other places where these conduits are used, is impracticable in Aberdeen, while experiments with bolted-down covers have also been unsuccessful. The results arrived at are, therefore, that without the presence of coal gas in the manhole an explosion will occur if a cable fails with a sufficiently heavy current behind it, while if coal gas be present, the explosion will be much more serious. The head of the gas department at Aberdeen has made the interesting discovery that coal gas may, by filtering through a sufficient thickness of earth, become quite odorless, but will continue to retain its explosive elements. The city electrical engineer reports that the only solution of the matter is the replacement of the conduit system by the solid system, and this has been agreed to by the Town Council.

Interesting figures are given in the annual report of the engineer to the City of London Corporation, in which he deals with a number of matters. He states that during the year 1906 the experiment which is being carried out in certain streets by the substitution of gas for electric lighting has resulted in a saving of about $2,500 in maintenance. Of course in this comparison he is comparing modern high-pressure gas lighting with arc lamps, with basket-pattern lanterns having very thick glass, installed 15 years ago. No doubt the new experiment and exhibition of street arc lighting which is to be conducted during the winter months will alter opinions in many quarters. In regard to overhead wires in the City—which, by the way, only has an area of one square mile—there are now nearly 750,000 spans crossing public thoroughfares, compared with 700,000 last year. Of course the National Telephone Company is largely responsible for this state of affairs, although it is a position forced upon it in the past. Complaints are frequently made of the obstruction to street traffic by the continual opening of street boxes, and it is to be noted that during 1906, in the City alone, the telephone manholes were opened on nearly 2,000 occasions; and this number does not include mere inspections.

Aluminum insulated cables have now been placed upon the market here by Messrs. Johnson & Phillips in sizes ranging from 0.05 to 1.0 square inch sections. Curiously enough, with the advent of these cheaper cables, from the metal point of view, there appears to have been a fairly substantial drop in the price of copper, which I see now stands at about $425.

In connection with my article a short time back upon the report of the committee appointed to deal with the interference caused by the Greenwich generating station of the London County Council, it is interesting to note the remarks of the Astronomer Royal upon the matter. In his annual report he strongly supports the recommendation that the whole matter should be reviewed in two years' time. The tremors caused by the vibration of the generating plant he thinks can be effectually damped out by making the film of mercury in the amalgamated trough as thin as possible, but he thinks there is a strong possibility that they cause the telescopes to oscillate to such an extent as to interfere with the delicate work of which they are capable, such as the observation of close double stars with the large telescope. He regards the recommendations of the committee as the minimum which is absolutely necessary, and thinks that a further reduction in the height of the chimneys may be required to safeguard the Greenwich meridian work.

The following figures taken from the accounts of the various electric railways in London throw interesting light upon the severity of motor-omnibus competition. The Central London Railway carried during the half year ended June 30th, 2,075,000 less passengers than in the corresponding period of 1906; the Metropolitan Railway carried 745,000 less; and the Metropolitan District 7,333,000 less. On the other hand the City and South London company's traffic increased by 1,004,000 passengers, and that of the Great Northern and City Railway by 1,417,000. But who carried the difference between these gains and the heavy losses on the other hand? G.

Dominion of Canada.

Winnipeg, Man., September 7.—Alexander & Budd supply light and power for the city of Calgary, Alberta. A rival company is making arrangements for the erection of a plant. The new power concern is to be established at Radnor, Alberta, and the promoters are the Alberta Portland Cement Company of Calgary.

The Winnipeg City Council has voted $20,000 toward paying the cost of one duct in conduits for the government telephone system to be built in Winnipeg. F. E. Cambridge, city electrician, can give particulars.

A sub-committee of the Winnipeg City Council has recommended to the council that at the next civic election the ratepayers be asked to vote on a bylaw for the raising of $200,000 for the construction of a conduit system in the central portion of the city in which electric wires for street lighting will be placed. Ducts in these conduits will probably be rented to the Winnipeg Electric Street Railroad Company and other companies using high-tension wires. The idea is to get all the wires in the city underground just as soon as possible.

The British Columbia Electric Street Railroad Company has planned a large amount of work in the vicinity of Vancouver, B. C. In order to demonstrate to the public the superiority of the "T" rail the company will retrack Hastings Street, Vancouver, with this rail, putting vitrified brick next to the rail. The company has also decided to put in a motor to swing the Lulu Island bridge, owing to the great delay occasioned each time the bridge is swung by hand power. The grading for the new pipe line, which is to add 10,000 horsepower to the present supply, is completed and a portion of the piping will be shipped to the grade at once. The rock work on the approach to the tunnel, through which the pipe line will run, is completed, and Messrs. Ironsides, Ranne and Campbell are driving the tunnel at the rate of 15 feet per day. The tunnel will be 14 by 6 feet. R. H. Sperling, Vancouver, B. C., is general superintendent of the company.

The receipts of the municipal street railway at Port Arthur, Ontario, for the month of August were $8,315.05, against $7,308.80 for the corresponding month last year.

At a recent meeting of the Winnipeg power committee the question of selling electricity to small towns between the city and the power plant at Lac du Bonnet was brought up. Application will be made to the Legislature for such rights. Cecil B. Smith, civic power expert, Winnipeg, is in charge. R.

Indiana.

Indianapolis, September 7.—Charles Murdock of the Fort Wayne and Wabash Valley Traction Company has gone to Philadelphia to attend a meeting of the officials with a view of closing a contract with an express company for the handling of express over the company's line between Fort Wayne and Lafayette. The United States Express Company is now operating over the line under a temporary contract. Several other express companies are also desirous of securing the concession.

The Central Indiana Lighting Company, which recently purchased the Columbus street-car system of Columbus, has discontinued the use of street-car checks and is now charging passengers a straight five-cent fare. Previously checks when purchased in quantities amounting to $5 were secured at the rate of three cents per check. The increase in the passenger rate is meeting with considerable opposition, notwithstanding the commendable improvements that are being made in the system.

The commissioners of Marshall County have ordered an election to be held October 5th to vote on a subsidy tax of $56,000 in Center Township in aid of the Logansport and South Bend Traction Company, which is building a line between Logansport and South Bend by way of Plymouth.

The important announcement is made from Hammond that the Murdock-Hanna street-railway syndicate has taken over the South Chicago City Railway and the Hammond, Whiting and East Chicago Electric Street Railway Company, and will hereafter operate them. It is also reported that Dwight E. Cameron and O. Gauthier, president and secretary, respectively, of these systems, have resigned. It is declared that the Murdock-Hanna syndicate has secured control of these lines for the purpose of obtaining ingress into Chicago for the Chicago, Lake Shore and South Bend interurban road now being constructed between South Bend and Indiana Harbor. This movement is regarded as one of the most important interurban movements that have taken place in Northern Indiana for several years.

As a result of a federal injunction the authorities of the city of Richmond were restrained from stopping the operation of cars by the Terre Haute, Indianapolis and Eastern Traction Company and the Dayton and Western Traction Company through Richmond. According to an ordinance adopted by the City Council, any attempt to operate cars after September 6th would have resulted in wholesale arrests of the crews. The injunction, however, was served on the mayor at midnight, and the merits of the question will be decided by a hearing of the case in the federal court at Indianapolis on October 7th.

The Board of Public Works of Richmond in a signed statement declares that the city's electric-light and power plant is not mismanaged nor the superintendent incompetent. The board admits there has been a series of accidents at the plant which have not been explained satisfactorily. The board intimates that while there is some belief that a conspiracy exists to damage the city's plant with a view of bringing it into disrepute and the sale thereof to a private corporation, there has been no real or tangible evidence upon which to base that belief. The citizens of Richmond are coming more than ever to the conclusion that a private lighting company controlled by an eastern syndicate will take advantage of the chaotic condition of affairs in connection with the municipal plant so as to prevail upon the City Council to consider the sale of the plant.

The Lowell Light and Power Company of Lowell, Ind., recently organized by Clifford Wiley of Chicago, which purchased the electric-light plant of the Lowell Electric Light Company, is making arrangements to build an entirely new and modern plant. S. S.

New York.

New York City, September 7.—The two cast-iron tubes of the Battery Tunnel from Manhattan to Brooklyn have proved so weak that it has been found necessary to strengthen them with a lining, which is practically another tube inside each original tube. The construction of the new tubes will mean that Brooklyn will have to wait many more months before the tunnel can be opened to the public. The most serious effect of this additional construction is to cut down the clearances for the cars by several inches. At an earlier date it was found that these same tubes had flattened out and had consequently cut down this clearance to a minimum, and it was found necessary to roud these tubes out and to put in special strengthening.

After a long conference with counsel of the Interborough-Metropolitan Company the authorities of that corporation have decided not to comply with the demands of the Public Service Commission, that it be permitted to examine the books of that company. The ground on which the demand is to be refused is that the commission, under the law of its creation, has not jurisdiction over holding companies.

The Public Service Commission of the Second District has announced that a series of conferences with the heads of the several mechanical departments of the leading railroads has been held to formulate plans and rules for the inspection of locomotive boilers and that these rules would go into effect at once. These rules provide for the time and methods of inspection of all parts, including steam gauges, safety valves, stay-bolts, etc.

Providing 50 50-horsepower motors was the only item to which the Coney Island and Brooklyn Railroad objected at the hearing which the Public Service Commission held on the recent order to the company to show cause why a certain number of improvements should not be made. Among the improvements to be made are the installation of new circuit-breakers on practically all of the cars, 100 drip pans and for 10 new combination cars to be equipped with 50-horsepower motors. Other orders related to a different sort of headlight and to the appearance of the numbers on the front of the cars. The Coney Island and Brooklyn Railroad is one of the first to be considered by the new commission, which will ultimately take up each and every railway and lighting system in and around the greater city. E. H. S.

Ohio.

Toledo, September 7.—Fall business among the local electrical establishments is not coming to the front as fast as some predicted that it would. The season is either considerably behind or else it will be lighter than usual.

The Lima and Toledo Traction Company is seeking an entrance into the city over its own right-of-way. Application was made last week for the purchase of a strip of state land needed to complete its right.

The Columbia Mutual Telephone Company at Elyria, Ohio, has purchased the exchange of the Elyria Southern Telephone Company, a toll company. The subscribers formed the mutual company and bought the system to avoid a raise in rates.

Chair cars and buffet service are in store for patrons of the Detroit United and Lake Shore electric railways between Detroit and Cleveland by way of Toledo. Estimates for the service are now being secured.

A proposition has been submitted by the Dayton Lighting Company to light the monument on North Main Street with 2,000 electric lights free of charge, the lights to be so arranged as to form the word "Dayton." Four streamers of electric lights will extend from the apex to the four corners of the base with a rope of light entirely around the base. It is probable that the city of Dayton will accept this generous offer to light the soldiers' monument.

The position of electrician has been provided by the authorities at Lima, Ohio, and will be filled by ex-Fire Chief Coates.

The total valuation of interurban roads in Ohio, according to the figures in the office of the auditor of state is $12,731,780, as against $11,664,041 in 1906, an increase of $1,067,739.

President Frank L. Beam of the Ohio Independent Telephone Association, Columbus, is enjoying a three weeks' vacation in Denver. H. L. S.

Illinois.

Peoria, September 7.—Springfield is getting ready for the state fair. This week the contract for placing the electric lights in the downtown district was let. The lights will be placed on each side of the street, about three feet apart, and arches will be built across the streets, which will make a canopy effect. The courthouse will also be completely covered with incandescent lights.

The Illinois Traction Company will put into [illegible] between Springfield and St Louis two new chair cars. These cars are larger and have a larger seating capacity than the regular car, being equipped with all the latest improvements, and provided with the regular passenger compartments, smoking room and baggage room.

The Central Union Telephone Company will be asked to secure a franchise through the village of Bartonville. The company says that it was on the ground before the village was incorporated and can see no reason why it should apply for a franchise.

Negotiations for the purchase of the express business of the Illinois Traction System by the Wells-Fargo Express Company are said to be in progress by the two companies. In the event of the express company taking over the business it will conduct it in the same manner as it does the steam-road business—the traction company will furnish the cars and haul them to the destination, but the express company will handle the business. The express company is now doing business with the interurbans in the states of Indiana and Ohio.

The Southwestern Electric Train Bulletin Company of Jacksonville has been incorporated with a capital stock of $50,000 to do a manufacturing business. The incorporators are Franklin A. Jennings, William L. Duff and William S. Phillips.

The City Council of the city of Quincy has granted the St. Louis, Terre Haute and Quincy Traction Company a 50-year franchise. The ordinance is very liberal and gives the company the use of some of the best streets. The company will lay two or three miles of track in the city limits and will have specially good accommodations in the business districts.

At a meeting of the Illinois railway and warehouse commissioners, Messrs. Willoughby and Kilpatrick reported that the fatal wreck on the Charleston and Mattoon electric interurban road was due to the lack of a system of dispatching. At the same meeting the commissioners instructed the secretary to at once notify all of the interurban railway companies organized and operating under the laws of Illinois to furnish the department with such rules and regulations for the operation of cars and trains on their respective systems as they now have in force. The company, as a result of the wreck, has gone into the hands of a receiver. W. T. Avery, cashier of the Mattoon Savings Bank, has qualified by filing a bond for $10,000. This takes with it the Mattoon City Railway Company and the Mattoon Light and Power Company. Mr. Avery announces that he will at once install a dispatching system to insure the passengers' safety. Many suits for damages are expected to follow. The directors of the three companies are E. A. Porter (president), Arthur W. Underwood (secretary), L. C. Rose (treasurer), P. S. Grosscup and Francis S. Peabody. V. N.

Pacific Slope.

San Francisco, September 4.—Louis Glass, vice-president of the Pacific Telephone Company, has been convicted of bribery of San Francisco supervisors, with the object of preventing the Home Telephone Company from securing a franchise for a competing system. According to the confessions of a number of the supervisors, they later took money from a representative of the Home company and granted the franchise for a comparatively small sum. E. J. Zimmer, whose testimony before the grand jury caused the indictment of Mr. Glass on charge of signing the check for the bribe money, refused to repeat his testimony before the first trial jury, and a disagreement resulted. On the next trial Mr. Glass was convicted on circumstantial evidence. He was committed to the county jail pending the hearing of a motion for an appeal and today was sentenced to five years in San Quentin.

The Southern Pacific Railroad Company has applied for an electric franchise in Alameda, Cal. It covers only the present broad-gauge and not the narrow-gauge roads, but several branch or feeder lines, along streets as yet untouched by railroads. The application is for an overhead-trolley system for 50 years, with five-cent fares between stations. There are two applications for the franchise, one made by the Central Pacific and one by the South Pacific Coast. The Central Pacific covers the broad-gauge, or north shore line, and the South Pacific Coast the south shore, or narrow-gauge route.

The Snow Mountain Power Company will enter the electric field at Napa, Cal., and also that of Vallejo and Oakland, in addition to supplying Marin, Sonoma, Mendocino, Glenn and Colusa counties. G. F. Connors of Calistoga, secretary of the St. Helena Gas and Electric Company, announces that by December 1st the lines of the company would be strung through the entire Napa Valley, and that not only every city and town would be supplied, but that Vallejo and Oakland will be furnished with light and power. At St. Helena the company will have a working agreement with the St. Helena Gas and Electric Company, whereby the present plant in operation will be remodeled so as to use the Snow Mountain current and to be used as a distributing station for the power, which will be sold to farmers throughout the entire valley.

The work of completing the tracks of the Central California Traction Company into Lodi, Cal., has been pushed to completion.

Acting on a favorable opinion from the city attorney, the Los Angeles City Council has voted to advertise for the sale of a third-rail franchise along Hill and West Sixteenth streets.

C. H. Weed, engineer and electrician, of Los Angeles, has been in Turlock, Cal., trying to promote electric-light and water plants. Mr. Weed desires to buy a block of land in a desirable location and erect an electric-light plant. Provisions are also made for a water system to be used for domestic purposes and fire protection. A company has been incorporated to be known as the Turlock Electric and Water Company.

Stone & Webster of Boston, under the name of the Puget Sound International Railway Company, have purchased the street-railway lines of Everett, including a line from that city to Snohomish. With the purchase of the line the company intends to supply Everett with power generated from the plant at Nooksack Falls, now in process of construction. Coupled with the Snoqualmie plant, said to be owned by them, the big power establishment at Electron and a new plant to be built on upper White River, the company will have four large plants, generating enough electricity to operate the network of railways owned by them.

The Wenatchee Electric Company, which increased its capital stock to $150,000 a few weeks ago, has filed a mortgage with the Scandinavian Bank of Seattle as trustee for $300,000, funds to be used in the development of a large electric plant in Wenatchee. Arthur Gunn is president of the company. The building of a gas plant is only the beginning of work in view by the company.

William Piggott, president of the Seattle Car Manufacturing Company, stated to the board of county commissioners recently that his corporation intended to build at once a $250,000 plant at Tenton to take the place of the one which burned at Youngstown.

A report from Vancouver, B. C., is to the effect that James A. Moore of Seattle will be in Vancouver next week to select a site for a large electric smelter, steel structural works and iron foundry for handling ore from Texado and Vancouver islands.

The City Council of Dayton, Ore., is investigating the matter of securing a waterwheel and dynamo, with a view to establishing an electric-light plant for Dayton.

In order to install the 33 fire-alarm boxes recently purchased by the Fire Commission of Portland, Ore., the ways and means committee has appropriated $35,433 to cover the expense of running wires and placing boxes in the different districts of the city. Wherever the Home Telephone Company lines run, its poles will be utilized.

Contracts will soon be let for the construction of an electric plant at Katolla, Alaska, to generate 1,500 horsepower for use in connection with railroad construction work. The Guggenheim interests are behind the new railroad project. The present plans include the construction of 10 to 20 miles of trestle work and the erection of general office buildings, hospital and 20 bunk houses and mess houses. A.

PERSONAL.

Mr. Samuel Insull, president of the Chicago Edison Company, returned last week from a short visit to England. It was his fifty-third transatlantic passage.

C. F. Hambfhy has been appointed general superintendent of transportation of the Illinois Traction System. The office is a new one, and Mr. Hambfhy will have charge of all the transportation of the large electric-railway system, with offices in Springfield, Ill.

The place left vacant by the decease of Henri Moissan, the noted French scientist, in the Council of the Astro-physical Observatory of Meudon, near Paris, has now been filled by Prof. Henri Poincaré, the well-known physicist and professor at the University of Paris.

James W. King, manager of the Citizens' Telephone Company of Columbus, Ind., has resigned to enter business on the Pacific Coast. The company is at present making extensive improvements in the plant and is gaining patrons. John Hosea of the New Long-distance Telephone Company, Indianapolis, has been appointed to succeed Mr. King as manager.

Charles Ross Thurman, who is connected with the General Electric Company at Lynn, Mass., and Miss Eliza Carter Thornton were married at the University of Virginia on August 28th. The bride is a daughter of Prof. William M. Thornton, dean of the engineering department at the university. Mr. Thurman graduated from the university with the degrees of electrical and mechanical engineer, and he has been with the General Electric Company for several years.

ELECTRIC LIGHTING.

The Eldorado Springs (Mo.) Electric Company's power house, valued at $15,000, has been destroyed by fire.

L. W. Nelson of Mescalero, N. M., has made application for an electric-light franchise in Higgins, Tex.

Gibbon, Neb., is considering the establishment of an electric-light plant. A committee has been appointed to investigate the cost.

The Baton Rouge Electric Company has been incorporated with a capital of $750,000 to operate a light plant and street-car system in Baton Rouge, La.

A lighting contract was recently closed between the city of Duluth, Minn., and the Water, Light and Power Company. It calls for 203 arc lights at $65 per lamp and additional ones at $58 each.

The White City Amusement Company of Hot Springs, Ark., recently incorporated with a capital of $500,000, of which $50,000 is paid, will put in an amusement park. The charter allows the operation of electric plants and waterworks.

The Americus Railway and Power Company has been incorporated with a capital of $250,000 to do an electric-railway, lighting and power business in and about Americus, Ga. Among the incorporators are W. A. Dodson and A. W. Smith of Americus, J. F. Lewis of Valdosta and Congressman E. B. Lewis of Montezuma, Ga.

City Electrician Pfiester of Cincinnati, Ohio, has made a detailed report on the proposed illumination of the Eden Park water tower. He recommends that 1,000 electric lights be placed on the tower in the form of a circle around the top of the dome and a vertical row from bottom to top. He estimates the cost of installation at $1,500 and the annual cost at $2,000.

Bids for the installation of a conduit system of lighting for artistic cluster lights will be opened by the Board of Public Works of Seattle, Wash., September 21st. Lights will consist of clusters of five each, four to be placed on each side of the street in each block. Cost of installation is estimated at $150,000 and will be borne by the abutting property. It is expected that installation will require one year.

ELECTRIC RAILWAYS.

The Milwaukee and Northern Railway Company has reported to the police of Milwaukee, Wis., that thieves had cut down and carried off about 25,000 feet of trolley wire between Milwaukee and Cedarburg.

A plan is being considered for an electric road from Minneapolis to La Crosse, Wis. This is being backed by the owners of the La Crosse Water Power Company, which has nearly completed its plant at Hatfield, Wis.

Work on the extension of the Northwestern Elevated Railroad from Chicago to Evanston, Ill., is to be rushed so as to be completed by the first of next year. Arrangements are being made to secure new cars and equipment for this branch; 40 cars are to be delivered before November 1st, and more are to follow.

To prevent accidents similar to that on the Mattoon-Charleston line, the Illinois Traction Company, which controls probably the most extensive interurban system in the state, is installing a block signal system on all its lines.

The Hattiesburg (Miss.) Traction Company has lately increased its capital to $500,000. It has secured the franchises of the electric light and power, gas and street-railway companies and will construct a large central power house for all these allied interests.

Rumors are current that the Chicago and Oak Park Elevated Railway is contemplating an extension to Elgin, Ill. Color was given to these accounts by an investigation made by Mr. Lloyd Jones, civil engineer for the road, into the probable difficulties to be encountered on the line.

PUBLICATIONS.

The Engineering Specialty Company, 143 Liberty Street, New York city, has just issued Bulletin 106, a descriptive booklet illustrating but one of its departments, viz., direct-current motors, dynamos and their various combinations. The company has a fully equipped modern factory with every facility for rapid and accurate production, and a competent engineering staff. This bulletin or any of those covering the four other departments will be sent on request.

"On the Art of Cutting Metals," by Frederick W. Taylor, M. E., Sc. D., which was the presidential address presented at the last annual meeting of the American Society of Mechanical Engineers, has been reprinted and bound in cloth by the society; price, $3. This or any other publication of the society may be had by addressing the secretary, 29 West Thirty-ninth Street, New York. It is not necessary to send orders through members. None of the publications of the American Society of Mechanical Engineers is copyrighted.

The New Idea Catalogue of electric-light and power supplies and net price list has just been issued by the Commercial Electrical Supply Company of St. Louis, Mo. It contains the 1907 Fire Prevention Bureau rules. The price list is made up with light-faced type for factory shipment material and heavy-faced type for stock shipment material. On the front cover of the price list are two columns to indicate change in prices during the current month, one indicating goods advanced and the other goods declined. It also contains complete information pertaining to conduit construction. The book will be sent upon request.

SOCIETIES AND SCHOOLS.

The electric-lighting plant of the University of Mississippi was burned a few days ago, entailing a loss of $10,000. Spontaneous combustion of the coal is supposed to have been the origin of the fire.

The Chicago Association of Commerce has published its constitution and by-laws as revised August 1, 1907. The purpose of this organization is toward a united non-partisan effort for the advancement of the commerce, industry and public interests of Chicago, and the officers and members are doing commendable work in this direction. Mr. David R. Forgan is president and Mr. Harry A. Wheeler is general secretary.

TRADE NEWS.

The Amateurs' Electric Supply Company, Peoria, Ill., has been organized as an electric mail order house, catering to the trade of youths and young men interested in experimental supplies. The company solicits catalogues and estimates from firms manufacturing goods in its line.

Announcement is made that the new building of the Westinghouse Electric and Manufacturing Company at its works at East Pittsburg, Pa., will be ready about September 15th. It is 400 by 70 feet in ground dimensions, eight stories high and cost about $500,000. It will be used for the detail and supply department.

The Bossert Electric Construction Company, Utica, N. Y., has disposed of the switchboard and panel-board department of its business to the Nyelee Switchboard Company, Twenty-eighth Street and First Avenue, New York city, which company has the sole right to manufacture Bossert type switches and panel boards. The former superintendent of this department at the Bossert factory will be in charge of the new factory, which will be represented by the R. B. Corey Company, 39-41 Cortlandt Street, New York city, as sales agent. That the business of its former customers in this department will be given to the new concern is the wish of the Bossert company.

Having been obliged for the last year to maintain Pacific Coast headquarters in Oakland instead of San Francisco, the Standard Underground Cable Company of Pittsburg has now permanently relocated at Nos. 511 to 514 Shreve Building, San Francisco, Cal. A. B. Saurman continues as Pacific Coast manager. The company's new Oakland factory is four times as large as the old factory which was destroyed by fire shortly after the earthquake last year. It is as nearly fireproof as possible, equipped with new up-to-date machinery for the manufacture on short notice of insulated wires and cables for practically any service. It is also equipped with complete warehouse facilities for handling the products of the company's eastern factories carried in stock for Coast delivery.

BUSINESS.

Following the tests recently made on the 1,000-kilowatt Allis-Chalmers turbo-alternator now in operation for some months past at the power house of the Kokomo, Marion and Western Traction Company, Kokomo, Ind., this company placed an order with the Allis-Chalmers Company for a duplicate of the turbine unit installed, comprising a 1,000-kilowatt turbine driving a 1,000-kilowatt alternator, with turbo jet condensing system complete. The second unit just ordered will be placed beside the first one in the power house at Kokomo and will furnish power for lighting and railway service.

A large order for railway equipment has just been contracted for with the General Electric Company by the Utah Light and Railway Company of Salt Lake City. The Utah company is planning large extensions to its present 90 miles of track and will install 50 new cars. The contract calls for 50 complete quadruple equipments, consisting of 200 GE-80 40-horsepower motors with K-28 controllers. In addition, the company has ordered 74 GE-80 motors, with extra controllers, circuit-breakers, rheostats, etc., for the re-equipment of old cars.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) September 3, 1907.

864,781. Universal Outlet or Junction Box. John L. Gleason, Boston, Mass. Application filed May 31, 1906.

Strip springs are provided on outside of opening with one end fastened to wall of box and other end extending slightly over edge of opening so as to permit a flexible conduit to be passed outwardly, but not inwardly.

864,782. Tumbling Barrel. Harry J. Guttman, Chicago, Ill., assignor of one-third to Alexander E. Keith and one-third to Samuel Cole, Chicago, Ill. Application filed August 7, 1905.

An electro-plating machine comprises a rotatable tumbling barrel, means for changing the angle or inclination of the barrel while the same is in motion. The barrel has cathode terminals on its inner walls and an axial anode.

864,798. Portable Hoist. James L. Pilling, Chicago, Ill. Application filed October 3, 1906.

A compact electric hoist; armature and fields both revolve, being geared together so that fields become winding drum.

864,840. Apparatus for Electrically Removing and Severing Metal. Royal E. Frickey, Berkeley, Cal. Application filed June 29, 1906.

An electrode and holder for same, surrounded by a refractory sleeve, having a detachable refractory thimble at its outer end.

864,842. Electric Drive for Paper-making and Like Machines. James R. Happer, Linwood, Scotland, assignor of one-half to James Bertram & Son, Limited, Edinburgh, Scotland. Application filed January 4, 1907.

A system of electrically driving machines composed of sections driven at variable speed, comprising supply mains, a motor generator for generating a current of variable voltage which may be opposed or added to that from the mains and a separate motor provided for each section having its own regulating device and driven by the current from the mains and the generator.

864,846. Power-transmission Device. Charles D. Jenney, Indianapolis, Ind. Application filed June 23, 1904.

A high speed motor is provided with brackets carrying a counter-shaft, a large pulley on which is connected to a small pulley on the armature shaft by a short belt tightened by means of an idler pulley.

864,858. Automatic Circuit-closer. Hermann G. Pape, New York, N. Y. Original application filed June 16, 1904. Divided and this application filed September 23, 1905.

An operator's receiver contains a switch, which closes when the operator puts the head band over her head.

864,887. Supervisory System for Telephone Lines. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed January 25, 1904.

A supervisory signal is connected with a cord circuit through relays, so as to operate when the cord circuit is used.

864,888. Trolley-wire Crossover. David H. Doak, Morgan Park, Ill., assignor of one-third to Charles Oldenburg, Chicago, Ill., and one-third to W. H. Conrad, Blue Island, Ill. Application filed October 11, 1905.

One trolley wire runs straight through on an insulated rough-shaped block; the other has two swinging runaways that are actuated by the passage of the trolley to span the gap occupied by the continuous wire.

864,899. Step Switch. Christian Krämer, Frankfort-on-the-Main, Germany, assignor to Felten & Guilleaume-Lahmeyerwerke Actien-Gesellschaft, Frankfort-on-the-Main, Germany. Application filed January 16, 1907.

A switch having an operating and a contact lever eccentrically mounted with regard to each other, so arranged that the operating lever moves the other only step by step in one direction, but freely in the other direction.

864,909. Sound-producing Device. John P. Northey, Toronto, Ontario, Canada. Application filed July 9, 1906.

A cylinder with annular orifices contains a hollow piston open at one end and having similar orifices; to the head of the piston is attached a piston rod having a direct current coil about it, making it a permanent magnet, beyond which is an iron core surrounded by an alternating current coil, which gives reciprocating motion to piston and produces sound.

864,912. Jointed Trolley Pole. Harry Padley, Elyria, Ohio. Application filed June 1, 1906.

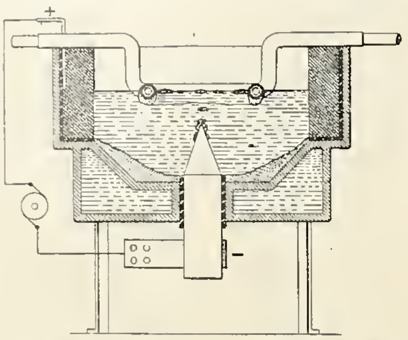
A two part trolley pole, hinged at center to permit swinging of the upper part inward and downward upon the lower part, and a spring fixed on lower part to catch and hold the upper part when the pole collapses.

864,915. Elevator Signaling Apparatus. Charles A. Reiners, Hoboken, N. J., assignor to the Elevator Supply and Repair Company, Chicago, Ill. Application filed April 9, 1907.

An electric signaling system adapted to two cars, has a light in each car controlled by passengers wishing to signal operator; this lights when car approaches floor and there also lights a signal lamp on floor; both these are extinguished when car passes the floor.

864,928. Electrolytic Production of Earth-Alkali Metals. George O. Seward and Franz von Kügelgen, Holcombs Rock, Va., assignors to the Virginia Laboratory Company, New York, N. Y. Application filed April 25, 1906.

The current density at a submerged cathode is maintained so high that the metal is formed there in a fused state and then passes through a cooler portion of the electrolyte to a suitable collector. (See cut.)



NO. 864,928.—ELECTROLYTIC PRODUCTION OF METALS.

864,930. Receptacle for Electrical and Other Devices. Robert Siegfried, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed October 3, 1905.

A tank for transformers or other apparatus has a separate base with an annular recess outside of tank, a cover with an annular channel to fit top edge of tank and bolts to clamp the tank between the base and the cover.

864,947. Clamp for Electric Wires. Elisha W. Buffinton, Fall River, Mass., assignor of one-half to Marietta M. Huggett, Fall River, Mass. Application filed May 1, 1907.

A knob or cleat consisting of base and cap, having two grooves for wires and a short groove and tongue between these to interlock the base and cap.

864,950. Telegraph Transmitter. Josiah A. Carter, Jr., Atlanta, Ga. Application filed March 4, 1907.

A combination of a vibrator, key lever, adjusting screw weights, an auxiliary lever contacting with the vibrator and with the key lever, and a movable stop; the key lever controlling the action of the vibrator, stop and bar. (See cut.)

864,957. Portable Search Light. John Dickens, Passaic, N. J., assignor to the Standard Sheet Metal Company. Application filed October 8, 1904.

A flash light set in a tube with some dry cells has an adjustably focussing lens and a special contact button.

864,959. Tank Alarm. Glen F. Elliott, Delmar, Del. Application filed April 20, 1907.

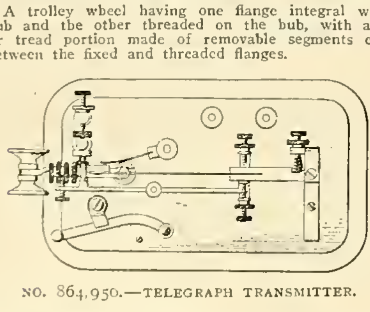
A weight controlled by the rise and fall of a float in the tank closes an alarm circuit at adjustable points.

864,961. Automatic Electric Gong-ringing Device for Street Cars. Nathan Fallek and George F. Wolfe, Denver, Colo., assignors to the Standard Electro-automatic Signal Device Company, Denver, Colo. Application filed April 22, 1907.

The top of the controller has a ring containing contacts; a contact arm extends from the controller shaft and engages these contacts, thus ringing the gong, when the controller handle is turned.

864,965. Trolley Head. James D. Gibbs, Louisville, Ky. Application filed January 15, 1906.

A trolley wheel having one flange integral with the hub and the other threaded on the hub, with a collar or tread portion made of removable segments clamped between the fixed and threaded flanges.



NO. 864,950.—TELEGRAPH TRANSMITTER.

864,968. Multiple Needle Holder for Electrolysis. Edward W. Johnson, Chicago, Ill. Application filed June 28, 1907.

A support having a number of arms ending in needle holders and means whereby these holders may be held in any desired position, the needle holders being in electrical connection with a socket on the support.

864,971. Electric Signaling Device. Alfred Larsson, Buffalo, N. Y. Application filed June 9, 1906.

An electromagnet has an armature to which is fastened a spiral spring and a hammer.

864,995. Junction-box-cover Rosette. Frank J. Russell, New York, N. Y. Application filed October 20, 1906.

A drop cord rosette has a base, with terminal plates and coupling sleeves, and a cap with service terminals and assembling screws.

865,011. Connection System for Direct-current Electric Motors. Raoul Brun, Havre, France. Application filed February 28, 1906.

The combination of a compound-wound motor and an auxiliary dynamo-electric machine mechanically coupled to the motor, the armature of the auxiliary machine being connected in series with the shunt-field winding of the motor so that the voltage of the said machine is opposed to that of the source of supply, and the field winding of the auxiliary machine being connected with the series winding of the motor.

865,013. Railway Block-signal System. Winthrop M. Chapman, Needham, Mass. Application filed January 24, 1906.

Every block has a signal at each end actuated by two magnets. When one is energized, signal moves to safety position; when other is energized signal moves to danger position; entry of a car into the block closes the circuits of the nearer safety moving magnet and of the remote danger moving magnet.

865,016. Electric Furnace. Walter G. Clark, New York, N. Y., assignor to the Electric Furnace Company, Portland, Maine. Application filed December 17, 1906.

The walls are of low resistance conducting material and an internal electrode is of relatively higher resistance except at its foot, which is at first in contact with bottom of furnace and is raised as soon as arc is formed.

865,038. Watertight Electric Bell. Walter C. Hill, London, England. Application filed May 19, 1906.

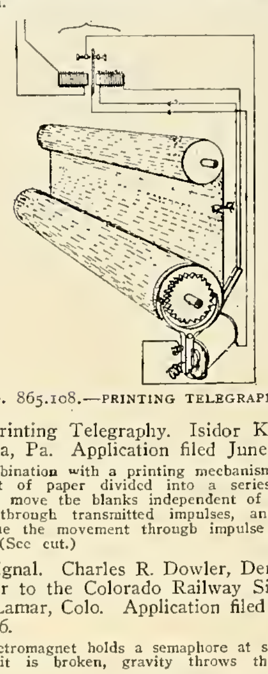
The mechanism is inclosed in the bell, which is in the form of a hollow flat cylinder.

865,068. Electric Generator. Klas Weman and Alfred Larsson, Buffalo, N. Y. Application filed May 21, 1906.

A magneto generator has two curved sheet metal pole pieces.

865,093. Current Transformer. Oswaldo de Faria, Paris, France. Application filed February 4, 1905.

An electrolytic transformer has a hollow carbon electrode, having horizontal perforations at its top and bottom, and a metallic electrode within this hollow one; the circulation of the electrolyte is like that in a thermo-siphon.



NO. 865,108.—PRINTING TELEGRAPHY.

865,108. Printing Telegraphy. Isidor Kitsee, Philadelphia, Pa. Application filed June 29, 1907.

In combination with a printing mechanism, a continuous sheet of paper divided into a series of blanks, means to move the blanks independent of the received message through transmitted impulses, and means to discontinue the movement through impulse locally generated. (See cut.)

865,169. Signal. Charles R. Dowler, Denver, Colo., assignor to the Colorado Railway Signal Company, Lamar, Colo. Application filed September 12, 1906.

An electromagnet holds a semaphore at safety; when the circuit is broken, gravity throws the signal to danger.

865,211. Binding Post. Earl H. Rollinson, Albany, N. Y. Application filed November 12, 1906.

Has a washer with projecting ears on its periphery to hold the wire.

865,212. Spark Plug. George W. Sage, Eureka, Cal. Application filed May 25, 1906.

A contact and release igniter that has a rotating electrode and two rocking electrodes mounted in and insulated from the body and adapted to be successively engaged by the rotating electrode.

865,215. Art of Telephony. Daniel M. Therrell, Charleston, S. C. Application filed July 23, 1904.

Covers various methods of increasing the currents in transmitter and line circuits, as by producing resonance and attuning to the essential frequencies of the sound to be transmitted.

865,219. End Connection for Conductors on Field Magnets of Alternate-current Generators. Miles Walker, Hale, Altrincham, England, assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Application filed July 13, 1907.

Conductors project from the core slots; a number of ring conductors are mounted concentrically with the core having outwardly and laterally projecting lugs, the ring conductors being arranged in two spaced groups with the lugs of the two groups projecting toward each other, and longitudinally extending conducting bars are connected, respectively, to the said lugs and provided with outwardly projecting radial portions that connect to the ends of the core conductors. (See cut.)

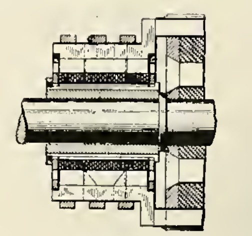
865,271. Long-burning Arc Lamp. Josef Rosemeyer, Lindenthal, Germany, and Gustave Dive, Bressoux, Belgium. Application filed March 7, 1905.

Provides a special construction whereby the globe is hermetically held to the casing.

865,285. Electric Smelting Apparatus. James C. Young, Jersey City, N. J. Application filed January 16, 1907.

Has a carbon forming one pole and a series of spaced receptacles mounted for rotation in a vertical plane forming the other pole, whereby an arc can be established or interrupted between said receptacles, one at a time, and the carbon.

865,291. Lightning Arrester. William J. Bell, Deerfield, Wis., assignor of one-third to Howell B. Fargo, Deerfield, Wis. Application filed September 25, 1906.



NO. 865,219.—END-CONNECTION FOR FIELD-MAGNET CONDUCTORS.

A non-conducting base has a socket into which fits a removable vertical carbon rod; a metallic cover fits over this rod, but is separated from it by a small air space; the line wire connects to the cover and the ground wire to the carbon rod.

865,305. Locking Device for Cross-wires. Adam Heim, Brownsville, Ind., assignor of one-half to Charles A. Rieman, Connersville, Ind. Application filed July 11, 1906.

A temporary wire clamp made of a single piece of resilient wire bent in the middle to fit over one of the cross wires and having its ends bent so as to lie along side of, and hook over, the other cross wire.

865,323. Trolley. Leslie S. Wilder, Northampton, Mass., assignor of one-half to Henry S. Wilder, Easthampton, Mass. Application filed January 10, 1906.

A trolley guard and finder has a stirrup pivoted at its ends near the trolley wheel axle and carrying divergent arms, the stirrup and arms being held out of contact with the trolley wire as long as the trolley wheel touches the latter.

865,330. Battery. Reuben S. Clymer and Thomas M. Woodhouse, Allentown, Pa.; said Woodhouse assignor to said Clymer. Application filed November 7, 1906.

Therapeutic battery has electrodes made of plates faced with absorbent material, the positive plate having a central projecting pin and the negative having a heating coil embedded in the absorbent material, both electrodes being connected to a source of current.

REISSUE.

12,691. Magnetic Composition and Method of Making the Same. Robert A. Hadfield, Sheffield, England. Application filed July 31, 1907. Original No. 745,829, dated December 1, 1903.

A magnetic material containing iron with an admixture of from one to five per cent of silicon, and treated by heat to at least between 700 degrees and 850 degrees C.; the treated material having magnetic permeability and electrical resistance increased and the hysteresis quality decreased to figures above and below respectively those which obtain with the purest iron commercially obtainable.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired September 9, 1907:

435,958. Method of Regulating Electrically Operated Mechanism. M. J. Wightman, Lynn, Mass.
435,967. Electric Lamp. Wm. D. Graves, Cleveland, Ohio.
435,982. Regulator for Dynamo-electric Machines. W. Stanley, Jr., Great Barrington, Mass.
435,983. Electrical Traction Apparatus. W. Stephens, Santa Rosa, Cal.
435,985. Rheostat. F. Thone, Oskaloosa, Iowa.
436,001. Electrolyte for Galvanic Batteries. F. K. Irving and F. M. Hill, Brooklyn, N. Y.
436,023. Electric Detonator or Primer. H. J. Smith, Pompton, N. J.
436,025. Electric Signal for Railways. G. A. Tower, Richmond, Va.
436,030. Electric Burglar or Automatic Fire Alarm. E. R. Wilder, Kansas City, Mo.
436,050. Secondary Battery Plate. T. P. Whittier, Saginaw, Mich.
436,087. Cut-out for Electrical Translating Devices. C. G. Perkins, Hartford, Conn.
436,107. Electric Switch. C. G. Perkins, Hartford, Conn.
436,113. Magneto Electric Machine. La Motte C. Atwood, St. Louis, Mo.
436,119. Electric Soldering Iron. C. E. Carpenter, Minneapolis, Minn.
436,125. Electric Lighting and Heating Apparatus for Electric Railways. M. W. Dewey, Syracuse, N. Y.
436,127. Electric Motor. T. A. Edison, Llewellyn Park, N. J.
436,154. Electric Signal for Railroads. F. C. Schroen, Baltimore, Md.
436,168. Electric Danger and Safety Signal for Railroads. E. M. Burt, Paris, Ill.
436,200. Electric Converter. G. Westinghouse, Jr., Pittsburg, Pa.
436,219. Electric Valve Controller. H. W. Deeds, Indianapolis, Ind.
436,275. Pulsating Current Battery System. C. J. Van Depoele, Lynn, Mass.
436,276. Adjustable Current Reciprocating Engine System. C. J. Van Depoele, Lynn, Mass.
436,277. Electric Power Hammer. C. J. Van Depoele, Lynn, Mass.
436,281. Portelectric. J. T. Williams, Mount Vernon, N. Y.
436,316. Electric Incandescent Lamp. J. S. Potter, Newton; D. J. Cartwright, Boston and B. B. Keyes, Chelsea, Mass.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, SEPTEMBER 21, 1907. No. 12

Power Plant of the Antwerp Railway.

By F. C. Perkins.

A modern power plant for electric-railway operation has recently been installed at Antwerp by the Compagnie Mutuelle des Tramways de Bruxelles, under the name of the Compagnie Generale des Tramways d'Anvers, with sub-stations, track equipment and rolling stock complete. The power station is located at Merxem, the engine and boiler rooms being located at the rear of the building and the offices in front.

The accompanying illustrations show the interior of the power house, with views of the switchboard, generators and engines, as well as the motor-generators and mechanical equipment. The sub-station and high-tension equipment are also shown, and there is a view of a car on one of the business streets of Antwerp.

In the boiler room a motor-driven coal-conveying apparatus has been provided for feeding the coal to the boilers, a large coal bunker being placed laterally to the boiler plant, permitting an easy storage of the fuel. There is a battery of six boilers, each having two fire boxes with a heating surface of 70 square meters, supplying steam from the boiler room to the engine at a pressure of 10.5 atmospheres. Provision has also been made for installing four boilers when desired. The boilers are provided with superheaters of the Büttner system, having a heating surface of 40 square meters, the superheat being from 350 to 360 degrees. A Green economizer installed has two sets of 198 tubes each, with scrapers operated by electric motors of three-horsepower capacity.

The boilers are supplied with water by triplex pumps having an output of 10 cubic meters per hour, driven by motors having a capacity of 5.5 horsepower. A duplex steam pump of the same output is also provided. These pumps are installed below the reservoir from which the water is fed. The chimney at this station is 50 meters high, with a diameter of 2.5 meters at the top. It stands on a cement foundation.

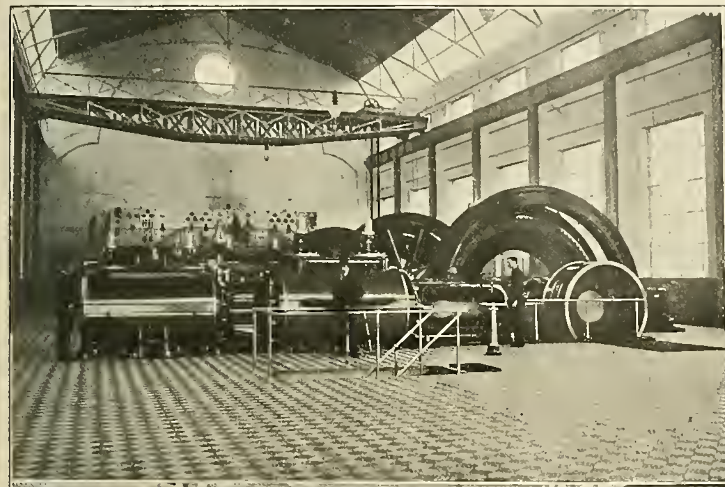
The engine and generator room is equipped with three units of 700 kilowatts each. The room measures 50 meters in length and 20 meters in width, space being provided for an additional unit of the same capacity. The engines installed at this station are of the Sulzer horizontal compound tandem condensing type having an output of 1,000 horsepower, but with an admission of 48 per cent. at the high-pressure cylinder, a maximum output of 1,650 horsepower may be obtained. The high-pressure cylinder has a diameter of 675 millimeters, and that of the low-pressure 1,100 millimeters, while the stroke of the piston is 1,150 millimeters. The speed of these engines, it is said, does not vary more than 1¼ per cent. with a change of load of 25 per cent., nor more than two per cent. with a variation of load of 50 per cent. The flywheel effect of the rotor of the alternator, which weighs 16.5 tons, is supplemented by a flywheel weighing 30 tons.

Three alternators of the three-phase type are in operation, each having a capacity of 700 kilowatts, and supplying current at 6,300 volts pressure with a frequency of 25 periods per second. The external diameter of the alternators is 4,320 millimeters, the width being 320 millimeters. The revolving field is of cast-steel, constructed in two parts, and weighs complete 16,500 kilograms, carrying 32 poles. It has an external diameter of 3,380 millimeters, the air-gap being 10 millimeters. The coils are wound with wire 69 square millimeters in section and are connected in series. The armature winding consists of 32 coils per phase, each occupying two grooves, there being 192 holes, or six per pole.

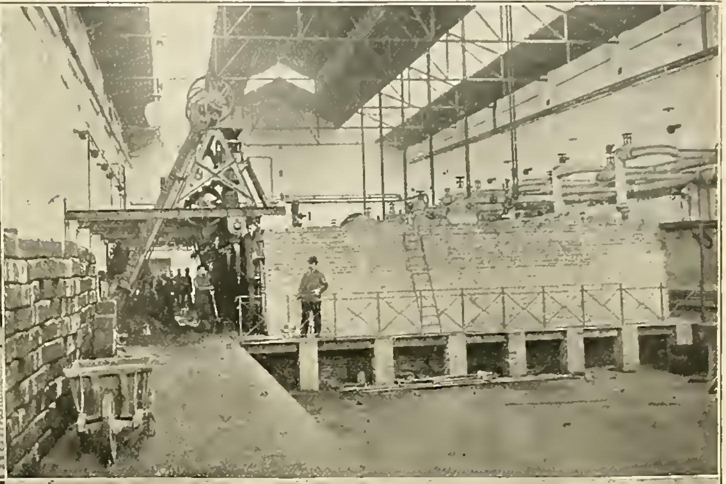
Excitation of the field coils is accomplished by a Tudor storage battery of 60 cells, having a capacity of 360 ampere-hours at a three-hour discharge rate. The battery is charged by means of a motor-generator set consisting of an induction motor operating at a pressure of 6,300 volts from the high-tension line and having a capacity of 112 horsepower, this motor being directly coupled to a direct-current generator supplying current at 120 volts. There is also installed in this power station a steam-driven exciter set consisting of a high-speed Carels engine directly coupled to a direct-current generator driven at a speed of 420 revolutions per minute, and supplying a current for field excitation at 120 volts. The extra 30 kilowatts provided is utilized for lighting the station as well as for operating auxiliary motors.

As shown in the accompanying illustrations, the switchboard is mounted on a gallery in the engine and generator room, the high-tension switching devices being installed underground. The switchboard is of white marble, having 14 stationary panels and a movable one. Three of the panels are equipped with measuring instruments, switches and controlling apparatus for the alternators; four panels are similarly equipped for the feeders, and two for the exciters and induction motors. There are also panels for the storage-battery and lighting circuits. The movable panel carries the synchronizing apparatus and is mounted at the extreme end of the switchboard gallery. The transformers and automatic oil switches are enclosed in a separate chamber to avoid danger to attendants.

The central power station is connected to the sub-stations by four feeder cables consisting of three conductors of 50 square millimeters each.

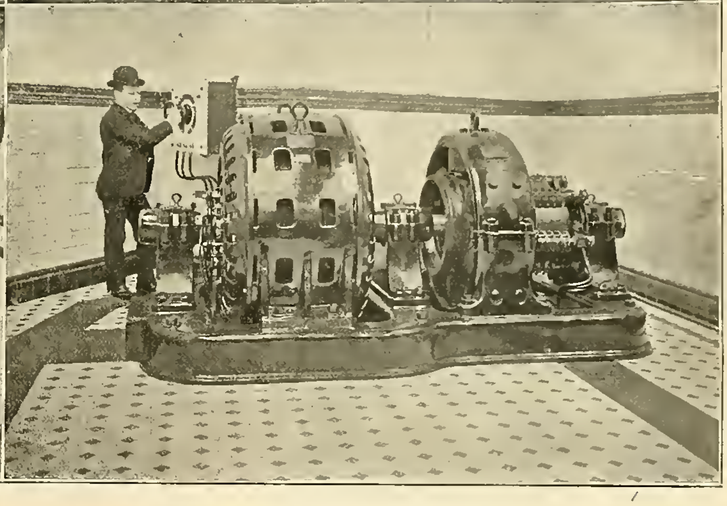


Engine and Generator Room in the Main Station.



A View in the Boiler Room.

Sub-station, showing Transformers and Rotary Converters.



One of the Motor-generator Sets.

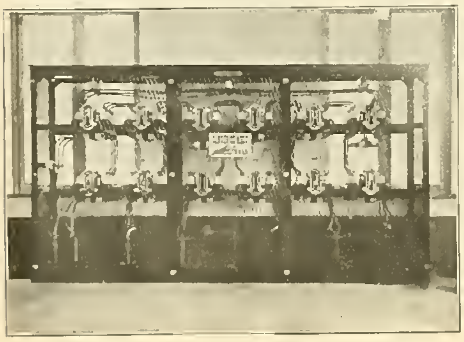
POWER PLANT OF THE ANTWERP ELECTRIC RAILWAY, IN BELGIUM.

The sub-stations are located at l'Avenue du Commerce and Rue Baudewyns, and are equipped with step-down transformers, reducing the three-phase current from 6,000 volts to 340 volts. Two Westinghouse rotary converters are also installed, each having a capacity of 550 kilowatts, and there is a storage battery having a capacity of 160 ampere-hours at a discharge rate of three hours, this accumulator installation consisting of 265 Tudor elements. For charging the storage battery a motor-generator group is used, consisting of an induction motor, operating from the step-down transformer circuit at a pressure of 340 volts, directly

STREET SCENE IN ANTWERP, BELGIUM.

coupled to a direct-current generator having a capacity of 85 kilowatts.

Each of the three monophase step-down transformers forming a group supplying current to the rotary converters has a capacity of 220 kilowatts. The primary winding of these transformers is designed for a pressure of 6,000 volts, receiving the current direct from the power-transmission line, while the secondary winding supplies a current to the rotary converters and asynchronous motors at a pressure of from 336 to 380 volts. The 550-kilowatt Westinghouse rotary converters are of the six-pole type, operating at a speed of 500 revolutions per minute and delivering direct current of 1,000 amperes at a pressure of 330 volts. The current from these rotary converters is utilized for



HIGH-TENSION APPARATUS OF ANTWERP RAILWAY EQUIPMENT.

operating the street railways of Antwerp, the storage-battery installations being provided as a reserve and for regulation.

The mechanical equipment of the Antwerp Railway power house was undertaken by the Ste. Carels de Gand and the electrical installation by the Ste. Electricite et Hydraulique of Charleroi, Belgium.

Great Western Power Extension.

Officials of the Great Western Power Company admit that the rights-of-way now being secured in Contra Costa County from Antioch to Richmond, Cal., by the way of Concord, are for their company and that the stringing of wires will not long be delayed. At Antioch the high-tension wires will cross the river on two high steel towers and will continue over a right-of-way more than 100 feet wide. This has given many the impression that the Gould interests, which are to a certain extent behind the power project, are planning to build an electric-railway feeder through Contra Costa County from Antioch to Richmond.

Transmission Plant of the Niagara, Lockport and Ontario Power Company.

From time to time the Western Electrician has kept its readers informed of the operations at Niagara Falls by the various power-generating and transmitting companies. Conspicuous among these companies is the Niagara, Lockport and Ontario Power Company, which on July 7, 1906, put in operation its first transmission lines, marking the inauguration of the first undertakings in the matter of distributing Niagara power over a large section of the country, and the beginning of an enterprise which is one of the most important of its kind in the world.

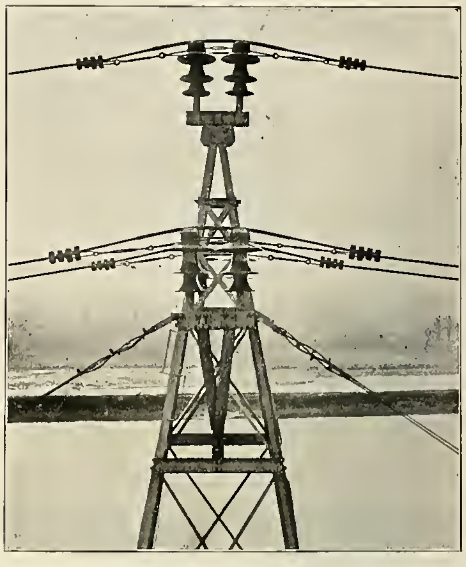
Several accounts of this company's plans and operations have appeared in the Western Electrician, the principal one being in the issue of February 24, 1906. Now that the plant is well in operation, a further account of the equipment and methods of operation will be of interest. The following details and illustrations are taken from the paper of Mr. Ralph D. Mershon, chief engineer of the company, read at the Niagara Falls convention of the American Institute of Electrical Engineers on July 26, 1907:

The plans realized at present and contemplated for the immediate future involve a maximum transmission distance of 160 miles. This distance puts the plant among the longest transmissions of the world. The prospective system is a comprehensive one for the delivery of power in the United States within an economic transmission radius of Niagara Falls, and especially for its delivery in the northern and western portions of the state of New York. The company expects within the next two years to be transmitting 60,000 horsepower, and its present right-of-way purchases are with reference to an ultimate transmission of 180,000 horsepower. The plans of the company as at present laid out contemplate the transmission of this power by means of main lines and branch lines therefrom; the contracts for power being, wherever possible, made for delivery of the power at the main-line voltage of 60,000 less line drop. Where, however, the business of a given territory will justify it, the company will install step-down transformer stations for the delivery of power at a lower voltage. Each of the main transmission circuits will be capable of receiving and transmitting 30,000 horsepower at 60,000 volts, and it is intended always to provide a sufficient number of spare main transmission lines to insure continuity of service on the main line.

The Niagara, Lockport and Ontario Power Company is a transmission company only; that is, it buys the power to be transmitted and has, therefore, no generating plant of its own. The power for the transmission is generated in the hydraulic power station of the Ontario Power Company, situated on the Canadian side of Niagara Falls. This plant has been described in the Western Electrician. The transmission lines of the Ontario Power Company extend from their transforming station to a point some six miles farther down the Niagara River, at which point the lines connect to circuits spanning the Niagara River. The Niagara, Lockport and Ontario Power Company takes delivery of the electric power at the international boundary line in the middle of the Niagara River.

The installation which the company has now in operation is for receiving 30,000 horsepower and delivering this amount, less the line loss. The main transmission consists of two lines in duplicate. From the Niagara River to Lockport, a distance of 16 miles, there are two lines on the company's private right-of-way, each capable of transmitting 30,000 horsepower. From Lockport to Mortimer, a distance of 57 miles, there is a line on the company's private right-of-way having a capacity of 20,000 horsepower. From Mortimer east to Syracuse, a distance of 81 miles, there is a line on the company's right-of-way having a capacity of 10,000 horsepower. From Lockport to a point about 11 miles east and thence south on the company's private right-of-way to the West Shore, thence on the West Shore to Pittsford, is a line having a capacity of 20,000 horsepower. From Pittsford on the West Shore right-of-way east to Syracuse is a line having a capacity of 10,000 horsepower. From Lockport south to a point south of Buffalo there are two transmission lines on the private right-of-way of the company, each having a capacity of 30,000 horsepower. These two lines south are tapped into the two lines coming from the Niagara River to Lockport, and constitute, therefore, at present, a branch line; but they will be eventually extended clear through to the Niagara River, and it is in anticipation of this extension that they are constructed with the full capacity of 30,000 horsepower. As will be seen from the above, the distance from the Niagara River to Syracuse is 154 miles. In addition to this the transmission from the transforming station of the Ontario Power Company to the Niagara River has a length of about six miles, making, as previously mentioned, a maximum transmission of 160 miles.

The power is brought across the Niagara River by means of aerial cables spanning the river, and delivery of the power is taken by the transmission company at the international boundary line. The cables are brought across the river in three spans, one span from steel cantilevers at the top of the cliff on the Canadian side to steel towers at the water's edge on the Canadian side, another span from the water-edge towers on the Canadian side to the corresponding towers on the American side,

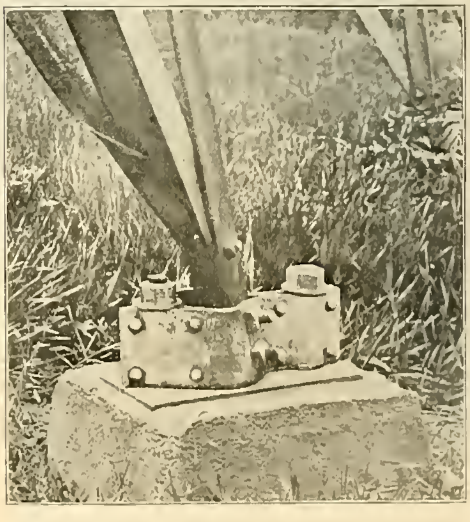


TOP OF DOUBLE-GUYED STEEL TOWER.

and a third span from the steel water-edge towers on the American side to the steel cantilevers at the top of the cliff on the American side. The use of cantilevers is necessitated mainly by reason of the steep angle at which the cable descends from the top of the cliff. Their use also makes possible the required clearance between the cable and the slope of the gorge, a point of special importance on the American side in view of the fact that one of the branch lines of the New York Central Railroad is on the American slope of the gorge. The steep slope of the cable at the cantilevers would make it bear upon the upper petticoat of the insulator supporting it, if the cable were attached to the top of the insulator in the usual way.

The steel cantilevers and the river-edge towers are all designed to withstand the most extreme conditions of sleet and wind that will probably ever exist. The requisite mechanical strength of the insulation at the points where the cables are attached to the steel structures is obtained by using a sufficient number of line insulators, and the proper distribution among these insulators of the forces which will come upon them is effected by means of malleable cast-iron caps cemented to the tops of the insulators, and to which the cables are fastened.

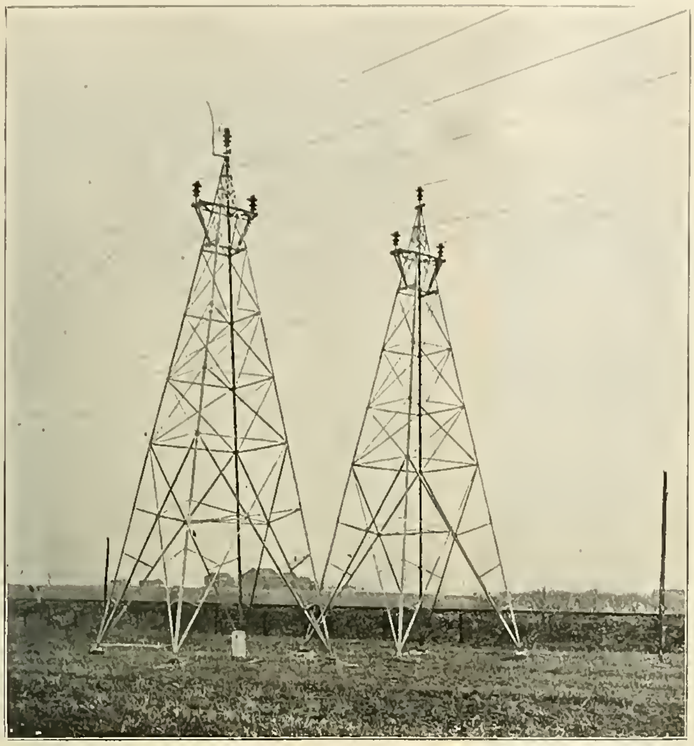
With the exception of that portion of the main line on the West Shore between Churchville and Syracuse, the main-line structures are all steel towers and the standard line-span is 550 feet. On some portions of the transmission line, however, much longer spans are used, the longest at present installed being 1,253 feet. In some cases these long spans had to be provided with towers heavier than



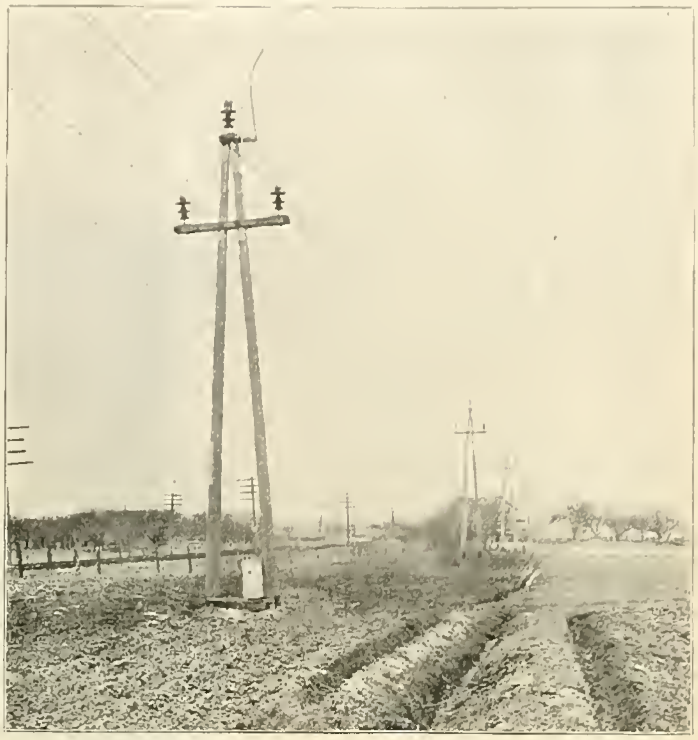
METHOD OF FASTENING TOWER TO FOUNDATION.

the standard, but in some cases it was possible to put them up with little, if any, modification of the standard tower construction. For a number of reasons, the principal one being lack of the requisite space, it was necessary to use on the West Shore right-of-way between Churchville and Syracuse wooden construction of special design, the standard span being 220 feet. In every case on the 60,000-volt lines, each line of towers or wooden structures carries only one three-phase circuit. The main-line conductors installed so far are all of aluminum cable, except on a portion of the line between Mortimer and Syracuse, where, because of the long spans employed, it is preferable to use copper.

The first of the steel towers installed were of the tripod type, made of lap-welded pipe; but the later towers, and those which in the near future will be installed, are of structural shapes and galvanized. The later towers are interchangeable; that is, the guyed and unguyed towers are exactly similar except for the guys and double insulators of the former. Contrary to the practice which has heretofore been followed in the matter of steel line towers, the towers of this transmission line are mounted on foundations of reinforced concrete. These foundations are designed to utilize the weight of the earth around them in resisting uplift. The towers and their foundations are capable of withstanding transverse forces which will be brought upon them when the line cables are covered with 0.5 inch of ice all around them and the wind blowing transverse to the line at a velocity of 75 miles an hour. The towers have the same strength in all directions; that is, they are capable of withstanding the same forces in the direction of the line that they are capable of withstanding transverse to the line; but to meet the contingency, not likely to occur, of all three cables breaking at once, in which case the full tension of all the cables might be brought upon the towers, there are at intervals along the line certain towers guyed both ways in the direction of the transmission line and having double fixtures.



Line-structure Lightning Arrester on Steel Tower.



A-frame Construction, showing Line-structure Lightning Arrester.

NIAGARA, LOCKPORT AND ONTARIO POWER COMPANY.

LOCKPORT SUB-STATION, SHOWING 11,000-VOLT OUTDOOR LIGHTNING ARRESTER.

As stated above, on the West Shore right-of-way it was necessary to use wooden line structures. The type of construction employed is that which has been designated by the company as "A-frame construction." By adopting this type of construction, in which each structure consists of two poles instead of one, it is possible to use twice the length of span that would be used in ordinary wooden pole construction, and employ therefore one-half the number of insulators. On some portions of the West Shore right-of-way it was necessary to use steel construction, and in such places there were installed galvanized lattice steel poles.

In a number of places on the main line, both on the West Shore and on the private right-of-way, it is necessary to cross the Montezuma marsh. Where this marsh was crossed with steel tower construction, the concrete foundations for the steel towers were built by first excavating the swamp through the soft mud until the soft marl, forming the substratum of the swamp, was reached. On the marl was laid a platform of two layers of corduroy, and on this platform was built the concrete foundations, the weight of which was made sufficient to take care of any uplift which will come upon the towers.

In some of the towers and A-frames there is a horn attached to a cap on the top of the insulator and another horn alongside of it fastened to the structure and extending some distance above the insulator. This comprises a combined line-structure lightning arrester, or spark-gap, and lightning rod. It has been decided to make a careful trial of this method of protection of the line before resorting to a grounded cable, partly because of the great expense of the grounded cable and partly because there is no reason to think, so far, that it will necessarily afford complete protection in every case. For the present these line-structure lightning arresters will be installed only on the top cable in view of the fact that during the last lightning season, in the course of which a number of insulators were broken by lightning, more than three-fourths of the insulators so broken were top insulators.

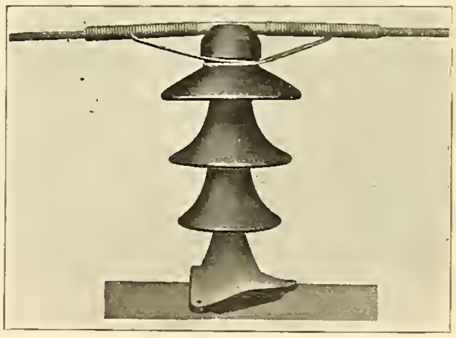
The insulator used on all the main-line construction is one especially designed by Mr. Mershon for this plant. It has probably the greatest factor of safety as regards flashing, etc., of any insulator in practical use today, and is considerably larger and heavier than any insulator of which corresponding use has heretofore been made. It consists of three shells nesting in each other and cemeted together by means of neat Portland cement, the whole insulator being cemented in a similar manner to a steel pin before attachment to the tower. The total height of it from the edge of the lower petticoat to the top of the head is 19 inches. The diameter of the upper petticoat is 14.5 inches. The insulator used on some of the branch lines is smaller and less expensive than that for the main line, partly because the branch lines receive in general a somewhat lower voltage than the main line and partly because the lines, carrying the small amounts of power they do, are not considered to be entitled to the same insurance as the main line.

Each branch line has in series with it, at the point where it is tapped off the main line, 60,000-volt outdoor fuses to cut out the line in case of trouble upon it. The fuses consist of lengths of thin copper wire 16 feet long, run through an ordinary small rubber bathroom hose and laid in clips on top of a wooden bar, supported at each end and the center by line insulators mounted on poles. The fuses are parallel to each other, in the same horizontal plane, and the distance from center to center is about 25 feet. These fuses have so far proved very satisfactory, but will probably in time be replaced with fuses of the expulsion type.

There are only three sizes of cables used on the main transmission line, designated by the company as 3/3, 2/3 and 1/3, respectively. The 3/3 cable is aluminum cable, consisting of 19 strands, and having a total area of 642,800 circular mils, being equivalent to 400,000 circular mils copper. The areas of cross-section of the other cables are, respectively, 2/3 and 1/3 that of the large one.

In ordinary straightaway work the cables lie in the top groove of the insulator, and the pull of the cable is taken care of by means of two aluminum wire ties around the neck of the insulator. One of these ties extends each way along the cable. The tie itself consists of a single loop around the neck of the insulator, the two ends of the loop being twisted around the line cable. The result is that the cable is not really fastened to the insulator at all, but simply lies in the top groove. The ties do not, therefore, perform any function, except when there is a pull on the cable tending to slide it in the direction of its length. The advantage of such a tie is twofold. First, the full strength of the tie wire is developed, which is not the case if a tie is twisted or "pig-tailed," since, in such case, the tendency is for the tie to cut itself in two at the twist; second, the tie does not damage the soft aluminum cable, as would be the case with most of the other ties usually employed.

In other than straightaway work, and where it is desirable that the method of fastening to the insulator shall be such as will withstand a pull equal to the full strength of the cable, in case the cable should break, the tie mentioned above is not used, but instead there is employed a cable-clamp and a yoke extending each way on the cable.



60,000-VOLT MAIN-LINE INSULATOR WITH TIE AND CABLE PROTECTION.

In every case the cable near the insulator is protected from possible arcs, so that in the event of an arc there will be a chance for the circuit-breaker at the generating station to open before the cable shall have been burned off. This protection is accomplished in the top groove of the insulator by means of sheet aluminum wrapped around the cable at this point to a thickness of one-eighth inch, and is accomplished on each side of the head of the insulator to a distance of 12 inches from the head partly by the turns of the tie-wire mentioned above and partly by an additional serving of tie-wire. Where, in the case of the use of cable clamps, no tie-wire is used, its absence is made up for by additional serving.

At intervals along the line there are provided disconnecting switches for sectioning the line to facilitate testing out in case of trouble or cutting out any portion of the line which is damaged. There are also provided at certain points in connection with these disconnecting switches cross-connecting switches, enabling the interconnection of different portions of the two lines.

On a considerable portion of the company's right-of-way is a wagon road for use in patrolling the line and delivering materials for construction or repair. At certain points along the line there are patrol houses for the storage of material, for taking care of teams and for the comfortable housing of the patrolmen. Each house has in it sleeping room, kitchen and sitting room. On all of the transmission lines also the company has a private telephone line on a separate set of wooden poles. Taps from this line are brought into each of the transmission houses, and in addition to this the line patrolmen have portable telephones which can be connected to the telephone line at any point.

Most of the contracts which the company has for the supply of power cover the delivery of the same at the main-line voltage, so that, so far, the company has installed only three sub-stations, two of them of considerable size at Lockport and Gardenville, respectively, and one at Baldwinsville, a very small and comparatively inexpensive one. The stations at Lockport and Gardenville have each a normal capacity of 3,000 kilowatts, not including the spare apparatus. They are so designed that their capacity can be indefinitely increased. The Baldwinsville station has a capacity of 750 kilowatts.

The 60,000-volt bus-bars at the Lockport and Gardenville sub-stations are outdoors; in other words, these bus-bars have been treated exactly as if they were part of the transmission line and located out of doors in a manner, so far as insulation is concerned, similar to the transmission-line cables. In connection with them are disconnecting switches for making various combinations of the apparatus connected to them. Of course the disconnecting switches are not intended to break the working current. When it is necessary to break the circuit under load, it will be accomplished by means of the 60,000-volt electrically operated oil switches installed in the station which, in the case of the Lockport sub-station, serve also for the control of the two lines to the Buffalo district.

Another feature out of the ordinary in connection with this station is the lightning-arrester equipment. This equipment is also out of doors and consists of a number of horn-type lightning arresters mounted on wooden poles in much the same manner as such arresters are ordinarily mounted. The installation differs, however, from the ordinary lightning-arrester installation of this kind in that, instead of there being only one pair of horns for each line conductor there are three such pairs. One pair is set for a comparatively low-striking electromotive force and has in series with it a high resistance; the next pair is set for a higher striking electromotive force and has in series with it a lower resistance; a third pair is set for very high-striking electromotive force and has in series with it a fuse.

The theory on which these arresters are installed is that for ordinary slight static disturbances in the line the arrester having the lower striking electromotive force will discharge, and since it has in series with it a comparatively high resistance the resultant disturbance to the system due to the generated current which follows the discharge will be comparatively slight. A more severe static disturbance (whether due to lightning or to any other source) will cause both the arrester having the lowest gap and the arrester having the next higher gap to discharge simultaneously, thus affording two discharge paths to earth, the combined resistance and inductance of which is considerably lower than that of the first path. This will mean a somewhat more severe disturbing effect on the system due to the generated current which follows.

There will be installed shortly on the company's system two switching stations, one at Mortimer and one at Syracuse. The one at Syracuse will be for taking care of the two incoming 10,000-horsepower lines and the outgoing lines to the consumers in Syracuse. The one at Mortimer will be for taking care of the two incoming 20,000-horsepower lines and five outgoing lines, two of them being a line in duplicate to Rochester; two of them the line in duplicate to Syracuse, and one the Avon branch line, supplying several installations, among them the station of the Erie Railroad Company, operating its trolley line between Rochester and Avon. Both these switching stations will be equipped with the 60,000-volt electrically operated oil switches, reverse relays and other apparatus necessary for properly manipulating the circuits which they control.

The transmission plant has been built in accordance with the design of Mr. Mershon, acting as chief engineer of the Niagara, Lockport and Ontario Power Company, and has been constructed under his supervision and that of his assistant in the work, Mr. H. L. St. George. The construction work has been done by the Iroquois Construction Company of Buffalo, headed by General Francis V. Greene, president, the construction work itself being directed by Mr. F. B. H. Paine, vice-president and chief engineer of the construction company, assisted by Mr. Walter S. Skinner and Mr. S. Piek.

Battery-propelled Cars on Standard-gauge Railways.

By Dr. Alfred Gradenwitz.

An interesting departure in the use of electricity for the operation of standard-gauge railways has been made recently on three suburban lines starting from Mayence, Germany, by running individual battery-propelled motor cars in the intervals between the ordinary trains. These cars are intended

MOTORMAN'S CABIN IN BATTERY-PROPELLED CAR.

mainly for dealing with the traffic of business men, factory employes, workmen and school children from the suburbs of Mayence to the city itself and vice versa, as well as for effecting connections to the stations served by express trains. The three suburban roads using these cars are the Mayence-Oppenheim, 20.41 kilometers; the Mayence-Ingelheim, 18.08 kilometers, and the Mayence-Rüsselsheim, 12.22 kilometers.

The carriages in question have been converted from old three-axle third-class cars of the Berlin Metropolitan Railway, the side corridors being done away with, making the seats continuous throughout the width of the car. The braking cabins have been extended to form the driver's cabin, comprising the controllers, measuring instruments and brake. An end compartment of the car can be used if desired as a second-class compartment. The cars are designed for briquette heating and electric lighting. Each compartment has an electric alarm for signaling the driver which is actuated in the usual manner by the emergency brake line from the interior of the car.

The accumulator battery, supplied by the Akkumulatoren-Fabrik, Ltd., comprises 180 cells installed below the hinged seats in boxes of seven to eight cells each. One of the accompanying illustrations is a view of the car with the doors open, showing the hinged seats which contain the batteries.

Each motor car is equipped with two 25-horsepower series motors driving the two end axles through simple toothed wheel gearing. These motors are designed for giving the car a maximum speed of 50 kilometers an hour on level track. In starting they are connected up in series and are changed to parallel after reaching a running speed of about 25 kilometers an hour. The working weight of each car is about 33 tons, of which about 10 tons represents the battery and six tons the motor equipment.

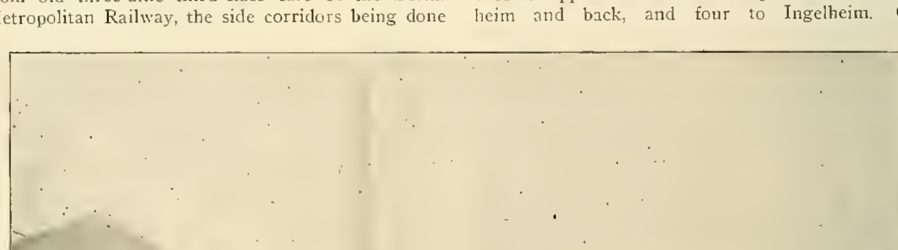
The charging station for the batteries has been installed at the Mayence railway station, the motor-car service comprising for the time being the three suburban lines mentioned. The permanent generating plant for charging, to be operated by a 100-horsepower Diesel engine, is being built. In the meantime the charging current is derived from the cables of the municipal electricity works of the city of Mayence, and as this supplies only alternating current, a special converter had to be provided. This is designed for an output of only 70 horsepower, an existing machine set having to be used owing to the hastened conversion of the cars.

The current derived from the municipal electric works is paid for at the rate of 15 pfennige per kilowatt-hour, while the Diesel engine plant is expected to produce the current at about six pfennige. It may be said that the city of Mayence, on account of the contemplated erection of a private charging plant, could not be induced to grant special rates, as the converter plant will have to be kept in the future only as reserve.

The recharging of the batteries is effected after completing a trip, the time table being arranged with a view to leaving sufficient time for recharging between each two runs. In the case of the Mayence-Oppenheim-Mayence and Mayence-Ingelheim-Mayence trips, 40 to 50 minutes are required, and on the Mayence-Rüsselsheim-Mayence run, 30 to 35 minutes. In charging the doors are opened and the seats turned up as shown.

The cost of conversion was about 30,000 marks for each car, of which the battery cost 10,000 marks and the motor equipment 14,000.

These cars, since their inauguration on February 18th, have been making four runs daily from Mayence to Oppenheim and back; eight runs to Rüsselsheim and back, and four to Ingelheim. Only three cars are used in ordinary operation, the fourth car being kept as reserve in permanent working order, while the fifth is used only as a repair car.



BATTERY-PROPELLED CAR WITH DOORS OPEN SHOWING BATTERY COMPARTMENTS UNDER THE SEATS.

The consumption of energy of each car is about 18 to 20 watt-hours per ton-kilometer. The time table has been included in the official railway guide, the time on the Mayence-Oppenheim line having been recently reduced by seven minutes.

Manufacture of Electrolytic Disinfectant at Poplar, London.

[From the London correspondent of the Western Electrician.]

The plant installed by the Poplar Borough Council, in which the Hermite process has been adopted for the manufacture and supply of electrolytic disinfectant for all purposes throughout the borough, has now been working 12 months and is reported by Dr. Alexander, the medical officer of health to the council, who introduced the idea, to be a complete success. This officer is to be congratulated for his persistence in face of great opposition to

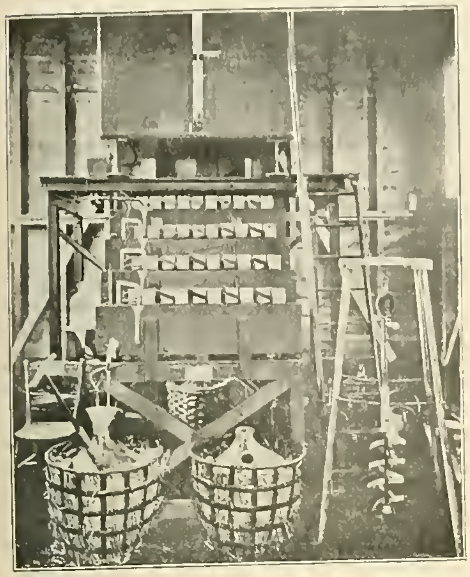


FIG. 1. ELECTROLYZER USED IN MANUFACTURE OF ELECTROLYTIC DISINFECTANT.

the scheme. He expresses himself as conscious that the step initiated has proved itself overwhelmingly satisfactory from every point of view, particularly that of the public health of the district.

A similar plant is in operation at Rolleville, near Havre, France, and a deputation from Poplar visited this installation. What it saw there assured the members of the ultimate success of the scheme in Poplar. It had been suggested that the health of the borough would suffer if such a disinfectant were introduced, but this, happily, has not proved true, for the annual notification rate per thousand living in the borough was 6.2 against the figure of 7.5 for London for the year 1906.

The system adopted at Poplar is to mix a certain quantity of fluid in an elevated tank, and then to allow this fluid to flow through four double troughs, or cells, placed one above the other, so that the liquid descends continuously by gravity. Each trough is divided laterally by a partition, and in each of the two divisions five distinct "elements" (consisting of one positive and two negative plates) are suspended. (See Fig. 1.) The positive plates are of thin platinum wire wound upon slate slabs, and the negative plates are of zinc. There are thus four troughs, each containing 10 "elements," or 40 cells in all.

The liquid enters through the funnel, visible toward the top left-hand side of Fig. 1, passes along the front division of the top trough, back through the division behind, over a weir, and into a subdivision, from which it is drawn off by the bent glass tube discharging into the second funnel; it passes along the front division, back through the division behind, over the weir, into the pocket of the second trough, and so on, to the final bent tube, which discharges it into a carboy.

A bottle arranged at the side of the tier of cells (as shown) supplies the sodium-hydroxide used as a preservative, which flows, drop by drop, into the carboy as it is filling, and serves to neutralize free hypochlorous acid. As the liquid passes through the troughs it is subjected to the action of a regulated current of 15 to 17 amperes at 230 to 250 volts, being 5.7 to 6.2 volts per cell. During the run the liquid in the carboy is thoroughly stirred by means of an ebonite rod, shown in the illustration, and provided with rubber flaps.

The objects aimed at to make the working of the apparatus and the manufacture of the fluid become simple and automatic were as follows:

(1) To see at a glance whether the apparatus is working properly. This is accomplished by a gauge glass in front of the large tank and another gauge glass on the little supply tank (Fig. 1), the first to show the quantity of salt liquid capable of being acted upon, and the second to show if the liquid is running properly into and out of the small supply tank, as the chloride of magnesium contains impurities which are likely to block up the valve of the small cistern and the taps leading to and from the same. A thermometer is kept in the small supply tank to note the temperature of the salt liquid, and another thermometer is placed at the outgo of the last electrolyzer; the difference of the temperature gives the rise in temperature due to the electrolysis, and which is found, when the apparatus is working satisfactorily, to be under 30° F. The small tank is necessary to keep a constant flow of the fluid into the electrolyzers. When first the apparatus was erected the fluid used to become unduly hot on account of the flow slowing down through diminution of the head of water in the large tank. The tank had ultimately to be raised onto girders and a small supply tank fixed at a lower level.

(2) The liquid to be electrolyzed in the large tank had to be stirred from time to time to keep the mixture of an equal gravity throughout, more especially as for obvious reasons a certain quantity of a solution of sodium hydroxide is added. To keep the liquid stirred a large, broad drilled plate of galvanized iron is used, one end of which acts as the fulcrum when the other is lifted up by means of a chain leading over pulleys to the ground, so that the attendant has only now and then to pull the chain to lift the plate up and down instead of running up and down the ladder and stirring the liquid with a rod.

(3) It is necessary to govern the electric current, which is taken direct from the mains, on account of the density of the salt mixture to be acted upon varying from time to time, owing to the temperature changes and consequent changes in conductivity. This difficulty is overcome by the current regulator, Fig. 2.

(4) To prevent shocks and waste of fluid while changing the carboys, a special glass tap has been made. (Fig. 1.)

(5) To prevent loss of available chlorine the solution of sodium hydroxide drips into a specially blown carboy at the same time as the fluid is running into it, and the two fluids are mixed with a stirrer inserted through an aperture in the neck of the carboy, and when the carboy is full a final mixing for about two minutes is given by means of a stirrer fixed to gear wheels. This apparatus is shown at the right in Fig. 1. Before the ebonite stirrers with rubber flaps were made, full carboys and half carboys had to be shaken rapidly for about 10 minutes, and this not always with the best results as to bringing about the desired stability, for when sodium hydroxide is added the precipitate falls to the bottom, and it is necessary to render the solution milky throughout.

(6) So far as oxychlorides are concerned, the apparatus in 10 months had only been taken to pieces and cleaned twice. Every day, after working, the electrolyzers are emptied by means of the mud holes by removing the rubber plugs, and the fluid which is run out is kept to recharge the electrolyzers. These latter, after being emptied, are washed out by means of a hose, and then, until the next working, are kept filled with water, which softens any deposit formed upon the electrodes, and before starting work the electrolyzers are emptied and washed out again, a matter which takes up a few minutes every day before and after each working.

During the 12 months of operation (the apparatus was installed at the beginning of February, 1906) some 17,000 gallons of fluid have been manufactured of a strength between 4.0 and 4.5 grammes of available chlorine per liter — 1,000. The fluid has been issued to the public in pint bottles, while for watering the roads, etc., has been furnished with nearly 10,000 gallons at one penny per gallon. There have been required 2,543 units of electrical energy, supplied by the municipal power station at 1½d. per unit; four tons of salt have been used at 24s. per ton; two tons of chloride of magnesium at £3 17s. 6d. per ton; caustic soda costing £4 8d.; water, together with that used for washing out the electrolyzers and for other purposes, £2 15s. 8d., including meter rent.

The cost of the plant, which is indestructible with the exception of the 40 zinc electrodes, which may occasionally have to be replaced at a cost of 7s. 6d. each after some years of wear, was £583 9s. 2d. The operating expenses and cost of manufacturing from February, 1906, to February, 1907, was £635 13s. 11d. Deducting receipts from the works department amounting to £37 19s. 8d., left the total expense for the year at £597 14s. 3d. This figure compares with £664 2s. 9d.; £771 6s. 11d. and £862 5s. 7d., respectively, for the years 1903, 1904 and 1905, when the ordinary carbolic disinfectants were supplied.

Bearing upon the stability of the fluid, it is stated that experiments carried out have shown that samples of fluid prepared a year ago showed a fall of chlorine not exceeding 0.5 gramme per liter (about 10 per cent.) in the first few months, since which time the chlorine has remained quite constant. Fluids prepared in October, 1906, by the improved method remained absolutely constant up to March, 1907.

On the evening of October 1st the Street Railway Association of the State of New York and the Empire State Gas and Electric Association will hold a joint meeting at Madison Square Garden, New York. The annual meeting of the Gas and Electric Association will be held at the same place on October 2d.

Three-wire Dynamos versus Motor Balancers for Three-wire Circuits.

A paper by B. Frankenfield, engineer of the Allis-Chalmers Company at the Cincinnati works, read before the recent convention of the National Electric Light Association at Washington, summed up in a concise statement the many advantages claimed for the motor balancer over the three-wire generator. The balancer system was devised for supplying a three-wire load from a station using two-wire dynamos. It is said that a station designed on this plan has the advantage in cost and simplicity over a station using three-wire dynamos. The inherent regulation can be made extremely good in shunt wound balancers and practically perfect in compound balancers, while perfect hand regulation can always be obtained with any balancer of the motor-generator type.

A comparison of the three-wire dynamo with the two-wire dynamo and balancer may be summarized as follows:

The three-wire dynamo cannot be regulated for equal voltage; the balancer can. The balancer can also be made to regulate inherently for equal voltage, which is not true of the three-wire dynamo. The balancer is capable of carrying a neutral overload with good regulation, while the three-wire dynamo can carry it, but only with poor regulation.

The three-wire dynamo represents extreme specialization in design. This means long delivery and also delay when it becomes necessary to make repairs. The two-wire plant with a balancer consists of standard apparatus throughout. This means quick delivery and quick repairs. The three-wire dynamo has complicated connections repeated for each unit in the plant, making it difficult to locate trouble, while the connections of a two-wire plant using a balancer are simple and easy to understand, and any trouble is easily located. The three-wire dynamo requires expensive switchboard connections and heavy cables. The two-wire plant with balancer does not.

A plant using three-wire dynamos occupies more floor space than a two-wire plant with a balancer. A two-wire dynamo will now operate successfully in parallel with a three-wire dynamo without remodeling. Any number of two-wire dynamos can be added to a two-wire plant with balancer without making a single change in their construction.

There is danger of a violent short-circuit when a three-wire dynamo is brought up to speed and paralleled. This same danger does not exist in equalizing a two-wire dynamo or in equalizing a balancer. Two double-pole circuit-breakers are required by a three-wire dynamo, while the two-wire

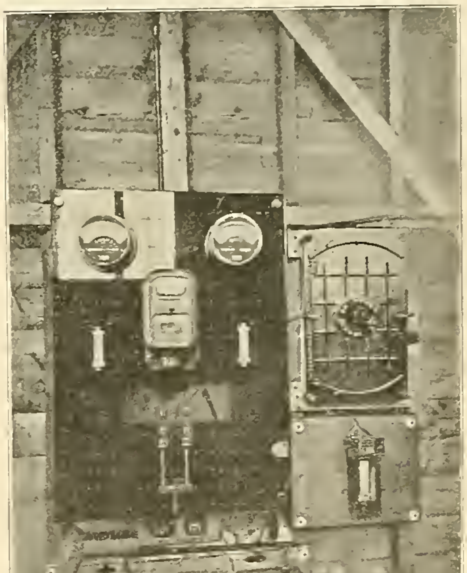

FIG. 2. SWITCHBOARD AND CURRENT REGULATOR IN POPLAR DISINFECTANT PLANT.

dynamo requires but one, and the balancer requires but one. The three-wire dynamo plant requires two equalizers. The two-wire plant requires one, and, where compound balancers are operated in multiple, the equalizer outlay for this portion of the plant is insignificant.

The three-wire dynamo plant requires two ammeters for each machine. The two-wire plant with balancer requires but one ammeter for each machine and one for the balancer. The balancer can be located at a distance from the station. The three-wire dynamo must reach out from the station to the distant point. Lastly, it should be emphasized that the balancer is not limited to small isolated-plant service, but is capable of heavier duty.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

DATES AHEAD.

Colorado Light, Power and Railway Association (annual meeting), Savoy Hotel, Denver, Colo., September 18th, 19th and 20th.

Central Electric Railway Association (regular meeting), Columbus, Ohio, September 26th.

New York Electrical Show, Madison Square Garden, September 30th to October 9th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

AFTER A LIFE of twenty years, for it was born in the same year as the Western Electrician, 1887, the Chicago Edison Company has passed out of existence, having been combined with the Commonwealth Electric Company on September 16, 1907, to form the Commonwealth Edison Company, which is now conducting the central-station business of Chicago, and will undoubtedly sustain this relation to the community for many years to come. While the change is one of name rather than of policy or administration, for the two companies have been owned by the same interests and closely connected for several years, yet the event is of much interest, for the Chicago Edison Company has veritably passed away, and during its span of life, a score of years merely, the central-station business of supplying electric light and power has developed to an amazing extent, and the Chicago Edison Company has been widely recognized as second to none for progressiveness in adopting new ideas, for enterprise in securing new business and for extending the sphere of central-station influence, for the excellence of its administrative methods, for broad-minded liberality in dealing with consumer and the public and for practical success as a business proposition. Mr. Samuel Insull has been president of the Chicago Edison Company for fourteen years and of the Commonwealth Electric Company for a somewhat shorter period, and it is but just to say that to him and to the staff of able assistants by which he is surrounded the conspicuous success of these companies is due.

Organized in 1887 to supply electric light and power, the Chicago Edison Company supplied the central portion of the city. It was a licensee company of the Edison Electric Light Company, and its first power house, abandoned a number of years ago as a generating station, was at 139 Adams Street, now the site of the Edison office building, which, although comparatively new, is already too small for the many departments of a great central-station service, several of which are sheltered elsewhere. In 1893 the company absorbed its principal competitor, the Chicago Arc Light and Power Company, and soon thereafter built the Harrison Street plant, famous at the time, but now completely overshadowed by the gigantic Fisk Street station of the Commonwealth company. On March 31, 1907, the company operated three generating stations and 22 sub-stations, and its connected load was equivalent to 1,924,886 16-candlepower lamps. Its outstanding capital stock was $13,614,115 and its bond issue $5,500,000. For 18 years the company had paid eight per cent. dividends.

In 1897 and 1898 various electric-lighting concerns doing business outside of the central district of the city were purchased by interests friendly to the Chicago Edison Company, and in May, 1898, these properties were consolidated in the Commonwealth Electric Company, thereby placing practically the entire central-station business of Chicago under one management. This company's franchise, granted by the City Council, runs for 50 years and covers every part of the city of Chicago. The company operated two generating stations and 10 sub-stations. One of the former is the great Fisk Street plant, the first central station in this country and probably in the world to install steam turbines and having a present maximum capacity of 110,000 horsepower and planned for twice that capacity ultimately. On March 31, 1907, this company's connected load (exclusive of the large amount of power supplied to street railways) was the equivalent of 1,313,852 16-candlepower lamps. The capital stock of the company was $10,000,000 and its bond issue $8,500,000.

Thus the consolidated company will possess five generating stations and 32 sub-stations. Its connected load (exclusive of railway power business) is more than the equivalent of 3,238,738 16-candlepower lamps. Its capital stock is $30,000,000. It is this great electric-light and power business, created within twenty years, which the new Commonwealth Edison Company is called upon to administer. We wish it all success, not merely because it is an important electrical enterprise, but because, in a wider outlook, its management, broad-minded and public-spirited as past experience leads one to expect, means so much, in this day and age, in the development and improvement of the great city with which its fortunes are bound up.

WHILE the electrical industry in this country is in a fairly satisfactory condition, barring some uncertainty owing to the price of copper, the state of affairs in England is not reassuring. The London correspondent of the Western Electrician takes a rather gloomy view of the situation, as will be seen by the following, written on September 6th:

"The close of the parliamentary session of 1907 causes one to reflect upon the very unsatisfactory result, from the point of view of the electrical industry over here. No new bills have been passed which will result in any considerable works being constructed, so that the manufacturing industry will not benefit to any extent worth mentioning. The rejection of the London County Council electric power bill has been a direct loss of several million pounds in orders for electrical machinery, and what this would mean at the present juncture in reviving the industry does not need much thought. None of the other private bills has anything more than a local interest, and all around it is generally conceded that the session of 1907 has been the dullest on record.

"No crumb of comfort has been offered, even, in an attempt at revising the general legislation relating to the electrical industry. As I have previously pointed out, we are now working under electric-lighting acts 25 years old and tramway acts still more ancient. In fact, the latter were passed before the days of mechanical tramways in any form. Year after year passes, and although the government is urged to make revisions to bring this class of legislation up to date, no movement is made. Meanwhile the stagnation in the industry becomes more acute; yet it seems hopeless to expect any reform."

This is rather depressing. But may it not be that the electrical men of England rely rather too much on government and not enough on their own initiative? Perhaps a Co-operative Electrical Development Association for Great Britain would be a good thing. Legislative reforms are undoubtedly badly needed; but it would be a pretty shrewd guess that even under existing powers a great deal of additional electrical apparatus could be put out by an intelligent, persistent campaign of solicitation, advertising and education addressed to the general public. In this country it is felt that only a beginning has been made in the matter of supplying the nation's electrical needs, and probably this is the case in the United Kingdom also.

TELEGRAPH POLES, or poles supporting electric wires of any sort, have usually been looked upon as necessary evils—something to be tolerated because very useful but nevertheless to be candidly regarded as adding nothing to the beauty of the landscape. But there is, it appears, another side to the question. A writer in the London Daily Telegraph, quoted in the English Electrical Review, defends the poles in what is described as an eloquent essay on the artistic effect of a telegraph line in a rural landscape. He notes the romance of the thrumming wires and the utility of the line as a guide in a strange land, and continues: "A man who cannot see the nobility of the long line of tall giants crossing the bare shoulder of a distant hill has little of the artist and nothing of the poet in his constitution. Silhouetted against a sunset, they have their own especial value, and modern artists have not failed to see their beauty in less obtrusive places. They form a black thread in the embroidery of Nature, and only those who have studied embroidery know of what infinite use that black line is in art. It must be used sparingly, as sparingly as gold, but its effect is as noble, and far more refined. . . . No artist, except your early Victorian dilettante, would dare to leave the poles out. I have known men wilfully and with vast wisdom aforethought put them in where they never were."

This is in refreshing and welcome if rather unexpected contrast to the contumely which has been heaped upon the humble telegraph pole. Unless this man is poking fun at us electrical folks, we shall quote him in triumph when overhead construction is next assailed as unsightly.

CANADIAN ELECTRICAL ASSOCIATION.

As previously announced, the seventeenth annual convention of the Canadian Electrical Association took place in Montreal, Wednesday, Thursday and Friday, September 11th, 12th and 13th. At the beginning it gave evidence of being a pronounced success, and when the proceedings were fully under way there was no room whatever for doubt. The total number registered was 261 in addition to a large number of ladies.

The week attracted to Montreal electricians from all parts of Canada and many from the United States, as conventions were held by the Canadian Electrical Association, Canadian Street Railway Association and the Maritime Electrical Association. The electrical exhibition was also a great attraction, being pronounced by visitors from the United States to be the equal for its size of anything ever attempted in that country. For the success of this exhibition too much credit cannot be given Mr. R. S. Kelsch, the vice-president and managing director, who gave his personal attention to the undertaking in a manner to insure the best possible results.

To revert to the Electrical Association convention, the chair was taken promptly at 10:30 on Wednesday by the president, Mr. R. G. Black. Unnecessary preliminaries were dispensed with, and, after a few brief remarks and the reading of the minutes of the last convention, the president delivered his address, which contained much food for thought. He emphasized the fact that at certain hours of each day every plant was taxed to its utmost capacity—the point known as the peak. The difficulty was that every plant had to be equipped to supply peak business, while during the rest of the day a large proportion of the plant was practically idle. With this factor considered, and the continually rising price of labor and almost every other element that entered into the commercial use of electrical energy, Mr. Black pointed out that the problem of earning dividends was ever growing harder instead of easier. As a way out of the difficulty he suggested the extension of the use of electric energy for electric heating and cooking and other household purposes. The result of the address was to impress the members with the fact, that, far from any general reduction in prices of electric power or light being within sight, the producers of electric energy must seek to extend their markets in order to make a reasonable profit at present rates.

The president then submitted the constitution of the association as revised by the managing committee, which was approved by the convention. The important feature in the new constitution is the formation of what might be termed a lighting section, following somewhat the plans of the National Electric Light Association. The new clauses covering membership are as follows:

Membership.—(a) The association shall consist of Honorary and Active members.

(b) Honorary members shall be any gentlemen who shall be elected as such by a two-thirds vote of Active members present at any sitting of any annual convention.

(c) Active members shall be owners, part owners, or directors, managers, superintendents, engineers or other employes of electrical undertakings, electrical engineers, students in electrical engineering, gentlemen engaged in electrical education or in the manufacture or sale of electrical apparatus or supplies, electrical contractors, and all other gentlemen whom the managing committee shall consider eligible as members.

(d) All Active members who are owners, part owners, managers, superintendents, engineers or other employes of electrical undertakings for the sale of electric light or power, owned by individuals or joint stock companies, who shall produce certificates from the owners or managers thereof that said persons are authorized to represent them, shall constitute the executive section of the association.

(e) Active members who do not form part of the executive section shall not be eligible to office in this association, and shall not be permitted to attend meetings of the executive session. This section does not apply to the offices of secretary and treasurer.

The report of the secretary-treasurer, Mr. T. S. Young, showed a balance in the treasury on May 31st last, the close of the association year, of $1,120. The membership at that date was 302. This, the report states, would appear to be a decrease as compared with the previous year, and a few words of explanation may be permitted. Until last year no steps were taken by the executive to remove from the membership roll the names of persons, who, although neglecting to send in their written resignations as required by the constitution, evidently did not consider themselves bona fide members of the association. The adoption of a less generous policy by the executive resulted in the removal of a large number of names from the register. That the association has made substantial progress, however, is shown by the fact that 62 new members joined during the year, and 28 members from May 31st to August 30th, or a total of 90 new members since the last convention. The present membership is 320. The report pointed out that the use of electric light in Canada has increased over 100 per cent. in five years.

The first of a varied programme of papers was then reached. It was entitled "Electric Heating and Cooking Devices," the author, Mr. A. B. Lambe, of the Canadian General Electric Company, delivering it extempore, in a very acceptable manner and exhibiting numerous devices calculated to increase the revenue of the central station. The advantages to the consumer, he argued, were such that though the cost of operation might be slightly larger than by the old system, the results were such as would insure their use, once the people realized the advantages. The results to the electric companies would be that, during the day hours, when the electric light was little used, the power could be applied to other purposes, and thus the general demand would be much more nearly equalized than at present.

R. S. KELSCH,
President of the Canadian Electrical Association.

At the afternoon session two papers were read, as follows: "Trials of the Operating Man," by Mr. M. A. Sammett of the Montreal Light, Heat and Power Company, and "Three-wire Generators," by Mr. B. T. McCormick, of Allis-Chalmers-Bullock. Mr. Sammett's paper is printed in another part of this issue.

In his paper Mr. McCormick said that three-wire generators can be operated in multiple with one another, or in multiple with two-wire generators, and it is often convenient to operate a 120-volt machine in multiple across one side of 240-volt three-wire systems, to maintain a better balance, in case that side is unloaded. The two-wire generator with rotating direct-current balancers, as a competitor of the three-wire generator, possesses a great many good points, but the cheapness, simplicity and compactness of the three-wire generator are points not to be overlooked in deciding on a three-wire system.

In the evening the members visited the electrical exhibition as the guests of the management.

Thursday's Session.

A paper on "High-tension Insulators from an Engineering and Commercial Standpoint," by Mr. C. E. Delafield of the Ohio Brass Company, Mansfield, Ohio, was the first on the programme for Thursday. As an illustration of the possibilities of delivering power at 150,000 volts, Mr. Delafield said it would be possibile to deliver the power generated at Niagara Falls economically to Boston, New York or Philadelphia, and, apparently, the principal hindrance to this consummation at the present time is in the fact that there is not on the market what might be termed a successful insulator for this enormous voltage, although the merits of a number of different types of insulators are at the present time being advocated for this purpose. An ideal insulator for all conditions of high-voltage stress should be one that would take care of climatic conditions, such as fogs, dust deposits, salt spray, etc., and should have as few still-air spaces as possible.

What might be termed a lamp session was next taken up. A. B. Fleming of the Canadian Westinghouse Company presenting a paper on "The Value of the Nernst Lamp to the Central Station," and J. M. Robertson of the Montreal Light Heat and Power Company one on "Incandescent Lamps." Mr. Robertson presented a short description of several types of lamps which are at present on the market, giving an outline of their characteristics and limitations, and comparing them as comparative new comers in the electrical field with the older and more familiar carbon lamp. The weakness of the carbon-filament lamp, he said, was the fact that its operating temperature must be comparatively low, not more than about 1,800 F. The best commercial efficiency which this lamp has attained is 3.1 watts per candle, but by far the larger part of the lighting business is done with lamps which consume 3.5 watts per candle or more.

The metallized filament lamp was the result of an effort to produce a carbon filament which could be operated at a higher temperature. Mr. Robertson's paper was illustrated, showing curves of resistance of the carbon, metallized, tantalum and tungsten filaments. The metallized filament, on account of its reduced diameter, as well as the increased brittleness of the material, is more fragile than the carbon filament, and consequently metallized lamps require greater care in packing and handling than the carbon type. The best efficiency of the metallized-filament lamp is about 2.5 watts per candle, and the life of the average lamp under good conditions of regulation is about 500 hours.

The process of manufacturing the tantalum lamp is similar to that of the carbon lamp. On account of the great length of filament required to obtain the necessary resistance, it has heretofore been impossible to make lamps of very high voltage or very low candlepower. At present lamps are obtainable in 20 and 40-candlepower units at voltages between 100 and 130 volts. At present the best efficiency of the larger lamps is about two watts per candle, with a life of about 800 to 900 hours. Recently the lamp has been improved to such a point that it may be used on alternating currents at the same efficiency as on direct current, though with a reduced life. Under ordinary conditions and on 60 cycles the life should average about 60 per cent. of the life on direct-current circuits under the same conditions.

The tungsten lamp, one of the latest productions to be placed on the market, follows in form the lines of the familiar carbon lamp. Its usefulness at present seems to be confined entirely to street lighting, where the conditions most nearly suit its peculiar properties. The efficiency of the lamp is $1\frac{1}{3}$ watts per candle, and the life on well-regulated circuits about 1,000 hours.

Curves were shown of comparisons between the results which may be obtained from the perfected carbon lamp and the higher efficiency type. The newer lamps show much better maintenance of initial candlepower than does the carbon lamp. In respect to relative costs of operating, it is shown that at one cent per kilowatt-hour the carbon lamp cannot compete with the metallized filament, which in turn must yield to the tantalum at two cents, and it in turn to the tungsten at four cents.

In conclusion, Mr. Robertson stated that while the position of the high-efficiency lamp is at the present time somewhat indeterminate, there seems no reason to doubt that within a reasonably short time lamps having an efficiency of one to two watts per candle will be obtainable in standard units and voltages, and the introduction of these lamps bids fair to be a somewhat disturbing factor in the electric-lighting business. Although the amount of light required by the ordinary customer is not measured by him in fixed units of illumination, but in dollars per month of cost, and he will usually respond to a reduction in price by an increase in his use until the new cost is about equal to the former bill, it is doubtful if this law will hold over such a wide cost ratio as three to one.

A lively discussion followed the reading of the two papers mentioned. The president referred to the helion lamp as one which was destined, according to the claims of the manufacturers, to work a revolution in the lighting business, but the opinion of the meeting seemed to be that this lamp was yet in the experimental stage. It was also argued that there would be plenty of time for the electrical industry to adjust itself to new conditions, and that in creating a market for these new lamps the general use of electric light would be encouraged and the business expand accordingly.

At the afternoon session a very interesting paper on "Frazil and Anchor Ice" was read by John Murphy, electrical engineer of the Department of Railways and Canals, Ottawa. Mr. Murphy went in detail into the subject of ice as a source of great difficulty to hydraulic plants. His simple, but effective remedies, were listened to with great interest. Further reference to the paper will be made in a future issue.

An illustrated address on "Methods of Illumination" was given by V. R. Lansingh, engineer and general manager of the Holophane Company, New York.

Election of Officers.

The election of officers took place at the executive session at 4:30 p. m. on Thursday, with the following result:

President—R. S. Kelsch, consulting engineer, Montreal.

First Vice-president—W. N. Ryerson, superintendent Ontario Power Company, Niagara Falls, Ont.

Second Vice-president—R. M. Wilson, Montreal Light, Heat and Power Company.

Secretary-treasurer—T. S. Young, Confederation Life Building, Toronto.

Managing Committee—A. A. Dion, superintendent Ottawa Electric Company, Ottawa, Ont.; B. F. Reesor, managing director Georgian Bay Power Company, Lindsay, Ont.; Charles B. Hunt, manager London Electric Company, London, Ont.; J. M. Robertson, Montreal Light, Heat and Power Company, Montreal, Que.; J. J. Wright, manager Toronto Electric Light Company, Toronto; W. Williams, Gas and Electric Light Company, Sarnia, Ont.; H. O. Fisk, Peterboro Electric Light Company, Peterboro; J. W. Purcell, Hiram Walker & Sons, Walkerville; R. G. Black, general superintendent Toronto Electric Light Company; J. G. Glassco, Hamilton Cataract Power Company, Hamilton.

R. S. Kelsch, the new president of the association, is prominent among the electrical men of Canada. He has been engaged in electrical engineering work for the last 20 years, during the first 10 in Chicago, in charge of large electrical properties in that city, and since April, 1897, in Montreal. He erected and operated the plant of the Lachine Rapids Hydraulic and Land Company, remaining in charge of same in the capacity of general superintendent and engineer until the Lachine company was absorbed by the Montreal Light, Heat and Power Company in 1903. He then established an office as consulting electrical engineer and was immediately retained by the Montreal Light, Heat and Power Company to consolidate the two plants, one system being three-phase 60-cycle and the other two-phase 66-cycle. He still acts as consulting engineer for the company in addition to an extensive outside practice. Mr. Kelsch is vice-president and managing director of the Canadian Electrical Exhibition Company.

Closing Session.

A morning session on Friday concluded the business meetings. Mr. G. Percy Cole, of Allis-Chalmers-Bullock, Ltd., read an interesting paper on "Modern Lightning Transformers," which was followed by an equally interesting contribution on "The Responsibility of Electric Company for Accidents," by Mr. George H. Montgomery, solicitor for the Montreal Light, Heat and Power Company. Both of these papers were fully discussed.

The Question Box, edited by Mr. A. A. Dion, was then taken up, but owing to insufficient time, it was necessary to confine the discussion to a limited number of questions.

The question of the next place of meeting was left with the incoming managing committee, the general opinion being, however, that it should be held in the West.

The entertainment programme included a theater party at His Majesty's Theater on Thursday evening, when the "Gingerbread Man" was produced. Owing to the inclement weather, it was necessary to cancel the tea, which was to have been provided for the ladies at the Royal St. Lawrence Yacht Club. On Friday afternoon special cars carried a number of the party to the race track, while the evening was devoted to a visit at Dominion Park.

Standard Symbols for Wiring Plans.

In the Western Electrician of September 29, 1906, was printed the complete set of standard symbols for wiring, which have now been adopted, with revisions here noted, by the National Electrical Contractors' Association of the United States, the American Institute of Architects of the United States, the supervising architect's office of the United States, quartermaster general's office of United States army, several municipal departments, many technical institutions, prominent architects and engineers, and numerous individuals.

Since the first edition was printed there has been a slight change in the symbols for center and bracket outlets, symbols for indicating "gas only" outlets having been added. The second and fourth lines contain the changes made. Otherwise the symbols are the same as the list printed in the issue mentioned. The suggestions in connection with the standard symbols are changed to read as follows:

SUGGESTIONS IN CONNECTION WITH STANDARD SYMBOLS FOR WIRING PLANS.

It is important that ample space be allowed for the installation of mains, feeders, branches and distribution panels.

It is desirable that a key to the symbols used accompany all plans.

If mains, feeders, branches and distribution panels are shown on the plans, it is desirable that they be designated by letters or numbers.

Height of Center of Wall Outlets (unless otherwise specified):

Living rooms .... [illegible] ft. 6 ins.
Chambers .... [illegible] ft. 0 ins.
Offices .... 6 ft. 0 ins.
Corridors .... 6 ft. 3 ins.
Height of Switches (unless otherwise specified) ...... 4 ft. 0 ins.

In presenting the revised symbols the National Electrical Contractors' Association says:

"We are informed that the use of these symbols has become quite universal, and are confident that with the recent endorsement of the American Institute of Architects and the government departments preparing wiring plans, the success of the symbols is assured. However, to make the standardization complete, it is necessary that everybody making wiring plans make use of the symbols. We fully recognize that the adoption of the system will entail some inconvenience at first, and individual systems will have to be sacrificed, but we believe that you will agree with us that the benefit obtained by the standardization is worth the sacrifice and trouble."

Additional copies may be had of the secretary of the National Electrical Contractors' Association, Utica, N. Y., or secretary of the American Institute of Architects, the Octagon, Washington, D. C., at small cost.

Copper Prices Declining.

A New York dispatch to the Chicago Record-Herald, dated September 12th, says:

"A crisis in the copper situation, due to a deadlock between the producer and the consumer, has resulted in a tremendous overproduction of the metal, and the Amalgamated Copper Company, the largest producer of copper in this country, will soon shut down its mines in and about Butte, Mont."

"The Amalgamated company, along with other copper companies, has been piling up a large surplus of metal for several months, and it is authoritatively stated that there is now a surplus of 250,000,000 pounds of refined copper in the United States.

"The present situation has developed from the seeming inability of the producer and consumer to reach a price for the metal that would prove satisfactory. The selling price of copper has been steadily reduced in the copper markets of the world, but the consumer has steadfastly declined to purchase except when needs were pressing. The official price for copper has been lowered from 25 cents to 18 cents a pound by the United Metals Selling Company. Copper producers on the metal exchange, in their efforts to tempt the buyer, have gradually cut the price to 15¾ cents for electrolytic, which figure was reached today. As a consequence of this acute copper situation, copper stocks have accumulated rapidly. The production of refined copper in September, it was stated today, will be 6,000,000 pounds less than last month. There were reports in the financial district this afternoon that certain banks have declined to carry any more copper metal in their loans."

Central Electric Railway Meeting.

The first regular meeting of the Central Electric Railway Association, after the summer vacation, will be held in Columbus, Ohio, September 26th. In addition to the report of the standardization committee, and discussion thereof, two papers will be read—one on the "Single-phase System of Operating Electric Cars," by George D. Nichol, electrical engineer of the Indianapolis and Cincinnati Traction Company, and the other on "The Twelve-hundred Volt Direct-current System of Operating Electric Cars," author to be announced. A good attendance is anticipated. C. C. Reynolds, superintendent of the Terre Haute, Indianapolis and Eastern Traction Company, will run a through car from Indianapolis to Columbus, leaving the Traction Terminal Station at 10 o'clock a. m., September 25th. Mr. Reynolds has invited a number of traction officials of Kentucky, Illinois and Michigan to go to the Columbus convention with him on the special train.

Distinguished Germans Study American Methods.

The commission composed of distinguished Germans sent by the German government to inspect electric railways and transmission lines in this country is finding much of interest. Last week members of the party were in Indianapolis inspecting the network of interurban electric railways centering in that city. The party was especially interested in the single-phase system of the Indianapolis and Cincinnati Traction Company and the power house at Rushville; also the new 1,200-volt direct-current railway and power house of the Indianapolis and Louisville Traction Company.

Arriving in New York from Europe the commission studied the power houses and electrical equipments of the New York Central, the Long Island and the New Haven roads and the plants of the Interborough Rapid Transit Company. Officials of these companies and of the General Electric Company entertained the party. At Boston the visitors were entertained by C. B. Davis of the General Electric Company, President Bancroft of the Boston Elevated, President Sullivan of the Massachusetts Street Railways, and C. L. Edgar of the Edison Illuminating Company. Albany was visited next.

At Schenectady the party was shown through the various departments of the works and entertained at the Mohawk Club. The reception committee consisted of Vice-president E. W. Rice, Jr., Vice-president J. R. Lovejoy, General Manager G. E. Emmons, General Superintendent E. B. Raymond, William S. Hules, M. A. Oudin, W. B. Potter, D. B. Rushmore, J. E. Noeggerath and Eugene Eichel.

Among those in the German party are Geheimrath Willfeld of the Prussian government, P. Pforr of the railway department of the Allgemeine Electricitaets Gesellschaft, William Shuly of Berlin; Prof. Reichel of the Royal Technical University, Berlin; Director Frischmut of the Siemens-Schukert Works, Director A. Flies of the A. E. G., and Director Jordan of the Lahmeyer Works.

Consolidation of Chicago Edison Company and Commonwealth Electric Company.

As foreshadowed in the Western Electrician of July 20th last, when the details of the plan were set forth, the Chicago Edison Company and the Commonwealth Electric Company were formally consolidated on September 16, 1907. Meetings of the stockholders of the two were held on that day to vote upon the question of consolidating the companies as proposed by the respective boards of directors. All the stock of the Commonwealth company and over 95 per cent. of the stock of the Edison company was represented at the respective meetings. The vote was unanimous for consolidation in each meeting.

One change was made in the plan of consolidation as heretofore announced, it having been found possible to avoid the issuance of trustees' certificates in exchange for Commonwealth company stock and to issue at once the regular stock certificates of the consolidated company therefor. A slight change was also made in respect to the subscriptions for the additional Edison stock recently subscribed for and in favor of subscription receipt holders by permitting these holders to pay in advance the deferred subscription installments and to obtain regular stock certificates of the consolidated company on account of their subscriptions when fully paid.

Circulars giving information to stockholders are to be sent out by the consolidated company in a few days.

As previously announced, the name of the new company is the Commonwealth Edison Company. Headquarters will be, as heretofore, in the Edison Building at 139 Adams Street. Mr. Samuel Insull, president, and the other officers of the two old companies (which had identical lists of officers) will remain in charge of the new company. The Commonwealth Edison Company will have capital stock of $30,000,000 and will operate under the Commonwealth franchise, which covers the territory of the city of Chicago and has still nearly 40 years to run.

Telephonic Marine Signaling System in the St. Lawrence.

Something unique in navigation aids—the telephonic marine-signal system—has just been established in the St. Lawrence River between Quebec and Montreal. This service is to provide for a system of communication between ship and shore, and will enable owners and agents to know of the progress of ships between these two great Canadian ports, and will also keep vessel captains fully acquainted with the condition of affairs in the river, enabling them to avoid any unusual or unexpected danger. At present, or until this new system is working, a vessel is outside of communication once it leaves Montreal or Quebec until it reaches either port. At some seasons of the year smoke from bush fires is blown out and covers the river like a dense fog. There was some difficulty experienced in arranging for a service of this description, and with no previous experience by which they might be guided the engineers were obliged to originate a service. Eleven stations have been erected along the river. At each station a tall mast has been set up having a cross spar 25 feet in length. From this cross spar signals will be displayed. A set of flag signals has been prepared for day use and an arrangement of lights for night, and all information desired will be communicated by telephone from station to station.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXXIV.—Electric Railways.

Direct-current Railway Motors.

Direct-current railway motors are always series wound for a pressure of from 500 to 600 volts, and are of the four-pole type. A series winding is absolutely essential for railway motors, as the speed is necessarily variable and a very high torque is required in starting a car from rest and accelerating it up to normal running speed. Most all railway motors are very similar in general outline and appearance, due to the fact that the restricted space which they occupy beneath the car limits the size and shape of the motor. Most city and suburban cars, as well as the majority of interurban cars, are equipped with wheels 33 inches in diameter, and the standard gauge of the tracks is 4 feet 8½ inches. Allowing for the necessary clearances between the motor and the ground below, and the car flooring above, the height of the motor is thus limited to a little over two feet, while the length between the wheel hubs in which it must be placed is less than four feet, and, except where larger-sized car wheels are used, the design of the motor must conform to these limitations.

The usual type of car motor is therefore, roughly speaking, of rectangular shape, with rounded corners and with four poles projecting radially inward at angles of 45 degrees from the horizontal. Most of these motors are split horizontally through the center, forming two castings, which are hinged together and arranged so that the bottom half may be opened downward or the top half opened upward for the purposes of inspection and repair. In this type of motor two of the poles and field coils are built into the top half of the motor, and the other two in the lower half.

Another type of motor which is used to some extent is known as the box type, in which the frame is cast in one solid piece. The bearing housings of these motors are made of large circular castings slightly larger in diameter than the surface of the armature and bolted to the frame of the motor. By removing these bearing housings the armature may be drawn out sidewise from the fields.

The choice between the downward-opening and the upward-opening field frames or the box-type frames depends entirely upon the equipment of the railway repair shops. If the repair and inspection work is done in pits under the car floor, the downward-opening fields are necessary. Where overhead cranes are available for lifting the car body off from the trucks, the upward-opening fields are preferable. With the box-type frame it is necessary to remove the motor from the truck before the armature can be removed.

Another feature which is characteristic of all car motors is the pair of heavy lugs extending out from the back of the motor which carry the car-axle bearings. As car wheels are pressed onto the axle in a hydraulic press and therefore cannot be readily removed, the axle bearings are split bearings, so that the motor can be removed from the axle by means of taking off the bearing caps. A gear wheel which is generally made in two halves is keyed and bolted upon the car axle, and the armature shaft carries a pinion on one end of it which meshes into the axle gear. The front end of the motor is supported from some part of the truck frame, and this support, instead of being rigid, is by means of heavy springs. This spring support is necessary to avoid violent shocks in starting, and it helps to prolong the life of the pinion and gear.

The general scheme of supporting a street-railway motor is shown in the accompanying diagram, from which it will be seen that the motor is free to revolve through a very small angle about the car axle, the amount being limited by the tension of the supporting springs. When the car is started suddenly an enormous strain is thrown upon the teeth of the pinion and gear. This force, instead of acting like a blow, as it would in the case of rigid suspension, is cushioned by the suspension springs.

Street-railway motors are built in various sizes ranging from about 40 to 200 horsepower. A large number of sizes are called for because street cars are built of various lengths and weights; the grades to be overcome vary widely, and the schedule speeds and number of stops differ on almost every road. It is, however, impossible to judge the fitness of any railway motor for any particular service from its horsepower capacity alone. It is in reality the rise of temperature which the motor will stand which determines its capacity, and with every street railway motor a curve sheet is always furnished, giving the characteristics of the motor, from which its performance under any conditions of service may be judged.

Rapid acceleration is one of the chief requirements for street cars making frequent stops. Acceleration in speed takes place from the moment a car starts until it attains its normal speed, and where stops are frequent, and the schedule speed is high, it is very important to save time by means of rapid acceleration; that is, by passing from rest to full speed as quickly as possible. This condition requires a starting torque of the motor many times in excess of its full-load torque, so that a motor which might be able to maintain a given schedule speed with but few stops would be entirely insufficient to maintain the same speed if the stops were numerous. This condition is mentioned merely to show the necessity of judging a railway motor by its characteristic curves rather than by its nominal horsepower rating.

Owing to the location of street-railway motors close to the surface of the ground, where they are exposed to considerable dust, mud and water, it is necessary that they be built waterproof and practically dustproof. As frequent inspections of the commutator and brushes are advisable, handholes

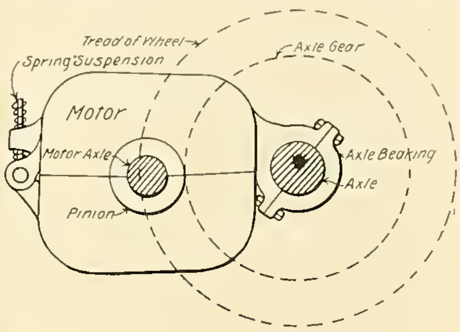

DIAGRAM SHOWING MOUNTING OF RAILWAY MOTOR.

for this purpose are made in the frame of the motor, and these handholes are provided with tight-fitting covers. Gear cases are also used to enclose completely the gear and pinion, and these cases permit the gears to be run in grease, which greatly reduces the wear on the teeth. Either oil or grease lubrication may be used on railway motors, but oil is generally preferred as being most efficient as well as more cleanly.

One, two or four motors may be used on street-railway cars, depending upon the size and weight of the car and the schedule speed at which it is operated. Street-railway cars are now always mounted upon trucks. Short cars may be placed on a single truck, while long ones require double trucks; that is to say, one truck near each end of the car. On very short light-weight single-truck cars a single motor may be used, but this is not considered good practice, and is rarely done, as only one pair of wheels is thus utilized for traction. If one 80-horsepower motor is sufficient to operate the car at schedule speed, it would be much better practice to use two 40-horsepower motors, placing one on each axle, so that both pairs of wheels could be used for traction; further, in the event of accident to one of the motors, the remaining one could be utilized for returning the car to the barns. On very long double-truck high-speed cars, four motor equipments are commonly used, and in some cases as much as four 150-horsepower motors per car have been employed. Two motor equipments are also frequently used on double-truck cars, in which case one axle of each truck is equipped with a motor.

Very recently there has been introduced a new feature in the design of street-railway motors which will undoubtedly be widely adopted in the future. This consists of the addition of auxiliary poles known as commutating poles or interpoles, whose function is to produce sparkless commutation. The theory of the auxiliary poles is as follows. The four auxiliary poles are very small in comparison to the poles producing the magnetic field, and upon these auxiliary poles there are placed coils of wire which are connected in series with the armature circuit and which therefore carry the full current taken by the motor at any time. In addition to the magnetic field generated in the poles of the motor, there is also a magnetic field due to the winding of the armature upon its core, and thus field of force from the armature current decreases, its reaction on the motor fields so that the point of commutation at some speeds is shifted several degrees from the normal neutral point.

The auxiliary poles are wound so as to produce a field which just counteracts the effect of the armature reaction upon the main motor field, and this prevents any shifting of the neutral point, and the point of commutation is therefore always the same whatever the speed of the motor. The armature reaction is greatest when the armature is carrying its maximum current, at which time the corrective influence of the auxiliary poles is also greatest, as the entire current of the motor is carried by the auxiliary pole windings. As the armature current decreases, its reaction on the fields also decreases, and the field of the auxiliary poles is correspondingly decreased.

As it is entirely impracticable to vary the position of the brushes on a street-railway motor, it is of great importance to have a fixed point of commutation. The commutator of a street-railway motor may be considered one of its weakest points, as it requires more care and attention than any other part of the equipment, and is also the part of the machine that attains the highest temperature. By providing a means of sparkless commutation the life of both commutator and brushes is greatly increased, and much of the work of repairing and turning down commutators is consequently eliminated.

The armature winding of street-railway motors is the series winding, so there is always an odd number of bars on the commutator. With this winding no cross connections are used, and only two brushes are required, which are placed 90 degrees apart. The number of slots in the armature core is usually much less than the number of coils, so that two or three coils are placed in one slot. If two coils per slot are used there will be one more coil than the number of commutator bars, in which case the ends of one cell are cut off and it always remains a "dead" coil. Where three coils per slot are used no dead coil is required. The armature coils on modern motors are wound on forms, and the wires in each coil are thoroughly shellacked and taped after being formed. These individual coils are afterward assembled on the armature core, the slots of which are previously lined with thoroughly insulated material. The coils are then secured in place by band wires wrapped around the surface of the armature and thoroughly soldered together. These bands are wound in recesses turned in the armature teeth, so that the band wires do not project above the face of the armature.

[To be continued.]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

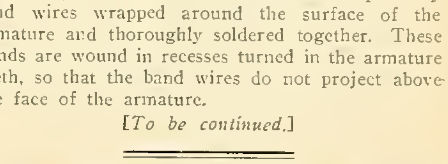
QUESTIONS AND ANSWERS.

Reading a Meter.

W. K. W., Chicago: Please give me some instructions about reading an electric meter. My meter has a dial numbered similarly to that in the sketch.

Answer.

The first circle, marked "1's," at the right-hand side of the dial, reads one kilowatt-hour for each division, or 10 kilowatt-hours for one complete



revolution of the hand. The second circle from the right, marked "10's," reads 10 kilowatt-hours for each division, or 100 kilowatt-hours for a complete revolution of the hand, and so on. It should be noted that the direction of numbering is reversed for adjacent dials on account of the multiplying gear train mechanism. When the hand is between two divisions, take the lesser as the reading. The dials shown read a total of 2,852 kilowatt-hours, not 3,852 as might appear, because the 1,000's hand cannot reach 3 until the next lower hand has completed its revolution to zero.

Trials of the Operating Man.[1]

By M. A. Sammett.

The difficulties in operating alternating-current systems may be subdivided into two main groups:

(1) Difficulties beyond control.

(2) Controllable difficulties.

Under the difficulties beyond control are to be included those met with every summer. Lightning still engages the attention of the best men of the engineering profession. Various types of arresters were developed, all more or less effective in lessening the disastrous results of lightning, yet none providing perfect protection. Numerous methods to protect the transmission line were introduced with a certain degree of success, but the annual visitor still does its work of destruction.

We shall not enter into the discussion of the existing protective apparatus. The subject has for some years past been most prominent in convention discussions.

The subject matter that will be considered is that of troubles that are controllable; trials that may be overcome by the operating man, provided he were given a plant of a certain amount of flexibility, and that he were provided with information which naturally belongs to him.

Taking up the various items, we will consider first the questions of liberality in the design of the plant. By liberality I do not mean the use of apparatus in capacities much in excess of the requirements. There is no necessity of installing units which will carry continuously 50 per cent. overload at moderate temperatures. This would mean a much larger installation, and naturally a more expensive one. What is essential is that the apparatus should be capable, under emergency conditions, to carry 25 per cent. or 50 per cent. overload for a specified interval. Higher temperatures will be allowed under these unusual conditions as long as the temperatures are not detrimental to the life of the machine.

Second in importance, under emergency conditions, will come regulation. What could be suffered under emergency conditions may not be tolerated under normally operating conditions, yet provision should be made for the service to be maintained with a fair degree of voltage regulation. Bearing these in mind, the design of the power house, sub-stations and the transmission circuits must be such as to provide for the temporary disability of a part of the plant and be in a position, at the same time, to handle the load without any serious interruption.

Under the present conditions of increase of raw material, and consequently of the finished product, the problem of maximum permissible units to be most advantageous under given conditions of operation is becoming prominent in power-house economy. This will naturally result in adopting units of larger capacity and will involve almost invariably transforming and regulating apparatus of artificial cooling. All these will tend to complicate matters for the operating man. The auxiliaries used in artificial cooling may at times become inoperative, and then it is for the operating engineer to be equal to the occasion and display his knowledge of the plant entrusted to him, executing his work with a degree of certainty and a full knowledge of existing conditions.

The operating man should know the behavior of his machines. With this information the operating engineer can handle his plant in an intelligent manner, and in emergency cases will be able to plan his work, being fully aware of the time at his disposal for safe operation of the machines under overload conditions, or under conditions of no artificial cooling.

It is evident that machines rated at a given capacity when operated under overload conditions will have a higher temperature. It takes a certain length of time before the dangerous temperature is reached, and it is essential that the curve of temperatures at overloads be known and should be used as a gauge when emergency cases arise.

In modern plants of liberal design, where provision of continuity of service is given due consideration, at least two lines should be constructed, and the design of these circuits should be such as to enable the carrying of the entire load on one circuit. The operating man, in such a case, will be confronted with the difficulty of low voltages on the receiving end. The increased load transmitted over one circuit would result in an increased drop in transmission. The provision made in the design of the line would only partially help matters, and to improve the receiving voltage it is necessary to increase the voltage of the generator. How far would it be permissible to increase this voltage? Reference to Fig. 1 will show that the increased voltage means increased iron loss in the armature laminations, consequently higher temperatures. It would also mean a larger field current, tending to increase the temperature of the apparatus still further. A higher impressed voltage on the step-up transformers will mean also a greater iron loss, resulting in higher temperatures.

1. Paper read at the Montreal convention of the Canadian Electrical Association, September 11, 1907. The author is in the testing department of the Montreal Light, Heat and Power Company.

Is it safe to increase the voltage of the machine by 10 or 15 per cent. to compensate for increased drop in the line? The answer to this question may be given only after the study of each particular machine. In the case under consideration we find from the core-loss curve, Fig. 1, that an increase of 10 per cent. in voltage of the generator is equivalent to an increased loss of 18 kilowatts. This increased loss is so much heat added to the body of the armature and the corresponding increase of temperature resulting from that will be approximately 5½° C., giving a maximum temperature of 41½° C. No difficulty should be anticipated from the above increase in voltage on the ground of increased potential between turns and layers of winding, or from increased strain to ground. The increase is too small, and the factor of safety is large enough so that no trouble need be expected from that source.

At the present state of progress in the electrical art, no difficulty is expected from running generators in parallel. With the refined methods of synchronizing, whether turbine or engine driven, generators will give no trouble. Engine builders have overcome the old-time difficulty encountered with engine-driven generators. The maximum fluctuations from absolute uniform rotation is kept within 2½ electrical degrees, and this problem has been solved.

With proper adjustment of field current the generators will divide the load proportionally. In this respect they are more under the control of the operating engineer than some of the less complicated apparatus, such as transformers. Over and under excitation of generators will cause a flow of circulating currents between the generators. The adjustment of the field currents will eliminate these idle currents. In this respect the use of power-factor meters on each machine is of considerable assistance.

In order that transformers may divide the load equally, or in proportion to their capacities, it is

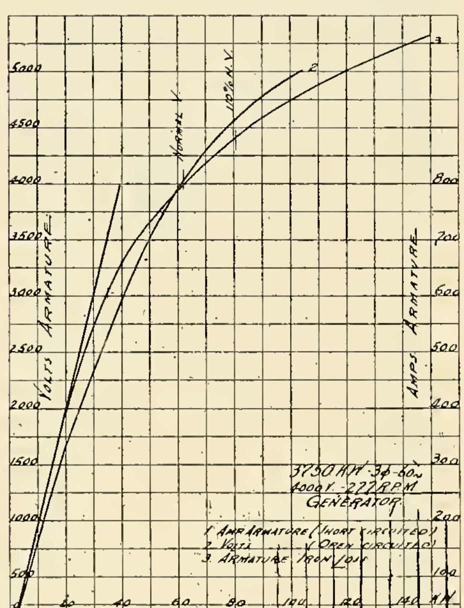


FIG. 1. CORE-LOSS CURVES.

necessary that their primary and secondary voltages be the same, also that they have the same impedance.

Many a station man has a tale of woe as a result of indiscriminate use of transformers, and, strange to say, sometimes using transformers of same make and type, but built at different times by the same manufacturer, guaranteed for successful parallel operation with transformers previously supplied.

To guard against unequal loading of transformers, the characteristics determining the division of load must be known. It is not necessary to have indicating ammeters showing the current on each transformer, as this would complicate the switchboard. It is advisable, however, to verify at the outset the division of load under actual conditions of operation, and results, if satisfactory, will remain unaltered.

In more than one instance was it the experience of the writer to find that transformers, though supposedly of the same characteristics, would not operate properly, and in one case when a bank of transformers was connected in service during the pressure of a heavy Christmas load, the bank burned out in a few days after installation, due to overload. Time could not be spared to test the transformers for impedance. They were connected in parallel on high and low-tension windings on the strength of the manufacturer's guarantee. A test made subsequently of two spare transformers supplied on the same order as those that burned out, revealed the fact that the new transformers had an impedance of 3.58 per cent., while the old transformers had 4.4 per cent., and consequently the new bank carried an overload of 19 per cent.

With transformers the question of proper parallel operation must be verified, and if they will not divide the load proportionally to their capacities, corrective reactances must be added to the transformers to equalize them in this particular respect.

Of the various types of transformers, the natural-draft transformer is obsolete in this country, whether in large or small sizes. The smaller sizes are almost altogether of the oil-insulated type, while in the larger sizes they are provided with forced ventilation, such as air blast or oil-insulated water-cooled. Let us consider the two types, air-blast and oil-insulated water-cooled transformers, as to the difficulty in connection with their operation.

Air-blast transformers are open to criticism on account of the ease with which they accumulate dust. This is objectionable, especially so in transformers of moderate voltage between 15,000 and 22,000 volts. In this type of transformers it is frequently found that the temperature of the upper portion of the coils is much in excess of the average winding temperature.

Whenever transformer coils are connected on top, the air passages are frequently blocked, and the temperatures reach a dangerous point, at which it will be unsafe to continue operation. To the above-mentioned objections must be added another, that of the danger of using compressed air for blowing out the dust. Unless the air is perfectly free from moisture, the use of it may result in the damage of the insulation and cause a burnout. If extreme precaution is not exercised, disastrous results will follow. To all these trials must be added another, that of the ease with which the flames are carried from one transformer to the other through the air chamber.

With the oil-insulated water-cooled transformer, many of the above enumerated defects will be overcome. With oil-insulated transformers a smaller amount of insulation wrapping the coils is necessary, hence the uniform ducts of larger magnitude are possible. The temperature of the coils with such construction of ample oil circulation will be more uniform.

The principal argument in favor of oil-insulated water-cooled transformers is their ability to withstand excessive overloads, and their immunity from breaking down at temperatures even as high as 200° C. This dangerous temperature was reached under abnormal conditions of phase transformation. One transformer was operating at about 72° C., while the other ran at a temperature of 200° C. Room temperature was 42° C. The difficulty was discovered when an inspection of the transformer installation was made. A thermometer of 150° C. range was lowered into the oil, and when removed to take the reading the mercury was up to the end of the scale, and the mercury bulb had broken. A larger range thermometer registered 200° C. When brought into the testing department the transformer was given an insulation test of 10,000 volts from primary to secondary and ground, also from secondary to ground of 5,000 volts, which it stood successfully.

Double voltage was applied across transformer terminals, and the insulation stood the test. The rating of the above-mentioned transformer is 24 kilowatts, 60 cycle, 2,000-550 volts.

A great advantage of the oil-insulated transformer is the higher effectiveness of insulation to resist induced high voltages, either through switching or through lightning disturbances. The fear of oil in the transformer as a fire risk is a matter of the past. Instances of stations destroyed by fire when oil-insulated apparatus such as transformers and regulators were the only machines saved, show the fallacy of the opponents of oil-insulated apparatus. Oil will extinguish the arc resulting from a short-circuit in the transformer, and prevent the burning of the insulating fabrics, thus doing away with the smoke filling the station, as is always the case with air-blast apparatus. The temperature of the oil-insulated apparatus is more uniform throughout than that of the air-blast type.

As to the oil siphoning through the leads and case joints, there is no reason why, with the proper construction and necessary precautions, the oil siphoning and leaks should not be done away with.

While it has many advantages, the oil-insulated water-cooled transformer has two main drawbacks:

1. Possibility of water getting at the winding.

2. Breaking up of the oil, forming a thick non-conducting mass.

A defective water coil or a coil allowed to have the water when the transformer is not in use during winter months will damage the transformer.

A water coil capable of withstanding 200 pounds hydrostatic pressure and proper connection of the coil to outside piping will guard against the former difficulty, while care exercised to remove the water from the coils by an air pump or by filling it with oil under pressure will guard against trials of water freezing in the pipes.

The breaking up of the oil takes place only at high temperatures, and if transformer temperatures are kept low no difficulty should be anticipated.

A sample of oil subjected to a temperature of 90 C. formed a heavy deposit in two weeks. Further tests could not be continued, due to lack of time, but it is safe to conclude, however, that it is not advisable to allow transformers to reach a temperature in excess of 70° C.

It happens sometimes that through no explainable reason the temperatures of transformers begin to rise. The cause may be due to either the iron aging, which would result in a higher iron loss, or to breaking up of the oil, or again to clogging of the water-cooling coils. In one instance where water was carried to the brass cooling coils through an iron pipe, the acidulated water passing through the iron pipe attacked the iron and then going through the brass tubes deposited the iron in the

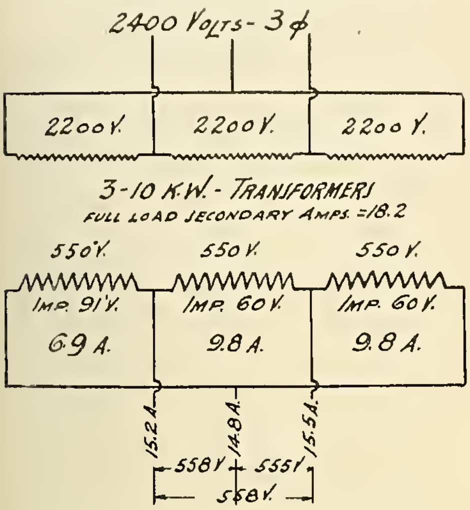

FIG. 2. UNBALANCING OF LOAD ON TRANSFORMERS OF SAME VOLTAGE BUT DIFFERENT IMPEDANCE.

form of a sediment, which reduced the coil opening to one-third its normal size, hence the consequent rise in temperature.

Transmission Line.

The connecting link between the generating and distributing ends is the transmission circuit. The trials here are caused by the insulators. Insulators should receive as much consideration as the power-house and sub-station machinery. They must have a liberal margin of safety. They must possess the requisite mechanical as well as electrical strength. While the dielectric strength is of great importance in selecting a suitable insulator, the surface leakage of the insulator should be such as to have, under conditions of rainstorm, a factor of safety of three times normal voltage for moderate voltage transmission. For voltages of 60,000 volts and above, this requirement will have to be modified and a smaller factor of safety will have to be adopted, since the insulator will otherwise prove too costly on account of size.

In selecting the kind of insulator attention must be paid to local conditions. The peculiarities of the country the line passes must be taken into consideration, and proper allowance made for local atmospheric and climatic conditions, for the effect of close-by chemical works, railway lines, with the unavoidable fumes, smoke, etc.

Rigid requirements of an insulator possessing a facor of safety of four times for arcing over under a breakdown test will justify the expenditure for a more costly insulator by minimizing breakdowns and insuring reliability and continuity of service.

Distributing Circuits.

The distributing circuits in Canada are almost invariably of 2,200 volts alternating current. The economy of distribution at the above-mentioned voltage and the severity of the Canadian winter compel the use of overhead distributing circuits. This system requires the extensive use of step-down transformers for both lighting and power service.

Transformers of 2,200 volts in sizes below 50 kilowatts, of pole-suspension type, are a very simple apparatus. They are self-contained and require no attention. If installed in sizes of ample capacity to handle the load there is no need of giving it any further thought. The experience of small plants will corroborate these conclusions. But as the plant reaches considerable magnitude, and the variety of types of transformers multiply, the difficulties begin to increase.

What are the trials in this connection?

They may be classified as follows:

1. Unequal division of load on parallel operation.
2. Unequal division of load on three-phase delta connections.
3. Phase transformation.

The chief requirement of transformers operating with proper division of load is the equality of impedance volts. In other words, given two transformers, either of same or different capacities but of same inductive drop at a given current, the transformers will divide the load proportionally to their capacities. Actual test figures should be accessible and the record of each transformer should contain this information.

Manufacturers from time to time improve their designs. As a result the impedance voltage may be diminished, while the type will still remain the same. Under parallel operation this may result in the better transformer burning out by overload. It is well to make it a rule not to operate small transformers in parallel. The practice will prove beneficial from considerations of efficiency, economy, as well as many trials attending parallel operation.

Single-phase transformers when connected on polyphase circuits for the supply of polyphase currents must possess the same characteristics with regard to division of load as one phase transformers connected in multiple on single-phase circuits. That is, three transformers connected for three-phase delta to three-phase delta must have their impedances the same, otherwise while the load on the group of transformers is balanced, each transformer will carry a load inversely proportional to its impedance volts, and the better transformer as to impedance will be forced to take a larger portion of the load and may carry a considerable overload. Figs. 2 and 3 will give a relative idea as to the inequality of the load on each transformer. In many instances transformers failed under overload conditions, yet records of connected load and actual ampere readings would lead one to believe that the transformer operated under normal conditions. To determine the load of each transformer, ampere readings must be taken on each transformer proper.

Phase Transformation.

Phase transformation, such as three-phase to two-phase, or vice versa, is more easily accomplished with shell-type transformers than with core-type transformers. Inasmuch, however, as for small units, the core-type transformer has become universal for distribution work, we will analyze this latter type. It is generally understood that in phase transformation the three-phase circuit requires the 50 per cent. of one transformer to be connected to the 86 per cent. of the other transformer. While it holds good with shell-type transformers, it will not apply to core-type transformers unless special provision is made for the interlinkage of coils of both primary and secondary winding. In the early days of the core-type-transformer development, the advocate of shell-type transformers maintained that a core type would not operate on a three-wire system. The table below will show same results when interlinkage of coils is not resorted to.

Test of 7½-kilowatt 60-cycle Core-type Transformer, 100-200 Volts. Three-wire Secondary Without Interconnected Coils.

	Side A.	Side B.
Load	0	0
Volts	104	104
Load	27 amps.	27 amps.
Volts	102.5	102.5
Load	27	0
Volts	87	125
Load	54	54
Volts	100.5	100.5
Load	54	0
Volts	63	150
Load	0	54
Volts	149	63

This difficulty was soon overcome by subdividing the secondary coils in two sections and interconnecting the sections. In phase transformation the

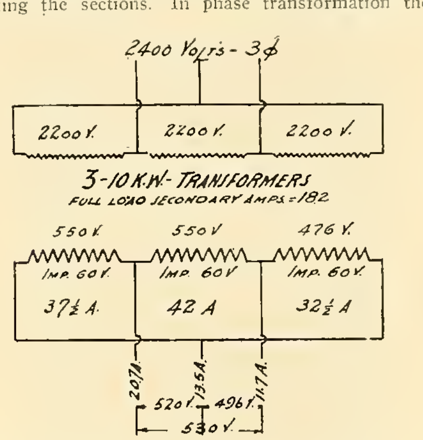

FIG. 3. TRANSFORMER OVERLOADED BY CIRCULATING CURRENT. SAME IMPEDANCE BUT DIFFERENT VOLTAGE.

same difficulty was encountered and the same remedy effected the change desired.

It may be said that in small sizes of 50-kilowatt and under the shell type has proven a failure, and that the core type is the recognized standard for both lighting and motor service.

The construction of the core-type transformer at once suggests the ease of insulating the high from the low-tension coils. In addition to that, whenever minimum material for a given capacity is not the principal object, the coils can be wound on a perfectly circular form, thus avoiding corners and insuring freedom from short circuiting the winding on account of the bends. While grounding of neutral points of low-tension transformer winding is effective in keeping the high tension out of the customer's premises, the possibility of the breakdown should be guarded against by selecting transformers possessing the necessary requisites as to construction features of the type and design.

A careful analysis will result in operating companies selecting transformers which, while of higher initial cost, will prove a better investment.

Often with the increased load, especially when the motor load predominates, it is difficult to maintain fair voltage regulation. Some stations run separate circuits for the lighting load, thus separating the lighting from the power circuits. Good regulation will be obtained from the use of automatic feeder regulators.

We will take up as the last point the question of aging. Aging of iron laminations has all these years been carefully studied by manufacturing companies, and at the present time the "eternal vigilance" has not ceased. Unless carefully guarded against inadequate iron, grievous results will follow. Poor iron affects the efficiency of the apparatus; it also influences the temperature of the machine. Sometimes the defect may not be evident at the outset, but will develop with time, and the aged iron, resulting in increased hysteresis loss, may cause the heating up of the iron to a dangerous temperature.

To keep track of the change in the iron it is well, wherever circumstances permit, that tests be made to verify the condition.

The aging of iron in many instances will explain abnormal rises of temperature with practically the same load. With artificial cooling, the difficulty is easily overcome by increased ventilation. It is well, however, to have full information with regard to the apparatus in use.

The phenomenon of aging applies to all electrical apparatus and affects largely the central-station companies on account of the extensive use of transformers. Inasmuch as aging increases with higher operating temperatures, it is preferable to purchase apparatus that will give the lowest temperatures.

To sum up, then:

Plants should be laid out with liberal provision for emergencies.

The performance of the apparatus under normal as well as emergency conditions should be thoroughly understood.

Small service transformers should be of the core type.

To insure proper parallel operation of transformers, records of transformers' impedance voltage should be kept.

Association of Edison Illuminating Companies.

The annual convention of the Association of Edison Illuminating Companies was held at The Homestead, Hot Springs, Va., on September 10th and 12th. Arrangements for the success of the meeting were prepared in the customary thorough manner and everything was carried out to the satisfaction of those in attendance. The social side of the gathering received much attention and was particularly enjoyed by the ladies present.

In the technical meetings among the papers presented were the following: "Smokeless Furnaces for Power Plants," by Mr. W. L. Abbott, Chicago; "Steam Heating from Central Stations," by Mr. B. R. Eales; "Experimental Data on Illuminating Values," by Dr. C. H. Sharp, New York; "The Boston Edison System in 1907," by Mr. L. L. Elden; "Organization of an Electric Supply Company with Particular Reference to Its Dealings with Customers," by Mr. R. S. Hale; "The Status of Municipally Owned and Operated Lighting Plants in Massachusetts," by Mr. L. R. Wallis.

Reports were presented by special committees on meters, storage batteries, electric heating, steam turbines, National Code, incandescent lamps. Each of these received considerable discussion, especially the subject of high-efficiency lamps. The tungsten lamp was looked upon as rapidly approaching a commercial proposition from the central-station viewpoint.

The following-named officers were elected for the ensuing year:

President—Alex Dow, Detroit, Mich.

Vice-president—George H. Harries, Washington, D. C.

Treasurer—Louis A. Ferguson, Chicago.

Secretary—W. W. Freeman, Brooklyn.

Executive Committee—Alex Dow, chairman, Detroit; Samuel Insull, Chicago; Joseph B. McCall, Philadelphia; John W. Lieb, Jr., New York; Charles L. Edgar, Boston; Thomas E. Murray, New York; T. G. O'Dea, Erie, Pa.; Louis A. Ferguson (ex-officio), Chicago; W. W. Freeman (ex-officio), Brooklyn.

Bailey Concrete Poles.

The manufacture of concrete poles under patent of William H. Bailey of Richmond, Ind., is to be taken up by the American Concrete Pole Company of Richmond, whose intentions are not only to construct concrete poles under contract but to sell the right to construct to other companies and users on a small royalty basis, or to sell the right to certain territory.

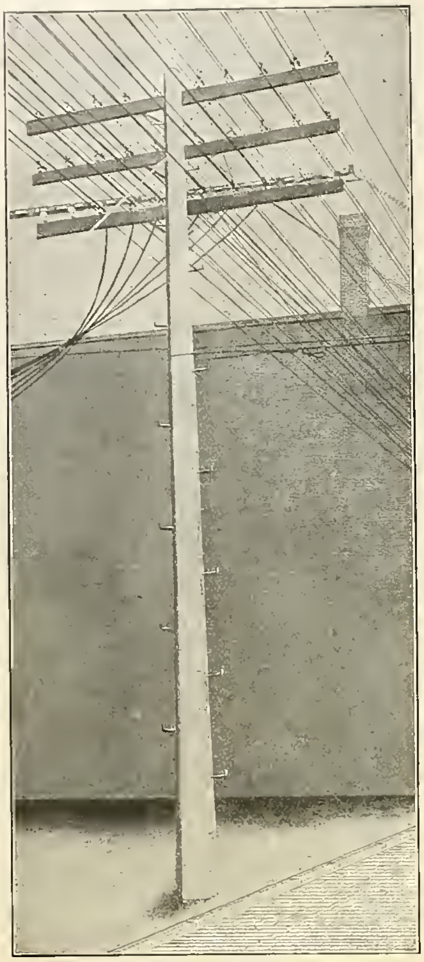

FIG. 1 CONCRETE POLE IN USE TWO YEARS.

Some of these poles have been in service for a year or more, and mention of their construction and durability in service has been made in the Western Electrician. With the reinforcement of electro-carbon twisted rods and spiral binding wires properly distributed in the column of cement the poles are said to be not only substantial and durable, but remarkable elasticity is displayed. A pole 30 feet in length will permit a deflection of 30 inches before the cement cracks. To obtain this result, it is pointed out, would require one-third greater horizontal strain at the top than would be sufficient to destroy a cedar pole of the same dimensions.

The cracking of cement under such a test would not impair the strength of the pole in the least, for after this takes place the reinforcement becomes active and takes the entire strain, the special rods being guaranteed to withstand a breaking strain of 50,000 pounds per square inch.

As will be seen in the illustrations, the poles are square, with the corners beveled off two or three inches, so that the top of the pole is octagonal in shape. This not only gives it a neat appearance but leaves the corners substantial and avoids a sharp edge that would be liable to chip off.

The rods are placed three-quarters of an inch off the surface of the cement at the corners and then bound together by a spiral wire encircling the four rods from top to bottom. This not only serves to tie the rods together but prevents danger of the cement shearing off, as the rods have a tendency outward when the pole is subjected to a lateral strain.

The smaller poles, up to and including 35 feet in height, are molded lying on the ground, and after they have been seasoned are set in place by means of a gin pole. The forms are laid with the butt near the hole and the reinforcement placed. Then the concrete is poured in and allowed to remain three to seven days, according to the weather. The forms are then removed so that they can be used again, and the pole is left to season. This process requires about three or four weeks. All poles should be built on the ground, upright in the hole or in position to be set up, thus saving the cost of hauling or unnecessary handling as this would increase the cost. Poles 40 feet in length and larger should be built standing, as this is the most economical method.

A line constructed across Whitewater River at Richmond, Ind., has poles from 40 to 60 feet in length, built in a perpendicular position. This piece of work is permanent. Fig. 1 shows a pole in detail, two years old, which has been subjected to all kinds of strain.

In Fig. 2, (1) (2) (3) (4) (5) and (6) give the detail construction of pole and reinforcement. (1) Shows the four electro-carbon rods as they are placed in the cement body, with the spiral binding wires pulled in place; (2) is a general view, showing shape of the cement body as finished; the steps and other bolts and holes are very easily made while the concrete is plastic; (3), (4) and (5) show cross-sections of poles with three different methods of binding; also two different methods of reinforcing, the scheme represented in (4) being only intended for extremely heavy construction; (6) gives detail method of the manner of securing cross-arms, a bolt or rod being placed in the form and removed within 24 hours after the concrete has been placed. This becomes a clean hole through which the bolt intended to hold the cross-arm can be placed; (7) represents the top or roof of the pole; this is easily put on after the pole is finished, but is not necessary except for appearance.

Mr. Bailey has also made application for a patent on forms varying in section from five to 15 feet each and divided up so as to be easily handled. The officers of the company which will manufacture the concrete pole are: President, A. C. Lindemuth; general manager, W. M. Bailey; secretary and treasurer, L. E. Browne.

Chicago Street-railway Situation.

At its meeting on September 12th the Chicago City Council granted the Chicago Union Traction interests an extension of time until February 1, 1908, in which to accept the settlement ordinance, by the terms of which the Chicago Railways Company would take over the North and West Side properties and improve them. If the disagreeing bondholders cannot get together by the time set the city proposes to compel the Chicago City Railway Company to take over the Union Traction lines.

In order to secure the extension of time, representatives of the traction companies were compelled to agree to put all the net proceeds of the lines into the work of reconstruction during the extension period. This plan will result in a default of interest on bonds, which probably will cause some equity holders to seek a decree of sale with a view to foreclosing. Such a turn, it is said, may bring the security holders together by agreeing to a reorganization plan to keep their holdings from the auction block.

Illuminating Engineering Gets Attention in England.

Under date of September 6th the London correspondent of the Western Electrician writes: "I have mentioned on one or two occasions that Mr. Leon Gaster has been agitating for a more complete study of illuminating methods and the science of lighting generally, aiming at the policy pursued in the United States. He has already attempted to form an association of illuminating engineers, although I am not aware to what proportions this has grown.

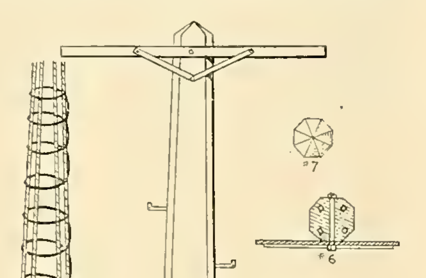

FIG. 2. DETAIL DRAWINGS OF BAILEY CONCRETE POLE.

"A further outlet for his energies in this direction has now been manifested, for I see he has registered a company for publishing a journal devoted to illuminating. This matter has a greater importance than may appear on the surface. The great need of combination between lamp makers is recognized by all, yet everyone seems afraid to move in the matter. The drawbacks attaching to the present inchoate position were exemplified at the discussion on lamps at the Institution of Electrical Engineers last winter."

Canadian Telephone News.

A new telephone company has been formed at Vancouver, B. C., to operate in that city. Steps are to be taken at once to secure a charter, and it is expected that construction work will be started this fall. The promoters say that they intend to install a complete plant at the start and so avoid the necessity of continual improvements that would keep temporarily impairing the efficiency of the service. The promoters are prominent citizens of Vancouver.

Contracts have been let for the construction of the Manitoba government exchange in Winnipeg. The exchange will be erected by James M. and John J. Kelly of Winnipeg. It will cost $97,172, which includes everything but plumbing and heating. The building is to be completed by August 1st of next year. The telephone subway contract was let to Stone & Green, Minneapolis, Minn., at a minimum of $83,000, as the exact amount of the work to be done has not yet been decided upon. The pole lines in Winnipeg will be built by the telephone department. In the trench contract there will be about 100 miles of conduit-feet. Orrin F. French, Winnipeg, Man., is superintendent of telephone construction for the province.

Walter Scott, premier of Saskatchewan, says that arrangements have been completed for the construction of government-owned long-distance telephone lines in Saskatchewan, and plans are now being prepared by Francis Dagger, telephone expert, for Saskatchewan. It is expected that a start will be made this fall.

Work on the provincial government telephones in the province of Alberta is progressing satisfactorily, and by the end of the present year fully 500 miles of government lines will be completed. In addition to the long-distance lines, some 12 or 15 local exchanges will be installed along the trunk lines. Construction work on the Lacombe-Stettler line is completed, and the Stettler-Daysland line will be the next, after which work will be transferred to the line now being built to connect Edmonton and Lloydminster. The exchange at Blairmore is now in operation, having been taken over from a private company and standardized. Eighty miles of the work on the line between McLeod and Blairmore is under construction and will be completed by the end of September. The rural line northward from Vegreville, which will supply a very rich farming country, will be completed about the same time. Work is in progress at Fort Saskatchewan standardizing the local exchange, which has been taken over by the government, and a metallic circuit is being put in. When the season's work is completed, it is said, the Alberta government will have in operation some 150 miles of line more than the Bell company has constructed in the province during the last 10 years. It is the intention of the government to build another 500 or 600 miles of line during 1908. R.

Indiana Telephone Items.

The United Telephone Company of Hartford City has decided to make improvements in its system that will require a large expenditure of money for material and equipment. A large force of men will soon be put to work costructing several new additional rural lines that are to run out of the local exchange.

The announcement of the New Long-distance Telephone Company and the Central Union Telephone Company that they would abolish their night rates for toll service in this state has occasioned a number of cities to examine ordinances under which the companies are operating. The city authorities of Kokomo are standing upon an ordinance provision, stipulated in 1904, regulating the companies and declaring that for no conversation within the limits of Howard County shall a charge in any contingency exceed 15 cents. Charles S. Norton, manager of the New Long-distance company, in explanation of the change, said: "All Independent toll-line companies with which we connect have gone to the three-minute basis, and have abolished a lesser rate for night service. Our operators do not know whether a message is passing entirely over our own lines or jointly over our lines and the lines of a connecting company. It is impossible for us to maintain separate schedules for business passing to and from the 6,000 or more stations with which we connect, and to enable us to handle the business with dispatch and uniformity, the easiest way out of the dilemma was to go to uniform basis with our connecting companies. We have found, by a careful method of checking, that the average initial period of business conversation is only a few seconds over three minutes."

The Town Board of Normal City has discovered that taxes that should have been paid by the Central Union Telephone Company during the last eight years to the town corporation have in fact been paid to the city of Muncie. The Town Board has made demands upon the company for the taxes, and the company in turn has cited the board to Muncie for payment. S.

Telephone News from the Northwest.

The North Dakota Independent Telephone Company is putting in a conduit system at Fargo, N. D. The Northwestern Telephone Exchange Company will begin work shortly on a similar system.

The Fox River Valley Telephone and Telegraph Company of Appleton has purchased the Wolf River Telephone Company's plant. This company went into the hands of a receiver several years ago. Creditors will now be paid in full.

The Brush Creek Farmers' Telephone Company has filed articles of incorporation at Ontario, Wis. J. O. Hoff is interested.

The Great Western Telephone Company has applied for a franchise at Pierre, S. D.

The Dell (Wis.) Co-operative Telephone Company has been incorporated with a capital of $25,000. Edward Clark heads the list of stockholders.

The night toll rates of the American Telephone and Telegraph Company in the Northwest have been made the same as the day tolls.

The Cannon Ball Telephone Company of Mott, N. D., has let the contract for the installation of a local telephone exchange and a line to Richardton.

The Northwestern Telephone Exchange Company will expend $75,000 to $100,000 in improvements to its toll lines in North Dakota.

The Mesaba Telephone Company has made a number of improvements to its local system at Virginia, Minn.

The Minnesota Central Telephone Company has closed its exchange at Kerkhoven, Minn.

Otto Kohn, local manager at New Ulm, Minn., for the Minnesota Central Telephone Company, has resigned.

The Wisconsin Telephone Company has annexed the Stevens Point, Wis., district to its Green Bay district.

A. R. Bloom of Minneapolis has taken a position at Fargo, N. D., with the Northwestern Telephone Exchange Company.

Alonzo Burt, president of the Wisconsin Telephone Company, has announced that the company will xepend about $1,50.0000 in improving its entire system. The construction work will begin next spring. R.

GENERAL TELEPHONE NEWS

Among the telephone companies incorporated in Nebraska recently are the Fox Creek Telephone Company of Curtice, J. W. Adams heading the incorporators; the Johnstown Telephone Company of Johnstown, William Coryell, and the Etna Mutual Telephone Company of Etna with C. O. Lind at the head.

The Canadian Independent Telephone Association at its recent convention in Toronto adopted a resolution expressing its disapproval of the affiliation or connection of the Independent telephone companies with the Bell company anywhere in Canada as being injurious to the cause of Independent telephony as a whole.

The Pacific Telephone and Telegraph Company's executive offices have been moved to the third and fourth floors of the Shreve Building on the northwest corner of Grant Avenue and Post Street, San Francisco. The engineering and construction departments are now located in the company's new two-story brick building at 140 New Montgomery Street.

Persistent criticism of the Chicago Telephone Company ordinance presented by the council committee on gas, oil and electric light caused the friends of the measure to abandon their plan of placing it upon its passage at last week's meeting of the council, and the ordinance was therefore not brought to a vote. Action was deferred on the measure until after the charter election. The voters on September 17th rejected the new charter for Chicago, which provided that any franchise to be granted by the city be subjected to a referendum vote. The telephone ordinance may be presented to the council next week.

Houston, Tex., is going to have the latest developments in its new automatic telephone system. The plans for it are now being made by McMeen & Miller of Chicago. Mr. S. D. Levings of this firm is engineer in charge of construction. He has just announced that overhead wires will be used as little as possible and conduits will be installed for the major portion of the lines. The stockholders of the Southwestern Home Telephone Company of Redlands, Cal., have authorized a bond issue of $1,000,000. Of this $100,000 is to be used to clear up the debts of the company and the remainder for extension and improvement of the lines.

CORRESPONDENCE.

Continental Europe.

Paris, September 4.—Three of the French transatlantic liners are now fitted with a very complete system of radio-telegraph apparatus which keeps them almost constantly in connection with the posts on shore at either end. The vessels are the Provence, Savoie and Lorraine, and the present apparatus has been installed under the direction of Chief Engineer Vivien. From the messages which are thus received from the coast stations of Poldhu and Cape Cod a journal is made up containing the most important news, and it is printed on board and distributed a few hours later. As to the greatest distance which can be covered by the present apparatus, it is said to be 1,700 to 1,800 miles, and thus the steamers are in constant connection with the posts on shore with the exception of a few hours. However, messages can be received from other vessels which lie within the range of the apparatus so as to fill up the gap. Regarding the character of the instruments which are now used on the French liners, the receiver is mounted in a form of helmet so as to be carried upon the head, and the operator receives the messages by sound. In order to find out at what time messages can be taken from other vessels passing within reach, each vessel is provided with a chart which shows the route of the vessels and the probable time when they are within range. With the present system the three steamers above mentioned are now publishing the daily Journal de l'Atlantique from their printing presses. Many other vessels are equipped with apparatus for short distances so as to be able to receive private messages.

At the recent Agricultural congress held at Vienna one of the interesting papers was that which Dr. Caro of Berlin read upon a new method of utilizing peat bogs for producing current in electric stations, the latter to be erected on the spot. The author showed in the first place that the manufacture of combustible by means of peat and the production of coke would hardly extend beyond a local interest. Peat, even when freed from water, is only a second-rate fuel, which cannot be transported to long distances. On the other hand, the coke manufactured from peat has a high price and thus cannot compete upon a large scale with good qualities of ordinary coke. Moreover, all these processes require the peat to be freed from water beforehand, down to 15 or 20 per cent. of water. Seeing that the method of natural drying must be used, great difficulties are found in preparing the combustible during the whole year. The new method proposed by the author consists in utilizing the peat on the spot. To this end it is burned in a gas producer of special form, and the resulting gas is used for different industrial purposes, especially for running an electric plant. By the author's process he is able to use peat all the year round which contains 50 per cent. of water. The by-products from the gas process serve to pay for the transport and other expenses of the plant, and thus there is practically no expense for the gas. Such electric plants can compete very well with hydraulic plants and will attract different industries to such regions.

To the different coast stations which have been installed on the coast of France by the postal and telegraph department is now added a post of considerable power at La Rochelle, on the Atlantic coast. It is erected in a tower located at the mouth of the harbor.

An electric tramway line is soon to be constructed between Boulogne, on the channel coast of France, and the suburban town of Outreau. Among other traction enterprises in France is a new line which is to run from the town of Maxeville, near the eastern frontier, to Champigneulles. A. de C.

Great Britain.

London, September 6.—The tale of woe continues from week to week in connection with the various London transport companies. This week half-yearly meetings of three of the tube railway companies affiliated to the Underground Electric Railways Company of London have been held, and it is patent that, although the concerns have not been in operation a sufficiently long time to warrant any direct comparisons being made, yet it is quite clear from the tone of the speeches to the shareholders that expectations have not been realized. The causes for this have been so repeatedly given that I will not go into them again. In fact, we have now reached the condition that all kinds of transport companies are attacking each other for undue rate cutting, and the whole position is one of complete indecision as to what the future is likely to bring forth. The directors of the tube-railway companies have turned their attentions in the direction of reducing the working expenses, but have run up against an item in the cost of working the electric lifts which defies reduction. In the case of the Great Northern, Piccadilly and Brompton tube the expense of working the lifts amounted, in half a year, to over $17,000. The three tube companies in question are practically working new routes, and the directors' explanation of an unsatisfactory state is that the public is slow to take advantage of new facilities. The position of these three companies is a serious matter for the Underground company, for they were the three lines selected by the late Mr Yerkes as affording the most profitable prospects, and the guaranteed dividends amount to a considerable sum annually.

A new view is being taken upon the question of linking up suburban termini by means of tube railways. Hitherto the very heavy burden of construction has been left to the manager of the tube lines, although the suburban companies' local traffic development has depended solely upon the existence of these terminal facilities. Now, however, the view is growing that in these circumstances part of the cost of construction should be borne by the other company. This is partly the reason for postponing the construction of an important extension of the Baker Street and Waterloo tube railway. This extension would link up with the terminus at Paddington, of the Great Western Railway Company, but how far the view expressed above will appeal to the management of that system remains to be seen.

An interesting letter appeared in The Times a few days ago, written by one of the members of the committee which considered the Radio-telegraphic Convention of 1906. This member, Mr. Macpherson, voted in the minority, and his explanation for writing the letter in question was that his action had given rise to a good deal of misconception. He, first of all, complains of the government for nominating both Mr. Buxton, the postmaster-general, and Mr. Lambert, who is at the Admiralty, upon the committee, seeing that both had expressed strong views in favor of the convention beforehand. He next states that the committee was absolutely incompetent to deal with the technical evidence placed before it, and that only Mr. Marconi really gave evidence in an impartial manner. But for Mr. Marconi's evidence he practically states that he would have been in the dark completely. He finally concludes with an appeal for postponement, and says that, although a Radical, he is not ashamed at putting in a word for the Marconi company, for if its business is a monopoly, he wishes there were more like it. I am afraid his letter has come at the wrong period of the year to be effective.

The final accounts of the Brighton Corporation telephone system, which was recently passed over to the postmaster-general at a price about $7,500 less than the capital cost, have just been published. Owing to the fortuitous circumstance that the corporation was enabled to purchase stock to pay off the remaining debt at a discount, the balance sheet shows that, after deducting the amount taken from the rates to maintain the system, there has been a net profit to the borough as the result of the sale of about $3,000.

Gradually the South Wales Electrical Power Distribution Company is disposing of its power stations to the local authorities in whose districts they are situated. The company possessed one large station, which it is continuing to work itself, and three small local power houses. It is these latter which are being disposed of at a considerable sacrifice.

A representative of a London daily paper has had an interview with Sir Charles Metcalfe, one of the consulting engineers to the Rhodesian Railways, and also to the Victoria Falls Power Scheme. He stated that, in addition to securing further valuable contracts for power, the power company had been of considerable service to the Johannesburg municipality in its recent trouble, and that this action had improved the prospects of the company very considerably. Mention of the Johannesburg plant reminds me that there is a strong possibility of the action of the corporation against the plant guarantors being heard in England.

Inquiries made among electrical manufacturing firms go to show that there is a strong disposition to eschew exhibitions of all kinds at present. It is quite possible that some large firms will not be found exhibiting at the Manchester electrical show next year for this reason. Those companies which experienced a bad time last year particularly are commencing their economies in this direction.

An announcement has been made that the Admiralty has approved the establishment of a separate branch for conducting radio-telegraphy in the navy.

Now, that descriptions of the New Haven single-phase equipment have reached this side, it is interesting to note that the engineers to the London, Brighton and South Coast Railway, upon the section of that line which is being equipped for single-phase working, propose to support the overhead wire by iron lattice girders standing at distances from 100 to 300 feet apart. I believe that upon the Midland Railway experimental line wooden poles are to be used. As I have previously pointed out, the company does not propose to erect a power station in the first instance, but to purchase energy from the local electric supply company. G.

New York.

New York City, September 14.—In order that it may be thoroughly and accurately informed as to the exact state of affairs in the Battery tunnel to Brooklyn, the Public Service Commission will shortly appoint two expert civil engineers, not in any way connected with the construction companies, to make a report upon conditions there existing, including the length of time it will take to finish the job. Last week it was stated that these tubes had been found entirely unsatisfactory, and would have to be lined with reinforced concrete in order to make them safe. William Barclay Parsons, consulting engineer of the Interborough Rapid Transit Company, after a thorough inspection of the tubes, states that 'the tunnel,' although much delayed, is now in good shape and that there is nothing to prevent its being opened to the public at an early date. Much interest is being attached to the date of opening, in view of the traffic conditions which are becoming more and more dangerous at the Bridge, due to the increasing traffic.

The United Wireless Telegraphy Company, which is reorganizing the American De Forest Company, is said to be capitalized at $20,000,000, of which $10,000,000 is common stock and the rest preferred. Sixty per cent. of this stock will be used in taking up the stocks and bonds of the American De Forest company. The United company now occupies the offices at 42 Broadway, formerly occupied by the De Forest concern. Abraham White, the president of the De Forest company, is said to be one of the largest creditors. It is declared that some of the patents have proved worthless and that others are infringements.

The air locks in each end of the Forty-second Street Astoria tunnel have already been removed and the work of preparing the tubes for actual operation has been begun and advanced to a point where the use of compressed air is no longer necessary. The cars to be used in the tunnel are at hand, and, in short, the operation of the tunnel is near realization. Actual work on this tunnel under its present control was begun July 12, 1905. Actual work on the Battery tunnel to Brooklyn was begun September 11, 1902, to be completed within three years. The time when the latter tunnel will be completed is still problematical. This fact shows what can be done when private rather than public interests are at stake. In order to possess themselves of the full value of the old Steinway franchise, the purchasers, the Belmont company, would have to have completed the tunnel to Astoria by January 1, 1907, and to this end a bonus of $200,000 was offered the contractors.

Such rapid progress is being made on the Hudson River tunnels from Manhattan to Hoboken that it is expected cars will be running between the shopping district and the Delaware, Lackawanna and Western terminal before the winter sets in. As to the cars which will operate between the terminals, the seats will run lengthwise, with doors at both ends and sides as well. Posts will be set up in each of the cars, to which passengers may "cling" in their three-minute passage under the river. For sanitary reasons the floors will be of cement and carborundum to prevent slipping.

An exhibition of Marconi wireless telegraphy will be seen at the electrical show at Madison Square September 30th to October 9th. It will be the endeavor of the Marconi company during the show to give practical demonstrations and instruction every afternoon and evening. There will be a receiving station in the Garden, which will be in communication with all incoming vessels employing wireless.

The cable steamer Silverton, with more than 1,300 miles of submarine cable on board, has left London. The cable is to be laid for the Commercial Cable Company between New York and Havana. The object of laying a new cable directly from New York to Havana, instead of following the old route between Cuba and Florida, is to create effective competition, to greatly reduce the time of transmission, and increase the reliability of the service. This latter could only be obtained by obviating the long coast lines along the Atlantic, which are subject to stormy weather, and substitute therefor an all-submarine line. E. H. S.

New England.

Boston, September 14.—In this city the telegraph companies have reopened the most of their branch offices and the Western Union officials report a practically full force in the main office. There is about 90 per cent. of the regular force at work in the Postal main office and the skill of the operators is good.

The Atlantic Insulated Wire and Cable Company's new plant at Stamford, Conn., has been completed, but all of the machinery has not been installed. The main structure is two stories high, 351 feet long and 80 feet wide. The power house is 44 by 100 feet. The mixing department has a daily capacity of 10,000 pounds of rubber compound and the insulating department can handle 600,000 feet of wire daily. The new plant has about three times the capacity of the one burned last November.

The New York, New Haven and Hartford Railroad Company expects to open its electric service between New York and Stamford, Conn., in about three weeks. Delays have been caused by the non-receipt of iron poles and other structural iron, and the overhead wiring has been slow in consequence.

During a large part of this week the Suffolk County grand jury has been listening to testimony offered by the New England Telephone and Telegraph Company's employes by which District Attorney John B. Moran expects to be able to obtain indictments based on the wrongful employment of men with political influence by the telephone company. The district attorney is getting after the politicians and not the company.

The Massachusetts Highway Commissioners' hearings on the conduct of the telephone business in this state are still being held. The commissioners have examined the company's daily charts of traffic. Frederick P. Valentine, an engineer in the New England Telephone and Telegraph Company's traffic department, gave some information regarding the expense of handling the business. E. W. Longley, auditor of the company, gave the number of times suburban subscribers called for Boston connections in May, 1907, as 228,123. The number of times Boston subscribers called for suburban connections during the same month were 88,251. Mr. Longley said that the company did not intend to furnish private telephones to municipal officials at a discount. He said that the company's investments in 1906 were as follows: For the Boston district, $14,489,383; for Massachusetts, exclusive of Boston and suburbs, $9,937,766; for territory outside of Massachusetts, $7,550,491; total, $31,977,640. The company's revenue from these investments was as follows: In Boston district, $1,400,782; in Massachusetts, exclusive of Boston, $361,832; in territory outside of Massachusetts, $183,520; total, $1,946,134. These figures are somewhat misleading, owing to tolls collected in the Boston division which were earned outside of the division. At a subsequent hearing Jasper N. Keller, vice-president of the company, explained the working agreement between the American and the New England Telephone and Telegraph companies. He said that the actual revenue per subscribers was $123.01 in 1896 and $56.69 in 1906. The company paid a dividend of six per cent. each of these years. The hearings are still in progress.

Otis F. Pettee, for many years treasurer of the Gamewell Fire Alarm Telegraph Company, died suddenly of heart disease at his home in Newton Upper Falls, Mass., on September 6th. He was 54 years old and left a wife. He retired from active business about 10 years ago.

Dominion of Canada.

Ottawa, Ont., September 14.—A special committee of the City Council of Hamilton, Ont., has recommended that the Council, as soon as possible, submit a by-law for the purchase of electric pumps for the waterworks system, with a capacity of 10,000,000 gallons a day. A deputation will visit Buffalo and other places.

An important special meeting of the shareholders of the Power, Light and Heat Company of Sherbrooke, Que., has been held to take into consideration the offer of the city to buy out the company's plant and business. The price offered by the city was $170,000, the city to assume payment of the company's bonds. It was decided to offer to sell to the city at $190,000 and the city to assume the bonds.

The striking telegraphers of the Canadian Pacific Telegraph Company have applied to the Department of Labor for a board of conciliation and arbitration under the new law passed last session of the Dominion Parliament and have named their arbitrator. The principal point in dispute is wages, though a variety of other topics will come up for adjudication.

It is expected that the wireless-telegraph service now being installed on the Pacific Coast by the government will be available, in part at least, within six weeks. The preliminary work, embracing the construction of stations and the introduction of the initial plants, is reported by Superintendent Morse to be well under way. The construction work at Pachena Point, Estevan Point, Shotbolts Hill, Victoria and Cape Laze is being advanced at rapidly as circumstances will permit.

The Royal Commission appointed to investigate the strike of the Bell telephone operators at Toronto last winter has made its report to the government. In a general way the commission reports the hours of work and strain of operating to be too severe for the young women who are employed at the switchboard and that their pay is too low. The company in 1903 reduced the length of day from eight to five hours. In January last the eight-hour day was resumed, and this caused the strike. The company said the shorter day had failed to promote efficiency of service, as the operators, having more time, tired themselves with housework or amusement. The pay was $20 a month for the first six months, increasing $2.50 for every six months to three years, when the maximum was reached. Both the Dominion and Ontario governments will introduce at their coming sessions legislation based upon the findings of the commission designed to improve conditions for the operators. W.

Ohio.

Toledo, September 14.—A fairly prosperous season is being felt by electricians and electrical supply houses throughout this section generally, although some portions, like Toledo, are suffering somewhat from local conditions, which are by no means applicable to the state of Ohio. Electric-railway construction in all parts of the state has been unusually active all summer, and while there is some let up now, the season has been a heavy one. The number of public buildings completed and now under way is large. Business blocks and private improvements have been perhaps as extensive as ever was known, taking the state as a whole.

Toledo, however, is still undergoing a season of depression in building operations, and the fall prospects are not as bright as might be wished for. There are several contracts under way that will furnish a fair business for the local dealers, but on the whole the season is far behind what it was last year. Buying among the electrical houses is limited at this time, this situation being due not only to local conditions but to the condition of the copper market. It is not thought that copper products will advance materially in the near future, but, on the other hand, predictions are being made that the present high prices will not continue. Supplies are therefore being ordered about as needed, and the surplus on hand is not permitted to increase. Local people are still hoping that a little later in the season there may be a rally from present conditions, but indications are not strongly pointing that way, and the chances seem to be that there will be no rush of business before next season.

The Hamilton Gas and Electric Company recently awarded the contract for a new building to J. R. Bender & Brother, the improvement to cost about $10,000 when completed.

A handsome contract is in store for Youngstown electricians when the awarding for the additions to the new Dollar Bank Building is made. The improvements contemplated will reach $125,000.

Plans have been prepared for a 15-story bank and office building for the Provident Savings Bank and Trust Company at Cincinnati. The building will cost $250,000, and a complete system of electric lighting will be installed, consisting of about 500 lights.

A large contract which will be awarded to Ohio electricians is that in connection with the new $1,000,000 courthouse to be erected at Youngstown. The lighting plans have not yet been completed, but will comprise no unimportant part of the equipment.

The Dayton Motor Car Company will erect a new five-story factory building. The work will be done by the Keppele Hall Engineering and Construction Company. About $15,000 will be expended.

More than $250,000 is being expended by the People's Railway Company of Dayton in the erection of a power house, office and repair shop.

The Citizens' Motor Car Company of Cincinnati has prepared plans and will erect a $100,000 garage in the near future. L. P. Hazen & Co. will also build a garage for the Reliance Motor Car Company of Cincinnati, at a cost of about $20,000.

Articles of incorporation have been granted to the Massillon, Wooster and Mansfield Traction Company, with a capital of $10,000. The purpose of the company is to build an electric road connecting Mansfield and Massillon.

The Cincinnati Traction Company contemplates the expenditure of $50,000 in the building of additions to its present car barns. The company is crowded for room at present.

Farmers along the right-of-way of the new electric line to run from Millersburg to Beach City have not only donated the right-of-way but are offering financial aid to the company. It is said the line will be in operation within a few months. A feature will be that there will not be a bridge, and but few culverts, along the entire 25 miles. H. G. S.

Indiana.

Indianapolis, September 14.—The Indiana Union Traction Company, with headquarters in Anderson, will expend $40,000 in the construction of a concrete arch bridge, of artistic design, over White River, near Chesterton.

A consignment of 18 carloads of steel rails has been received at this place by the Chicago New York Electric Air Line. This and other activities make it appear that the line will be constructed, through Indiana at least.

J. B. Crawford, superintendent of transportation of the Fort Wayne and Wabash Valley Traction Company, announces that through trolley service between Lafayette and Fort Wayne will be inaugurated October 1st, when new and modern fast limited cars will make regular trips between the two cities.

The Indianapolis Traction and Terminal Company, which spent $60,000 for new copper cable and new equipment for its line to the state fair ground, during the last week transported passengers to the state fair on the scheduled rate of one car every 15 seconds. Four hundred cars were operated on this line without a hitch or accident of any kind.

During the last week the 12 interurban electric lines operating in and out of Indianapolis carried over 100,000 persons to the state fair grounds, and, so far as known, no accident or mishap of any kind occurred to throw the cars out of their regular schedule.

That traction sleeping cars will be in demand in the immediate future is being seriously considered by a number of Indiana traction officials, who recently made a nine-hour trip between Indianapolis and Detroit by the way of Toledo. They say it is now possible for people to travel from Indianapolis by trolley to most any point in Ohio, Michigan and Illinois, and that sleeping berths will be in order in a short time can no longer be disputed. In this connection Mr. Harrison F. Holland of Indianapolis has just completed plans for a new palace car, similar to the former Holland car designed by him. The new car will be propelled by four 85-horsepower motors, which will make the car lighter by at least six tons than the original Holland car. This change will make the cost of the car at least $5,000 less than the former car, the cost of which approximated $20,000. The new car will be equipped with comfortable chairs and roomy berths, with capacity for 44 passengers. A company will be organized to construct the new palace cars, by which time it is thought a good demand will be made for them by the progressive interurban lines of the Central States.

The Warsaw City Council is attempting to force the Warsaw Gas and Light Company, which is controlled by Detroit men, to accept the terms of a new franchise submitted by the city. The franchise is to have a life of 25 years, and regulates the rate to be charged for the commodities.

The Town Board of Summittville is experiencing trouble with the municipal electric-light plant. The plant was erected and equipped in 1902 by two Summittville men, who eventually sold it to the Summittville Town Board for $55,000, making a good profit. The board has continued to operate it at a loss. The board has resolved to separate the electric-light and water funds from other funds in the treasury, so that other funds may not be applied to electric light and waterworks, and in this way involve the town beyond its capacity. In other words, it is an attempt to make the electric-light plant stand or fall by the grace of its earning power.

The City Council of Terre Haute has again refused to authorize the payment of the quarterly street-lighting bills to the Terre Haute Electric Street Railway and Lighting Company, the whole amount now due being $24,000. It is asserted that the light is not up to the standard contracted for.

Articles of incorporation have been filed by the Miller Electric Company of Terre Haute. The company proposes to establish and equip a factory for the manufacture of electrical machinery and supplies of all kinds. The incorporators are Frank B. Miller, Jacob W. Miller and W. E. Coordes.

S. S.

Illinois.

Peoria, September 14.—A party of Montreal men accompanied by G. M. Mattis, assistant treasurer of the Illinois Traction Company, and Secretary Everson, made a visit to this city this week to inspect the properties of the company. The party included R. D. McCraig and C. H. Lewis, Canadian men who are interested in the Illinois Traction Company.

The Clayton Farmers' Union Telephone Company of Clayton has been incorporated with a capital stock of $1,000 by John W. Wallace, Charles C. Cain and Henry J. Beckman.

Work of grading has been commenced on the Carthage-Nauvoo interurban electric line. The road goes through a country that requires a very little grading, and it is expected to have the line in operation by the first of the year.

A new interurban is to be surveyed from Kirkwood to Monmouth. George M. Jamieson, who is behind the project, has engaged an engineer to survey the proposed route and make a report as to the cost to build the line.

The Village Board of Chandlerville has allowed F. P. Schaaf, to whom the electric-light franchise has been granted, a period of six months in which to consider the proposition. The promoters will undoubtedly have the plant in working order in a much shorter time.

The Illinois Traction Company interests have incorporated another company under the name of the Danville and Southeastern Railway Company, the principal office to be in Danville, with capital of $10,000. It is proposed to construct a line from Danville to a point in the southeast corner of Georgetown Township, Vermilion County. The incorporators and first board of directors are W. H. Carnahan, B. E. Bramble, George M. Mattis, Charles Zilly and C. E. Cox, all of Champaign.

The grand officers and the grand executive board of the Electrical Workers' Union are holding a meeting in Springfield this week, and it will continue for a week or so. One of the matters to be brought before the board is that of a building for the national headquarters. A number of [illegible] under consideration.

The Illinois Traction Company has let the [illegible] tract for the nine piers that will be required for the bridge across the Mississippi to the Missouri Valley Bridge and Iron Company for the sum of $385,795.50. The piers are to be built to a footing 70 feet below low water mark and will be 130 feet high. Contracts for the upper parts of the bridge will be let about the first of the year. The intention is now that the bridge shall be ready for use in February, 1909. The total cost is estimated at $2,500,000. The bridge will carry the cars into St. Louis and will also be able to carry wagons and foot passengers, but it is not expected to accommodate steam railroad.

The Hoskins Electric Heating Company of Chicago has been incorporated with a capital of $130,000 to manufacture and deal in heating apparatus. Incorporators are E. F. Hoskins, Daniel Weber and Elmer E. Beach.

The Tri-county Mutual Telephone Company of Creston has increased its capital stock from $2,500 to $6,000.

V. N.

Michigan.

Grand Rapids, September 14.—At the special election held at Paw Paw for the purpose of bonding for an electric-light plant and waterworks, the proposition carried by 201 to 7. The amount to be bonded for is $50,000.

Recently the Cartier Lumber Company of Ludington leased to Arthur J. Whipple and Lewis J. Highland, for 20 years, for an annual rental of $480, the Hamlin dam and waterpower. It is stated that these men will soon organize a corporation to be known as the Chicago-Michigan Power Company. They get the right, so far as the lease is concerned, to maintain a head of 15 feet, and get the right-of-way for poles. It is reported that the power will be utilized for an electric road from Ludington to Manistee, but some doubt is expressed as to whether sufficient power can be generated at Hamlin for this purpose.

The Niles Milling Company, the oldest manufacturing concern in the city, will go out of existence within a few days. Several months ago the company's big brick flour mill was destroyed by fire, and the waterpower and the company's frame buildings will be taken over by C. A. Chapin, who desires, it is said, to raise his dam in the St. Joseph River at Buchanan.

The Michigan Agricultural College is to have a complete electrical engineering course with the completion of the new $100,000 engineering building. A combination electrical and mechanical laboratory in the rear wing of the building is 40 by 60 feet, and it will be fully equipped.

Though the franchise granted to the McMichael interests for the building of an electric road to Dowagiac from Benton Harbor has expired, with the line constructed as far as Eau Claire, officials declare that the line will go through within a few months. F. M. Mills, president of the concern, has bought a farm near Dowagiac for $25,000, which, it is expected, will be converted into an amusement park.

L. W. B.

Northwestern States.

Minneapolis, September 14.—Capitalists of La Crosse, Wis., are planning the purchase and further development of the waterpower at Hokah, with the object of furnishing light and power to the villages of Hokah, Caledonia and Spring Grove, Minn.

Henry Sherry of Neenah, Wis., proposes to form a stock company to develop the waterpower on Wolf River near Antigo. It is estimated that 5,000 horsepower could be developed.

F. E. Hatch of Pellston has secured an option on Boney Falls, near Escanaba, Mich., and proposes to build a large power plant there.

The Mille Lacs Power, Light and Heating Company has been formed and will build a light and heating plant at Wahkon, Minn.

The Wausau (Wis.) Street Railroad Company has closed the contract for the erection of a new car barn.

The Northwestern Interurban Railway Company has filed an application at Grand Forks, N. D., for a franchise.

It is proposed to build a municipal electric-lighting plant at Cudahy, Wis.

The City Council at Valley City, N. D., has reconsidered its former action and has voted to sell the municipal light plant.

The Rodolf mill and electric-light plant at Muscoda, Wis., is to be purchased by that village.

J. C. Enright of St. Cloud has given orders to begin work at once on a new concrete power dam to be constructed at Cold Spring, Minn., for a power plant for the mill there.

The City Light and Gas Company of Beatrice, Neb., has filed articles of incorporation with a capitalization of $90,000.

The City Council at Valley City, N. D., has reconsidered its former action and will offer the municipal lighting plant for sale.

A company has been formed at Hartley, Iowa, for the purpose of building a trolley line from [illegible]

The [illegible] Interurban Railway Company has withdrawn its petition for a franchise at Grand Forks, N. D., and announced it intends to [illegible] that field.

The South [illegible] Company has purchased the machinery for a new electric light plant at Redfield, Iowa.

Surveys have been started on the proposed Spirit Lake, Emmetsburg and Fort Dodge (Iowa) interurban railway line.

R.

Pacific Slope.

San Francisco, September 11.—The first authentic information relative to the plan of the Great Western Power Company to establish on the Oakland estuary a large auxiliary electric generating plant is given out by H. P. Wilson of the firm of Brown, Wilson & Co. Mr. Wilson confirms the purchase of a tract of about seven acres. The adopted plans contemplate a building 250 feet long and 100 feet wide. It is proposed to install turbine generators of 5,000 horsepower each besides the necessary steam-generating plant. The auxiliary station is to be independent of the long-distance transmission and is designed to furnish power in an emergency. The company will expend $2,500,000 on the auxiliary plant on the estuary. Contracts have been let for turbines, generators, boilers and all other machinery required, according to the company's announcement.

A contract for two 650-kilowatt Westinghouse-Parsons turbo-generators has been closed through Hunt-Mirk & Co., the Pacific Coast agents, which are to be installed in the new power station which is to supply light and power for the Claus Spreckels Building on the corner of Third and Market streets, San Francisco.

John Hayes Hammond and other owners of the Mt. Whitney Power Company, whose plant is located near Visalia, Cal., are the movers in a new corporation known as the National Park Electric Company, which is preparing to put in an electric power plant near Sonora in Tuolumne County. It is rumored that the new company will take over some of the other electric enterprises on the Tuolumne River.

Work has been commenced on the southern extension of the power lines of the California-Nevada Electric Power Company. This line will extend from Pickle Meadows, near Bridgeport, Cal., to Tonopah and Manhattan, a distance of 220 miles.

The Board of Supervisors of San Francisco has voted unanimously to deny the petition of Daniel O'Connell and others for the revocation of the street-railway and telephone franchises in this city and asing that bonds amounting to $22,000,000 be issued for the acquisition of the street-railway and telephone systems.

The City Council of Alameda, Cal., has set Saturday, September 21st, as the date for the bonds election for public improvements. The proposed bond issue will include $50,000 for the municipal electric-light and power plant. If the bonds carry a substantial two-story power station building will be erected.

This week the Southern Pacific Railway Company applied for franchises in the cities of Alameda and Oakland, which, when granted, will enable the company to transform its local steam lines in the city of Alameda into electric lines, in following out its avowed policy of changing all its local system on the east side of San Francisco Bay into electric lines. So far, the applications in Oakland apply only to the line which runs into Alameda, but additional franchises will be asked for soon.

The City Council of Los Angeles, Cal., has called for bids for street-railway franchises on Hill and Sixteenth streets on which the Los Angeles Pacific company was recently prevented from laying a third rail. The council has ordered that a bond of $25,000 be given for each franchise.

The Board of City Trustees of Sacramento, Cal., has granted a freight franchise in that city to the Northern Electric Company. The franchise provides that other roads may pass over the lines of the Northern Electric Company.

H. E. Huntington has issued orders to discontinue all preparations for further extension work on the Pacific Electric and Interurban electric systems in Los Angeles, Cal., the order taking effect at once. General Traffic Manager McMillan says in regard to the move: "It appears to be the policy of the present administration to make it as difficult as possible to operate our lines. We are made to pay for franchises, and these are taxed, and all improvements made are assessed at exorbitant rates, and then we are made to use fenders which cannot be operated safely on our large swift cars. The Pacific Electric and the Interurban have not paid expenses for the last three years."

The entire issue of common stock of the Pacific Gas and Electric Company, amounting to $20,000,000, has been turned back into the treasury of the company as a result of the failure of the holders of all of the stock to pay the last $10 assessment. The assessment on the preferred stock, amounting to $1,000,000, has been paid in full in cash. The issue of $20,000,000 of the common stock has been held by N. W. Halsey & Co., and their representatives here say that the action of the house in turning the entire stock held by them into the treasury has resulted in putting the corporation on a firmer financial footing. The sum realized on the assessment of the preferred stock will be used for restoration work and extensions of the service made necessary during the last 16 months. The general belief among financial men here is that the latest move in the stock of the company is preliminary to a completion of a merger with the Great Western Power Company, which was rumored some months ago.

A controlling interest in the Lytle Creek Power Company has been sold by Judge John L. Campbell of San Bernardino, Cal., to F. A. Worthley of Riverside, Cal., who is superintendent of the Riverside municipal lighting plant and a large owner in the Southwest Electrical Company. It is given out that a number of extensions will be made at once.

Contracts have been closed in the East by one of the electrical engineers of the Southern Pacific Railroad Company for 10 large boilers which are to furnish steam for the operation of the two 5,000-kilowatt Westinghouse-Parsons turbo-generators that were recently contracted for. It is probable that a third unit, of the same capacity, will also be ordered from the same company, for installation in the power house which is to be erected in Oakland, Cal., near the foot of Fruitvale Avenue. The alternating current will be transformed at sub-stations and direct current used to operate electric cars on the railroad company's local lines in Oakland and Alameda. B.

PERSONAL.

C. W. Reese has been made manager of the Northwestern Telephone Exchange Company for the St. Paul office.

Otto Schilling has been appointed superintendent of the Mattoon and Charleston (Ill.) interurban electric road. Mr. Schilling was formerly with the Illinois Central Railroad as division superintendent.

W. S. Townsend, master mechanic of the East Liverpool Traction and Light Company, East Liverpool, Ohio, has been appointed a member of the Central Electric Railway Association standardization committee to succeed W. H. Evans, formerly of Indianapolis, but now of Buffalo, N. Y.

The Holophane Company has added to its engineering department Mr. T. W. Rolfe, engineer, and Mr. C. W. Heck, designer. Mr. Heck resigned from the Safety Car Heating and Lighting Company to establish a department of special fixture designing for the Holophane Company, this department being necessary to take care of the growing number of large lighting installations being handled by the Holophane illuminating engineers.

Hugh J. McGowan, president of the Terre Haute, Indianapolis and Eastern Traction Company, and also of the Indianapolis Traction and Terminal Company, has returned from a three-month tour of Europe, where he traveled 5,200 miles in an automobile. Mr. McGowan reports traction facilities in Europe, especially in England, as away behind. "There are scarcely any interurban trolleys, and in the cities there is little or no effort made to carry or accommodate the people," he said. "We are away ahead of them when it comes to the traction business. Between Liverpool and London, about 110 miles, there is not an electric line, and the land is as level as a floor. Within a radius of 50 miles of Liverpool there is a population of 7,000,000 and no trolley lines for their accommodation. Throughout Great Britain, France, Germany and the most of the other European countries there is a great opportunity for developing the electric-railway business."

ELECTRIC LIGHTING.

L. W. Chilton has been granted a franchise for an electric-light system in Goliad, Tex.

The City Light and Power Company of Beatrice, Neb., has been incorporated with a capital stock of $25,000.

The Ola Lumber Company contemplates establishing an electric-light plant, to furnish lights to the town of Ola, Ark.

The Chickasha (I. T.) Water Power Company is now ready to begin the construction of its electric-light and power plant.

J. J. Osborne and associates have incorporated as the Texahoma (Tex.) Light, Water and Ice Company, with a capital of $15,000.

J. C. Berger and others of Denver, Colo., have purchased the Sterling (Colo.) Electric Light Company and will enlarge the plant.

The Greenville (Ky.) Light and Water Company was organized last week with a capital stock of $35,000, all subscribed. Work will be begun at once on a modern light and water plant for the city. A dam will be constructed near town which will give a supply of 50,000,000 gallons of water annually. J. A. Gilman has planned the plant and will superintend its construction. He will be general manager of the plant when put in operation.

George I. Waters of Victor, Mont., and others plan establishing a power plant on a nearby stream which will supply electric lights to Stevensville and Victor.

The Superior (Wis.) City Council recently voted to abandon further plans for a municipal lighting plant and decided to renew the contract with the local lighting company at a lower rate than formerly. Most of the aldermen and the mayor were elected on municipal-ownership platforms, and, after employing an engineer to make plans and estimates, came to the conclusion that no money would be saved by the municipal project.

The large number of gas and electrical engineers, architects and central-station men who are becoming interested in illuminating engineering, and who call upon the Holophane Company for data on this science, has led to the engagement by the company of Mr. T. R. Pemberton, in the position of office salesman and demonstrator. The Holophane Company has a very complete demonstration room, in which the illumination value of its product is shown.

The Utah Light and Railway Company of Salt Lake City, which controls all the electric lighting and street railways of that city, has decided to relinquish all its restrictions of the city's use of the power deeded to the city from its power rights in Big Cottonwood Creek by the franchise of 1905. This is on condition that the City Council validate the 1905 franchise and extend its life to 50 years. The city has been trying to secure this privilege so it could use the power as it wished instead of for purely municipal puroposes only.

ELECTRIC RAILWAYS.

The Little Rock (Ark.) and Pine Bluff Traction Company is preparing to let the contract for its power plant. J. J. Fiske is president.

The Northern Texas Traction Company of Fort Worth, Tex., will double the capacity of its power house. H. T. Edgar is general manager.

The Lancaster, Oxford and Southern, now operating as a steam railroad near Lancaster, Pa., will probably be electrically operated after the McCalls Ferry dam is completed. President W. M. Franklin of the road recently sought permission of the Oxford Borough Council to extend the line through some of Oxford's streets and to the fair grounds, promising to use electric power over the entire system.

The Board of Trade of Red Lodge, Mont., has practically decided to build an electric road from Red Lodge to the Bear Creek coal-mining camp, four miles away from Red Lodge. This is a rich mining district that has not been developed to any extent on account of the topographical difficulty of building a mining town there. The projected line will make Red Lodge the business and residence town of this coal district.

The Los Angeles Pacific Company has made an issue of $20,000,000 mortgage bonds, of which about $8,000,000 will be used for extension and improvement of its lines and the remainder for refunding an old bond issue. Among the improvements will be new power houses and sub-stations, a large new depot in Los Angeles, besides many other modern stations along the lines. The new extensions to Hollywood and Santa Monica will require several subways and will have a rock-ballasted roadbed laid with 90-pound rails. The new rolling stock will be of the finest type obtainable.

RADIO-TELEGRAPHY.

An Australian record in wireless telegraphy has been achieved by the successful transmission of messages from the British warship Challenger, of the Australian squadron at present stationed in Hobson's Bay, to the flagship Powerful, which at the time was moored in Farm Cove, Port Jackson. The Challenger was in communication with the flagship, by means of wireless telegraphy, the whole of its voyage and never once lost touch with it. The longest message, one flashed over a distance of 410 miles, in a direct line, constitutes an Australian record.

POWER TRANSMISSION.

The Flathead Water Power Company is building two power houses at Kalispel, Mont., each to develop 1,000 horsepower.

The California-Nevada Power Company, which purposes to transmit electric power at 100,000 volts from a hydro-electric plant in the mountains of California over a long transmission line extending to Goldfield and other Nevada mining camps, has matured its plans. It is reported that it has been decided to award the contract for the generators for the plant to the Westinghouse Electric and Manufacturing Company. The power company has offices in the Chronicle Building in San Francisco and also in Denver.

PUBLICATIONS.

The publication office of The Electric City, published by the Chicago Edison interests, has been moved from the Edison Building, 139 Adams Street, to the Electric Block, 84 to 88 Market Street, where the entire second floor has been equipped for the publication of the magazine. The telephone service remains the same as before, Main 1280.

The McGraw Publishing Company has moved into its new building at 239 West Thirty-ninth Street, New York city. The building is 11 stories high and is interesting because constructed entirely of reinforced concrete. From it the Electrical World, Street Railway Journal and Engineering Record will be issued. These journals are to be congratulated on what are apparently admirable quarters.

SOCIETIES AND SCHOOLS.

The annual reunion of the Old Time Telegraphers and the United States Military Telegraph Corps, which was to have been held at Niagara Falls on September 16th, 17th and 18th, has been postponed to a date to be determined later. Unsettled conditions prevailing in the telegraph field at this time are given as the cause of postponement.

MISCELLANEOUS.

The steam end of the 6,000-kilowatt Allis-Chalmers turbine-alternator unit which was recently shipped to the Kings County Electric Light Company of Brooklyn, a subsidiary company of the Brooklyn Edison Company, is said to be one of the largest and most powerful so far built. As an indication of its size it is interesting to note that a piece of steel forging weighing 240,000 pounds, made by the Bethlehem Steel Company, went into the construction of its spindle.

The trustees of the Sanitary District of Chicago have decided to begin work on the North Shore channel running from Lake Michigan a little north of Evanston to a point on the North Branch of the Chicago River. A pumping station near Evanston will be required. To save that city from another smoke nuisance, it has just been decided to use electrically operated pumps. Mr. E. B. Ellicott, electrical engineer of the District, estimates that there will be a saving of $55,573 in initial expenditure by the adoption of this plan. The cost of the building and equipment he places at $255,927.

The Graphic Arts Company of Buffalo, N. Y., recently purchased a new Allis-Chalmers 45-kilowatt type "H" generator with a complement of seven five-horsepower type "K" direct-current shunt motors built by the same company for operation at a speed of 1,050 revolutions per minute and two three-horsepower type "K" motors for operation at 1,025 revolutions per minute. Five of the five-horsepower motors are for belting to presses, one will be belted to a paper cutter, another to a roughing machine, while a three-horsepower machine will be mounted on the bronzing machine.

Experiments are being carried on with a view to replacing the rails now in use on the railway lines owned and operated by the Belgian government by rails of heavier weight—a change necessitated by the increased weight of the rolling stock. The weight of locomotives now in use has doubled, being from 80 to 90 tons, with cars of from 20 25 tons in weight. So far the heaviest rails used are what are known as the Vignole rails, having a maximum weight of about 90 pounds per meter (39.37 inches). The weight of the new rail with which experiments are being made is about 125 pounds per meter. The line selected for experimental purposes is that from Liege to Germany. It is obvious that the use of these heavier rails will necessitate corresponding modifications in other appliances on the lines affected by the change.

TRADE NEWS.

The Domestic Supply Company of Chicago has certified to a change of name to the Ray Electric Company.

The Standard Electric Company of Omaha, Neb., has been incorporated with a capital stock of $25,000 by E. F. Schurig and associates.

The Edgecombe Company of Cuyahoga Falls, Ohio, announces that it has taken up electrical contracting in connection with its mechanical and electrical engineering business, and will be pleased to receive copies of late catalogues of electrical supplies.

The sales force of the Holophane Company has recently been augmented by the addition of Morgan P. Ellis and Harry P. Struben. The former comes from the Electric Appliance Company of Chicago, and will travel the Northwestern States. Mr. Struben was, until lately, connected with the engineering department of the Pennsylvania Railroad Company, with headquarters at Baltimore.

He will have the southwestern territory for Holophane.

The United States Circuit Court for the District of New Jersey filed an opinion a few days ago in the suit of the Westinghouse Electric and Manufacturing Company against the Prudential Insurance Company of America on Nolan patent No. 582,481, granted May 11, 1897. This opinion is the outcome of a suit brought by the Westinghouse company against the Prudential company, charging the latter with infringement of Nolan patent No. 582,481, in the generator manufactured by the Bullock Electric Manufacturing Company of Cincinnati. The Nolan patent in suit relates to means for fastening the laminae of the cores of electrical machines together and to the casting by which they are supported. Judge Lanning in this opinion holds that claims two and four of the Nolan patent are valid and infringed.

BUSINESS.

The J. W. Morrison Lumber Company of Minneapolis, Minn., has just finished pulling its large stock of white-cedar poles from the river at Cohasset, Minn., and will commence shipping at once. This stock runs largely to long poles, and the company solicits inquiries from electric railway and light people.

The Cherry Cotton Mills of Florence, Ala., have recently placed a contract with the Allis-Chalmers Company, Milwaukee, covering a 500-kilowatt steam turbine and alternator unit, together with turbo jet condenser and engine-driven exciter complete. The cotton mill industry of the South, which has known such phenomenal growth in the past decade, owes no small portion of its success to the use of electricity to drive its looms and spindles.

An up-to-date exhibit of incandescent lamps, reflectors and globes at the Montreal Electrical Show was that conducted by the National Electric Lamp Association on behalf of the Sunbeam Incandescent Lamp Company of Canada, Ltd., together with the Holophane Company. Among the many lamps displayed were the following: Fifty, 100 and 250-watt Gem metalized-filament, operating in multiple at $2\frac{1}{2}$ watts per candle efficiency; meridian of large round bulb as well as straight side tantalum, in 40 and 80-watt sizes, two watts per candle; multiple and series tungsten, $1\frac{1}{4}$ watts per candle, the former being 110 volts, 80 candle-power, and the latter 40 candlepower, four, $5\frac{1}{2}$, 6.6 to, $7\frac{1}{2}$ amperes, miniature tantalum and tungsten from one half to eight candlepower, $1\frac{1}{2}$ to 28 volts. One of these lamps was running on an ordinary dry cell. Very interesting demonstrations were given. Many of the lamps in this exhibit were used in conjunction with Holophane reflectors. The efficiencies given herein, however, are of lamps bare. The Holophane Company had a very pretty display of reflectors and globes, notable among same being the Holophane arc or cluster. In a dark room it was easily seen that lamps equipped with these reflectors would give much more downward light. Bulletins containing information on high efficiency, metalized and metal filament lamps, and also on modern illumination, were placed within easy reach of all who cared to help themselves. These bulletins, nine in number, can be had for the asking. Among the representatives present were B. G. Tremaine of the National Electric Lamp Association, S. E. Doane, chief engineer of the association; W. E. Irving, manager of the Sunbeam company; W. M. Skiff, George Loring and George Merrill of the engineering department of the association, and T. W. Rolph and Mr. Jones of the Holophane Company.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) September 10, 1907.

865,307. Fluorescent Electric Lamp. Thomas A. Edison, Llewellyn Park, N. J. Application filed May 19, 1896. Renewed April 29, 1902.

This is a Röntgent X-ray tube or screen, the glass having a crystalline fluorescent powder, such as tungstate of calcium, fused to it.

865,368. System of Electrical Distribution. Justus B. Entz, Philadelphia, Pa. Application filed December 30, 1905.

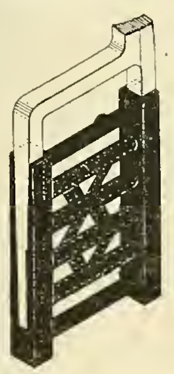
A booster for storage battery work has two main fields, one in the main load circuit and the other in the booster armature circuit, and an auxiliary coil adapted to oppose the first field.

865,377. Automatic Suspending Reel for Electric Incandescent Lamps. John H. Gordon, Snoqualmie, Wash. Application filed January 11, 1907.

The line wires connect through the horizontal axles to brushes inside the drum. The lamp wires connect to the brush terminals in such a way as to permit these wires to be wound up on the drum.

865,379. Combined Jack and Restoring Drop. Emadia J. Grenier, Menominee, Mich. Application filed April 18, 1906.

The drop is provided with a vertically pivoted shutter and a restoring mechanism. Below the number plate and shutter is a spring-jack mounted on the same block.



NO. 865,503.—ACCUMULATOR.

865,383. Controlling Device. Arthur E. Handy, Providence, R. I., assignor to the Rhode Island Elevator and Machine Company, Providence, R. I. Application filed December 31, 1904.

An electric controller has an electromagnet provided with a plunger core and armature. A series of circuit closing fingers arranged in sets is connected to the armature so as to alternately release the fingers of each set and thus cut out resistance step by step. Pivoted arms are connected to the plunger core so as to simultaneously render all the fingers inoperative.

865,384. Timer. Charles S. Hardy, Summit, N. J. Application filed January 21, 1907.

This is a periodic contact maker having a contact arm that can be turned in one direction only. This engages, one by one, a series of contacts, each consisting of a rod held in a bushing by a spring tangentially against the rotating arm.

865,387. Portable Dust-suction Apparatus Worked by Means of an Electromotor. Adolf Hein, Berlin, Germany, assignor to the Vacuum Cleaner Company. Application filed February 21, 1906.

A motor is connected by flexible transmission to a double throw crank shaft that operates two suction bellows, all but the motor being in a dust-tight casing.

865,388. Control of an Electrically Driven Air Compressor. Ebenezer Hill, Norwalk, Conn. Application filed April 1, 1907.

The motor controller is actuated by the differential action of pistons in two cylinders, one trying to put the arm into running position, the other forcing it back.

865,389. Control of Electrically Driven Air Compressor. Ebenezer Hill, Norwalk, Conn. Application filed May 24, 1907.

The controller arm is moved by a plunger working in a cylinder containing a liquid to move it slowly. The variations in pressure govern the action of the plunger.

865,412. Attachment for Electric Motor Controllers. Albert H. Mathewson, Thompsonville, Conn. Application filed March 28, 1907.

This attachment has arranged in a circle a series of pockets holding balls. A finger fastened to the controller handle is arranged to pass over the balls when turned in one direction, but to engage them in the other direction and to be thus held till moved to the proper position.

865,428. Automatic Time Switch and Alarm. Frank H. Quade, Jr., San Francisco, Cal. Application filed December 28, 1906.

An automatic automatic alarm mechanism has an electromagnet, automatically energized at a predetermined time. A segment carrying an armature for the magnet is provided with a pawl turning a ratchet that has a series of contact studs, engaging a stationary contact successively which rings an alarm.

865,432. Electric Time Switch. William D. Ross, Providence, R. I. Application filed December 1, 1906.

A rotary dial carries adjustable arms provided with projecting pins that engage escapement levers for operating the switch.

865,470. Printing Telegraph. John E. Wright, New York, N. Y. Application filed May 6, 1904.

A printing telegraph receiver has two independent line circuits. A type wheel having a plurality of circular rows of characters thereon is moved by an electromagnet in one of the independent circuits step by step in line with its axis. An electromagnet in the second independent circuit simultaneously rotates the type wheel about its axis.

865,473. Break-arm for Electric Wiring. Walter A. Arthur, Manchester, N. H. Application filed April 5, 1907.

Two branches extend on opposite sides of the base. At the ends of the branches are angularly adjustable insulator brackets.

865,474. Trolley. Joseph Ashurst, Chicago, Ill. Application filed March 25, 1907.

A trolley head has a pair of current collecting wheels on vertical axes on each side of the wire, bearings for the wheels and guard plates. The whole is arranged to oscillate vertically and horizontally.

865,482. Wire Payout Reel. John F. Delphey, Toledo, Ohio. Application filed April 8, 1904.

This is a frame with a number of U-shaped members joined together at their ends, at which pivots are supported that carry the reels.

865,483. Insulating Coupling. Gustave F. Dreher, Schenectady, N. Y., assignor of one-half to Gustave F. E. Dreher, Schenectady, N. Y. Application filed April 9, 1906.

This coupling is made of two parts. One has a T-shaped head, the other a hooked end adapted to fit over the head of the first, an insulating strip separating the adjacent portions.

865,501. Motor Truck. William F. Kiesel, Jr., Altoona, Pa. Application filed March 25, 1907.

A car truck has motor frames mounted upon the axles, the frames having noses resting on a suspension bar fastened by links to the center-plate of an independent bolster.

865,503. Electrical Accumulator. John Knobloch, New York, N. Y. Application filed December 26, 1906.

This storage battery plate has a conducting framework with consecutive compartments holding the paste. The whole is surrounded by a pervious insulating envelop secured to it. Special insulating separators are arranged to separate and brace the plates. (See cut.)

865,516. Electric Regulator. Frank C. Newell, Wilkinsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company. Application filed October 22, 1904.

This regulator is for a generator having a rheostat in series with its main circuit. The field circuit connects on one side to the main terminal and on the other to adjustable contact on rheostat. This contact is operated by a coil placed inside the resistances.

865,527. Heating Device. Albert A. Radtke, Chicago, Ill. Application filed October 27, 1906.

An electrical egg-cooking device is made of a base and cap shaped to fit closely about the egg. Each is lined inside with resistance wires connected through a switch to a source of current. The windings are brought in series when the cap is placed over the base.

865,536. Selector for Automatic Telephone Exchanges. Charles E. Scribner, Jericho, Vt., and Claude D. Enochs, Chicago, Ill., assignors to the Western Electric Company, Chicago, Ill. Application filed April 10, 1905. Renewed July 11, 1906.

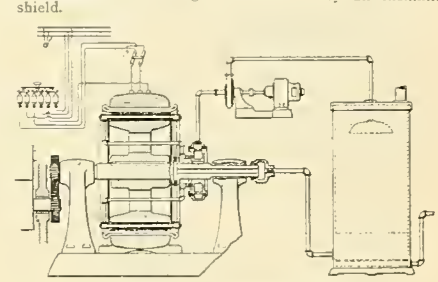
This selector comprises a series of connection terminals and a ratchet wheel carrying an arm with insulated switch fingers adapted to engage any pair of terminals. A magnetically oscillated pawl actuates the ratchet and advances it before the inertia imparted to it by a heavy disk on its shaft is overcome.

865,555. Automatic Electrical Signal System. Edwin T. Ackerman, Chicago, Ill. Application filed September 26, 1904.

The system has a number of circuits including relays closed by the hands of a clock, the relays each operating circuit closers for a number of signal circuits. Means are provided for cutting in or out any of the circuits and of interchanging them.

865,567. Fuse-plug. Robert C. Cole, Hartford, Conn., assignor to The Johns-PrattCompany, Hartford, Conn. Application filed March 4, 1907.

This plug is arranged to fit into a standard socket and contains a cartridge fuse covered by an insulating shield.



NO. 865,617.—INDUCTION MOTOR.

865,574. Recording and Reproducing Sounds. John F. Dirzuweit, Philadelphia, Pa. Application filed April 29, 1907.

This is an apparatus on the order of the phonograph, but works on different principles. A microphone transmitter acted on by the sound waves produces electric pulsations in a Tesla tube mounted so as to move over a photo-sensitive plate. The fluctuating actinic rays from the tube thus leave a permanent record on the sensitive plate. To reproduce the sounds the process is reversed.

865,588. Electric Switch. Edward M. Hewlett and Theodore E. Button, Schenectady, N. Y., assignors to the General Electric Company, New York. Application filed November 19, 1902.

This switch is operated by a reversible electric motor connected to a three-wire system, one brush being permanently connected to the neutral wire and the other arranged to connect to either of the outside wires, the motor being operated through a distant control switch.

865,598. Programme Clock. De Witt H. Leas, Delaware, Ohio. Application filed October 24, 1906.

A device for operating electric signals at predetermined intervals has a gear wheel carrying pins that successively close an electric contact. Electromagnetic means are provided for repeating the series of signals.

865,604. Target. August C. Meyer, Worcester, Mass. Application filed January 4, 1906.

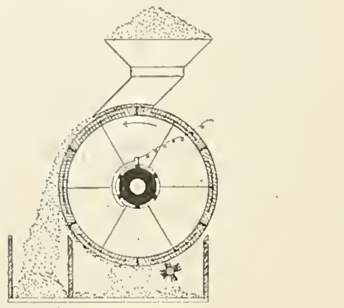
A score-keeping device has a target having movably mounted value rings, and an electric circuit arranged to be closed by the movement of the rings. An indicator has corresponding value rings, a marker for each ring and means operated by the closing of the circuit to expose a marker in a position corresponding in value to the location of the hit upon the target. A register has a dial with an index, a pointer, and means operated by the closing of the circuit to advance the pointer along the index to register the total value of such hit added to the previous scale.

[illegible] Insulating Material and Method of Producing the Same. Charles L. Norton, Manchester, Mass., assignor to the Asbestos Wood Company. Application filed February 23, 1907.

The process consists in heating a body composed of asbestiform fiber bonded with magnesium hydrate, and impregnating it while heated with a liquefiable hydrocarbon, such as ozocerite.

865,608. Process of Baking Carbon Electrodes and Heating by Electricity and Combustion. Edgar F. Price, Niagara Falls, N. Y. Application filed April 22, 1905.

This process consists in initially heating the electrodes by combustion, and then heating the hot electrodes to a higher temperature by passing an electric current through them.



NO. 865,711.—METAL SEPARATOR.

865,609. Process of Smelting Refractory Ores and Producing Low-carbon Ferro Alloys. Edgar F. Price, Niagara Falls, N. Y. Application filed November 14, 1905.

This is a process for producing ferrochromium, and consists in smelting a charge containing ferrosilicon, an oxidized compound of chromium and a basic flux by means of an electrically-heated resistance-conductor.

865,612. Insulating Machine. Howard D. Saylor, Philadelphia, Pa. Application filed August 13, 1906.

The machine is used for winding cotton or silk insulation on wires. It has sleeves for grinding the wire, means for moving the wire, thread cups carried by each sleeve and eye members for moving the thread around the wire.

865,617. Induction Motor. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Application filed August 7, 1905.

The rotor of this motor has hollow high resistance conductors, hollow end-rings forming both electrical and pipe connections between like ends of all the conductors and means for forcing a cooling fluid to circulate through the conductors from one end-ring to the other. (See cut on preceding page.)

865,618. Production of Nitrous Compounds. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Application filed April 20, 1907.

This process consists in forcing a current of air through a chamber in which there is an electric arc that is deflected and rotated by a rotating magnetic field.

865,638. Thermostat. Harry G. Geissinger, New York, N. Y. Application filed July 16, 1906.

A U-shaped thermal bar has the end of one leg fastened near the pole of an electromagnet and carries a contact point at the end of its other leg, which can close the circuit of the magnet coil.

865,648. Electrolysis of Fused Salts. Franz von Kügelgen and George O. Seward, Holcombs Rock, Va. Application filed May 26, 1905.

This relates specifically to the production of magnesium-calcium alloy by the electrolysis of a fused mixture of $CaCl_2$ and MgF_2 regulated so that the secondary reaction between calcium and MgF_2, takes place only to a limited degree.

865,650. Valve and Sparking Mechanism for Hydrocarbon Engines. Levi E. Lowe, Columbus, Ohio. Application filed December 3, 1906.

The sparking device has a contact point at the end of a finger attached to an oscillatory arm which periodically engages a stationary contact in the path of the gas flow past the valve head.

865,662. Igniter System. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed May 11, 1906.

This system has a battery and a dynamo as alternative sources of current, a single point cam lever that can be in circuit with either source and that can be momentarily shunted.

865,663. Ignition System for Explosion Engines. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed October 8, 1906.

A cam causes one vibrator to open a dynamo circuit and another vibrator to close a battery circuit.

865,687. Process of Making Nickel Films. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed January 19, 1907.

This process for making a film of metallic nickel consists in first chemically depositing on a suitable cathode a film of metallic copper, electrolytically depositing a copper film thereon, then depositing on the latter film a film of nickel, next stripping the composite sheet from the cathode, and finally dissolving the copper in an [illegible] copper sulphate solution.

865,688. Process of Making Metallic Films or Flakes. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to the Edison Storage Battery Company, West Orange, N. J. Application filed January 19, 1907.

This patent is similar to the preceding one, but is broader so as to include other metals than copper and nickel, such as cobalt, for instance.

865,697. Insulator. Robert E. Henderson and John N. King, Los Angeles, Cal., assignors of one-fourth to E. O. Williams and one-fourth to James W. King, Los Angeles, Cal. Application filed May 16, 1906.

This insulator is mounted eccentrically on the pin. The thick side is flat and has a groove extending inwardly and slanting upwardly to hold the wire.

865,701. Alternate-current Generator and Motor. Alexander Heyland, Brussels, Belgium. Application filed June 9, 1902.

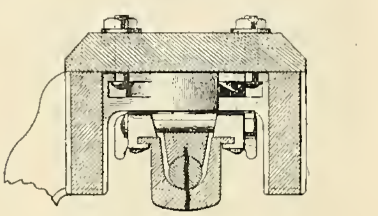
This machine has a stator winding and two rotor windings, one of which is a direct-current circuit and the other an alternating-current circuit in series with the stator winding. The latter winding includes a commutator and is used to overcome the armature reaction of the machine.

865,707. Self-sustaining Field-magnet Coil. Elbert W. Jodrey, Lynn, Mass., assignor to the General Electric Company of New York. Application filed December 28, 1906.

This method of producing a self-sustaining universally-wound wire coil consists in winding a few layers, securing a strip of paper about these layers, and then winding on the remaining layers.

865,711. Separating Metal from Deposits. Isidor Kitsee, Philadelphia, Pa. Application filed June 20, 1907.

A method of separating particles of metal from natural deposits consists in passing the mixture over the surface of a non-conducting drum, in which surface are embedded both eelctrodes of a high-tension circuit. (See cut.)



NO. 865,879.—CONTACT RAIL.

865,730. Controlling System for Railways. Max Trautmann, Dresden, Germany, assignor to Bertha Trautmann, née Sprie, Dresden, Germany. Application filed March 21, 1907.

A series of conductors corresponding to the number of passing trains is arranged in two groups. Line contacts are actuated by the trains and operate indicating devices in the circuit of the conductors. Means are provided for restoring the indicators to initial position when train arrives at next station.

865,732. Dynamo or the Like. Charles A. Vandervell, London, and William H. W. Proctor, Coventry, England. Application filed March 6, 1905.

In a machine in which both armature and fields are rotatable, one is driven and the other is provided with a brake adjustable by hand so as to keep the relative speed of rotation of the two parts at a desired value.

865,771. Electric Signal Bell. Harold W. Eden, Detroit, Mich., assignor to the P. R. Manufacturing Company, Detroit, Mich. Application filed July 18, 1906.

The new feature about this bell seems to be that the brackets for supporting the magnet coils and armature are struck up from a plate of sheet metal.

865,781. Electric Railway Signaling Device. Edward B. Howell, Butte, Mont. Application filed June 25, 1906.

This system has poles alongside of the track carrying one or more continuous signaling wires upon which runs a trolley connected by means of a flexible cable to signaling devices in the moving car.

865,811 to 865,819. System of Motor Control, Method and Means for Controlling Electric Motors and Motor-control System. William H. Powell, Norwood, Ohio, assignor to the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Applications filed April 16, 1906, to January 28, 1907.

These nine patents relate to systems of controlling motors for variable speed operation and cover various methods of accomplishing this, as by the simultaneous regulation of the field strengths of generator and motor, the use of auxiliary generators and motors, and the use of self and separate excitation for the fields.

865,820. Motor-control System. Walter J. Richards, Norwood, Ohio, assignor to the Allis-Chalmers Company. Application filed March 25, 1907.

A number of motors and generators have separately excited fields all connected in series. An auxiliary dynamo is shunted across one of the field windings.

865,821. System of Motor Control. Walter J. Richards, Norwood, Ohio, assignor to the Allis-Chalmers Company. Application filed March 1, 1907.

The armature current of the motor is supplied by a dynamo and the motor fields have a cumulative winding supplied by two additional sources of current. The fields of the dynamo are differentially supplied by these same additional sources.

865,822. Method of and Means for Controlling Electric Motors. Louis E. Bogen, Cincinnati, Ohio, assignor to the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed May 27, 1907.

This method comprises a generator and motor with armatures connected together, two separate sources of current for the field windings of the generator and motor respectively, and regulating devices for these two separate sources, the electromotive force of the generator exciter being reversible.

865,848. Automatic Signaling Apparatus. James S. Anderson, Ames, Neb. Application filed May 20, 1907.

Adjacent to the railroad track is placed a series of poles, each having a box and an arm, the latter being moved by a passing locomotive to close a circuit through buttons in the box.

865,862. Thermostat for Centrally Heated Plants. Robert Brukenhaus, Haspe, near Hagen, Germany. Application filed January 22, 1904.

A maximum and minimum thermometer has electric contacts and through electromagnetic devices operates a branch steam valve.

865,866. Block Signal. Pierre I. Chandeysson, St. Louis, Mo. Application filed December 23, 1905.

A semaphore signal has a movable color disk in front of a lamp. A semaphore arm and the color disk rotate on a shaft operated by an electric motor connected to the shaft by a magnetic clutch.

865,879. Electric Contact Rail. Ed W. Farnham, Chicago, Ill., assignor to the Farnham Company, Chicago, Ill. Application filed July 17, 1905.

This rail has a U-shape cross-section, the closed end of the U being on bottom and forming the contact side. A continuous conductor lies in the groove of the rail. (See cut.)

865,888. Sound Magnifier for Telegraph Instruments. Frederick O. Hanson, Victoria, Kan., assignor of one-half to William Schrenkler, Walker, Kan. Application filed February 21, 1907.

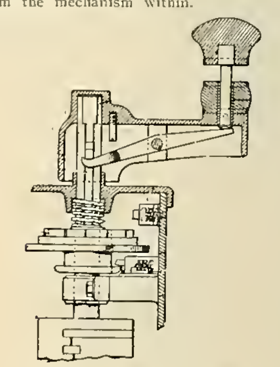
The armature lever strikes an anvil plate and the sound is transmitted to a diaphragm in an adjustable horn.

865,907. Coil for Electrical Purposes. Elbert W. Jodrey, Lynn, Mass., assignor to the General Electric Company of New York. Application filed October 26, 1905.

A tubular support of insulating material has several coils wound upon it, adjacent ends being separated by a space. A conductor, connecting terminals of the coils is embedded in the support.

865,937. Telephone Receiver. Edwin J. Quinby, Portland, Me. Application filed November 22, 1905.

This receiver has a metallic casing insulated by bushings from the mechanism within.



NO. 865,970.—MOTOR CONTROLLER.

865,970. Controller for Electric Motors. Charles S. Lee, Troy, N. Y. Application filed June 4, 1906.

This controller operates a circuit-breaker and has means for compelling the operator to close the controller contacts successively, after the circuit-breaker is once closed, and also means for opening the circuit-breaker when the operator releases the controller handle. (See cut.)

PATENTS THAT HAVE EXPIRED.

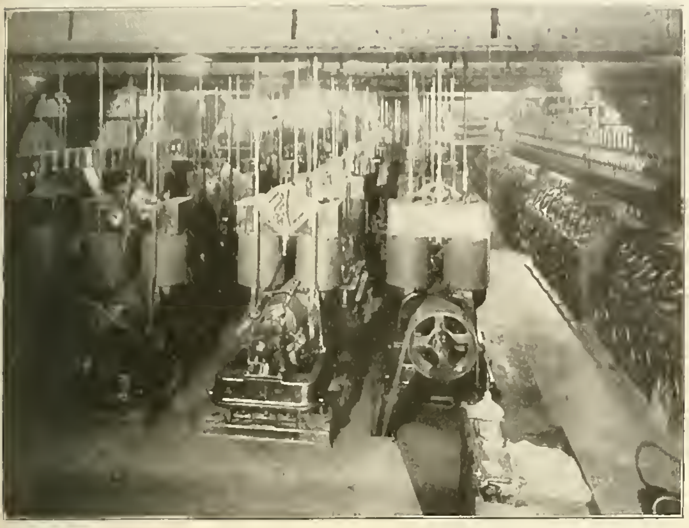
Following is a list of electrical patents (issued by the United States Patent Office) that expired September 16, 1907:

436,335. Telephone. W. Burnley, North East, Pa.
436,387. Socket for Incandescent Electric Lamps. H. E. Swift, Boston, Mass.
436,408. Dynamo Electric Machine. S. D. Field, Yonkers, N. Y.
436,410. Electro Magnetic Bell. J. Greary, Philadelphia, Pa.
436,425. Electric Railway. H. W. Libbey, Boston, Mass.
436,432. Electric Conductor. W. E. Oehrle, Philadelphia, Pa.
436,439. Electric Motor Car. W. Robinson, Boston, Mass.
436,440. Electric Motor Car. W. Robinson, Boston, Mass.
436,512. Telephone. S. Lloyd Wiegand, Philadelphia, Pa.
436,513. Telephone. S. Lloyd Wiegand, Philadelphia, Pa.
436,514. Telephone Relay. S. Lloyd Wiegand, Philadelphia, Pa.
436,516. Galvanic Battery. J. F. Wollensak and W. E. Gill, Chicago, Ill.
436,560. Electro Mechanical Gong. G. Doyle, Watertown, Mass.
436,571. Trolley for Electrical Railways. D. A. Ainslie, Richmond, Va.
436,602. Storage Battery. W. B. Hollingshead, Bronxville, N. Y.
436,640. Electrical Automatic Fire Alarm System. W. F. Singer, Carthage, N. Y.
436,677. Electrical Head Light. J. Thorne and E. B. Burr, London, England.

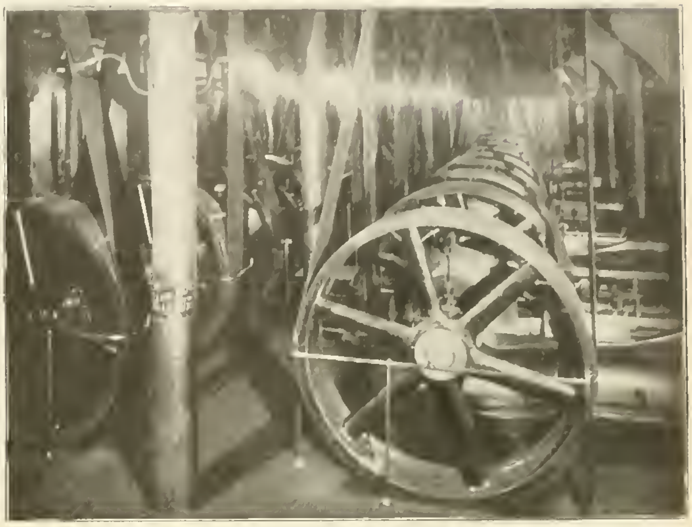
WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, SEPTEMBER 28, 1907. No. 13

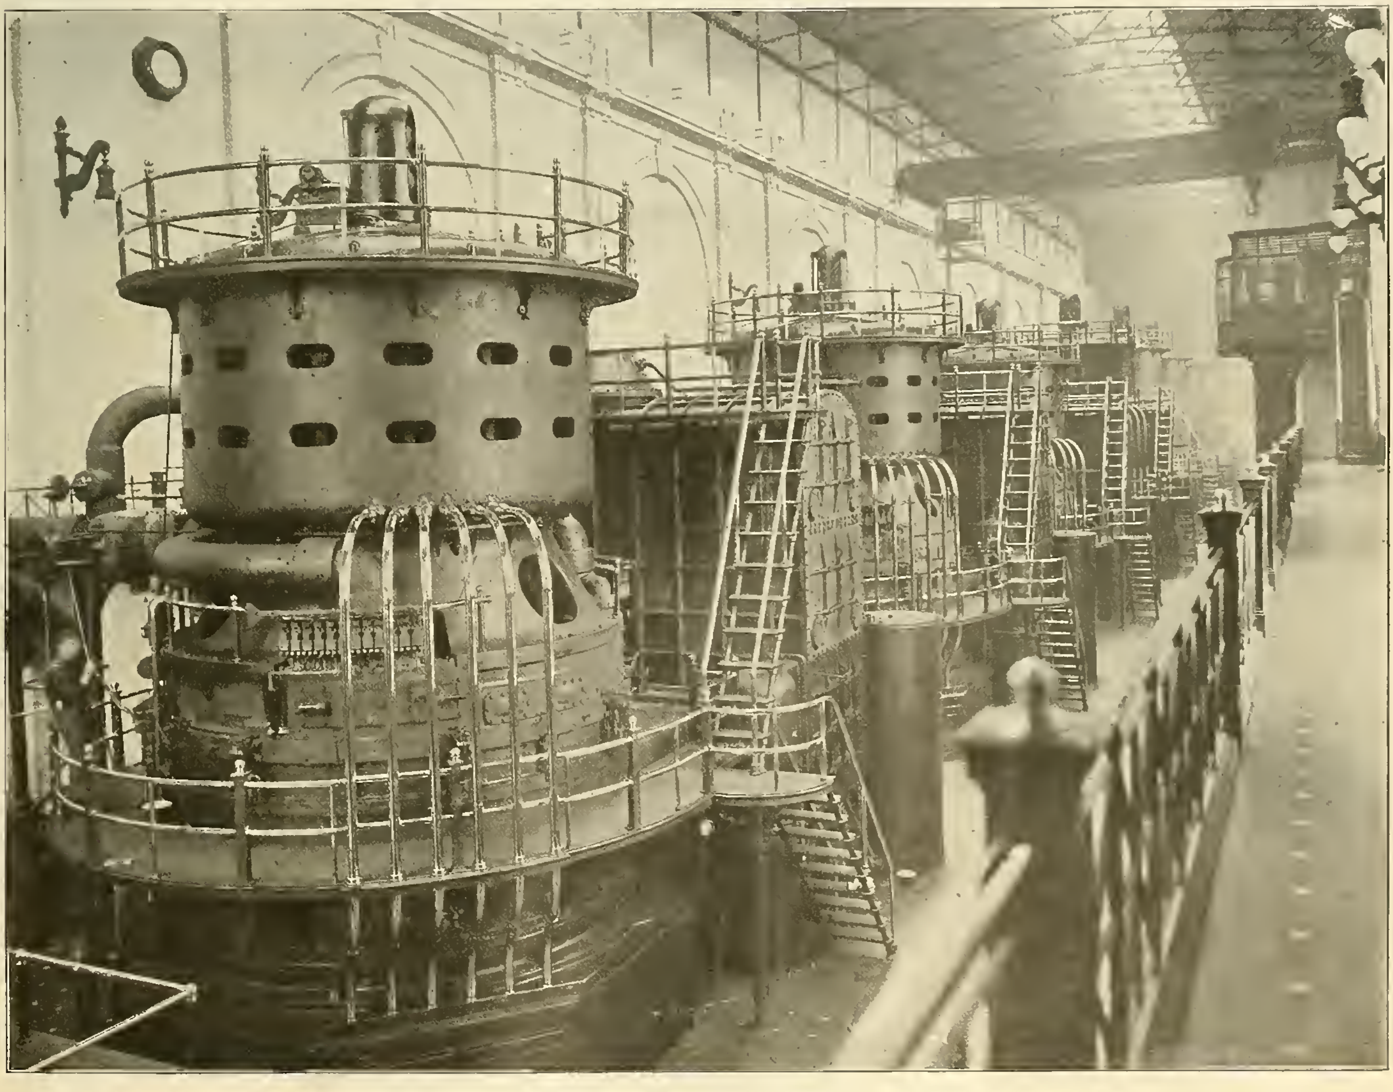


Bipolar Edison Dynamos on Upper Level.



Small Belted Steam Engines Driving Dynamos from Lower Level.

INTERIOR VIEWS OF OLD ADAMS STREET EDISON STATION, CHICAGO, IN 1890.—CAPACITY ABOUT 4,000 HORSEPOWER.



This Station has a Present Maximum Capacity of 130,000 Horsepower in Ten Turbine Units, Two of which are not Shown in Picture.

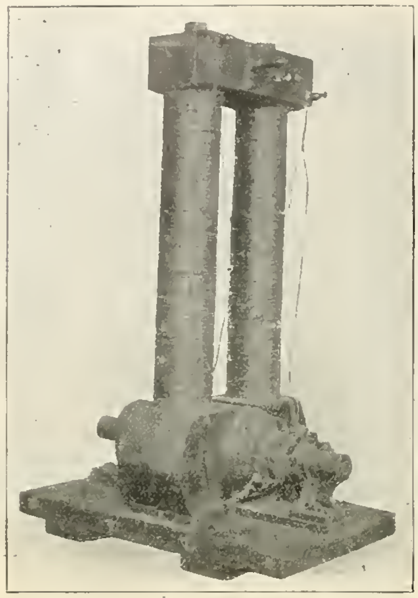
INTERIOR VIEW OF FISK STREET STATION OF COMMONWEALTH EDISON COMPANY, CHICAGO, SUCCESSOR TO THE ABOVE, IN 1907.

STRIKING CENTRAL-STATION ADVANCE IN LESS THAN TWENTY YEARS.

Some Recollections of Central-station Development.

By Samuel Insull,
President, Commonwealth Edison Company, Chicago.

THE first central-station installation which I ever saw was the first one that was ever built. It was installed at Menlo Park, N. J., by Mr. Thomas A. Edison in the winter of 1880-81 for the purpose of demonstrating the success of what

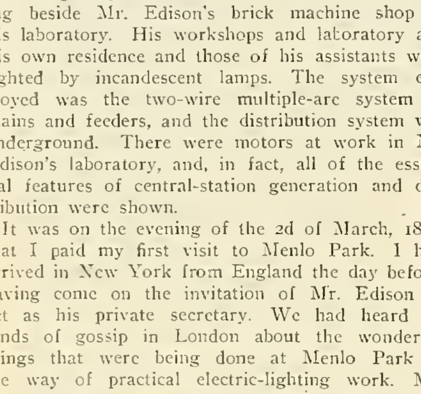


EDISON "Z" TYPE DYNAMO (CAPACITY, 60 LAMPS) OF 1882.

was popularly called the subdivision of the electric light.

The generating station was composed of nine or ten 60-light dynamos and was situated in a building beside Mr. Edison's brick machine shop at his laboratory. His workshops and laboratory and his own residence and those of his assistants were lighted by incandescent lamps. The system employed was the two-wire multiple-arc system of mains and feeders, and the distribution system was underground. There were motors at work in Mr. Edison's laboratory, and, in fact, all of the essential features of central-station generation and distribution were shown.

It was on the evening of the 2d of March, 1881, that I paid my first visit to Menlo Park. I had arrived in New York from England the day before, having come on the invitation of Mr. Edison to act as his private secretary. We had heard all kinds of gossip in London about the wonderful things that were being done at Menlo Park in the way of practical electric-lighting work. Mr.



"JUMBO" STEAM DYNAMO OF 1882, EXHIBITED AT CHICAGO WORLD'S FAIR 11 YEARS LATER AS AN ANTIQUE.

Edison had been writing to his English friends for two years prior to the date of my arrival in New York telling of his success, but as we had had no demonstration of it on the other side of the water and as scientists on both sides of the Atlantic expressed their doubts as to the results of Mr. Edison's experimental work, my natural desire when I arrived here was to pay an immediate visit to Menlo Park and cable my English friends that I had actually seen Mr. Edison's central-station system at work.

So far as the service rendered, this first experimental plant at the birthplace of the central-station industry was as perfect as the service now given by any of the central-station companies in our large cities. And although, instead of using in the generating station steam turbo-generators of a capacity from 10,000 to 15,000 kilowatts, small bipolar machines of from six to ten kilowatts capacity were used, yet the main essentials of central-station engineering, as practiced today, were shown in this original and successful effort at central-station building. There was the multiple-arc distribution system with feeders running from the generating station to various points in the system of mains in order to equalize the pressure, incandescent lamps and motors running in multiple, and the street wiring system thoroughly insulated and laid underground; in fact, all the essentials of modern central-station distribution.

At the same time and running from the same generating station Mr. Edison had in operation about a mile of electric railway, the track being partially insulated and used for conducting the current. A speed of 42 miles an hour was attained, and over 5,000 people rode on this experimental electric railway.

While Mr. Edison used the bipolar form of machine in his first experimental station, belted to a slow-running Corliss engine, he had in mind, even at that early date, that the direct-connected unit was the true engineering practice, and he had built an experimental Porter-Allen engine of about 100 horsepower, running at a speed of 600 revolutions per minute, directly connected to a bipolar machine laid on its side with an armature of the bar-and-disk type. It was found, however, that the speed of this unit was too great, and, beyond a few experimental runs, nothing was done with it.

The exhibition of this first central-station plant at Menlo Park closed what might be called the experimental development period of the business, and the next step was the building of the first commercial central-station system, which was located in New York in the downtown district, between Wall Street on the south, Fulton Street on the north, Pearl Street on the east and Nassau Street on the west, the generating station being located near the corner of Fulton and Pearl streets, and consisting of six direct-connected units, driven by Armington & Sims engines running at about 350 revolutions per minute, each unit having a capacity of about 700 16-candlepower lamps, the lamps in use at that time consuming about one ampere at 110 volts. It is interesting to note that the machine was the first successful direct-connected steam dynamo, and was known as Edison's Jumbo machine. This same type of machine was subsequently used in London (England), Milan (Italy) and Santiago (Chile). This plant was started on the 5th of September, 1882, with 5,500 lamps connected, and at the end of 14 months of continuous running had 508 customers and was wired for between 12,000 and 13,000 lamps.

At the same time that this station was under construction in New York city a much smaller central-station plant was built at Appleton, Wis., and on account of its smaller size was in operation a few months earlier than the New York plant, so that the first commercial central-station incandescent lighting plant started anywhere in the world was at Appleton, Wis.

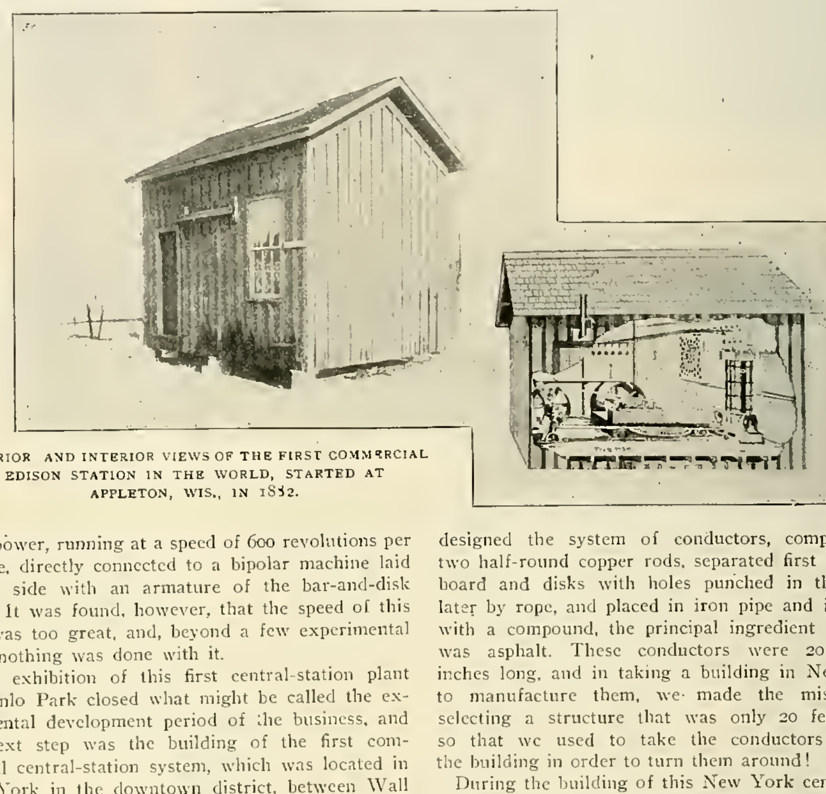
I can well remember the early experiences in central-station construction in New York in the winter of 1881 and the summer of 1882. The men familiar with the work could at that time be counted on the fingers of one hand. There were Mr. Edison and three or four assistants.

After Mr. Edison got through with his experimental work at Menlo Park, he and his assistants had to pick out the territory in New York for central-station distribution, decide on the generating capacity necessary and the size of conductors required. Then, after the general specifications for the work had been prepared, it was necessary that there should be provided factories in which to build the generating machinery and underground conductors needed; also supplies, such as lamps, sockets, switches, meters, etc. All these establishments had to be started and organized and the machinery produced and put in place and the necessary central-station operating force taught to operate and take care of the central-station system.

This work—all of it—had to be done by a few men whose only experience was that gained in demonstrating experimentally at Menlo Park Mr. Edison's inventions and ideas for central-station work.

One of the greatest troubles Mr. Edison had to contend with was the manufacture of the underground conductors. No manufacturer at that time would undertake the work. No one believed that large volumes of current, even at so low a potential as 100 volts, could be successfully distributed by an underground system in the city of New York.

Mr. Edison, assisted by the late Mr. John Kruesi,



EXTERIOR AND INTERIOR VIEWS OF THE FIRST COMMERCIAL EDISON STATION IN THE WORLD, STARTED AT APPLETON, WIS., IN 1882.

designed the system of conductors, composed of two half-round copper rods, separated first by cardboard and disks with holes punched in them and later by rope, and placed in iron pipe and insulated with a compound, the principal ingredient of whch was asphalt. These conductors were 20 feet 6 inches long, and in taking a building in New York to manufacture them, we made the mistake of selecting a structure that was only 20 feet wide, so that we used to take the conductors outside the building in order to turn them around!

During the building of this New York central-station system I was mainly engaged in the daytime in looking after Mr. Edison's business affairs. The laying of underground conductors used to take place at night, and the work of laying was superintended by Mr. Edison and Mr. John Kruesi, the latter being occupied in the day in manufacturing the conductors, or, as they were then known, "Kruesi tubes." I was in the habit of assisting them at night, my main duty being to sit on a street corner and watch a galvanometer used in testing the tubes for insulation.

While the original system in New York city was financially successful, it was very difficult to get capital to embark in the business generally throughout the United States. For some years the business went very slowly indeed. Efforts were made to cheapen construction and adapt the apparatus to the requirements of small towns. Mr. Edison invented the three-wire system in 1882; and the development of the central-station business, while really starting on a large scale in New York, was for a number of years afterward confined to the smaller towns of Pennsylvania and New England, and the development and growth of the business in the larger cities outside of New York did not commence to make substantial progress until some years later.

While the direct-current business was being exploited by the Edison companies, the Westinghouse Electric Company and the Thomson-Houston Elec-

ELECTRICITY BUILDING AT NIGHT.—CHICAGO WORLD'S FAIR OF 1893.

tric Company were engaged in pushing the alternating-current business and using as a basis for it the old arc-light companies which in a number of cities had been formed mainly by the Brush Company for doing city lighting. For a number of years there was the most heated and acrimonious discussion between the champions of the two different forms of current (direct and alternating), but all this has long since passed away, and current of both descriptions is being used by the large companies at the present time; in fact, among the largest manufacturers of alternating current in the country are the old Edison local companies, which have always kept the lead in connection with central-station development.

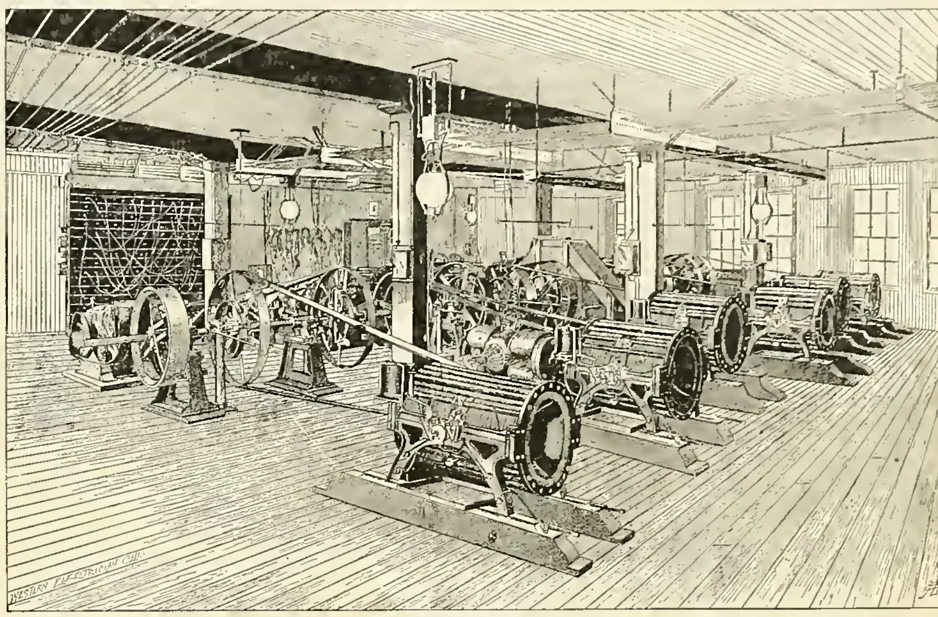
Some of the earliest three-wire central-station installations with overhead conductors were made at Sunbury, Shamokin and Mt. Carmel, Pa., and at Piqua, Ohio, the early three-wire underground systems in the smaller cities being laid in Brockton, Fall River and Lawrence, Mass., Rochester and Newburgh, N. Y., and Detroit, Mich. Among the larger cities, Brooklyn, Boston and Philadelphia had Edison three-wire plants in operation before any attempt was made to install large central-station three-wire plants in the West. It was not until 1887 that the Chicago Edison Company was organized by the men who originally controlled the Edison light and power patents for Illinois and some of the surrounding states. The Chicago Edison Company started with a capital of $500,000.

In 1885 the Edison companies had grown to such proportions that there were enough Edison companies to form the "Association of Edison Illuminating Companies." The first convention of this association was held at Harrisburg, Pa., on April 15th of that year, under the presidency of Mr. James S. Humbird, who at that time was interested in the Cumberland (Md.) company.

Just prior to that, on February 25, 1885, the "National Electric Light Association" was formed, holding its first convention at the Grand Pacific Hotel, Chicago, Mr. J. Frank Morrison of Baltimore being the first president.

Both of these associations have had great influence in assisting in the development of the central-station business, and are today the two representative bodies of the industry.

The development of the central-station business in the West dates practically from the formation of the Chicago Edison Company in 1887. While at this time there were a very large number of series arc lighting companies throughout the Central West



Reproduced from the Western Electrician of May 5, 1888.
DYNAMO ROOM OF THE CHICAGO ARC LIGHT AND POWER COMPANY.

and the far West, a number of which were operating alternating-current plants, the rapid growth in the West of the central-station business on a large and comprehensive scale did not take place until after the first Edison station started in Chicago in 1888.

This was followed by the establishment of Edison low-tension plants in most of the larger western cities, until by 1892 there was scarcely a large center of population in the United States that had not a flourishing central station company in operation. In later years, the old rivalries having passed away, the Edison and alternating-current plants have consolidated, as a rule into one organization in each city, much to the advantage of the public in the direction of lower prices and better service, and to the investor in a better return on money invested owing to the stoppage of the duplication of investment and organization.

Today in the cities of the first rank the central-station business has got to the point of a vast manufacturing business, the tendency being to install large turbo-generators of from 10,000 to 15,000 kilowatts capacity, producing high-tension alternating current, which is transmitted to rotary sub-stations where it is transformed into direct current of various pressures dependent on whether it is to be used for electric light and industrial power purposes or street-railway work. In other cases the sub-stations are composed of step-down transformers to reduce the voltage to that ordinarily used for alternating electric light and power distribution.

The experiences of the last few years have shown very distinctly that if the central-station companies of the large cities are to maintain their positions, they must go more and more into the wholesaling of current to large users, such as street-railway companies, elevated-railway companies, and possibly later on to the larger transportation companies of the country.

There is no business that I know of that is benefited more than the central-station business in the way of reduced cost of production by the increased amount of output. The introduction of the steam turbine is especially conducive to the economical production of electric current in very large quantities, both from a capital and operating point of view; and I look forward with confidence to the day when the electric energy required in each of our large cities will be produced under one organization for each city, with a few large generating stations for the production of alternating current, the electric energy being converted into whatever form may be best adapted for the purposes for which it is required.

A canvass of any of the central blocks of buildings in any of our large cities will show an amount of investment in power-producing machinery out of all proportion to that which is really required to render the service demanded within a given territory. As these plants deteriorate and go out of use, central-station connections are taking their place, leading to a saving alike of capital expenditure and operating expenses.

The same remark will apply to a canvass of the power facilities of the various companies using electric energy, such as the street-railway companies, the elevated-railway companies and the interurban-railway companies, in any given territory.

It is easy of demonstration that the most economical thing to do is to produce all the electric energy required in a given territory under one organization, and the central-station company that

ELECTRICITY BUILDING AT ST. LOUIS WORLD'S FAIR OF 1904.

works toward this end will, in my opinion, show a far greater return on the money invested by its stockholders and be able to quote a lower price to its customers than the company which undertakes to do the purely retail electric light and industrial power business of the community, as the latter forms but a small portion of the possible business offering.

The Rise of the Electric Railway.

By Bion J. Arnold,
Chairman, Board of Supervising Engineers, Chicago Traction.

VARIOUS histories of the electric railway have been written at different times, but the development has been so rapid and the progress so remarkable that no article on this subject will fairly represent the magnitude of the work done in this field of electrical endeavor unless of comparatively recent date.

Although the principle of the electric motor was discovered by an Englishman (Barlow) in 1826, and this principle first put into practice in a scientific way by an Italian (DalNegro) in 1830, while its application to the propulsion of a traction vehicle in a miniature way was made by an American (Davenport) in 1835, to be followed by a score or more of scientific experiments of more or less practical value, the first extensive application of the electric motor to the propulsion of electric cars, and the one which probably gave the greatest impetus to the remarkable development which followed, was made by an American (Sprague) in 1887.

BION J. ARNOLD.

While the results of the struggles of the early pioneers were of great scientific value, they nevertheless brought forth no device which could be utilized in the propulsion of electric cars until the invention of the direct-current dynamo by an Italian (Paccinoti) in 1861, the development of which by a Belgian (Gramme) in 1871, combined with the discovery that one dynamo could be operated as a motor from another dynamo, made by two French engineers (Fountain and Breguet) at the Vienna Exposition in 1873, made the electric railway possible. From this date until 1887 the development was comparatively rapid, and numerous lines were built at expositions and in other places, which gave them an opportunity of being of more or less commercial value, the culmination of which came with the construction of the Richmond road in 1887.

It is with the succeeding twenty years, during which time the most remarkable development in the history of the world has taken place in the application of a new force to the uses and conveniences of man—it is to this period that the attention of the readers of this article is directed.

Following the successful operation of the Richmond road came a most rapid conversion from animal power to electric power of street railways of the principal cities of the country, so that by the year 1895 it might be said that almost every city of any magnitude of the United States and many of the principal cities of the world were equipped with electrically propelled cars, requiring for their operation in the United States alone over 8,000 miles of electric railway, using 18,000 cars, and involving an investment of more than eighty millions of dollars.

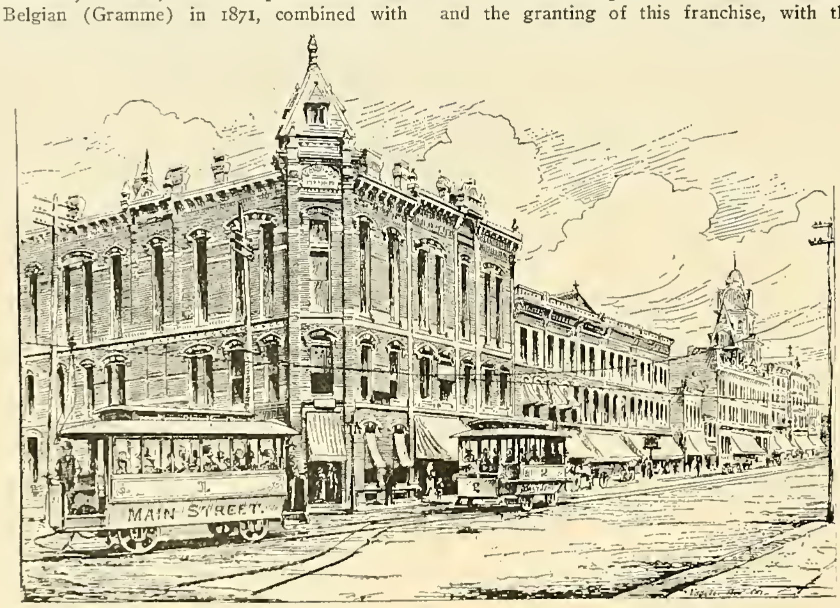
CAR DESIGNED FOR SHORT'S ELECTRIC-RAILWAY SYSTEM.

In 1893, at the World's Columbian Exposition in Chicago, there was put into operation the Columbian Intramural Railway, the first elevated electric railway to be operated in the world, and although the London underground road was placed in operation slightly prior to this date, and the Liverpool overhead road soon after, the opening of the Intramural Railway marked the beginning of the conversion of the elevated railway from steam to electricity. The successful operation of this road caused the announcement by the promoters of a proposed road, since built and known as the Northwestern Elevated Railway of Chicago, to make application for a franchise in 1893, from the Chicago City Council, and to use as one of their main arguments in favor of the granting of this franchise the assurance that the road would be operated by electricity.

The successful operation of the Intramural road and the granting of this franchise, with the distinct understanding that electricity instead of steam would be used as a motive power, not only gave to Chicago and the West the honor of having demonstrated the practicability of electricity for the propulsion of heavy trains, but also marked the doom of the steam locomotive for elevated-railway service. The Northwestern Elevated went into operation in 1900.



Reproduced from the Western Electrician of September 10, 1887.
VAN DEPOELE ELECTRIC STREET CARS IN LIMA, OHIO.

During the construction of the Intramural Railway there was under construction in Chicago an extensive elevated-railway system known as the Metropolitan Elevated Railroad, the work upon which started in 1892. Much of the structure of this road was completed prior to the operation of the Intramural Railway, and its entire structure had been planned for the use of steam locomotives. The success of the Intramural Railway, however, converted the promoters of the Metropolitan to electricity, with the result that contracts for the steam locomotives were countermanded, arrangements made for the propulsion of its trains by electricity, and when it went into operation in 1895 it was an electric road.

Contemporaneous with the construction of this road and that of the Northwestern Elevated, came the conversion, in 1896, of the Lake Street Elevated Railroad, begun in 1891, and which had been put in operation with steam locomotives in 1893. The electrification of this road and the completion of the Northwestern Elevated was soon followed by the construction of the Chicago Union Elevated Loop in 1897, and the electrification of the South Side Elevated Railroad in 1898, steam locomotives having been in use upon the latter road since its completion in 1892.

Thus within a period of five years all of the elevated railways of Chicago were electrified, and on account of the fact that two of them had been operated by steam for several years, conditions were thus created for the securing of valuable information regarding the relative cost of operation by steam and electricity.

The results of the operation of these roads after electrification, and those of the Liverpool overhead and London underground railways, were so favorable to electricity that it led to the subsequent electrification of all the elevated railways of New York city in 1902 and the construction of additional elevated electric railways in Berlin and Boston in 1901, thus establishing the supremacy of electricity for this class of railway work.

In the electrification of the street railways of cities and for elevated-railway work direct current had been used exclusively, due to the fact that the stops were frequent, the distances to which energy must be transmitted were short, and the special adaptation of the direct-current motor for intermittent work. After the street railways of the cities had been equipped, however, the engineers and others engaged in electrical pursuits sought new fields for their endeavors, with the result that the interurban road came into being, which opened up a field wherein was soon shown some of the disadvantages of the use of direct current for this class of work, due to the great distance over which electrical energy had to be transmitted. To overcome this objection the rotary converter was brought into use and first placed in commercial operation on an extensive scale on the Chicago and Milwaukee Electric Railroad by the writer in 1898, who, following the general practice prior to that time, had used in the construction of the Intramural Railway and other electric railways which he had built, the direct-current system of transmission exclusively.

The successful operation of this road demonstrated the advantages of the high-tension rotary

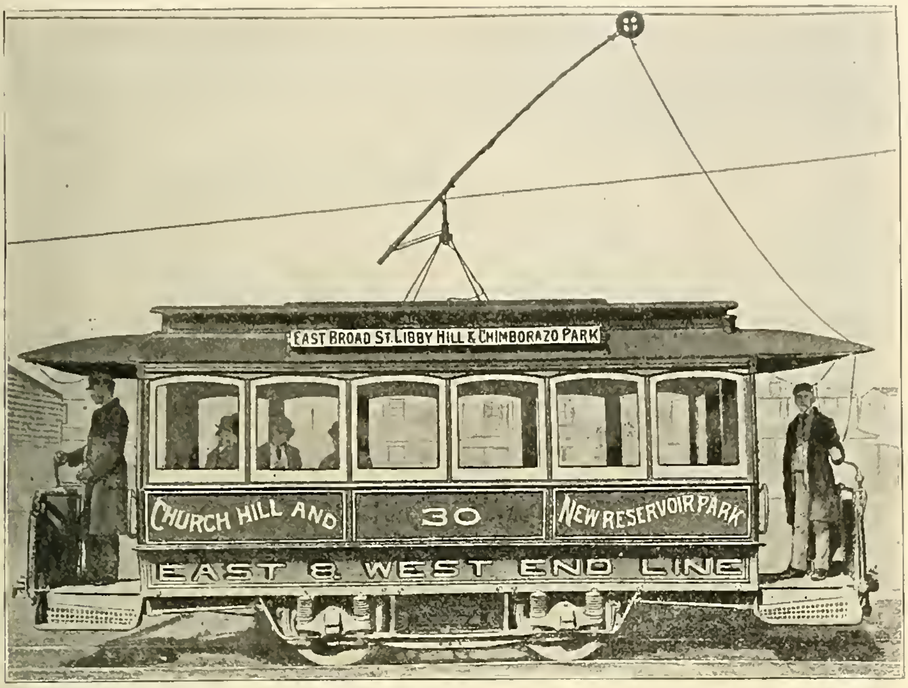
VAN DEPOELE DESIGN FOR BRACKET CONSTRUCTION.

converter transmission plan so thoroughly that the practice became standard, with the result that this system has been used in almost all of the interurban roads built since, and by its use rapid transportation has been established between the various cities and towns of the United States as well as between those of other countries, resulting in the great improvement of sociological conditions of those living contiguous to these roads.

An idea of the remarkable development in this field may be obtained from the statement that at the present time there are in operation in the United States alone something over 12,000 miles of interurban electric railway, connecting with urban systems which bring the total electric railway mileage up to something over 30,000 miles, and aggregating in cost probably over $600,000,000.

The electrical engineer and his associated allies having thus devoted their energies to successfully equipping the street-railway systems and the interurban railway systems of the country, have in addition to these accomplishments been devoting their energies toward the electrification of steam railroads, with highly successful results.



Reproduced from the Western Electrician of May 12, 1888.
ONE OF THE CARS ON THE HISTORIC RICHMOND (VA.) LINE.

In 1902 the New York Central Railroad Company, having in view the elimination of the objectionable conditions surrounding the operation of its tunnel through Park Avenue and the improvement of its service within the vicinity of New York, had the question of the feasibility of the electrificaton of its terminal investigated by the writer, with the result that electrification was finally decided upon by its board of directors. A commission was organized in 1903 to prosecute the work, with the result that it was decided to electrify some 300 miles of track and to haul all of the trains of the system by electricity while entering the Grand Central terminus.

Some time subsequent to this, although practically contemporaneous with this work and induced by it, came the electrification of the New York, New Haven and Hartford Railroad from New York city to Stamford, Conn., 30 miles from New York, involving the electrification of something over 80 miles of track, with a fair prospect of the extension of electrical operation toward Boston.

The application of electricity to railway terminals has brought about another condition of far-reaching effect, for it permits the construction of terminal stations in such a manner that trains may enter at different levels and provide equal convenience to the passengers of all, thus making a tunnel entrance to a city equally as desirable as a surface entrance. This advantage is being utilized on a grand scale in the construction of the terminals of the Pennsylvania and the New York Central railroads in the city of New York, and it is not improbable that it will soon be utilized in the city of Chicago.

In the case of the Pennsylvania company, tunnels are now being constructed from the New Jersey side, passing under the Hudson River, across Manhattan Island, then under the East River to Long Island City, through which the passenger service of this road will be carried, thus making possible the construction of a magnificent terminal station in the heart of the city of New York without vitiating the atmosphere or encumbering the streets.

The New York Central terminal will be constructed on a double-deck plan, the suburban service coming in on the lower level, while the upper level will be occupied by express trains.

The result of the labors of those engaged upon these works is worthy of note. Not only will the trains of the Pennsylvania company, which now stop at Jersey City, be brought into the center of New York city, but all of the passenger trains of the New York Central Railroad and practically all of the suburban trains of the New York, New Haven and Hartford entering the New York terminal of these roads are propelled by electricity. Soon all of the trains of the New York, New Haven and Hartford Railroad will be thus operated, thereby eliminating the steam locomotive from the city of New York forever—a condition which has been brought about by the active co-operation of the engineering, financial and executive talent of these roads with the manufacturing companies furnishing the apparatus, and the judicious expenditure of approximately $300,000,000 for electrical apparatus and terminal improvements made possible by the adoption of electricity.

Furthermore, the construction of passenger subways for passenger service in New York, London, Berlin, Budapest and Paris are other notable examples of the application of electricity to the transportation problem. In Chicago there has been constructed something over 50 miles of freight subway underlying the principal streets, through which the freight from the various railway terminals will be delivered into the basements of the principal business houses, thus removing from the streets the obstructions and objections incident to the movement of this freight upon the surface. When Chicago has put into effect plans now contemplated there will be, in addition to the elevated and surface tracks, three levels of subways below the surface, thus making it probably the greatest example of the development of this class of service in the world.

Other cases might be cited, such as the Baltimore tunnel of the Baltimore and Ohio Railroad at Baltimore, which has been in operation since 1895; the St. Clair tunnel of the Grand Trunk Railroad system under the St. Clair River between Port Huron, Mich., and Sarnia, Ont., and the Detroit tunnel of the Michigan Central Railroad at Detroit, under the Detroit River, where electricity will soon supplant steam in the hauling of heavy freight and passenger trains.

In addition to these prominent examples there are now in operation a number of railways built from the start as electric railways, operating under conditions approaching steam-railroad practice, and these, with the examples above mentioned, the Simplon Tunnel line (by which the traveler is conveyed from Switzerland into Italy without the annoyance of obnoxious gases from the steam locomotive), the Erie Railroad, the Lancashire and Yorkshire of England and the Valtellina line of Italy, all of which are in operation, are conspicuous examples of what electricity is now doing in heavy railroad work, and while this list is by no means complete, it indicates what may be expected in the future.

In addition to the conclusive evidence of the successful operation of the roads above mentioned there are now either under contract for construction or under contemplation numerous other important applications of electricity to steam-road conditions, as shown by the contract recently let for the electrification of the Cascade division of the Great Northern Railroad, by means of which it is expected that the capacity of the Cascade division of this road will be greatly increased and its operation made more safe. The Southern Pacific Railroad Company is also contemplating the electrification of one of its heaviest divisions through the Sierra Nevada Mountains for the purpose of eliminating the difficulties due to tunnel operation, and has recently let a contract for the electrification of its entire terminal system at Oakland, Cal.

The writer, although the first to put into extensive use the rotary converter sub-station system for railway work, soon realized its limitations, which caused him to conduct a series of experiments at Lansing, Mich., from 1900 to 1903, with the object of using the single-phase alternating current directly in the car motor, so as to eliminate the sub-station feature of the then standard system and at the same time economize in copper by using a higher working pressure on the working conductors.

These experiments so stimulated the work of others that various single-phase systems were developed and placed upon the market in 1904, so that, although the direct-current system had been adopted by the New York Central commission when it had to make its decision in 1903, by the time the engineers of the New York, New Haven and Hartford were required to act, the single-phase system had been sufficiently developed to be considered a formidable rival of the well-established and well-behaved direct-current motor.

These engineers decided in favor of the single-phase motor, with the result that we now have two of the leading railroads of the world operating their trains into the same terminal and over the same tracks for a considerable distance, but using entirely different systems and methods of applying electricity to the propulsion of their trains, one using the direct-current motor with the third rail for a working conductor, while the other uses the single-phase alternating-current motor and an overhead conductor.

Thus we have a splendid example of a "battle royal" on a grand scale of two formidable rivals for supremacy in the application of electricity to steam-railroad work.

In the meantime the three-phase system as developed in Hungary has been in successful operation on the Valtellina line and the Simplon Tunnel previously mentioned, and has been recently adopted by the engineers of the Great Northern Railroad Company in this country for its Cascade division, while the single-phase system has been adopted by not only the Grand Trunk Railroad Company for its St. Clair Tunnel installation but for a number of other installations involving heavy work. Therefore, we stand a fair chance of soon realizing from the results of actual practice the relative merits of the different systems.

Concluding this brief outline of what has been accomplished in the electric-railway field we may reasonably ask, what of the future?

In writing upon this subject in 1904 the writer then announced that it was his firm opinion that conditions would compel the steam-railroad companies to absorb the principal interurban lines paralleling them and convert them into local feeders for their through-line trains; that the steam-railroad companies would, either for the purpose of producing more economical conditions of the operation of their terminals, or from the force of pressure brought about by the officials of municipalities, which would compel them to equip their terminals electrically on the ground that steam locomotives in our cities are a public nuisance, become not only owners but operators of electrical properties; that with their terminals thus equipped electrically and the interurban roads between these terminals operated electrically the next step would be the electrification of the trunk-line passenger tracks between these electrified terminals. Thus when one road which ran through a territory sufficiently populous to warrant the operation of passenger service by electricity became equipped electrically, other roads competing between the same cities for passenger business would be compelled to do likewise, owing to the advantages afforded to passengers by electrically propelled trains. In this manner the roads would gradually be electrified and ultimately the principal trunk lines of companies operating in populous districts would be operated by electricity.

The first step has already been taken in the absorption by principal steam-railroad companies of many of the competing trolley lines. The second step is being rapidly realized by the electrical equipment of the terminals in the city of New York, the recent awarding of a contract for the electrification of the terminals of Oakland, Cal., and the present agitation for the electrification of the terminals in the city of Chicago. The third step, the connection of the main terminals and the operation of electric trains between them, seems to be but a question of time, although it should not be assumed that the steam locomotive is soon to be banished from its legitimate field, wherein it excels as an economical agent for moving heavy trains at infrequent intervals.

Pacific Gas and Electric Association.

Writing under date of September 18th the San Francisco correspondent of the Western Electrician says: "The annual convention of the Pacific Gas and Electric Association is now in session at the Casino, Santa Cruz, Cal. The convention opened Monday and will close today. About 75 delegates from different parts of the state are in attendance. On the main floor of the Casino is a creditable exhibit of gas and electrical appliances for heating and lighting. Last night the association was banqueted in the Casino grill, and today the delegates are the guests of W. J. Dingee on a trip of inspection to and through the big cement works of Davenport."

Electric Heating and Cooking.

Although it is only within the last half dozen years that electric heating and cooking has really been taken seriously as an important branch of the industry, the art dates back at least 18 years and perhaps farther than that. At the Chicago World's Fair of 1893 there was quite an extensive exhibit of this character, with a colored cook in charge of the demonstrations, and it attracted much popular attention. Development was slow, however, owing partly to defects in earlier types of apparatus and partly to apathy of central-station managers, but mainly to the expense to the user, compared with other methods, due to cost of current. But of late years the business has been pushed energetically; appliances have been improved, simplified and multiplied in number; central-station men have been aroused, owing largely to the success achieved by the humble electric flatiron; and, with the constantly decreasing cost of electric current, electric heating and cooking seem to have a bright future.

In a paper read before the convention of the National Electric Light Association in May, 1904, Mr. James I. Ayer, manager of the Simplex Electric Heating Company, said:

"The earliest work of a substantial character was begun by the Carpenter Electric Heating Company of Minneapolis in 1889, and continued through a checkered career for several years. Other companies were numerous and short-lived, as most of them deserved to be. While the earliest products were not all that could be desired, and much crude experimenting was conducted at the expense of the enterprising public, some of the product justified itself in the way of fair performance. Had there been a more general use of current in residences and industrial establishments to make the market worth while, a different history would have been written.

"Considerably less than ten years ago there were few central stations outside of the largest cities which supplied current in the daytime. In such cities the rates were high, with the use of constant-potential current limited largely to the most important stores, few residences, and fewer industrial enterprises. The isolated plants were small and used entirely for lighting for a few hours a day.

"Six or seven years ago the conditions rapidly changed, but prior to this, because of the early numerous failures of electric-heating companies and the sad experience of the public with much of their product, electric heating had become as much discredited as had the storage battery earlier. Extraordinary efforts were required to place the storage battery where it rightfully belonged, even several years after its revival abroad pointed the way, so strong was the prejudice of our fraternity due to their faith in tradition.

"Electric heating, while not meriting the same consideration, was very seriously retarded in its development by this same prejudice, and after eight years' effort, during which period much improvement had to be made to make possible such success as has obtained, I can say that the present results would have been achieved much earlier had there been no past.

"The future of electric heating is assured, and yet it has in it disappointing elements for its advocates who do not rightly comprehend its limitations. In the early days of electric lighting the salesman confidently asserted that all the speculative dreams of the inventor could be accomplished by anyone who would purchase his particular dynamo and appliances. Electric heating is capable of being misunderstood to a considerable degree. The engineer, without some thought, will wonder how we can successfully heat with electricity the staterooms of an ocean liner, competing with steam, while deriving power from steam, when we cannot heat an office with current from waterpower at $30 a year per horsepower, or by meter at three cents per horsepower; yet it is true. If this is a problem to an engineer, how does it appeal to the layman?

it will be found that many things are possible that are not commercially practical, and many that appear so are not, and because of this I want to appeal to you as central-station men to get a grasp of the elements of electric heating, and a knowledge of working conditions, that you may move rapidly and reap the benefits of intelligent application of this branch of development."

It is interesting to note the steady advance of the business in recent years. For the last four years the Western Electrician's New Year's estimates of the value of electrical heating and cooking apparatus produced in the United States were as follows: 1903, \$325,000; 1904, \$425,000; 1905, \$650,000; 1906, \$850,000. Unless all signs fail, the value of such appliances made and sold in the United States in 1907 will be well over a million dollars.

Electric Street Lighting Twenty Years Ago.

By Albert Scheible.

In street lighting as in many other applications of electricity the early part of 1887 showed that unrest which usually precedes decided advances, and before the year was old four important forward steps had been realized. The first consisted in the introduction of alternators and transformers where only direct-current machines had formerly been used. Profiting by the European work of Gaulard, Gibbs, Zipernowski and others, three American firms developed alternating-current apparatus. Stanley (then electrician of the Westinghouse Electric and Manufacturing Company), Elihu Thomson and Slattery worked with almost feverish haste. The National Electric Light Association received a decidedly favorable report on the practicability of induction systems for electrical distribution, and the foundation was laid for the gradual crowding out of the direct current for street lighting.

A second step of great bearing on street lighting was the development of low-resistance incandescent lamps, suitable for use on series circuits. Up to that time street lighting had simply meant the use of series arc lamps (all direct-current "open" arcs) with crude supporting arrangements, though some few places supplemented the arc lamps with a so-called "series-multiple" system supplied by the Brush Electric Company. This system used incandescent lamps by connecting five (specially selected for practically equal amperage at the same voltage) in multiple and inserting them directly in the series arc circuit. Its use simply reflected the crying need for some means of running incandescents on circuits whose high voltage meant economical distribution, but the difficulty of balancing the resistances of the lamps of each group if separated by more than a few yards limited this plan greatly. A few places did use street incandescents in series but on circuits of very low amperage, as, for instance, Lawrence, Mass., where three-ampere circuits were used with an electromagnet at each lamp to shunt the same when the filament burned out. During 1887 Bernstein (in England) developed a low-resistance incandescent lamp suitable for use singly on series circuits of 6.9 and even 9.6 amperes, and the Thomson-Houston Electric Company also offered lamps for the same purpose.

But while the demand for a more subdivided light led to the making of series incandescents for use as small and widely scattered units, the same period was also marked by warm controversies as to the use of towers for lighting cities by groups of arcs forming units of very high candlepower. A number of American cities had already been lighted in this way, but some were dissatisfied with the plan, as, for instance, New York city, where 23 arc lamps on poles were substituted for the tower lamps in Madison Square and Union Square. In Europe the Eiffel Tower project gave a concrete basis for a lively discussion of the same topic, in which prominent engineers took an active part. This was to be expected, as the stone tower (for which Eiffel's steel design was substituted because of its lower first cost) was originally planned by Bourdais with the prime object of lighting the entire city of Paris electrically. Some held that arc lamps supported 300 meters above the ground would make this an effective "sunlight tower," while others tried to calculate the absorption of light by the air, the possible increase of efficiency by placing a band of mirrors above the lamps, and the size of enclosing globe or lantern needed for diffusing the light so as to avoid dazzling the eye.

The same tendency toward the use of towers led to plans for stringing distribution wires on high towers instead of running them on poles or in conduits. Projects for thus placing the wires on poles 80 to 130 feet high were proposed for cities like New Orleans and St. Louis. But the reaction soon set in, so that most electric-light men of today look upon towers as mere historic relics, although there still may be many places where their use would be both practical and economical.

The fourth turning point came in the introduction of specially designed line material in place of the improvised construction previously permitted. Up to that time crude materials had been gathered from various sources. Thus hay-fork pulleys and ¾-inch manila rope for hoisting the lamps, with the rope run diagonally down from the pulley to a cleat on the pole and a bungling coil of rope there, made up the arc-lamp suspension. For insulation a broomstick with a porcelain knob at each end guided the line wires over each lamp, the wires themselves having the wonderful "underwriters' insulation." Now the art was ready for better construction, and the materials for it came almost simultaneously from the East and the West. Thomas Brady and Harry Cutler, with their mast-arms, and John Fletcher, with his sleet-proof pulleys, paved the way for modern construction. Bell insulators, safety pulleys or hanger cut-outs were still far in the distance; but before the year ended energetic dealers were pushing practical devices which marked the introduction of a higher grade of material.

Thus the epoch of transition and growth during which the Western Electrician saw its birth, and which it undoubtedly speeded, showed four decided effects on electric street lighting:

First—It proved the practicability and economy of distribution by alternating currents.

Second—It brought out low-resistance incandescent lamps, thus making series incandescent lighting feasible.

Third—It showed tower lighting to be quite limited in its effectiveness for modern street lighting.

Fourth—It introduced properly made appliances for supporting and insulating street lamps.

Yet with these important transitions no one dreamed of enclosed arc lamps or alternating arcs, 150-light series dynamos, tub transformers, rectifiers, shunt boxes, Nernst lamps, flaming arc lamps or magnetite arcs. All these have come with the last twenty years. Does not that fact in itself show how rapidly we have progressed in electric street lighting?

FIVE DISTINGUISHED ELECTRICAL INVENTORS OF THE WEST.

Progress in Telegraphy.

During the last twenty years telegraphy, which is the oldest of the electrical arts, dating back to 1844, has shown considerable advance, particularly in the introduction of more rapid means of sending by automatic or machine methods, in the substitution of dynamos for batteries as current producers, in the great extension of submarine cables and in the striking increase in the number of code messages.

Robert C. Clowry.

Edward J. Nally.

TWO LEADERS IN TELEGRAPHY IN THE WEST, NOW IN NEW YORK.

The most important question now facing telegraphic administrations is undoubtedly the substitution of automatic for manual sending. The present strike of telegraph operators will no doubt have not a little to do with the expediting of this movement. Three years ago, in a paper read before the International Electrical Congress, Mr. J. C. Barclay, the assistant general manager of the Western Union Telegraph Company, made the following interesting observations on this subject:

"Machine telegraphy is undoubtedly destined to play, if not a dominant, at least a highly conspicuous part in the telegraphy of the future. For the present, and probably for a long time to come, the Morse system will continue to be the standard system employed in this country. It is doubtful indeed if the Morse apparatus—representing as it does the very acme of simplicity—will ever be wholly superseded, but new and improved as well as more economical methods of working will,

SOME OF THE MEN PROMINENT IN THE ELECTRICAL DEVELOPMENT OF THE WEST.

slowly perhaps, but nevertheless surely, limit its field of operations.

"The advances made in recent years in the direction of developing and perfecting a printing telegraph system, adapted to meet all the requirements of a modern telegraph service, have been of such a practical and progressive character as to leave no room for doubt that the successful advent of such systems into the domain of commercial telegraphy will soon be, if it is not indeed already, an accomplished fact."

Another change that has made for greater speed in telegraphing is the great increase in the number of code messages. As shown by Mr. D. McNicol in an article contributed to the Western Electrician three months ago, a cipher telegram was the exception fifteen years ago, while today the plain-language telegram constitutes only about half of the business handled. Other changes are the substitution of the dynamo for the gravity battery and the almost universal requirement that operators shall use the typewriting machine in receiving.

Submarine telegraphs have been greatly extended in all parts of the world, the twentieth century witnessing the spanning of the Pacific, thus supplying the last remaining link in a telegraphic circuit of the globe.

Wireless telegraphy is briefly treated elsewhere.

Electric Power Transmission.

By Chas. F. Scott,

Consulting engineer, Westinghouse Electric and Manufacturing Company.

TWENTY years is in most things a short interval, but in electric transmission of power it is an epoch.

The long-distance transmission of power, as commonly practiced today, was unknown twenty years ago. Some of its fundamental elements had not been discovered, and apparatus and methods which have been in common use for many years were yet to be invented and deevloped.

CHAS. F. SCOTT.

Practically all transmission today is by the alternating-current three-phase system. Twenty years ago the first alternating-current central station in this country had been in operation but a few months. The introduction of the alternating current was encountering the most strenuous opposition, by technical argument, by commercial antagonism and by attempted legal prohibition. There was no commercial alternating-current motor. It was not until May, 1888, that the Tesla patents on polyphase apparatus and transmission were issued and published.

Transformers rarely exceeded two kilowatts in capacity and 1,000 volts in pressure. Insulators and lightning arresters had hardly become clearly differentiated from their telegraphic predecessors, from which they were evolved. Even the direct-current stationary motor was a commercial novelty, and all the electric railway systems in the country aggregated a length of track which could be traversed at present speeds in less than an hour.

Beginning of the Niagara Development.

It is less than twenty years ago that an international technical commission was formed to determine the methods to be adopted by the Niagara Falls Power Company. It was not until 1893, during the World's Fair at Chicago, that final action was taken against the sentiment in favor of direct current by the formal decision to use polyphase alternating current.

At that time commercial frequencies were shifting from 133 cycles to 60 cycles. It was necessary to determine the frequency for the Niagara circuits. It was believed that much of the power would pass through large induction and synchronous motors, or synchronous converters, although such apparatus was more apt to be found in experimental testing rooms or in exhibits than in service. There was very little experience upon which to base the bold recommendation of a low frequency for so large an undertaking. The turbine speed had been fixed at 250 revolutions per minute. The power company's advisers proposed that the generator have eight field poles, giving 16 2-3 cycles (2,000 alternations); the Westinghouse Company recommended 16 poles and 33⅓ cycles (4,000 alternations). The only possible intermediate course was finally chosen—12 poles and 25 cycles (3,000 alternations).

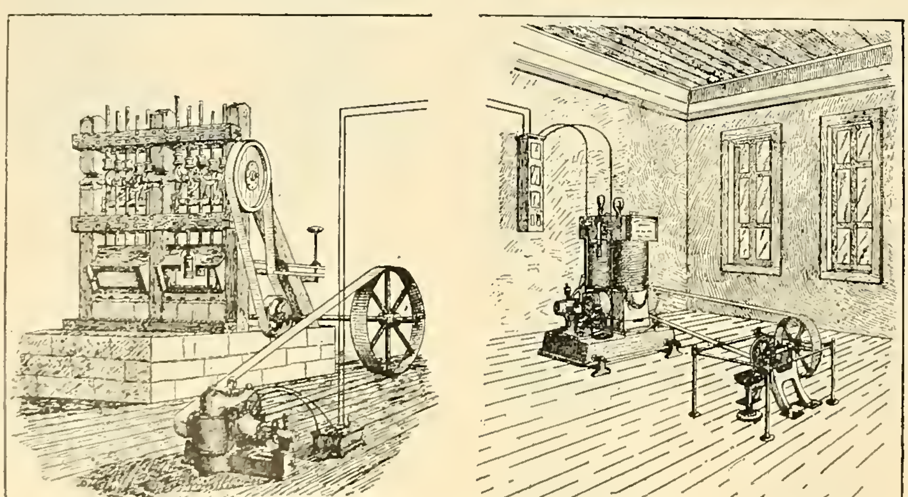
Pomona and Telluride Plants.

In 1892 the first 10,000-volt transmission plant in this country began operation in Southern California, transmitting single-phase current from San Antonio Canon for lighting Pomona and San Bernardino, approximately 14 and 28 miles. There were two banks of transformers, raising the pressure from 1,000 to 10,000 volts. In each bank were 20 six-kilowatt transformers, with primary 1,000-volt windings in multiple and secondary windings (each transformer giving 500 volts) in series. The transformers were oil-insulated, and the cast-iron cases were provided with ribs to increase the cooling surface. The transformers were connected to the line through simple disconnecting switches. The line consisted of No. 7 hard-drawn copper wire supported on specially designed glass insulators which were then considered of quite formidable size. At each sub-station there was a bank of transformers duplicate of those in the power house. There were no lightning arresters—nor was there lightning. The system was about as simple as a typical diagram of a transmission circuit with raising and lowering transformers.

The Telluride single-phase synchronous motor plant was started in 1890. A 100-horsepower motor was operated at 3,000 volts at a distance of several miles. The Redlands plant in southern California, the first 10,000-volt three-phase transmission system in this country, was started about the beginning of 1894.

Then and Now.

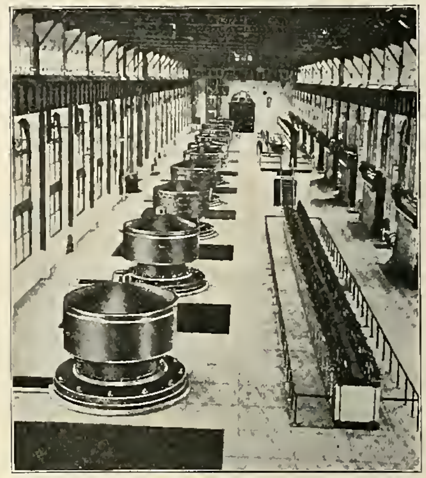
One may look through several volumes of the Transactions of the American Institute of Electrical Engineers in the early '90's and find scarcely a paper on transmission subjects; now the work of the transmission committee is one of the leading features of the Institute publications.



This curious illustration is reproduced from the Western Electrician of June 23, 1888. The text very briefly explains that the power was transmitted four miles, with 25 per cent. loss in transmission, to operate a motor for driving a stamp mill in Idaho.

AN EARLY POWER TRANSMISSION.

At the opening of the International Electrical Congress held at Chicago in 1893, it was found that there were no papers on power transmission among the considerable number which were on the programme. Dr. Louis Duncan came to the writer and asked that he prepare something to help start a proposed discussion on the subject. The outcome was an introductory paper, dealing particularly with the induction motor, by Dr. Duncan, and a description of the Westinghouse exhibit of polyphase apparatus in operation at the World's Fair, by the writer. These papers were followed by an animated discussion, which dealt with general principles rather than particular apparatus or methods. At the similar congress in St. Louis in 1904 there were many papers in the section on Power Transmission, most of them dealing with the results of experience and details of construction and operation.



INTERIOR OF A NIAGARA FALLS POWER HOUSE, SHOWING 10 VERTICAL 5,000-HORSEPOWER GENERATORS.

Such, then, was the early condition of transmission work. A score of years ago it was nil; during the following seven or eight years several sample plants were installed; it was only about ten years ago that operating voltages got much above 10,000 volts, and power transmission assumed commercial importance.

What have been the changes which have taken place in apparatus and methods since the transmission system could be represented by the elementary textbook diagram showing generator, raising transformers, line, lowering transformers and load?

Each element in the system has undergone a remarkable development. Each increase in voltage and in current and in power has called for higher and better quality in design and in construction. Not only has each of a great number of detail parts been individually improved to meet the new requirements upon it, but there has been a general adaptation of parts and elements to form a single great system. In fact, the transmission elements are only a part. The generating plant, the distributing system and the utilization of the power all constitute elements in the system, of which the transmission is but a part. And, further, aside from the engineering and operating features of the system, it in turn has its financial and commercial and economic relations in the general affairs of life. The prices of coal and of copper and the growing uses of power are in a broad sense factors in power transmission just as much as the insulator or the transformer oil.

It will be useful to take a hasty glance at the development which has taken place in the various elements of the transmission system.

Generating the Power.

In the power house the generators have been increased from about 100 kilowatts to sizes varying all the way from 5,000 to 10,000 kilowatts. These generators are alternators usually delivering three-phase current. This is somewhat remarkable, since a general discussion fifteen years ago was apt to treat transmission by direct current or single-phase current with high respect and anticipation.

In connection with the larger generators have come consequent developments in the switches and controlling appliances between the generator terminals, bus bars and raising transformers.

The Transformer.

The transformer has grown from a few kilowatts to a few thousand kilowatts in output and from a few thousand volts to commercial voltages ranging all the way to 100,000 volts. In the transformer questions of general type, the kinds, the quantity, the arrangement and treatment of solid and fluid insulating materials, the methods of arrangement and mechanical support of the coils for withstanding not only the forces of normal operation but those which may occur in a short-circuit on the secondary lines, the construction of the case and terminals, are all features which have required the most careful consideration. Some of these seemingly minor points have received the attention of experts for years. One of the terminal bushings on a large 100,000-volt transformer of today weighs about as much as one of the complete transformers for the Pomona line.

Insulators and Line Construction.

The insulator, upon which rests probably the greatest responsibility in the transmission system, has grown from the sizes now used for telegraph circuits to most formidable proportions. The matter of surface leakage, which was thought by some to be so important that oil cups were proposed in connection with the inner petticoat for increasing the surface resistance, has been found to be of little consequence compared with other features. It has been only ten years since the attempts in the making of large porcelain insulators resulted in a porous construction, so that the material inside of the glazing would absorb a drop of ink as would a lump of sugar.

In its various features of size and geometrical proportions, of materials, mechanical strength and manufacture, the insulator has called for the best efforts of designers and makers. So far, the development has been almost entirely along a single line. The largest insulator is similar to that used for telegraph lines in that it is mounted upon an upright pin, carries the wire near its top, and secures surface distance by means of petticoats. This simple type loses much of its simplicity when large sizes are reached. The conductor is so high above the cross-arm that cross-arm and pin and insulator must be made large and strong to secure mechanical strength. Insulator petticoats are large and fragile. The insulators are heavy and difficult to handle, making the replacement of a broken insulator a serious matter. The ordinary type is such that increase in size makes the mechanical stresses very much greater. Thus the addition of insulating strength brings new difficulties. This time-honored form is now threatened by a radical modification. In one new type the wire is below the insulator and the insulator is in the form of a series of disks linked together to form an insulating flexible suspension.

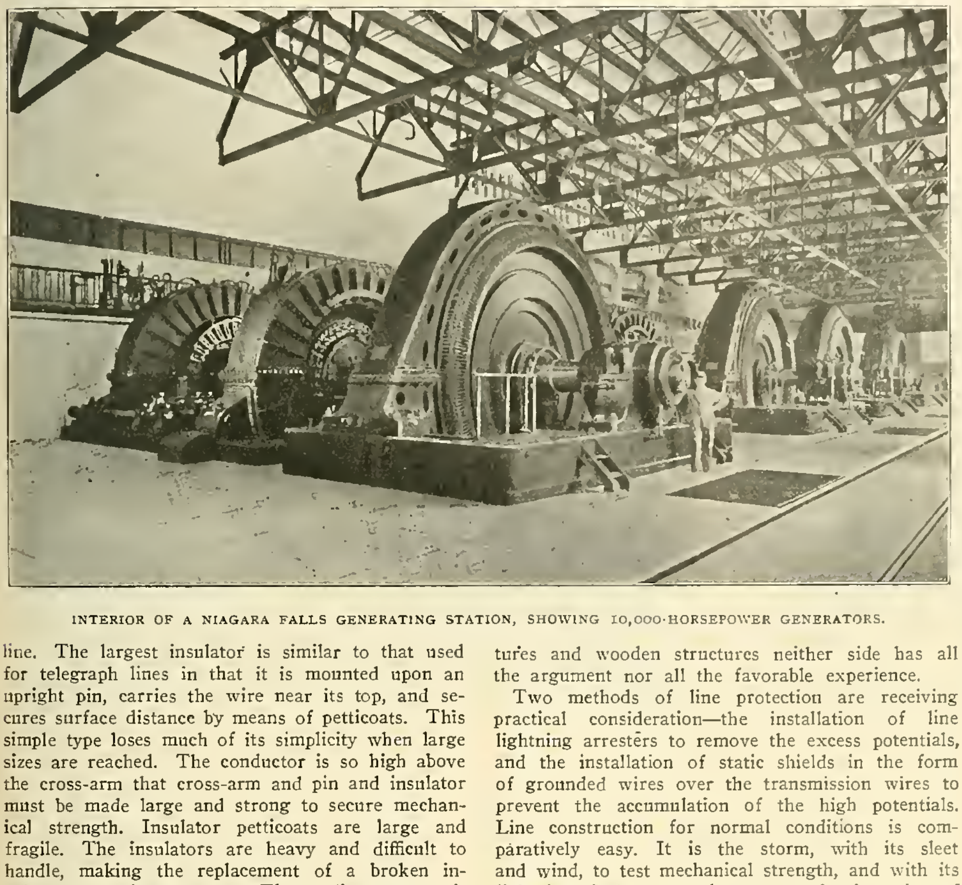
The pole line followed for many years the orthodox method. Wooden poles, 100 to 150 feet apart, with cross-arms, are now giving place to steel towers ranging from a few hundred to a few thousand feet apart. The long spans are made possible by the larger sizes of conductors, made necessary by the transmission of larger quantities of power.

Lightning Protection.

Lightning arresters have taken an important place in transmission development, as a matter of investigation, discussion and observation. The general phenomenon of lightning, both the kind that comes from the heavens and that which comes indirectly from the dynamo in the form of line surges, has made a common field for theoretical investigation, for laboratory research, for design and invention, and for observation and test. Probably no single element has brought together so closely the theoretical and the practical as lightning protection. In the arrester itself the simple spark-gap, with suitable resistances for limiting the current, is now finding a somewhat radical modification in the electrolytic arrester, which realizes in simple form many of the requirements of an ideal arrester, as it is practically impervious to the dynamo current, but responds readily and freely to higher voltages.

It is coming to be generally recognized that lightning protection is not a matter of some simple device to be attached to a system at one or two points, but that the disturbances which are involved are such as require much more general and radical consideration. The design of transformers, of terminals, of switching appliances and of insulators are all involved. The location of the lines, the form and character of the supports for the wires, the protection of the line itself, as distinguished from the apparatus at its terminals, are all elements in the general problem.

In many of the transmission systems the troubles from lightning are not station troubles but line troubles. The apparatus in the station does not suffer, but some part of the line remote from the station. Wooden poles are shattered or burned. Insulators are punctured. Iron pins and iron poles protect the structure, but make the insulator more vulnerable. In the contention between iron structures and wooden structures neither side has all the argument nor all the favorable experience.



INTERIOR OF A NIAGARA FALLS GENERATING STATION, SHOWING 10,000-HORSEPOWER GENERATORS.

Two methods of line protection are receiving practical consideration—the installation of line lightning arresters to remove the excess potentials, and the installation of static shields in the form of grounded wires over the transmission wires to prevent the accumulation of the high potentials. Line construction for normal conditions is comparatively easy. It is the storm, with its sleet and wind, to test mechanical strength, and with its lightning flash or stroke to try the integrity of the insulator, which makes the problem so difficult. The haven of safety for the wires is the earth, and if the wires cannot be put underground, then the ground should be put over the wires.

This problem of line protection from static disturbance is one of the most serious in transmission development, having to do so vitally with continuity of service.

Controlling Devices.

The switching and controlling devices on the high-voltage circuits, which became necessary when the transmission system developed from a line connecting the power house with a single sub-station into a network of many lines and many stations, furnishes in itself material for an extended article. Oil switches; fuses, notably those of the expulsion type; disconnecting switches; station wiring, with compartments for the high-tension bus-bars and wires—all have increased in capacity and efficiency. A radical departure in station arrangement is now proposed by which the bus-bars, high-tension connections and transformers will be located out of doors.

The Development of the Art.

The steps which have marked the progress from the transmission of a hundred kilowatts at 10,000 volts to the systems of today have been little steps. They have not been taken by one man, nor by one company, but by many men in many places. Theoretical study, painstaking experiment, widespread observation and experience, have all contributed. The freedom with which designing and operating engineers have interchanged their knowledge and experience through the reading and discussion of papers has been an effective element in this advance. There are few departments in which engineering co-operation has been more extended and has been fruitful of larger results than in power transmission.

Great as have been the developments which have taken place in the details of the various elements involved in power transmission, they are equaled by the general commercial development, by the amount of money which is invested in transmission systems, by the general confidence in which long-distance power transmission is now held, and the substantial place it is now assuming in modern affairs.

In looking back over the last few years we note the very great development which has taken place. There is no indication now that the limits have been reached. The fact that the principal increases have been made in size, until recently, when new types are being introduced, is significant of the kind of changes which the future may have in store. The introductory sentence of a recent paper by Mr. Frank G. Baum before the American Institute of Electrical Engineers is significant and will bear careful thought: "In designing power-transmission systems it is always well to bear in mind that the ultimate development of the art and of the country has not yet been reached."

Radio-telegraphy.

Radio-telegraphy or wireless telegraphy dates from 1895 and may be fairly said to have been invented by G. Marconi, who, in Italy, in that year, established wireless communication over as long a distance as two kilometers. Early in 1906 Marconi went to England to develop his invention, and in June of that year he obtained his first patent for radio-telegraphic apparatus. The specifications for that patent clearly show, according to Marquis Solari, that up to that date (June 2, 1896) Marconi had not only made the first practical application of Hertzian waves to wireless telegraphy, but had conceived a theory of their action which was broader and more comprehensive than that imagined by Maxwell and contemplated by Hertz, neither of whom had given evidence of their belief that the effect of these waves might not be bounded by the limitations of the electromagnetic theory of light.

Since then great strides have been made in the art, which has engaged the attention of many physicists and inventors, to say nothing of financial promoters. It is said that messages have been sent across the Atlantic, although there seems to be some mystery on this point. At any rate, messages have been sent, received and read, at sea, for distances of more than a thousand miles. Transmission over land has not been so successful, although accomplished for considerable distances.

Among those who have contributed to the technical advancement of the art are Marconi and Solari in Italy, Popoff in Russia, Lodge, Fleming, Preece and Muirhead in England, Branly, Du Cretet and Rochefort in France, Slaby, Braun, Ruhmer, Brandes, Drude and Schloemilch in Germany, and De Forest, Fessenden, Stone, Massie, Squier and others in the United States. Nearly all the important warships and seagoing passenger steamships are equipped for "wireless," while it is believed that there are about 400 land stations in operation throughout the world. Nevertheless, there is little indication that the newer method, now prominently before the public for more than a decade, will supplant electrical communication by wires where the latter can be attained. It is unfortunately true, also, that the financial operations of some of the companies exploiting the various "wireless" systems have not been such as to merit unreserved commendation.

A good review of the art was given in Mr. D. McNicol's recent serial in the Western Electrician on "Wireless or Radio-telegraphy," which was concluded in the issue of February 16, 1907.

Duluth, Minn., and Superior, Wis., are now getting electric power from the large hydro-electric plant of the Great Northern Power Company on the St. Louis River. The first unit was started about two weeks ago. The second will be ready in a few days.

Dynamo-electric Machinery and Its Evolution During the Last Twenty Years.

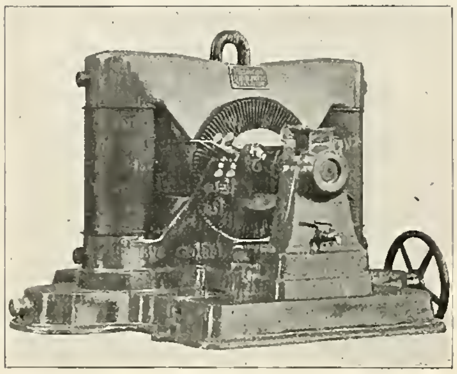
By B. A. Behrend,
Chief Engineer and Chief Designer, Bullock Works, Allis-Chalmers Company.

When the historian-engineer writes upon the evolution of electric machinery during the last twenty years, he must needs write a story in which his own work and the work with which he has been associated form a more prominent part than is desirable in an impartial historical review. But every writer has the defects of his qualities, and the historian-engineer is prone to be either too much of a historian, or too much of an engineer, in relating the story of the growth and development of electric generating machinery and electric motors. No one who has ever carefully read history can deny that the bias of the author lends a peculiar color to his views and statements, and, in writing this article, I cannot plead guiltless of a similar bias.

BERNARD A. BEHREND.

Twenty years ago we find a number of gifted physicists and engineers, the latter mostly of the telegraph type, engaged in fathoming the mysteries of electricity for the purpose of making machines which generate electric energy. Great masters of physical science, as Faraday, William Thomson and Maxwell, understood all about electromagnetic induction, but did not care to build dynamo-electric machinery, or, perhaps, heresy though it may be to say so, could not have done it. Here the engineer stepped in, a little lame, perhaps, in the mastery of theory, but with that creative imagination and poetic vision which form an important quality in the designing engineer.

There were dynamos built by Gramme, by Deprez, by Edison, by Elihu Thomson, by Siemens, and others whose names are beginning to fade from our memory. It must be irreverently stated, however, that our college boys would laugh to scorn these attempts and deem themselves greatly superior designers to the pioneers. The weakness of these early machines was not confined to the electrical design; in point of fact, it has always struck me that these early designers were more deficient in knowledge and experience in mechanical matters than in electrical. And there was much less excuse for this, as the mechanical art was developed and could be utilized without much difficulty. To this condition is to be attributed the deplorable patent situation in the electrical field, which has led to the protection by patent of mechanical features, known for many years, applied to electrical machinery because of the profound ignorance of the mechanical arts displayed by the electrical experts.



HIGH-VOLTAGE DIRECT-CURRENT DYNAMO OF 1887 (OERLIKON).

I have always contended that electrical designing is but a branch of mechanical engineering, as the design of heat engines is considered but a branch of the same field. That, of course, the electrical engineer should possess a thorough familiarity with the principles of electrical phenomena is as fundamental a requirement as that the steam engineer should know thermo-dynamics. These electrical machines which generated electricity but came to pieces in the process, burning out their bearings and being altogether nothing but toy machines turned over to a millwright, started the procession. And as any glaring faults are often made the starting point for improvements, so the dynamo-electric machine was taken out of the instrument makers' hands and placed with mechanical men in machine shops. In America I believe it was the Westinghouse & Schmidt Company, the precursor of the Westinghouse Electric and Manufacturing Company, which greatly improved the mechanical features of dynamo-electric machinery, while in Europe the Oerlikon Company made machines in which the art of mechanical engineering was utilized to the full.

To all those who have followed the recent discussions about the relative merits of single-phase alternating currents and of high-voltage direct current for railway work it must be interesting to be reminded that the first electric generators of any account were direct-current machines of from 50 kilowatts to 150 kilowatts, generating from 1,200 volts to 3,000 volts, and being used for the transmission of power as series-wound machines. These machines were of the Manchester type, credited to Hopkinson, being bipolar and having copper brushes. Both the careful mechanical and electrical work which was put into these forerunners of modern electric machinery is testified to by the fact that a number of these plants are still in operation with commutators whose once cylindrical surfaces have been worn into bodies of revolution with fantastically curved outlines. The series winding of these machines was, of course, an essential condition; but we have in the interpole, which is over twenty years old, and which has recently been unearthed, a means of obtaining equally satisfactory results with shunt-wound generators.

While intent upon the development and improvement of the direct-current machine, there came the startling work of Nikola Tesla, which prevented any further concentration of thought on anything excepting alternating currents and their combinations into polyphase currents. The work of Tesla has never been clearly understood or appreciated according to its intrinsic value by the majority of engineers. Mr. Tesla's early papers are classical contributions to the art of engineering and rank with the best that have been written. This statement is altogether independent of the validity of his patents—a matter which is not here under discussion.

Mr. Tesla is the victim of his friends. It is a peculiar trait of ignorant men to go always from one extreme to another, and those who once were the blind admirers of Mr. Tesla, exalting him to an extent which can be likened only to the infatuated praise bestowed on victims of popular admiration, are now eagerly engaged in his derision. There is something deeply melancholy in the aspect, and I can never think of Nikola Tesla without warming up to

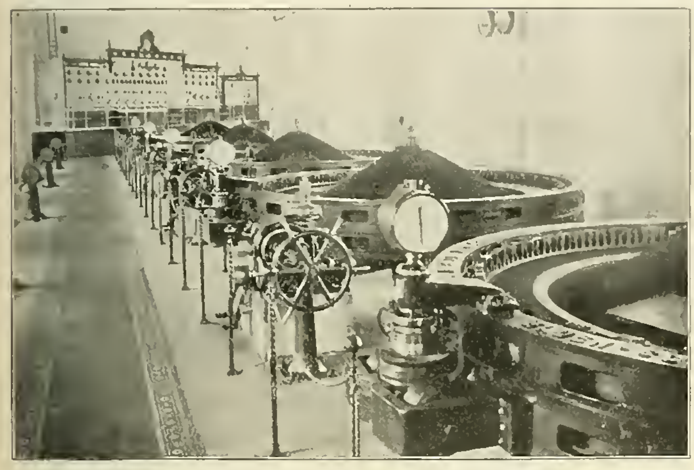
my subject and condemning the injustice and ingratitude which he has received alike at the hands of the public and of the engineering profession. A child of genius, springing from a race not inured to the poisoning of flattery, he came to this country and did great and imperishable work. His admirers feted and celebrated him, and he took them seriously. It was only natural that his later work did



UMBRELLA-TYPE REVOLVING-FIELD ALTERNATORS (BROWN-BOVERI), 1897.

not show the clearness and originality which characterized his work on polyphase machinery, and which made him famous. The engineering profession, unjustly and ungratefully ignoring his early work, labeled him a charlatan, and the public, always on the lookout for new sensations, dropped Mr. Tesla and forgot him. As my professional work for almost a score of years has had for its object the

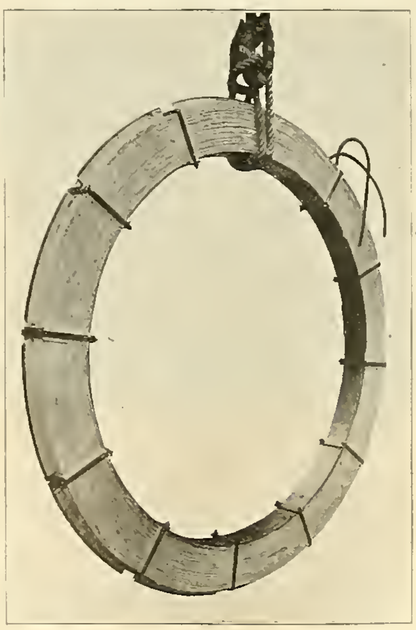
20,000-VOLT TRANSMISSION LINE, OERLIKON WORKS, 1892.

development and improvement of electrical machinery, for which Nikola Tesla has done much, I wish to take this opportunity to pay a tribute to his work done at the opening of the epoch which has culminated in the large industry of electrical engineering.

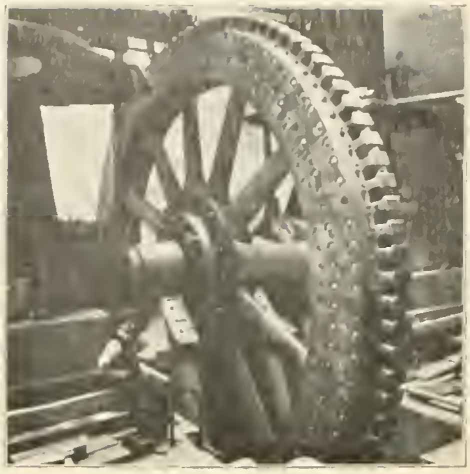
As the early direct-current machines were all wound as Gramme rings, there became established a preference for this construction in alternating-current generators. Besides the ironless types represented by Mordey, Ferranti and Siemens alternators, we notice the iron-core alternators of Kapp and of Schuckert, in which flat rings are wound with coils, in principle like the Gramme ring. The application of mechanical principles soon created reliable mechanical construction by using drum windings, and we record the next step in improvement of dynamo electric machines when we refer to the direct current generators built by the Westinghouse & Schmidt Company and the Thomson-Houston Company in America for railway work. Mr. Sidney H. Short, of the Walker Company, should here receive honorable mention for his pioneer work in this respect.

It has always seemed to me that the designs of electrical machinery in the early '90's lacked a clear recognition of underlying principles until the designing genius of C. E. L. Brown had done for the art what Corliss and Reynolds had been doing for the steam engine. Unity of plan enters into the field, and the present dynamo-electric machines become stereotyped. The direct-current generators have become multiple-wound multipolar units, with cross connectors in the armatures, and with commutators and brush-holders which we are all familiar with in present designs. The alternating-current generators are multipolar machines with internal revolving fields and external stationary armatures with windings arranged similar to those of drum-wound armatures. No more are we tempted from the straight path of engineering by such will-o'-the-wisps as Lauffen types, inductor types and other patent articles. The general design and construction have become established and will remain established until the introduction of entirely new principles which will relegate present dynamos to the past.

In reviewing the evolution of dynamo-electric machinery during the last twenty years, we must needs comment on the careful development of details and upon the adoption of rational processes for the manufacturing of this machinery. Fifteen years ago it was quite customary to manufacture the core plates by using circular shears and to build up the plates without slots, these being milled in the cores after



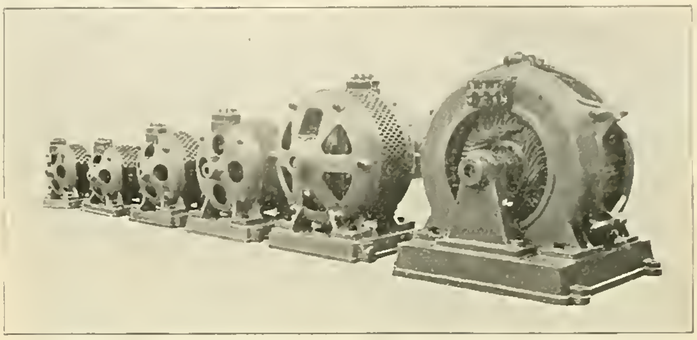
STATIONARY FIELD COIL OF INDUCTOR ALTERNATOR (OERLIKON), 1896.



REVOLVING FIELD OF 3,200-KILOWATT ALTERNATOR (BULLOCK), 1902.

the cores were built up. The manufacture of a large number of machines of the same size has made it possible to use dies and punchings for this operation, so that sectional plates completely slotted and dovetailed for fastening can be turned out with the greatest accuracy.

Field coils which, in the early dynamos, were made

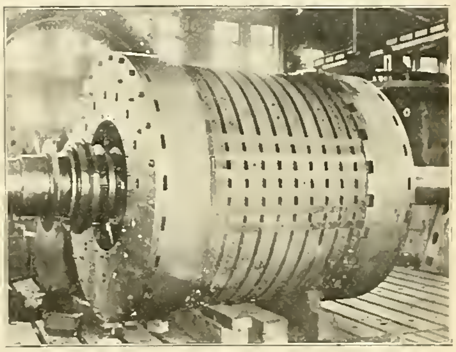


A LINE OF RING-WOUND INDUCTION MOTORS (OERLIKON), 1893.

of insulated wire, are made of copper strip bent on edge, and coils thoroughly mechanical and strong have thus been evolved.

Instead of hand-wound armatures, the winding of which required great skill and patience, form-wound armature coils were introduced, leading to mechanical construction with easy possibility of repair.

The gradual evolution from step to step which is pursued by Nature is also pursued by engineers in



FOUR-POLE REVOLVING FIELD OF 10,000-HORSEPOWER TURBO-GENERATOR (ALLIS-CHALMERS), 1904.

the development of an art. Different steps are evolved by different designers in different parts of the world in almost exactly the same way, because this evolution is the product of the human brain, which is the same the world over. It appears, therefore, most preposterous to any thoughtful man of culture and knowledge to designate these intrinsically small steps as inventions, and to bewilder the mind with claims couched in words of ambiguity and prolixity which apply to the objects they are meant to describe as well as to the process of the creation of the world as related to us in the first chapter of Genesis.

Much yet has to be done to educate the public, and the engineering public in particular, to understand the philosophy of progress and invention and to appreciate a complex situation created by a well-meaning institution like the Patent Department, but here, as elsewhere, human institutions founded with the best of intentions have defeated their own purpose. In an art which has hastily grown and whose principles have been considered mysterious, it may be excusable if certain means for mechanically fastening pole-pieces, for example, are represented to serve certain occult purposes conducting magnetism; but it seems pitiful that experts can be found to give their support to such humbug.

Though the perfection of the present dynamo-electric machines can be traced step by step from a modest beginning, yet there is a vast gulf between the first slow-speed machines and the present 7,500-kilowatt generators operating at 750 revolutions per minute. Yet little or nothing has had to be changed in the principles underlying the design of electric machinery, and the engineers must be filled with pride who, twenty years ago, recognized in the principles of Faraday and Maxwell the leading light of their art.

The Industrial Uses of the Electric Motor.

By E. W. Lloyd,

Contract agent, Commonwealth Edison Company, Chicago.

Extraordinary indeed has been the growth in the use of the electric motor for general power purposes during the last twenty years. The fact is well known to those interested in electrical matters, but the layman, perhaps, is not so well informed.

Before the year 1887 the use of electric motors was confined to small applications, and the motors as a rule were very unreliable.

Although Faraday, in 1831, discovered the principle that the generator could be used on an electric circuit as a motor, the value of the discovery was not appreciated.

Gramme, in 1871, displayed the celebrated ring-wound armature, which marked the advent of the first practical motors and dynamos. Motors, however, were generally considered only as toys at this time, and it was not until in the '80's, when Van Depoele, Edison and Sprague demonstrated the use of the motor in connection with the street car, that the electric motor began to be used more in a practical way.

Some of the first motors put into practical use in this country were the Baxter and Excelsior, and they were used on series arc circuits in sizes usually under ten horsepower. At the present time the very large motors run into thousands of horsepower in the capacity of individual units.

Before 1887 some motors were operated on 500-volt, continuous-current circuits, but not to any great extent. It has really been since that time that the great advances have been made in the use of electric power.

The growth of the power load of the Chicago Edison Company and Commonwealth Electric Company of Chicago since that time is indicative of the development throughout the world. The following figures show this growth:

In 1890 less than 1,000 horsepower in motors was connected.

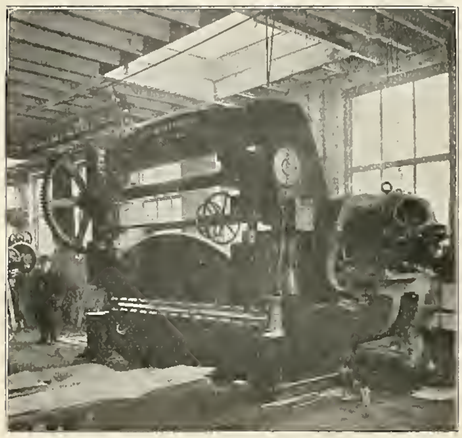
In 1895 about 3,000 horsepower.

In 1900, 19,107 horsepower.

In 1905, 69,053 horsepower.

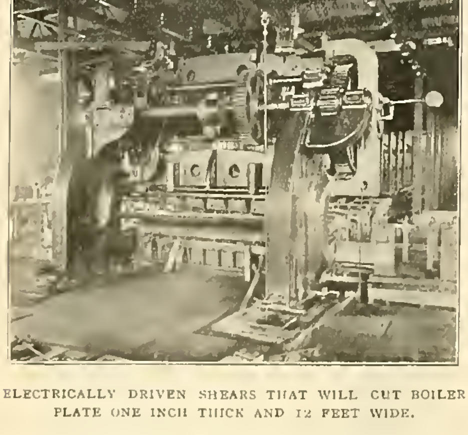
In 1907, 101,267 horsepower

The electrification of the street railway has been accomplished in the last twenty years. The vast network of urban and interurban lines in the populous states throughout the country owes its existence to the electric motor. The growth in this direction has perhaps been the most marvelous of all the progress made in connection with the use of the motor. Hundreds of thousands of horsepower is generated in central stations for use in this way, and it is possible to travel for hundreds of miles between large cities at comparatively low cost by comfortable and even luxurious trains, some of the roads going so far as to use sleepers.



A 15-HORSEPOWER MOTOR DRIVING FORMING PRESS IN SHEET-METAL WORKS.

Further progress has been made in this direction by the New York Central Railroad by installing large power stations in small towns adjacent to New York city by which power is furnished to the company's trains entering New York. This imposing undertaking is nearing completion; it involves the expenditure of millions of dollars. The great high-power electric locomotives used are a revelation to those examining them. The speed attained by these electrically operated trains is in excess of that of the fastest steam passenger trains.



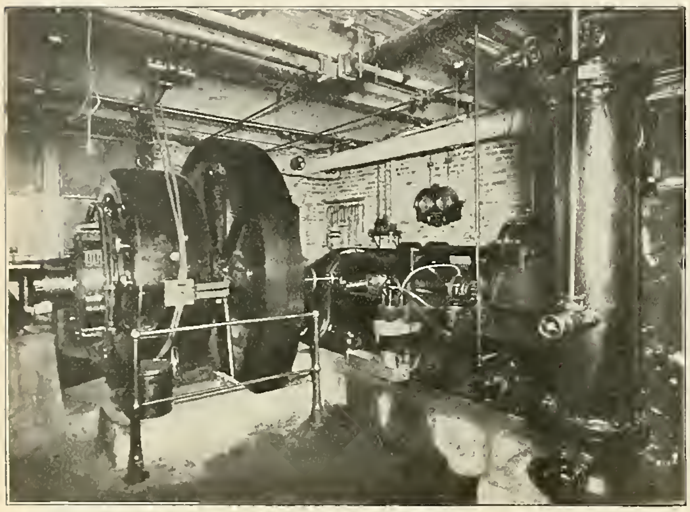
ELECTRICALLY DRIVEN SHEARS THAT WILL CUT BOILER PLATE ONE INCH THICK AND 12 FEET WIDE.

Such industries as mining, smelting, steel and iron mills, shipyards and textile mills owe their economical operation to the electric motor. A modern department store is dependent to a large extent on the use of the motor in connection with its many mechanical devices, such as the cash-carrier system, refrigerating system, package-carrying system, escalators, elevators, ventilating fans and numerous other machinery.

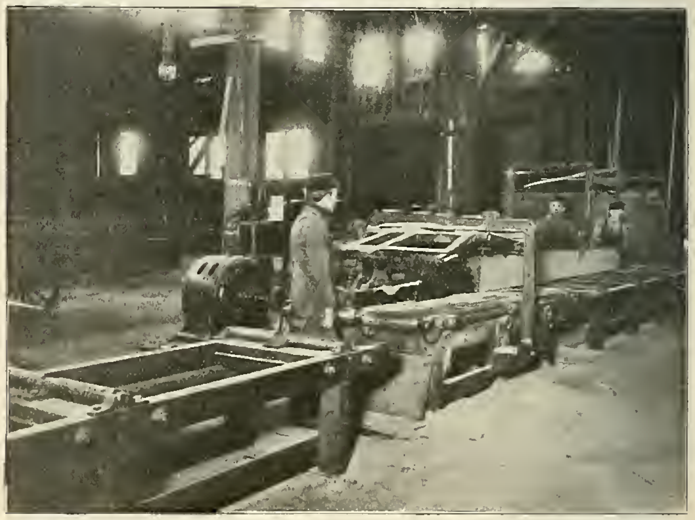
Pneumatic tubes, for carrying mail in large cities, have their air-compressing apparatus operated by electric motors. It would be difficult to operate such systems without their use, as, should electric power be not available, it would be necessary to erect steam-generating stations in various parts of the city where it is necessary to install the compressors for the correct operation of the system.

Clothing manufacturers are dependent to a large extent on electricity for the economical operation of their factories, and in the larger cities these manufacturers are obtaining, in the aggregate, a very large amount of power from the central station—very much larger than is generally appreciated.

In fact, large manufacturers of all descriptions have seen the great advantages in the motor, and there is now scarcely a large enterprise which is building new works of any description where the owners consider anything else for driving their machinery.



DIRECT-CONNECTED ELECTRIC MOTOR AND ICE MACHINE OF 137 HORSEPOWER (LARGEST IN CHICAGO).



This saw will rip a timber 12 inches square and 12 feet long in one minute.
48-INCH SAW DIRECT-CONNECTED TO 40-HORSEPOWER MOTOR.

The modern battleship could not operate without the use of the electric motor, and most of the large engineering works now in course of construction would be immeasurably slower in their progress without the motor. This piece of apparatus has not only been produced in very large numbers, but its efficiency has improved until it it is recognized as the most efficient machine for driving other machinery that is known.

The motor has not only been adapted to tools and machinery used by the different manufacturing interests, but it is made in diversified forms for use in hundreds of ways in every line of industrial and home life; in fact, is indispensable.

Electric power for the home has received great encouragement in the last few years by different inventors designing apparatus to be used for almost every service heretofore done by manual labor, such as washing, meat grinding, refrigeration, buffing and cleaning, the use of air compressors in connection with the removal of dust, to say nothing of elevators and many other domestic power applications.

The central station has been the large factor in the introduction of electricity for power purposes, and to the men who have been identified with these interests is due the credit for the largest share of this immense growth.

As these central stations increased in size toward the end of the '80's, the managers realized the necessity of developing a power load to fill up the valleys in their load curve.

For the first ten years the growth was very slow. The power was used only in the large cities by small consumers where modern methods and city environment had made the use of ventilators and other apparatus necessary.

Small manufacturers renting rooms needed small motors and were glad at any price to get the motor and central-station supply.

After getting that business, which of necessity took central-station service, it was the difficult task of the central-station manager to convince the small user of power to use this service. There were many difficulties in the way of this development. The motor in the early days was not the efficient and reliable machine it now is, and its price was very high. The price of electricity was also high. Furthermore, the cost of apparatus and operating costs were much in excess of what they are at present. As a general rule central-station mains were confined to a comparatively small area, and as manufacturing establishments in cities are usually located outside of the business center, the central station was unable to furnish service to these plants, due to the fact that it was impossible, on account of the low-tension dynamos in use, to install feeders of any great length. Furthermore, the size of generators was limited, and it was impossible to handle large power loads on this account. The central station was, therefore, forced by circumstances to increase its power load in small amounts in the business district, thereby building up gradually a network of mains of sufficient capacity to take care of larger demands.

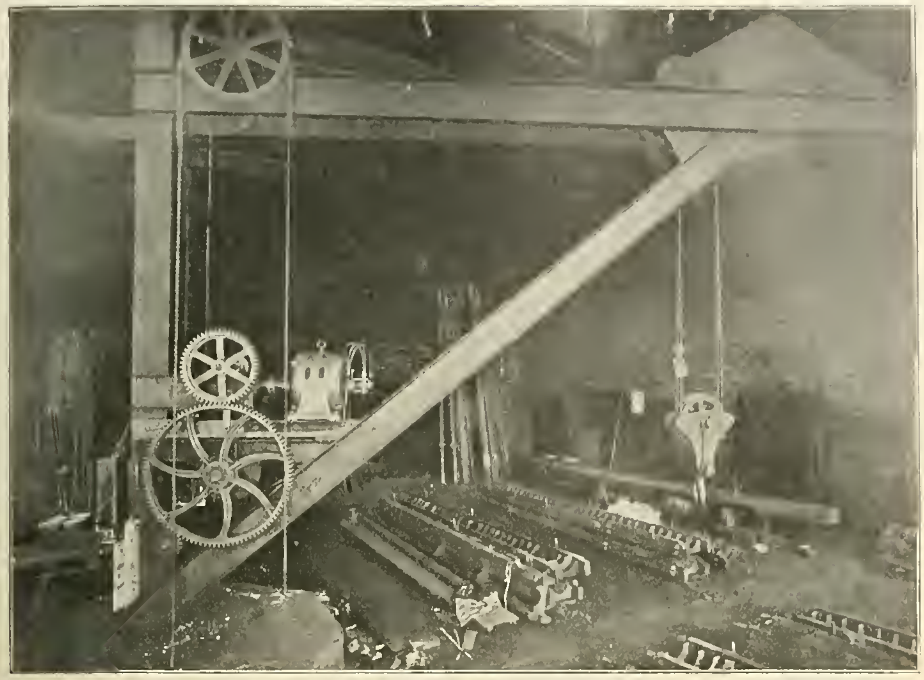
With the advent of the rotary-converter substation, and the perfection of alternating-current generating apparatus, it was possible to spread the network to the outlying districts, first for direct-current service, and within the last few years by polyphase alternating-current circuits serving customers having single-phase, two-phase and three-phase motors.

While the demand for direct-current motors on the low-tension mains has not ceased, and will not for years to come, it seems probable that the growth of the use of alternating-current motors will exceed the direct-current motor in a short time, due primarily to the fact that it is possible to distribute alternating current at high tension over wide areas, and again because the induction motor has been perfected to the point where it is available for almost every kind of service except where variable speed is required.

Even at the present time apparatus is being perfected for use in connection with alternating-current motors which permits of some variation in the speed of the motors. The traveling crane, equipped with alternating-current motors, is giving very satisfactory service. In fact, in some instances the manufacturers using them prefer them to the direct-current crane.

The single-phase alternating-current motor is used quite satisfactorily in small sizes in connection with machinery requiring variable-speed operation, and there are a large number of these motors in use. More recently it has been found possible to start and stop automatically alternating-current motors, driving air compressors and other tools required to be automatically started and stopped.

Another development which has been assisted by the electric motor is the freight and passenger elevator. The direct-current motor has been in use in connection with this service for about twenty years. The growth was extremely slow at first, but has now reached the point where the motor for this class of service is a serious competitor with the well-known hydraulic machines, which have, up to within a short time, been generally used in very large office buildings.



A JIB CRANE DRIVEN BY A 10-HORSEPOWER ALTERNATING-CURRENT MOTOR THAT HANDLES 12 TONS WITH EASE.

The adapting of the motor to this service has been a great aid to the central-station companies, as it is now possible to equip all of the different apparatus in a building with motors, whereas previous to the time when the elevator motor was satisfactory, a great many people preferred to use steam and hydraulic power for all purposes in preference to having a mixed installation of part steam and part electric.

Within the last few years the single and polyphase motors have been designed for use on electric elevators with considerable success. At first such installations were made where it was impossible to get direct current, and where steam was not available at a low price. The development in this class of elevator has been improving rapidly of late, and the promises of manufacturers are that within a short time the alternating-current motor will be in use in connection with elevators, giving satisfactory results both as to continuity of operation and cost.

At the present time, with the large network of both direct-current and alternating current lines in the larger cities and even in the country and smaller towns, it is possible to purchase electric power in almost any quantity from central-station companies.

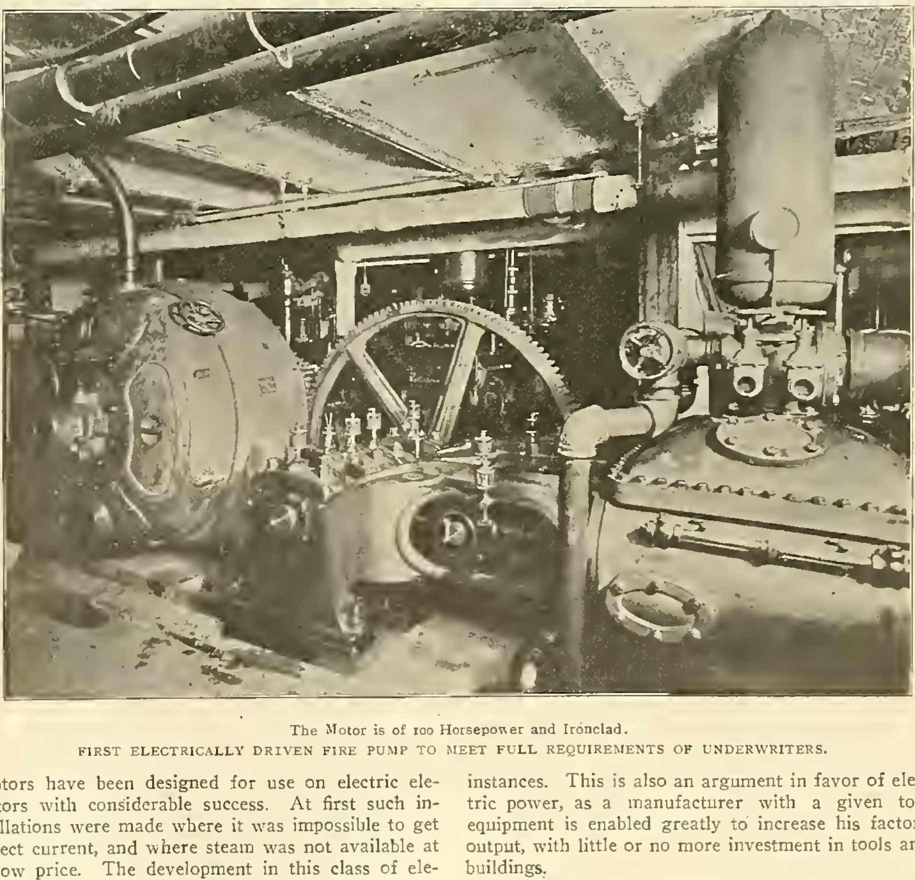
The growth of the use of central-station service has been phenomenal, and while the amount of electric power installed during the last five years has increased to a wonderful extent over previous periods, it seems reasonable to suppose that the increase will be greater in the future, as the cost of production of electricity is reduced, due to improvements in all branches of the service, from the boilers to the distributing system.

From the viewpoint of the manufacturer using a large amount of power the electric motor is the logical motor for his purpose. It allows him to locate his factory wherever he desires. He can lay out his machinery to suit his conditions, without regard to the location of line shafting. Power can be applied directly to any tool in existence in a most economical manner. The output of machinery equipped with motor drive is considerably more than the old fashioned methods, and no one will dispute the sanitary conditions of a shop so equipped.

When motors were first used for industrial purposes very little had been accomplished in the methods of regulating the speed. Motors were principally used to drive line shaft, and machines were driven from these shafts. The possibilities of making motors of any speed, and having a wide range of speed, became familiar to manufacturers, with the result that the manufacturing of the motor received great impetus, and perhaps this improvement in the motor is one of the main reasons wny manufacturers use it to such a large extent.

One of the principal reasons for making motor installations, either individual drive or well-designed group drive, was because such installations materially reduce the power required for a given output in a given factory. The reduction in friction load, due to properly designed installations, is one of the most important points in connection with the use of such apparatus. Thousands of horsepower are being saved every year in factories for a given output where proper motor installations are being made. This in itself is a strong argument in favor of their use.

Where it is possible to equip tools with individual motors it has been found that the increase in the output of such machines has been doubled in many instances. This is also an argument in favor of electric power, as a manufacturer with a given tool equipment is enabled greatly to increase his factory output, with little or no more investment in tools and buildings.



The Motor is of 100 Horsepower and Ironclad.
FIRST ELECTRICALLY DRIVEN FIRE PUMP TO MEET FULL REQUIREMENTS OF UNDERWRITERS.

In addition to this, the cost of labor for a given amount of work is materially reduced, notwithstanding the fact that it has been possible to increase the wages of the men operating motor-driven tools by offering them a premium for the extra output.

While it may seem from all that has been accomplished that a large share of the industrial machinery used throughout the country is driven electrically, as a matter of fact I believe it is safe to say that less than ten per cent. of the power required by the industries of the country is electrically applied.

There are constantly developing uses for electricity that were not known years ago, and it is safe to say that this progress will continue and that within the life of the younger generation the use of electric power will become almost universal.

The electrical distribution system seems to be the logical method by which to deliver power, as this system has many advantages over any other form of power known up to the present time. It is clean, sanitary, flexible, safe and economical, and should be a great factor in the problem of eliminating smoke in large cities. Central stations can be located in the less desirable parts of these cities and the power distributed over the vast network of mains to wherever desired.

The future of the electric motor seems well established, and we have every reason to believe that the growth will be at a great percentage of increase from year to year. In another twenty years we will no doubt look back in the same manner as we are at present, with the idea in mind that in 1907 the amount of electric power used was very small indeed, and that the adaptation of this piece of apparatus to different machines requiring power for their operation was in a very crude state.

Twenty Years of Telephone Development.

By Samuel G. McMeen.

One way of appreciating what progress has been made in commercial telephony in twenty years is to get before us a general picture of the conditions which existed twenty years ago.

No foreign country has made the advance which has been made in the United States, and it may be well to confine our thought to our own country for the present.

S. G. M'MEEN.

Twenty years ago there were distinctly fewer than 200,000 telephones in use in the United States. No city of under 10,000 inhabitants supported a telephone exchange at all adequate for its needs, and most such cities either had supported an exchange which had declined or had none at all.

Practically all towns having postoffices had at least a toll station, but the limit of "long-distance" conversation was about fifty miles, and the service rather unsatisfactory even at that distance.

Rural lines furnishing service to the suburbs of towns and cities did not exist at all.

The wire plant within and between towns was almost wholly made up of iron or steel wire carried on cross-arms and brackets, and those lines entered the exchanges in most cases by way of house-top fixtures.

These fixtures in the larger exchanges were enormous structures, often occupying the entire roof of the central-office building. The number of buildings owned by operating companies was insignificantly small.

The only general use of cables was in carrying the lines from the roof fixtures to the switching apparatus. These cables joined the outdoor iron wires in a "tower" on the roof, and the point of connection between cables and outside wires was made to serve the purpose of a main distributing frame.

The outside lines and the office cables were all of a single wire per line, as all telephone currents used the earth as a return.

Protective mechanism was limited to a sawtooth open-space lightning arrester or its equivalent; such arresters occasionally stopped lightning charges of moderate strength.

Sub-station equipment was more nearly in a standardized condition than today. It is true that the standard was bad and that each set had defects rather clearly recognized at the time, but if there be an advantage in uniformity, it existed at that time. The telephone receiver was of the single-pole type and was associated with a Blake transmitter. The latter utilized a solid carbon button with a polished face, bearing against a rounded platinum stud. A black-walnut box, with a hole in the door for a mouthpiece, contained the transmitter and the induction coil.

The central office was called by a magneto generator, and signals were received, as now, on a polarized ringer, the resistance of which was uniformly about 80 ohms. When a number of stations occupied one line, all the ringers were connected in series. The switch contacts of the magneto-bell outfit were innocent of platinum at any point.

The current for the transmitter was furnished by a single cell of Le Clanche battery.

The amount of maintenance labor to be spent on such lines and such sub-station equipment need not be called to the mind of the older telephonists, as most of them would rather forget than remember. It may be appreciated in a degree by those who have entered telephony in a more fortunate time, when it is said that the life of galvanized-iron wire varied from three to seven years, and that the number of opens, crosses and grounds on a rainy day often reached 20 per cent. of the total number of lines in an exchange admitted to be fairly well managed. To this had to be added the attention necessary to keep local batteries renewed, transmitter buttons cleaned and polished, transmitter tensions adjusted, and switch-hook contacts cleaned. If the latter were not done, and well done, the subscriber would be entertained by a continuous sizzling, frying noise, often great enough to prevent commercial conversation.

Of the central-office equipment, it may be said that it was robust enough to give as little trouble as any equipment that has been devised since. The multiple switchboard with an audible busy test was well established, and all of the larger cities were so equipped.

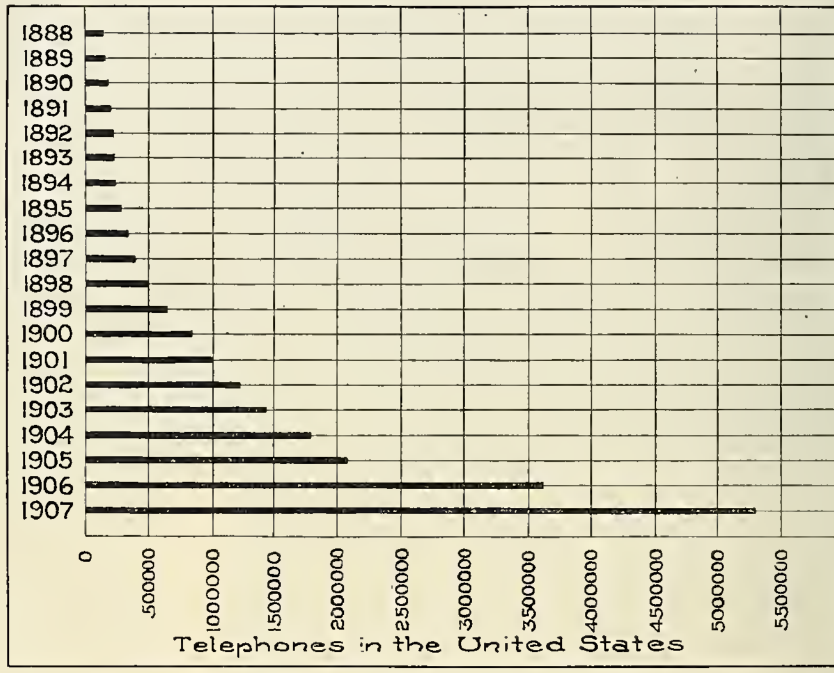
Compared with the simpler transfer switchboard, however, the multiple outfit was costly; and, in addition, a royalty had to be paid on the multiple feature itself. It resulted naturally that there were many fewer multiple boards in the country than good service really was demanding.

The multiple switchboards were varied in type, some having operators' equipments consisting of pairs of cords with listening and ringing keys and others having a single plug and cord per line, each line having its own listening and ringing outfit associated with the cord. These single-cord boards had many advantages assisting speed of operation, and records have been made on them which compare more favorably with what can be done today than would now be imagined. This speed was due, however, not to a convenient and positive system of signals to indicate the state and progress of the call and connection, but to a mechanical arrangement of the keys and cord circuits, which reduced the motion required to make the connection and the disconnection.

The nearest present-day counterpart of a single-cord switchboard is a manual incoming trunk section. If one of the early single-cord boards could have been equipped with automatic signals, such as now are possible, there is no doubt that its performance would have been still more remarkable. But the single-cord type of subscribers' switchboard ceased to be made when metallic circuits succeeded the single-wire line.

In the foregoing I have tried to picture the general aspect of conditions twenty years ago. It is true that metallic circuits were not wholly unknown. The granular carbon (Hunnings type) of transmitter was in sight. It was recognized that platinum contacts must be introduced for hook switches, and that it would be well to improve or abandon the primary local battery. A few traction systems had appeared and the first steps toward curing the difficulties so introduced were being taken.

What has happened since then in the commercial development of the art can well be shown graphically, and I have prepared a diagram stating what probably are the facts as to the number of telephones in the United States year by year. It shows



that the number twenty years ago was smaller for the United States than for Manhattan Island today. It shows the leisurely growth for the first eight years and the remarkabale acceleration since, and it may be that it indicates what we may expect in the future.

If similar diagrams were to be drawn for the growth of long-distance conversations, they would show that the limit of fair commercial transmission has been increased over 2,000 per cent.; that the rate of growth in interurban-wire mileage is as remarkable as the growth of telephones in use, and that the conversation-miles per inhabitant per annum have increased at a rate beyond either.

The causes which have stimulated growth in telephone development since 1895 are more than the expiration of the basic patents and the appearance of competition. Probably this competition has been the most powerful cause, but there are mechanical reasons as well. Principal among these are the rearrangement of things which has reduced the complication of the subscriber's telephone and increased that of the central-office equipment; the changes in methods of line construction, the introduction of automatic switching equipments, and of manual switchboards with automatic signals on line and cord circuits.

I have spoken of the early multiple boards as being robust when of the type first introduced. Somewhat less than twenty years ago, however, as the number of subscribers' jacks required to be placed within a section within the operator's reach began to become very large and the spring pressure per jack to grow small, the presence of series contacts in such jacks introduced a new and serious trouble. A good many ways of reducing or avoiding this trouble were tried, but the solution most successful was the entire elimination of all contacts required to close the line through the jack on the withdrawal of the plug. A rearrangement of circuits was necessary, resulting in the "bridging" or "branch terminal" switchboard, with automatically self-restoring and locking drops.

Many such switchboards were installed, most of them being equipped with the additional refinement of an intermediate distributing board, enabling the

A. S. Hibbard. Henry C. Paine (deceased). John I. Sabin (deceased). H. B. Stone (deceased).

FOUR MANAGERS OF LARGE TELEPHONE PROPERTIES.

traffic of the office to be readjusted from time to time so as to even up the work of the various positions.

In an effort to avoid the large cost and royalty expense of multiple switchboards, there was produced on the Pacific Coast, at about the time of the advent of the bridging multiple board, a local trunking or transfer switchboard, equipped with automatic signals. Its performance aroused sufficient interest to cause its operation to be studied in detail, with the discovery that the important advantage lay not so much in the use of local trunks, or transfer circuits, between parts of the switchboard (as a substitute for a multiple of the lines) as in its use of automatic signals. It was then but a simple step of logic to the conclusion that if automatic signals were to be applied to the multiple switchboard a maximum of advantage would be gained.

At that point the present type of common-battery multiple equipment came into existence, and what has been done since upon it, while of great value, has not been revolutionary in any way.

The conditions required for the operation of automatic line and supervisory signals fitted in so well with the requirements for supplying the subscriber's transmitter with current from the central office that common-battery transmission came into being almost as a matter of course.

The earliest commercial installations of automatic switching equipments were made before the expiration of the basic telephone patents, and the early development of the automatic art was about contemporaneous with that of the branch-terminal magneto board. Viewed in the light of total accomplishment, the development of automatic switching equipment is quite as remarkable as any other phase of the art; and more so in view of the strong prejudices which had to be overcome, the continuous discouragements which were met, and probably the difficulty of prosecuting the development with so little support from the telephone-consuming public.

It is interesting to note that while in manual telephony the present grade of central-office service only has been reached by abandoning the local trunking system and adopting the multiple system, in automatic telephony the opposite is true.

The earlier automatic equipments were all of the multiple type, and the large automatic equipments of to-day only are possible because the multiple feature has been discarded and the complete local trunking arrangement adopted in its stead.

With an equal possibility of a high quality of voice transmission; with the marked advantage of instantaneous disconnection; with the ability to handle the largest groups of subscribers' lines and to care for private-branch-exchange service, an automatic system is to be considered one of the great certainties of future telephone equipment.

The principal changes in sub-station equipment in twenty years have been the provision of platinum contacts; the change of ringers from a low-resistance series type to the high impedance bridging type, and the provision of a granular carbon transmitter free from the tendency to pack and with a great range of resistance-change when spoken into. The adoption of the bipolar type of receiver also has improved the equipment in a small degree.

Just as metallic circuits were a rarity twenty years ago, so grounded circuits are the rarity today. The reasons for this radical change, practically doubling the wire plant for a given number of lines, were three.

One of them was the arrival of electric traction, whose return currents made telephone lines extremely noisy and caused unbearable false signals; another was the limit placed on long-distance speech by the noises in grounded lines from earth currents and atmospheric charges; the third was the cross-talk between neighboring lines when carried as grounded circuits in cables of more than a few hundred feet length.

This rather complicated group of reasons is a fairly good instance of the causes of change in all branches of telephony.

The McCluer system of common wire returns as a substitute for ground returns helped out the electric-traction difficulty very usefully, but was of no advantage in solving the other two problems. The enormous masses of open wires in the streets were causing the operating companies to wish, and the municipalities to demand, some other method of distributing telephone lines. After a short time of denying it to be possible, the inevitable underground system appeared, and there are more telephone wires in the earth today than there were above it a dozen years ago.

But even with a pair of wires shut up in a cable within a lead sheath in a duct in the ground, with all external disturbances excluded, the line problem was not solved. Indeed, a new difficulty had been introduced. This was the substantial increase in the electrostatic capacity of the two wires forming the line, and with the clearly articulating but low power Blake transmitter the short circuiting effect of this capacity amounted to a very hurtful loss. A solution of this new problem came in the paper-insulated, highly aerated telephone cable of present practice. A still further and most admirable solution was contributed by Dr. Pupin, which inserts an inductance in series with each wire of a pair to neutralize the effect of the capacity across it.

The effect of such a series of inductances upon the electrical voice waves is so similar to the effect of a molar loading of a light string upon "string-waves" that the treatment of a telephone line by Pupin inductances has come to be called "loading."

Lines in a given cable can be worked for greater lengths at a given loss when loaded, and the result is a new series of economy factors in laying out the many central offices of a city, and the adoption of underground instead of aerial long-distance trunks between cities many miles apart. As a matter of comparison it may be noted that it is possible to talk farther through an underground cable of small copper wires today than one could talk over an open aerial circuit twenty years ago. It is not apparent why all interurban trunks ultimately may not be placed in the earth.

The advantage of an entire underground system of loaded trunks between cities is not merely a reduction of interruptions and the elimination of pole decay. The principal gain is in the nearly uniform hurtful capacity effect to be cured and the almost absolute certainty of uniform transmission.

Inspired by the success of repeaters in long telegraph trunks, a telephone repeater for a similar assistance has been dreamed of. One inventor seems to have remembered the dream after waking, as the commercial success of the Shreeve repeater has at least shown that a repeater is not impossible. Whether the perfected repeater will co-operate with line loading on long circuits, supplant it, or render it unnecessary, furnishes an interesting field for speculation.

The operation of telegraph and telephone service over the same wires at the same time, in successful operation for many years past, has had the effect of reducing the financial burden which long-distance telephone circuits otherwise would need to carry. It is now possible, under favorable conditions, to work each side of a long-distance pair quadruplex and the pair itself for speech.

No record of the principal features of the development in telephony should omit to note the opportunity of a switching system combining the best features of manual and automatic equipments; the very valuable investigations in electrical acoustics made possible by the use of the oscillograph, and the recent advance in radiotelephony through the use of energy in the form of Hertzian waves.

I have confined my attention so far to conditions in the United States. Growth in other countries has been less rapid than here, and in the main the methods and appliances less well developed. For some years, however, Sweden led the world in density of development of the larger cities. This

MEN CONNECTED WITH THE INDEPENDENT TELEPHONE MOVEMENT.

is not now true, as there are a number of American cities with a ratio of telephones to population greater than in any Swedish city.

The literature of telephony is an excellent index of the progress which the art has made in twenty years. The telephone man's library of long ago consisted of a single volume, written by the dean of telephone engineering, Mr. Thomas D. Lockwood. Today a library of telephony occupies several shelves, and one may receive half a dozen periodicals exclusively devoted to the art.

Electrical Engineering Education.

By Henry S. Carhart,
Professor of Physics, University of Michigan.

The history of electrical engineering for the last twenty years reads like a tale from the Arabian Nights. The faculty of the imagination is a useful one in scientific research. It refuses to be confined within the boundaries of the known and searches the future. But no imagination was vivid enough twenty years ago to foresee what would happen in applied electricity by this year of grace, 1907. If, when the Western Electrician was launched, an engineer, intoxicated with his subject, should have predicted that by 1907 electric generators approaching 10,000 horsepower in capacity would be under construction, he would have been heard with a compassionate smile and regarded as a fit subject for a retreat.

HENRY S. CARHART.

Instruction designed to prepare engineers for this giant work has of necessity kept abreast of practice. In fact no insignificant factor in the rapid advances of applied electricity has been the presence of men in the profession who have been trained in the schools. If practice has stimulated advances in electrical education, education has reacted strongly on practice. Hence the present situation that the leading men today among electrical engineers and in the great manufactories devoted to electrical appliances are college trained men. It was not so twenty years ago, and the first graduates in electrical engineering had to break into manufacturing *vi et armis*. High finance and the captains of industry owe a great debt to engineering schools because of the young men who have gone from them in shoals headed for the workshop and the ranks of consulting engineers.

The course in electrical engineering inaugurated scarcely a quarter-century ago by Professor Anthony at Cornell marked an epoch in engineering education. It was introduced in connection with physics, and this practice has been followed in many universities since. The Institute of Technology in Boston repeated Cornell's experiment, and both have been eminently successful.

The course in electrical engineering in the University of Michigan was approved by the Regents in June, 1889. At that time engineering students were included in the Department of Literature, Science and the Arts, and the electrical course was under the wing of physics. It maintained this relation to physics until four years ago. The first graduating class numbered only two men; the last one, 33. The University Calendar for 1890-91 contains in this course the names of F. E. Barnum, G. A. Damon, A. C. Marshall, G. H. Rowe and F. A. Sager, all of whom are now well known in their chosen field. The Calendar for the following year adds to this list such names as C. G. Atkins, M. S. Connor, S. P. Grace, A. M. Haubrich, H. R. King, Walter Robbins, Fay Woodmansee, and the lamented H. W. Wyckoff. At that same period there was in the department as a graduate student and assistant Mr. Louis C. Hill, now superintending engineer of the United States Reclamation Service and third in rank in that branch of the government's activity. It is no small satisfaction to look back fifteen years and then to consider what these men are now.

The University of Michigan was not the first state university to introduce a course of study in electrical engineering. Such a course was established in the University of Kansas by an act of the Legislature in 1887 as a branch of mechanical engineering. In the University of Wisconsin the course was inaugurated as a separate engineering course in 1891 upon the appointment of Professor Jackson. In the University of Nebraska an elective course in applied electricity was authorized in 1890-91. According to the catalogue this course contained at first only five hours of applied electricity in the senior year, but in three or four years it had already become one of the important courses of the university.

Other institutions of learning east and west have added a course in electrical engineering, one after another, until now no engineering school is at all satisfied without it. Even the Rensselaer Polytechnic School, for so many years devoted to civil engineering and the scene of Rowland's first great work in magnetism, has at last succumbed and joined the rest in electrical education.

At the present time the number of students enrolled in electrical engineering is nearly as large as in either civil or mechanical engineering. The curriculum has been enriched from year to year as the subject has enlarged, until the difficulty now is to find room for all the courses within the conventional four-year period.

SOME ELECTRICAL ENGINEERS, EDUCATORS AND DESIGNERS IDENTIFIED WITH THE WEST.

The question has often been debated as to what portion of the entire course should be devoted to practical work in the laboratory and in visiting works. It is not uncommon to hear students express some complaint that too little time is given to so-called practical work. On the other hand, the other extreme has at times been touched in attempting to make the course little more than workshop practice, with some lectures on prevailing applications thrown in for good measure.

The writer has taken pains to learn the views of many graduates after two or three years' experience in practical work. The universal testimony is that engineering courses should be devoted largely to fundamental subjects and to theory, and that more practical experience can be gained in the factory in six months after graduation than it is possible to get in a four years' college course.

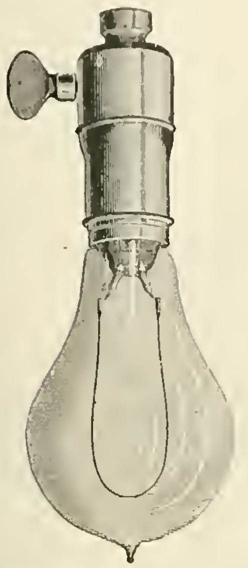
The laboratory is an essential part of engineering training, but it should be subordinate to the main purpose—that of training the mind and the acquisition of those fundamental principles of science and engineering, without which a man is only an artisan and not an engineer. A generous amount of laboratory work is essential to a thorough comprehension of the principles involved in the applications of electricity and to give the graduate some confidence in his knowledge of the manner in which these principles work out in practice. Beyond that he would better repair to the factory and get enlarged experience there, for no schooling can possibly take the place of experience, just as no workshop can be a substitute for the college lecture room and the personal contact between the enthusiastic teacher and the ambitious student.

The laboratory presents a concrete exposition of the principles taught in the lecture room. It is an auxiliary to didactic instruction and the study of text-books. It supports imparted information by an appeal to things one can see and handle for one's self. It puts the young graduate in a condition "to light on his feet" when he enters the big factory and is assigned to duty. Without it his attainments would be unavailable until he had learned to connect his unfruitful knowledge of principles, embodied too frequently in mere language, with their material embodiments in iron, steel and copper. But no amount of laboratory work alone, in the absence of substantial attainments in principles, mathematical theory and general insight, can equip a young man for the work of a successful modern electrical engineer.

After all, in the final analysis, something more must be added to educational attainments to make a successful engineer. Engineers, like poets, are born, not made. To education must be added character; to character, tact in dealing with men; to tact, originality in conception of design; and to originality, a calm judgment that reaches the wisest solution of an engineering problem under given conditions.

It is not inappropriate to refer to one good service which the electrical course has done for engineering in America. I refer to the support it gives to the adoption of the metric system of weights and measures. Electrical engineering and design are strictly scientific, and fundamentally they use the language and ideas of the centimeter-gram-second system. The results are often translated into the English system of measurement, but always as a departure more or less grave from the fundamental concepts. Practically the capacity of all generators is now expressed in kilowatts, and electric motors are commonly rated in terms of the same unit. It would be a great gain if kilowatts could replace horsepowers universally.

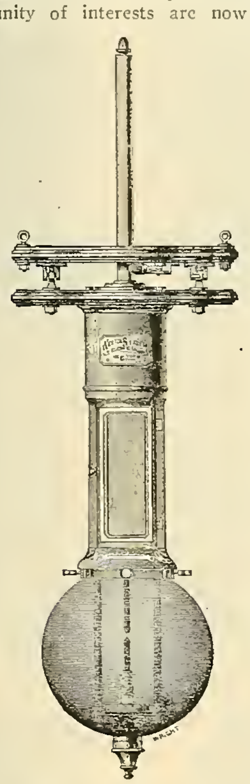
We already have a universal system of electrical units and standards, the details of which will undoubtedly be settled within a year or two on a basis of universal acceptance by all the civilized nations of the world. This universal system furnishes a splendid object lesson for engineering, and calls for a similar universal use of an identical system of weights and measures. Most unaccountable prejudice still stands in the way, even in England and America, which pride themselves on being foremost. No obstacle is harder to overcome than a system, however absurd or illogical, which has become entrenched by long usage, and which has little more to commend it than mere familiarity. But there are some happy signs of relief. Education is slowly introducing the effective leaven. The widest use of the metric system is furnished by the Universal Postal Union, in which the agreement respecting the weights of letters and packages adopted by all the



AN INCANDESCENT LAMP OF TWENTY YEARS AGO.

participating governments is expressed in terms of the metric system. If we translate the agreement into ounces, we do so as a rough-and-ready compliance. The postal convention adopted by the nations of the earth uses only the metric system.

What large question in engineering education is pressing for solution in the near future? It is this: Shall we continue to segregate civils from mechanicals, mechanicals from electricals, etc., or shall we consolidate and extend the course to five years instead of the conventional four? The latter has little more to commend it as a period of educational gestation than that it is divisible by two. Consolidation and community of interests are now the watch-



AN ARC LAMP OF TWENTY YEARS AGO.

words. It is time to undertake the education of engineers without any limiting adjective. The term civil engineering was adopted years ago as the antithesis of military engineering. But the word civil as applied to engineering has lost its early significance. All engineering is essentially civil in type.

The present practice is to separate engineering students into groups with some differentiation of subjects, but distinguished more by the accentuation placed on the same subjects in different groups than by anything else. It would not be a task beyond accomplishment to lay down a universal course in engineering with sufficient degrees of freedom to permit choice of a few subjects for special stress and intensive study. Then we should no longer have the familiar spectacle of an engineer, who has been educated in one group, practicing in another for which he has made no special preparation.

Electric Welding Progress.

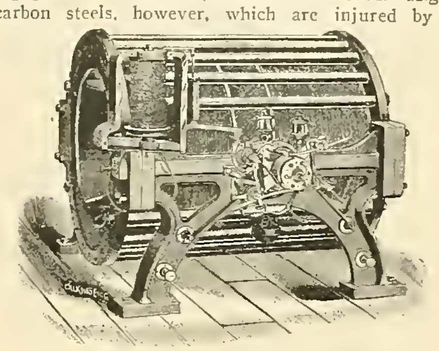
By Elihu Thomson,

Electrician, General Electric Company

IRON has been welded in the forge fire for so long a time that the memory of the first beginnings is lost. In fact, the early production of iron masses depended upon the union by welding of the plastic particles reduced from the ore in the primitive furnaces, which long antedated the blast furnace for iron smelting, now producing in enormous quantities the more fusible cast-iron containing carbon in considerable amount. About twenty years ago the electric-welding art had its origin, and during the period since then it has become an important adjunct to many manufactures, and has, in numerous instances, provided new means of accomplishing results and given rise to new manufactured products.

ELIHU THOMSON.

The fact that by electricity not only iron, but practically all of the metals, may be united piece to piece, and often one metal to another metal, indicates the manageability of the process itself. Many metals which contract a film of oxide in the air demand a flux such as borax to dissolve this film in order that clean metal surfaces may be brought together in a weld. Where, as in the case of iron, the oxide itself melts below the melting point of the metal, no flux is needed. High-carbon steels, however, which are injured by a



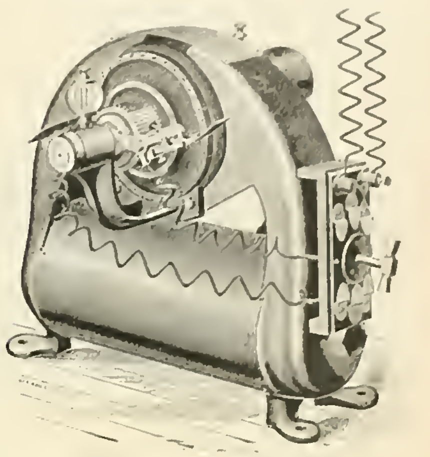
FAMILIAR SQUIRREL-CAGE TYPE DYNAMO OF TWENTY YEARS AGO.

temperature which would melt the oxide or scale, require careful treatment in electric welding, as well as in forge-fire work, and in each case an easily fusible flux allows the work to be done at a comparatively low and safe temperature.

Gradually, the heating effect of the electric current is being made use of more and more extensively to do the work of the forge fire in welding, and the welding transformer is the modern substitute for the forge fire.

Work which was either impracticable with the forge fire or which demanded very high manipulative skill is often accomplished with great facility by electric methods. Each year witnesses the extension of these methods into new fields. It is important to distinguish between arc fusing, wherein the high temperature of an electric arc is used actually to render liquid refractory metals, and cause union with solid masses, as in filling holes in castings, melting edges of plates together, and the like, and the Thomson process, in which the pieces to be united are pressed together by being held in massive conducting clamps or holders and a very heavy current at low voltage is passed across or through the proposed joint, thereby causing heating, softening and union. The important standing which this method of work has won is due to the rapidity, flexibility, cleanliness, neatness, accuracy and economy of the electric process over the older modes. The advantages are such that a continued extension in the application of electric welding is assured. The work of the electric welder is characterized by uniformity, and it is therefore best adapted to repetition work on the large scale. The operation of welding is controlled with exactness, and the localization of the heating to the particular parts being brought into union is often important. The electric welder can be used to unite copper, brass, bronzes, and even fusible metal like lead, and may readily be adapted to brazing or hard soldering.

It is not necessary here to describe the construction of an electric welder or welding transformer. Neither will any attempt be made to enumerate the many applications of electric welding in the arts. It may be, however, interesting to note the character of the work which is now being done



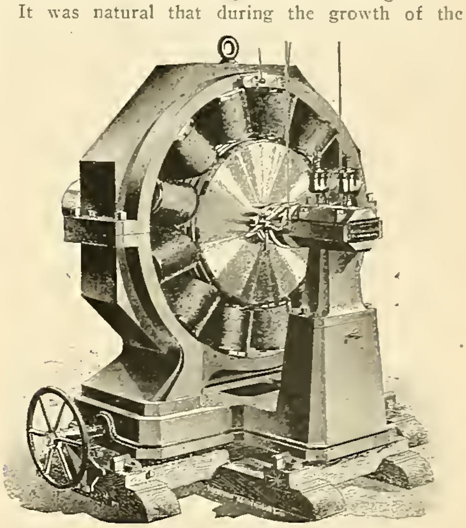
Reproduced from the Western Electrician of August 6, 1887.

AN EARLY TYPE OF ELECTRIC MOTOR.

extensively by the electric-welding process and the direction in which development has been more recently taking place.

Among the earliest applications of electric welding was the production of wheel tires of all sections, also hub bands and vehicle axles, fifth wheels, and more recently shifting rails, steps, shaft irons, etc. Since the advent of the rubber tire the process has been extensively employed for joining the ends of the steel wires running through the tire, for securing them in place in the channel rim, and also for uniting the ends of the channel metal itself. The application to carriage work has been indeed quite extensive, and most of the dash frames used in carriage construction are now made by electric welding, while in agricultural machines the iron and steel wheels are frequently built up or have their parts united by electric welding.

It was natural that during the growth of the



Reproduced from the Western Electrician of February 18, 1888.

SLATTERY'S ALTERNATING-CURRENT DYNAMO.

bicycle industry a great many parts of these useful machines should be united by electric welding and that the welding transformer should be applied for locally heating the parts in electric brazing or hard soldering, as well as for upsetting, bending or shaping. As products in which electric welding had its part may be noted bicycle crank hangers, pedals, seat-posts and fork ends, frames and brake parts, and the like.

More recently, since the automobile has come into existence, electric welding has entered into the construction of wheel rims for pneumatic tires, crank-shafts, cam-shafts and other parts.

One of its early applications which has gradually grown has been in tool manufacture, as in the production of drills, reamers, taps, band saws and circular saws, drawing knives, carpenters' squares, printers' chases, etc., and sometimes for the production of special machine parts. Teeth are inserted into gear wheels and saw bodies are provided with teeth welded on, while special stone saws have been for a long time built up by electric welding. As instances of machine parts may be mentioned inking rolls used in printing machines and fallers for looms, which are now constructed with the aid of the welding transformer.

Similarly, in the wire industry, the value of electric welding has shown itself, and the progress in such work goes on steadily. Beginning with the simple action of producing long lengths of iron, steel and copper wire from shorter pieces, there came the welding of wire or strips into hoops for barrels, tubs, pails and similar vessels, and numerous machines are now in operation resembling electric looms for turning out electrically welded wire fence in continuous rolls. In this case the wire used is usually zinc-covered or galvanized, and the machine is made entirely automatic, placing the wire in position, welding and cutting off the various pieces, while such machines are frequently adjustable to vary the size of mesh in the wire netting which constitutes the product.

Perhaps in few instances of welding has the electric welder shown its special adaptability more strikingly than in the welding of pipe lengths for the production of long lengths of piping from shorter pieces. Such long lengths are frequently wound up into coils and are, therefore, without couplings or screw joints. More recently, machinery has been constructed to weld continuous lengths of pipe to be laid in the ground, where, of course, it is desirable to secure absolutely non-leaking joints, as the joints are hidden out of sight. To this purpose the electric welder lends itself admirably.

Those interested in the development of street railways are, of course, familiar with the fact that hundreds of miles of street-railway rails have been electrically welded into continuous lengths and that long lines of these rails now exist in many cities. In this case the machinery is carried upon car trucks along the line of the rails and the welder suspended at the end of one of the trucks for applying the splicing bars and welding them to the rail ends. In general, the energy is taken from the trolley line by a series of transformations whereby the current is at last reduced in potential to the welding voltage of two or three volts and increased in current volume enormously for heating large sections. This constitutes some of the heaviest work done by electric welding, and on a similar scale with it is the local annealing of armor plates on warships. On the other hand, the delicacy of the operation can be made such that fine wires of one-fiftieth of an inch in diameter may be welded, and such small work as buckles, typewriter bars and umbrella rods is easily dealt with.

Oftentimes electric-welding processes prepare the material for subsequent working, as in the case of the welding of strips into plain bands or cylindrical rings which are afterward rolled into any section desired. A good example of this is the production of automobile-wheel rims, bands for roving cans, stove rings, etc. In a similar manner, yet for a different result, crank-shafts are built up from drop forgings, and the rough shaft so produced requires only light machining and finishing to its correct size.

Somewhat akin to pipe welding, but a somewhat more recent development, is its application to the forming of metal vessels for withstanding high pressures, such as soda-water cylinders, carbonic-acid reservoirs, and steel bottles for nitrous-oxide gas. In this case the cylindrical part of the vessel has the heads welded on, very much as two sections of pipe are welded end to end.

It is a feature of welding application that very frequently the fact of the article having undergone the welding process does not show in the finished article. A good example of this is in its use in the production of table cutlery, such as knives and forks. In such case the handles are formed hollow, of sheet steel, by a kind of drawing process, and welded to the knife or fork portion, after which the articles are finished by grinding, silver-plating and polishing, as usual. The neatness and quickness of the work which can be accomplished by special machines developed for this purpose are worthy of note.

In the development of electric-welding machinery there may be said to be several types. We have, for example, a machine designed to do a variety of work in which, perhaps, the sizes and the forms of the pieces are quite different. In such case the adjustments are usually entirely manual, the pieces being clamped by hand, the electric current being applied by the operator manipulating a switch, while the mechanical pressure is obtained either by a lever or by hydraulic means under the operator's control. In other types of machine, as in the welding of copper, iron or aluminum wire, the machine may be largely automatic. The pieces, it is true, may be placed in position in the machine manually, but the pressure for welding is automatically applied, and an automatic switch cuts off the current when the work is completed.

In still other cases, especially for work upon identical pieces or rapid repetition of the same operation, the entire sequence of actions is definitely determined in advance by the construction. In other words, the machine becomes practically entirely automatic. Such a machine may be driven by a belt or electric motor, and, by means of gears, cams and the like, the clamping of the pieces is accomplished, the current and pressure application following, and, further, the switching off of the current and release of the pieces takes place finally. A machine of this kind may, of course, be fed by manual operation, or, if the pieces allow it, they pass into the machine in sequence without the attention of the operator.

The electric-welding looms which are used in the making of wire fencing, as also chain-welding machines, which produce continuously long lengths of electrically welded chain, are indeed so completely automatic that the operation goes on uninterruptedly so long as the material holds out. This will be in the case in the fence machine alluded to when the reels from which the wire is fed are emptied. In such machines a number of joints are made simultaneously, and the welding is practically instantaneous, the division of energy supplied to the various joints being substantially perfect.

One of the most interesting developments in electric welding has been its application to the production of longitudinal seams in piping or tubing. This work has demanded the development of elaborate machinery, especially adapted to this particular operation. In this case the skelp or long strip of sheet metal is rolled up so that its edges meet, and in this form it enters between the welding rolls, whereby there is a local heating across the meeting edges first produced at one end of the strip, and as it advances this local heating follows the line of the joint, whereby a pipe of which the walls are of even thickness and the diameter uniform is produced. Sometimes this pipe is used in the form as it leaves the machine, but in other cases it is afterward drawn to an exact size. The joint presents itself at first as a delicate bead along the length. Naturally the stock from which the pipe is made can be quite thin if desired, while the localization of the heat to the seam has the result of the preservation of the finish and surfaces of the other parts of the metal not concerned in making the joint, and, therefore, there is no waste of material by scaling. By modification in the operation taper tubes may also be formed. Such a tube-welding machine has been constructed of size sufficient to make tubes or shells up to 16 inches in diameter from sheet steel or iron.

This brief sketch of some of the more important developments of electric welding would not be complete without reference to work which is being undertaken in the line of welding thin sheet-metal pieces flat-wise face to face so as to avoid the necessity for riveting. Methods have been developed within a comparatively recent period whereby this character of welding can be done practically on a large scale without difficulty, and it has a large field of application in the production of sheet-metal ware which is afterward to be enamel-coated, and the outlook for the expansion of these methods is quite extensive.

It is interesting to note, also, that the growth of the use of reinforced concrete has been assisted by the electric welder, which produces a wire mesh which can be embedded in the concrete, and the joints of which mesh are firm and incapable of slipping and of material of high tensile strength. Considerable use of this product has already been made. Other applications of electric welding are in process of development, which, however, cannot be described at this time.

It will be readily understood that electric-welding apparatus is in most cases of the nature of special machinery, and as such has demanded in its development an intimate knowledge, not only of electrical principles, but of a wide range of arts and manufactures. The experience gained in adapting it to any particular use is often of great value in determining how to proceed in making further developments for other uses. In general, it may be said that where the welder is applied on a large scale for continuous work or continuous repetition work the duty of the attendant is now practically limited to seeing that the machine is in order, and in some cases to the mere placing of the pieces in the clamps, while the rapidity and uniformity of the results obtained demonstrate the advantage of working by electricity in these special ways.

The Electrical Upbuilding of the West.

By B. E. Sunny,

Vice-president, General Electric Company.

THE manufacture and distribution of electric current in a successful and satisfactory way is such an everyday affair now that it is difficult to realize the problems of twenty years ago. In the light of twenty years' experience it seems rather ridiculous to consider what were then problems as problems at all.

B. E. SUNNY.

We had then the Edison system, made up of small bipolar generators, driven by belts from high-speed engines. The current was used for arc and incandescent lighting exclusively. Little or nothing had been done in the design and development of the stationary motor. Arc lighting was furnished by arc dynamos generating constant current.

SOME OF THE MEN WHO HAVE BEEN IDENTIFIED

The central station with the largest number of small high-speed engines driving arc and incandescent dynamos—the engines and dynamos installed in a straight line from one end of the station to the other—was generally regarded as the best exhibition of electrical engineering.

Later on, the engineers came to the belief that a more efficient plant included the use of a large Corliss engine at, say, from 500 to 800 horsepower, driving a jack-shaft, the latter in turn operating the belts to the small electrical units. This type of installation was the popular one for perhaps ten years, until the advent of the direct-connected unit.

Twenty years ago we had only the single-phase 125 or 133-cycle alternator of 1,100 volts, and consequently each machine had its own circuit, and there was no such thing as multiple operation. It took perhaps five years to get a successful single-phase alternating-current machine to operate at 2,300 volts, because of the difficulty of insulating for so high a voltage.

One of the greatest problems that had to be solved by the central station was the distribution of high-voltage currents through underground conductors. In Chicago the use of underground conductors was forced on the companies by an ordinance by the city prohibiting the stringing of wire overhead.

The local company, which was made up of the consolidation of many smaller companies, bought a very large quantity of lead-covered cable, with an insulation of three thirty-seconds between the conductor and the lead sheath, which insulation was regarded as ample to carry a current of 9½ amperes at 2,500 volts for arc lighting. The experiment—for it turned out to be an experiment—was a disastrous failure, and the cables frequently burned out under the strain, and the service furnished was very unreliable. The large dry goods stores on State Street were deprived of light when they were filled with a crowd of holiday purchasers, and fires in buildings, caused by arc-light circuits, were of daily occurrence.

The cable problem was entirely beyond any electrician of that day, and, in desperation, it was decided to get cables of twice the insulation, with the hope that they would be able to furnish a reliable service. Cables of six thirty-seconds insulation were then made and installed, and the trouble disappeared. Later on, we scraped up enough courage to reduce the insulation to five thirty-seconds, and this has proven to be the standard for that character of service to this day.

The solving of the problem of underground circuits for arc lighting in Chicago was of the greatest interest to all of the cities, especially in the East. Delegations from New York, Boston and Philadelphia, to look over the work and pass on the service performed, were of weekly occurrence.

The value of the power business was fully recognized, and an effort was made to take care of it by the use of motors operated from arc circuits. The Baxter motor was of a very good type and furnished fairly good service. It was noisy, however, and it also flashed wickedly at the commutator, which had a terrorizing effect, so that it was rather uphill work to get any large number in service. Of course, the arc-circuit type of motor has almost entirely disappeared, and its place has been taken by the more satisfactory direct-current and alternating-current motors.

The advent of the direct-connected unit was rather interesting. Mr. D. G. Hamilton and Captain Robert McCulloch of the Cass Avenue Railway, St. Louis, wanted to make an important addition to their power house, and insisted on a 750-kilowatt generator and a 500-kilowatt generator being supplied them, direct-connected to Corliss engines. An effort was made by the electric companies as well as the engine builders to dissuade them from their purpose, but they were firm in their demand, and finally the contract was closed, not without the greatest possible hesitation, for the two units.

Both of the manufacturing companies were in a condition of fear and dread for months, while the designing and construction was going on, because of the boldness of the undertaking, but when the units were installed, the results were gratifying beyond all expectations.

This was probably the beginning of the manufacture and installation of direct-connected machines of considerable size.

The history of the business during twenty years is full of incidents of the above type. It is rather difficult to credit them, in the light of the situation of today, when the steam turbine, the multiphase generator of very large capacity, the long-distance transmission of current, the electrical equipment of steam-railroad terminals and interurban lines, have become accepted accessories of our everyday business.

While we seem to be in rather a finished condition with respect to present manufactures, it goes without saying that in the next twenty years there will be important developments, but it is not possible that they will be of as great importance as the developments of the twenty years just passed.

WITH THE ACTIVITIES OF THE "ELECTRICAL WEST."

Early Underground Electrical Construction in Chicago.

What is believed to be the first example of underground electrical construction in Chicago was carried out in 1877 by Mr. J. P. Barrett, then superintendent of the city fire alarm telegraph, who laid a short distance of fire-alarm circuits underground on the North Side, to serve the district known as "The Sands," at the request of some nearby residents who objected to overhead wires. As far as known, these underground wires are still in use.

The first electric-light cable to be laid underground in Chicago was put down in 1883, and a portion of it is illustrated by the accompanying picture.

Underground telephone cables in this city date back to 1885, when about ten miles of cable was put down in the central part of the city under the supervision of Mr. B. E. Sunny, then connected with the Chicago Telephone Company. The joints in these cables were about 500 feet apart, and the construction excited much attention at the time.

A PIECE OF THE FIRST UNDERGROUND ELECTRIC-LIGHT CABLE (NATURAL SIZE) LAID IN CHICAGO.

The electric-light cable illustrated consisted of two half-round copper rods embedded in insulating compound and enclosed in an iron pipe 1¼ inches in diameter. Each copper conductor measures one-half inch along the chord and is three-sixteenths inch in thickness. The whole constituted perhaps the earliest type of "Edison tube" and was laid in lengths of 20½ feet. The interesting relic shown in the picture was put down, as stated, in 1883, and when dug up, many years later, was presented to R. C. P. Holmes, purchasing agent of the Commonwealth Edison Company, who laid it originally when connected with the Western Edison Light Company. The tube was used to convey current at 110 volts from an isolated plant in a barn in the rear of J. W. Doane's residence on Prairie Avenue, near Eighteenth Street, to three other houses in the same block.

Colorado Electric Light, Power and Railway Association.

On September 18th, 19th and 20th there was held the annual convention of the Colorado Electric Light, Power and Railway Association at the Savoy Hotel, Denver, Colo. There was a good attendance at both the social and business meetings. The entertainment features consisted of a theater party at the Broadway Wednesday evening; a visit to the Northern Colorado Power Company's plant at La Fayette Thursday afternoon; visits to the plants of the Denver Gas and Electric Company and of the Denver City Tramway Company Friday afternoon; banquet and meeting of the "Sons of Jove" Friday evening, besides special automobile rides for the visiting ladies.

Among the papers read at the business meetings were the following: "Incandescent Lamp Outlook," by Francis W. Willcox of Harrison, N. J.; "High-tension Porcelain Insulators," by Frank E. Johnson of Denver, Colo.; "Lightning Protection in Colorado," by Leonard Wilson of Denver, Colo.; "Central-station Power Problems," by Charles Robbins of Pittsburg, Pa.; "Notes on Modern Boilers," by B. E. Buttles of Denver, Colo.; "Business Building by Commercial Departments," by George E. Putnam of Denver, Colo. Each of these subjects was discussed as well as the power-transmission situation in Colorado and the technical problems met with.

At the final meeting the association voted to include Montana, North and South Dakota in its territory, and elected the following-named officers for the coming year: President, W. G. Matthews of the Denver City Tramway Company; vice-president, C. R. Durbin, United States Light and Traction Company; secretary and treasurer, J. Frank Dostal, Denver Gas and Electric Company.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

IN GLANCING BACK through the vista of twenty years of electrical development, as is done in this Twentieth Anniversary Number of the Western Electrician, it will be interesting to reprint the very first editorial utterance of this journal, not only to see what were the aims of the new enterprise, but also to gain some idea of the state of the art of applied electricity at that time. Here, then, is the introductory editorial of Volume I., Number 1, dated July 2, 1887:

"In presenting the Western Electrician and explaining its mission it is unnecessary to dwell on the marvelous achievements in the electrical field during the last few years. The telegraph, the telephone and the electric light have followed in quick succession. The electric motor is at hand, and its promise of commercial success is as great as that of its predecessors. But these four great electrical accomplishments are not all by any means. Apace with them has been the development of a host of minor electrical appliances, many of which have become distinct branches of industry. Today the development and manufacture of electrical appliances command more thought, more labor, more capital than almost any other department of trade. Yet we stand only at the edge of a comparatively unknown field, the exploration of which is going on more rapidly than ever before.

"While keen minds and skillful hands the world over have contributed to the researches and inventions which have placed applied electricity in its present position, it is in the United States that these applications have reached their greatest commercial success, and no part has shown greater activity than the West. It is a question if any other portion of the country has equaled the West during the last eighteen months. Certain it is that in this section electric-light manufacturers have found the most extensive market for their products. Certain it is that the promoters of the telephone have found it easier to acquire paying subscription lists in small western towns than in similar towns in the East. If we mistake not, a western city enjoys the distinction of being the first in America to adopt and practically operate an electric street-railway system of more than one or two cars. It is in the West that telegraph companies make their heaviest earnings. Today the West is the great electrical market of America. Its advancement to this position has been rapid and sure. Many eastern manufacturers discovered the tendency of trade long ago, and, realizing the impossibility of handling their western business from remote distances, have either moved west or established important agencies in our larger cities. In every case the wisdom of the move has been proven, and in many instances it has been found that a larger and more profitable business has been done in the western department than at the home office. The West, too, is the home of a number of the largest electrical concerns in the world. They have realized the benefits of proximity to a good market.

"No local pride dictates these words. They have not been written with the intention of disparaging any other section. The facts, however, cannot be controverted; and we are but reflecting the experience of the past in stating that the West is worthy of the closest cultivation by manufacturers and dealers in electrical appliances.

"Notwithstanding the remarkable activity in matters electrical in the West, western electricians and manufacturers have been dependent on eastern publications for their literature, and for channels through which inventions and manufactures could be brought to public notice. The need of a representative western electrical paper has been apparent for some time. The subject of establishing such a journal has been urged by western electrical men, and their assurances of hearty co-operation and substantial support have not been wanting.

"The warmth of the welcome with which the project of issuing the Western Electrician has been received is strongly evinced by the extent of our advertising columns. Our reading columns give a foretaste only of what is to be provided in that department. We believe we are well equipped for the work. With the auspices of the undertaking, and the incentives before us, we hope to place the Western Electrician not only in the foremost rank of papers of its class, but in the lead. To accomplish this end no thought, labor or money will be spared.

"At the outset we wish to define our position. No man connected with the Western Electrician is bound to any other electrical enterprise; we are therefore in a position to publish an independent, unbiased and honest journal. No newspaper is worthy of the name unless it provides the news. It will be our endeavor to place before our readers the thoughts, experiences and accomplishments of those interested in the department of electrical investigation. Not only is our editorial staff composed of practical electricians and writers of experience, but our correspondence will be from among the leading electricians and scientists of this country and the old world. We have planted our standard high, and we confidently look forward to the time when the weekly receipt of the Western Electrician will be more warmly welcomed than this, our first number."

So far as the Western Electrician itself is concerned, we believe that our readers will agree with us that it has striven worthily to maintain the high standard it set for itself. It has been an "independent, unbiased and honest journal" and a leader in technical journalism, while at all times, we believe, of real interest, value and help to its readers. A retrospective glance at the career of the paper, such as we indulge in on the opposite page, shows that the record is one in which we may take an honest pride. Mr. McKinlock kindly says, in his article given elsewhere, that the Western Electrician has been "a guide and friend to all western electrical interests," and we shall endeavor to warrant a continuance of this praise in the future.

The present issue speaks for itself. It gives some idea of the extent of the electrical application of today in the principal avenues in which it is directed, and this particularly in the West. It may be compared with the beginnings of the great expansion of the electrical industry, as referred to in the editorial of twenty years ago, which has been quoted.

Marvelous indeed have been the changes, the growth and the number of new developments in the electrical arts and industries during these twenty years. The authors of the articles presented in this issue tell the story, and it reads like a fairy tale. And yet the account is given soberly and without exaggeration by men who are undisputed authorities on the subjects on which they have been induced to take time to write for this anniversary issue of the Western Electrician. Indeed, we are especially proud of our contributors; they are men who stand high in the electrical community, East or West; and we now take occasion to thank them, individually and collectively, for their kind co-operation in making this number what it is.

Aside from the historical value of the many excellent articles in the Twentieth Anniversary Number, the careful reader will find many suggestions that loom large toward the future. Thus, Mr. Insull lays stress on the importance of wholesaling current to large users, such as the street-railway companies, and he seems to think it not unlikely that the "larger transportation companies," meaning perhaps the present steam-railroad companies, may be buyers of central-station current in the future. This is a most interesting suggestion, and one which will give more than one plant manager food for thought. It inevitably leads to the consideration of the great question, "Will the trunk-line railroads be electrified?" In his electric-railway article Mr. Arnold does not hesitate to give it as his opinion that the answer to this question is in the affirmative. It is only a question of time, he thinks. Thus it seems probable that the principal steam railroads will be electrified. If so, will the central station benefit by the change?

One of the most interesting articles in this number is by Elihu Thomson, who shows the amazing extent to which the electric-welding process has been developed. Few, even among electrical men, we imagine, realize the great diversity of processes in which electric welding plays a part, and this article is of wide educational value. Professor Carhart proposes an important change in the engineering curriculum. But we must not go on dipping into these various articles. Here they are—a storehouse. Many are for profit, some not without entertainment. All may partake and be content.

The Western Electrician Twenty Years in Retrospect.

Dated July 2, 1887, the first issue of the Western Electrician marked the beginning of electrical journalism in the West. The paper was issued from the start as a weekly, and it appeared in the familiar blue cover which has been distinctive ever since. The size of the page was practically the same as at present, and the first number consisted of 24 pages, of which 13 were devoted to advertisements. Since then the number of pages issued weekly has greatly increased. The present Twentieth Anniversary Number is made up of 96 pages, of which 60 are advertising pages.

The paper was founded by Mr. W. A. Kreidler, the first editor and manager, and Mr. Kreidler has continued to be the guiding spirit of the enterprise from that day to this.

From the start the paper gave evidence of the excellent illustrations and handsome typography which have remained characteristic. A prominent feature of the first issue was the beginning of an illustrated serial on "The Elements of Electric Lighting," by Dr. Philip Atkinson, while another serial was begun on "Theory of Telephone Cables," by Dr. V. Wietlisbach, translated from the Elektrotechnische Rundschau. Other articles were "Millimetrical Measurement of Wire," by F. R. Welles; "Telephone System for Large Buildings," illustrated; "New Series Incandescent Lamp" (Thomson-Houston), illustrated; "A New High-speed Engine," illustrated; "A Corner on Electric-light Carbons;" "Chicago Electric Club" (an account of the organization); "Electricity as a Mode of Motion," by Dr. Atkinson, and "Electricity Applied to Air Brakes." An interesting feature was the introductory editorial, which is quoted in full on another page. There was a department of "Personal Paragraphs" and others relating to "Electric Lighting," "The Electric Motor," "The Telephone," "The Telegraph," "New Enterprises," "Miscellaneous Notes" and "Business Mention."

In the third issue was begun a description of the electrical patents issued by the United States Patent Office during the preceding week, and this valuable feature of the publication has been preserved ever since. In passing it is interesting to observe that of the 28 electrical patents issued on July 5, 1887, one was to Thomas A. Edison for a system of electrical distribution. It was thus described: "Two or more dynamo-electric machines are connected in series, and a circuit from these machines extends to sub-stations, at each of which feeding circuits are taken off to supply that particular district." So the sub-station idea is not a particularly modern feature of electric-light distribution. Other patents were granted to John Kruesi of Brooklyn for a junction box and an electrical conductor, while J. J. O'Connell of Chicago was granted a patent for an annunciator, William H. Eckert and John A. Seely of New York one for a police telephone system, and Stephen D. Field of New York another for a printing-telegraph transmitter.

In a technical journal the advertising pages are no less interesting, perhaps, than the "reading matter." The first issue of the Western Electrician was patronized by 24 advertisers—a creditable number when it is considered that they accepted the publisher's representations entirely on faith. Here is a list of the names of these original advertisers:

E. P. Allis & Co., Milwaukee.
Brush Electric Co., Cleveland.
Central Electric Co., Chicago.
Cleveland Electric Motor Co., Cleveland.
Edison United Manufacturing Co., New York.
Electrical Supply Co., Chicago.
Forest City Electric Works, Cleveland.
Fort Wayne-Jenney Electric Light Co., Fort Wayne, Ind.
Giles Bros. & Co., Chicago.
A. L. Ide & Sons, Springfield, Ill.
Jarvis Engineering Co., New York.
Jenney Electric Co., Indianapolis, Ind.
Leonard & Izard, Chicago.
Midland Electric Co., Omaha.
New York Safety Steam Power Co., New York.
B. W. Payne & Son, Elmira, N. Y.
Pond Engineering Co., St. Louis.
Railway Telegraph Supply Co., Chicago.
Standard Electrical Works, Cincinnati.
Thomson-Houston Electric Co., Boston.
United Carbon Companies, Cleveland.
United States Electric Lighting Co., New York.
Van Depoele Electric Manufacturing Co., Chicago.
Western Electric Co., Chicago.

In the present issue, by way of contrast, it may be mentioned that there are 204 distinct advertisements. But more than that—significant as showing the standing and character of the paper—it is pleasing to note that practically every one of the first-issue advertisers that is now seeking electrical trade is still represented in the pages of the Western Electrician, twenty years after, by itself or its successor.

With succeeding issues the paper was improved and broadened. In the second number Forée Bain gave "An Electrician's Views on Belting," for belting was an important subject in those days. It was also noted at that time that the American Institute of Electrical Engineers had nearly two hundred members. Ralph W. Pope, then as now the secretary of the Institute, was hustling to get together an electrical library. The first electric lighting plant described and illustrated was an isolated one—that at the Cook County Hospital. An illustrated article in the third issue was on "The Silver Voltameter and Its Use," by Prof. H. S. Carhart, who is also an esteemed contributor to the present issue.

With its third issue the Western Electrician began the practice of printing the papers and discussions of the Chicago Electric Club, of which Mr. Kreidler was secretary for several years. This feature was of real value, for important technical questions were threshed out before the club, and its deliberations attracted wide attention at home and abroad. A history of this unique organization—a technical society and a social club combined—is given on another page.

From the beginning the Western Electrician was warmly received, not only by its western friends but by its older electrical contemporaries in the East, and it may be said to have been successful from the start. It showed enterprise in chronicling the progress of the art; it used the telegraph freely; it was liberal with illustrations when cuts cost more money than they do now; it presented the electrical news of the day with intelligence and fidelity; it rose to important occasions, as in "covering" conventions and the like.

One early example of enterprise that attracted wide attention was the issuing of a Daily Western Electrician every morning at seven o'clock during the sessions of the National Electric Light Association in Chicago in February, 1889. Each issue contained from 20 to 28 pages, well illustrated, giving a complete report of the preceding day's proceedings. This was undoubtedly the most ambitious undertaking in the history of electrical journalism up to that time.

The World's Fair of 1893 in Chicago was of particular importance to the electrical interests in many ways. As early as 1890 the Western Electrician recorded the first movement for electrical representation, and from that time until the close of the exhibition the electrical interests at the Fair found in this journal their warmest champion. The plans of the Electricity Building were first made public by drawings published in the Western Electrician, and the first perspective view was drawn in the office of the paper from the architect's plans and afterward adopted by the World's Fair authorities as an official picture. It was the Western Electrician, also, which led the opposition to the evening-closing rule, which was eventually repealed. In the week ended May 6, 1893, a distinctive World's Fair issue was published, and it was highly complimented. Eleven years later, dated April 16, 1904, another handsomely illustrated World's Fair issue appeared from the office of the Western Electrician, this time relating to the electrical features of the Louisiana Purchase Exposition at St. Louis.

The Twentieth Century Souvenir Number of January 5, 1901, was another issue that attracted wide attention, and it is proper to remark, also, that the Western Electrician was the first electrical journal to prepare its own estimates of electrical manufactures for the New Year's number. And so other important events in the career of the paper might be enumerated if time and space permitted. But, after all, the more essential thing is the value of the service that a technical journal performs for its patrons week by week; and no doubt it is the character of this service, rendered 52 times a year, that has brought about a continuance of favor through twenty years, through good times and bad, and which induces a confident outlook toward the future. It may be added that the paper's total business for 1906 was the largest in its history, and its business for the first six months of 1907 was the largest six months' business it ever had.

A company is being formed for the purpose of building a trolley line from Superior to Ashland, Wis. It is proposed to have the road financed by people along the line, which will be about 100 miles long.

In the Good Old Days.

By F. S. Terry,
First Vice-president, National Electric Lamp Company.

It was in November, 1884, that John Wallace, then manager of Wallace & Sons, the large copper rolling mill concern, sent me out from Ansonia, a small town in Connecticut, to open up an electrical supply store in Chicago. I was given a draft for a thousand dollars and some good advice, and the trip was made by the West Shore Railroad, which had just been completed.

F. S. TERRY.

Chicago was then a city of 500,000 inhabitants. It had wooden sidewalks on all excepting the principal downtown streets, and with a different elevation in front of almost every house, so as one passed along he was continually going up and down steps, to reach the different levels. Within easy walking distance from the center of the city one could gaze out on the prairie with hardly a house to obstruct his view.

Why I was selected to start an electrical supply house is more than I can understand. I had had no business experience, and did not know a push-button from a binding-post. Forée Bain, who was then, as now, in Chicago, was engaged to teach me the science of electricity, and my first lesson was in setting up an electric battery.

The concern with which I was connected was called the Electrical Supply Company, and John Reid and myself were made joint managers of the new branch. We secured a room in the second story of a building on Lake Street, and soon a few bells and batteries, the first goods for our stock, arrived, and with these we opened up the store. Fortunately, most of our customers knew little more of the electrical business than ourselves, so we got along fairly well.

John Reid had had a little experience in the electrical business, and was therefore our electrical expert, but soon he and I disagreed and parted company, and the management of the business remained with me.

The Western Electric Company had been doing all of the electrical business in this part of the country, and at first seemed to resent our breaking in, but I presume after they had looked us over, their enmity turned to pity, and we became good friends. E. M. Barton was then, as now, president of the Western Electric Company, and Charles A. Brown, the patent attorney, was its manager.

The volume of the business done by the Electrical Supply Company each year increased, until, in 1893, the year of the panic, when the business was closed, owing to the failure of Wallace & Sons, it was doing a business of nearly a million dollars a year, which in those days was a large electrical supply business.

One of the closest friends I had during my first year in Chicago was Myron A. Knapp, who was then making telegraph instruments; we were both having a hard time with business, and would meet every noon at luncheon for mutual sympathy.

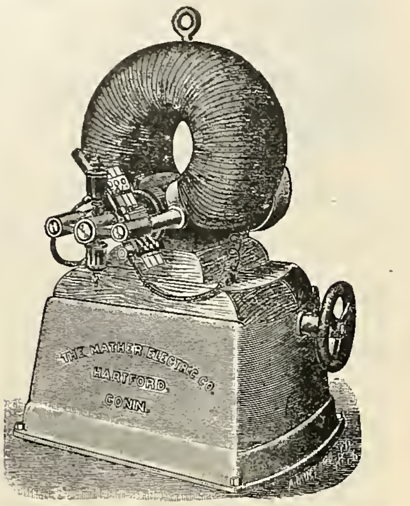
One of the first ones to call upon me at the electrical supply store was W. A. Kreidler, the western representative of the Electrical World, and he soon convinced me that an advertisement in the Electrical World would result in my obtaining all the business that I could take care of. He had prepared the copy for my first advertisement, and he had a contract all filled out for the space he thought I should take, and the deal was closed.

About this time Charles W. Price came to Chicago from the West, and was the Chicago representative of the Electrical Review. There was Fred Degenhardt, who was the most genial and perhaps the finest fellow that I have ever known. There was a young fellow who was selling engines, who was full of life, energy and push; I think his name was W. A. Hammett. Everyone in the electrical business or who sold anything to electrical people would at once become well acquainted, because there were so few of us.

A. K. Stiles was running the Van Depoele Electric Manufacturing Company, and E. A. Sperry was the electrician of the Sperry Electric Motor and Car Brake Company. R. T. McDonald was the whole thing in the Fort Wayne-Jenney Electric Light Company. F. B. Badt and Henry Hine were with the United States Electric Light Company; C. C. Warren was its western manager.

One day B. E. Sunny, who was then with the Chicago Telephone Company, came into the supply store for prices on cross-arms, insulators, etc.

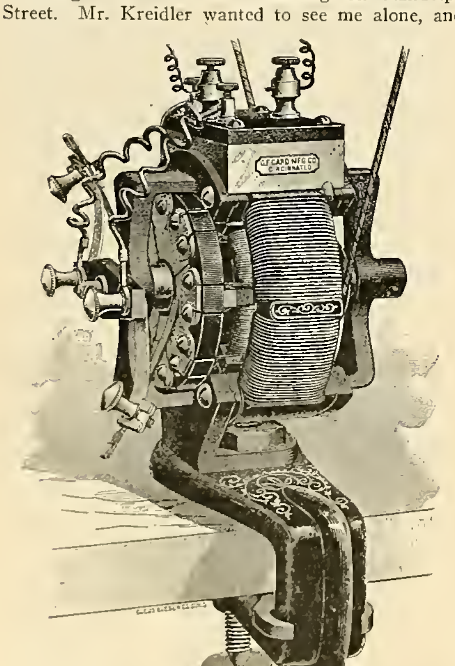
George S. Bowen was the proprietor of the Elgin Electric Light Company, and one day about the end of 1884 he expressed the opinion that the electric-lighting companies throughout the country should have an association similar to the one the gas companies had, and he suggested that we get together at the Grand Pacific Hotel and discuss the matter. This we did a few evenings later, and it was decided that the meeting should be called, and Mr. Sperry and myself were made a committee on invitations. Mr. Price had an announcement inserted in the Electrical



Reproduced from the Western Electrician of October 15, 1887.
A DYNAMO WITH HORSESHOE FIELD MAGNET, ONCE FAMILIAR BUT NOW RARELY SEEN.

Review, and we all awaited with much interest the arrival of the delegates, who came from all parts of the country, and the meeting was held in February, 1885, at the Grand Pacific Hotel, Chicago. This was the beginning and the first meeting of the National Electric Light Association.

A year or two later, I think it was one day in the summer of 1887, W. A. Kreidler came into my office, which had then been moved to larger quarters on the ground floor in a building on Randolph Street. Mr. Kreidler wanted to see me alone, and



Reproduced from the Western Electrician of November 5, 1887.
AN EARLY MOTOR FOR ARC CIRCUITS.

told me he had something to tell me which to him was of very great interest; he told me he had resigned from his position with the Electrical World, and he then brought out a dummy of the Western Electrician, which he said was to be a new electrical publication to be owned and operated by himself.

Mr. Kreidler had a personality which was irresistible, and it did not take him long to persuade me that the proper thing for me to do was to take a choice page in the new paper on a year's contract. The subject of circulation was not even mentioned. The Western Electrician gave evidences of progress and prosperity from the very beginning, which was due to the energetic work of Mr. Kreidler, as there was never a moment that he was not doing something for its advancement, and he had a host of friends who seemed to be equally anxious for its success.

An account of these times would not be complete without referring to the Chicago Electric Club. This was organized in about 1887, and was the scene of many pleasant times, some of them being of a lively character. We used to meet at the club for luncheon, and besides those I have mentioned, were H. Ward Leonard, who was then connected with the western branch of the Edison Electric Light Company, and S. A. Barton who was the western manager of the Thomson-Houston Company. Those of us who were the most active in the club will easily remember the dinners that were given, when the word would be passed to keep the champagne glasses full, and with the songs, speeches and good fellowship we probably never had more enjoyable times. The Electric Club continued so long as a few of us were willing to make good its deficits, but in 1893, the year of the panic, we had other uses for our money, and the club went with our other luxuries.

The Evolution of the Supply Business.

By Geo. A. McKinlock,

President, Central Electric Company, Chicago.

One of the world's most entertaining, analytical and greatest writers took for the title of one of the most important books of his most interesting series "Twenty Years After." From the advanced period of twenty years, looking backward, there passes before the reader's mind a sequence of incidents and events which appeared during the transitory time as incoherent and irrevelant; and so in looking backward in the electrical supply business twenty years, one sees a sequence of advances in the business, although during the period what appeared to be violent changes seemed to have no reference to the progress of the business.

GEO A. M'KINLOCK.

It seems only a few days ago that Mr. Kreidler climbed the stairs at 38-40 La Salle Street, second floor, to make a call on the youngest, but now oldest, electrical supply house in the country. There was but one other in existence at that date. Mr. Kreidler came to herald the approaching birth of the Western Electrician, which he said might be looked for almost any time.

It would be hard to describe a "Western Electrician" of that date, so that the reader who never met the genii would find it difficult to construct from a description, however complete, the living and breathing personality.

That he was "practical"—we took his word for it. He rarely if ever made any claims to being theoretical, leaving that field to the "E. E.'s," who furiously contended with each other in the columns of the electrical journals of that date, much to the profit and edification of the laity.

The name chosen seemed to be at least practical, therefore, but as events and the high character of the paper have since shown, it has been a guide and friend to all western electrical interests, practical, technical, theoretical, and commercial, and I have every confidence that in the files of the Western Electrician for the past twenty years will be found a more interesting and instructive story of the progress and evolution of the electrical business in this great Central Market than is possible to be prepared at this time. Its advertising pages will be found lively reading and will show forth better than tongue can now tell the energy, enthusiasm and zeal of the "boys" of those days.

The electrical supply house twenty years ago was established to supply electrical merchandise in a field which was very much restricted, due to the fact that the manufacture of the machinery which produced the electric current was in the hands of a very few manufacturers, who laid claims to control patents on the machinery as well as on the method and process of distributing the electric current.

The manufacturers of electric-lighting machinery (the electric-railway and power business came later), as is well known, offered to buyers complete equipments, and controlled, or claimed to control, the manufacture and sale of the detailed parts that went to make up their installation systems. The only field that was, therefore, open to the supply dealer was the sale of construction material, telegraph supplies, electric bells, fire-alarm and experimental apparatus and such other detail construction and wiring supplies as were not controlled by the manufacturers. It would have been a serious offense in those days for a supply dealer to offer an incandescent or arc lamp for sale.

The rapid development of the business taxed the manufacturers' capacity to its utmost, as well as the promoters', with the result that there was attracted to the electrical field all kinds of talent. Inventors with divers inventions, devices and schemes thronged the market place, and every small machine shop had its Edison.

During this period the process of sifting went on, and the centralizing tendencies which appeared in the commercial world were quickly at work in the electrical field, and then came consolidations, in groups, of the manufacturers of devices and inventions of merit.

Improvements in the manufacturer's art and the appliances widened the scope of the supply dealer's business. As the business broadened, in the absence of any manufacturer's ability to carry a full stock and distribute to the buyers according to their needs, the supply business came into its own.

During all this time an element of every successful business became more and more prominent, until now it is recognized as one of the most important elements to the success of the supply business. This element is the question of credit. During the early days of the period of the last twenty years this question was of little, if any, importance, as it was always assumed that anyone that wanted to buy electrical goods must of necessity be in good credit, and the talent of the supply man was exhibited in his ability to get from the manufacturer merchandise to fill the demands of his customers. Of course, there were some losses, but profits were so large that losses were taken lightly.

Today the business of buying and selling electrical merchandise is on a firm and permanent foundation, and is subject to all the vicissitudes and experiences of any merchandising business, and if conducted successfully must be carried on according to the recognized rules of the best business practice.

The business today offers attractions and opportunities for ambitious, active, intelligent young men of character and education. I have always regarded the educational work done by the Western Electrician as being of great value in assisting in the training and education of young men without school or college experience and advantages, who felt drawn to and adopted the electrical business as their life work.

Surely the electrical journal that has contributed to the building of the electrical West is to be congratulated.

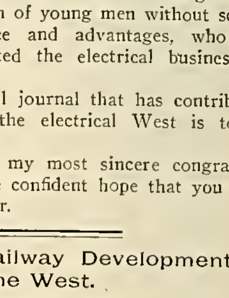
I therefore extend my most sincere congratulations and express the confident hope that you may live long and prosper.

Early Electric-railway Development in the West.

By Aaron K. Stiles.

In accordance with request, I submit a short article relative to the early days of the electric-railway industry in Chicago and the West.

Much that has been said regarding the pioneer days of the electrical industry has been quite misleading, emanating probably from persons who are anxious to sell stock in schemes for the promotion of so-called electric railways. The public in general has but little idea of the real facts in regard to the work that was done in early days.



AARON K. STILES.

The Van Depoele Electric Manufacturing Company, whose factory was at 15 to 21 North Clinton Street, Chicago, was the company that did the work in introducing electric motors and electric railways in the United States. The majority of the capital stock of this company was owned by me.

Charles J. Van Depoele, electrician and inventor of electric motors and electric railways, was a native of Holland and came to Chicago from Detroit, Mich., about the year 1882, when the Van Depoele Electric Manufacturing Company was organized. Mr. W. A. Kreidler of the Western Electrician knows that Mr. Van Depoele was an original inventor of electric railways and that the Van Depoele Electric Manufacturing Company worked to introduce this system up to the year 1887, when the company sold out its rights to the Thomson-Houston Company.

During the time the Van Depoele Electric Manufacturing Company was doing business the principal difficulty encountered was in getting the right to put up the electric wires as they are used today. The prejudice of the public was so strong against the use of electricity that the people had to be educated in its use. It was difficult to convince the public that persons riding upon the cars would not be killed by the electric current.

Mr. Van Depoele was born in 1840 and commenced the study of electricity at a very early age at Poperinghe. While at college in 1861 he produced his first light of 40 Bunsen cells. He afterward moved to Lille, France, where he attended regularly the lectures and experiments of the Imperial Lyceum from 1864 to 1869. When he came to this country he exhibited his first lights and electrical appliances at Detroit, Mich., where he had established his home. As early as 1874, when he was engaged in Detroit experimenting with electrical generators, motors and other electrical apparatus, it occurred to him that trains of cars and ordinary street cars could be run by electricity. On many occasions the belt of his 10-horsepower engine was disconnected from his main shaft driving the shop machinery and the engine was made to operate a large dynamo which drove another dynamo. In 1882 the Van Depoele Electric Manufacturing Company made its first exhibit of a small electric railway in Chicago. About the first week in February, 1883, a plant was put in real operation, and commencing September 10, 1883, a small installation was put in operation at the Chicago Interstate Fair.

In 1884 the Van Depoele company ran an electric railway in Toronto, Canada, carrying passengers from the street railway into the grounds of the Toronto Exposition. The company at this time used an underground conduit, owing to the prejudice of the people against an overhead electric wire. In the fall of 1885, on the same track, the Van Depoele company carried all of the passengers into the Toronto Exposition grounds, a distance of about a mile. An overhead wire was used the same as those now used by electric companies. The number of people carried in five days was over 50,000. To my knowledge, this was the first electric railway where the contact was made with the overhead wire by means of a pole and trolley running under the wire.

The several roads that we had equipped in different parts of the country previous to this time had used a trolley running on top of the wire, the wire being suspended on a hook which allowed the trolley to pass over.

In 1886 we equipped a temporary road running from Minneapolis to Lake Minnetonka, and on one occasion ran ten cars, loaded with all the people that could be piled in, from Minneapolis to the lake. This was to show what could be done, an agreement having been made with the Van Depoele company that the road would adopt the system if it were successful. The Van Depoele company did all that it agreed and more, but the contrct was not consummated, as the president of the railway company had been offered one-half of the capital stock in a soda motor which at that time had come into existence. The railroad company not being responsible, we withdrew for other fields.

In 1886 a railroad was equipped in Montgomery, Ala., where the road did good service, and I suppose is in use to this day. During that year we also equipped a road at Lima, Ohio, and another at Windsor, Ont., and a short road at Detroit, Mich. During the same year we equipped a road at Appleton, Wis., and another at Scranton, Pa., running from Scranton to Nayog, which was called the Scranton and Suburban Railroad. The Lima street railway was put in operation July 4, 1887. In the month of June, 1887, we equipped the Washington Street and State Asylum Railway at Binghamton, N. Y. Here the length of track was five miles and the single overhead wire system was used. In 1887 we also constructed a double-track railway from Brooklyn to Jamaica on Long Island, a distance of six miles, and it was a perfect success. Other roads electrically operated were at Ansonia, Conn., Dayton, Ohio, and Port Huron, Mich. In all, 14 electric railways were equipped. For all of these roads we built power stations and equipped the stations with dynamos from our shop in Chicago.

It was difficult to get car companies to build cars for us, as the general impression was that the electric-railway business would not be a success. The Pullman company built the cars for the Scranton Railway, Brooklyn and Jamaica road, and the Ansonia Railroad; also, I think, the cars for Appleton, Wis. John Stevenson of New York, who was the principal, in fact the first car builder in the United States, refused to build any cars for us without the money being deposited for payment in advance. Outside of those built by the Pullman company, the Brill company of Philadelphia was the first whom we could induce to build cars for us. During this time, in all of our literature, of which I have some specimens, our aim was to convince the people that not only would the cars operate, but that people would not be killed while riding.

It seems at this time very foolish to obtain certificates as to what an electric railway will do, but it was a serious necessity in early days.

During the seven years we worked at this business I spent about 18 hours a day, on the average, to make the electric-railway business a success, but no one would be convinced at that time that cars could be run by electricity except by actual observation.

The Van Depoele Electric Manufacturing Company used motors for power in its shop as early as 1884, doing away with shafts belted from engines.

We had the first cases of electrolysis, so far as I know. There were hundreds of circumstances during the time that we were equipping these roads with electricity which were perfectly ridiculous, and viewed from this long distance are laughable. But at the time they appeared serious enough.

During all of this time I was the general manager of the Van Depoele company, holding most of the stock of the company, which had been unloaded upon me by the other stockholders who had lost faith in the enterprise.

We installed the first electric arc lights in Chicago, and were the second company to make such installations in the United States, the first company being the Brush of Cleveland, Ohio, which had previously put electric arc lights in Detroit and several other places.

It seems now, since electric railways have proved a success, that all kinds of fakes are foisted upon the public; some of these schemes appear to me absolutely ridiculous, but they seem to gather in money.

Such schemes as the one which is to run cars to New York in ten hours are, I think, absurd; also the electric railways that are advertised to run at the rate of 200 miles an hour.

Electric railways have done all that was predicted for them, have built up the suburbs of the large cities and are at present carrying the largest share of the suburban passengers, but I doubt that for extreme long-distance service they will be made to pay. Large amounts of stock and bonds have been disposed of on the interurban electric lines in the United States, most of which are not listed on the stock board in New York, and from which cash on short notice cannot be realized. A large number of interurban roads are undoubtedly making money; but there are others that have been built and are being built to make long-distance connections, which, in my opinion, will not pay for many years. They have done a great deal of good and are entitled to credit for what they have done as interurban roads, but I do not believe that for long distances and for freight business they can yet compete with steam roads.

Some Municipal Lighting Plant Failures.

The City Council of Princeton, Ill., has advertised for bids for the sale of the municipal electric-lighting plant. If the bids are unsatisfactory, it reserves the right to reject them and adopt the alternative plan of expending from $8,000 to $10,000 to put the plant into good condition. It was never a popular venture.

The Galena (Ill.) lighting plant, which has been operated by that city for a number of years, has been sold to a western syndicate at a price much lower than the original cost. The plant never paid expenses and was such an unprofitable investment that the citizens were glad to dispose of it. A contract for furnishing light has been closed with the syndicate for 25 years.

The business men of Washington, Ind., have just refused to advance any money to keep the municipal electric plant there in running condition. It has been estimated that it would cost $85,000 to make requisite repairs. The people have from time to time spent large sums of money upon the plant without seeing any improvement in service or reduction in operating expenses. A majority are demanding the sale of the plant and the execution of a lighting contract with a private company.

The city electric-lighting plant of Topeka, Kan., is said to still show a steadily increasing deficit. The public is asking for better service and a reduction of taxes required for running the plant. Unless a much better showing is soon made, tbe sale of the outfit may be demanded.

A Backward Glance in Kansas City.

By Edwin R. Weeks.

Reminiscence of the early days of electric light and power recall the phenomenal development of this industry in Kansas City, where many of the initial trials of its various devices were made. It is but 26 years since the first central station in the world employing Thomson-Houston apparatus was installed in Kansas City. Yet in that brief period not only the practice but the very nomenclature has so changed that many of the old terms need explanation to the younger generation of electrical engineers, and the development of the industry has been so great that its exposition has exhausted the vocabulary of miraculous achievement.

EDWIN R. WEEKS.

Twenty years ago I served as court appraiser on the remains of what had been one of the world's first attempts at commercial operation of street cars by electricity. The apparatus employed was assembled and in part invented by J. C. Henry of this city, and consisted of single 7½-horsepower motor equipments for two cars, together with a double overhead trolley, and a power house containing one small boiler and a Ball engine belted to a 250-volt direct-current generator. The trolley wires were run ten inches apart, and two pairs of trolley wheels were tentatively held by springs in lateral contact with each wire. The four pairs of wheels were mounted on a single carriage and were connected with the motors by flexible duplex cables. The motors were bipolar, shunt-wound, were in continuous operation, and were equipped with friction clutches for starting and stopping the cars. The motorman, who, to be ready for emergencies, wore overalls, stood in a pit in the center of the car. Even under ordinary conditions he was kept busy shifting the brushes as the load changed or the direction of the car reversed; while the passengers had plenty of exercise dodging the oil which flew in every direction. The troubles of operation through a populous street over adverse grades and track conditions resulted in an assignment for the benefit of the creditors.

But crude and brief as this trial was it was a demonstration, and in the twenty years which make the life of the Western Electrician, the electric railways of Kansas City have been built and rebuilt and now comprise 280 miles of track and 600 cars, requiring a power house capacity of more than 30,000 horsepower, with an annual output of over 80,000,000 kilowatt-hours.

Twenty years ago the oldest Thomson-Houston central station served 500 T-H "drop-and-lift" open series 9.6-ampere arc lamps, 300 "hook-and-eye-contact" Sawyer-Man incandescent lamps, and several constant-current motors, chiefly of the Baxter type. The station was equipped with common tubular boilers and Corliss engines belted to counter shafting, from which were belted T-H dynamos ranging in capacities from 10 to 30 arc lamps. The oldest of these dynamos were made in the "basket factory" at New Britain, Conn., before the T-H factory at Lynn, Mass., was ready for business, and all T-H constant-current dynamos were fitted with the T-H automatic regulator, the most valuable feature of the T-H machines.

In order to save copper these dynamos were run two or more, sometimes six, in series, and the circuits being all overhead, the "underwriter's insulation" with which they were generally covered was put to its test and found wanting. We had, however, already begun to substitute other kinds of insulation which to a greater or less degree insulated under operating conditions. Some of those employed were "P. & B.," "Grimshaw," "Simplex" and "Okonite."

The incandescent lamps on this station were run from a compound-wound, constant-potential dynamo, or by means of "distributor boxes" on the arc-lighting circuits, or, in the case of the first residence lighting, from a 70-volt generator, which was located in the house of the writer and which was driven by a two-horsepower constant-current motor on a street-lighting circuit.

As the T-H "system" of this period had no service meter, contracts were made on the basis of tbe average gas bills, substituting a 16-candle incandescent lamp for each five-foot gas jet. From the beginning the writer protested against the unbusinesslike character of such a basis of service, and we soon found we were getting pay for only 32 per cent. of our output, as consumers whose bills did not depend upon their own economy allowed their lamps to burn even in the full glare of a noonday sun. The prime need of a meter was so apparent that I made a renewed and continued demand upon my good friend, Prof. Elihu Thomson of the T-H Company, for a measuring instrument, with the result that after scrapping a few meters, among which was one that we called "the Thomson teeter meter," he finally brought out the Thomson recording wattmeter, which has since been generally accepted as the standard for all kinds of service.

Twenty years ago the Edison Electric Light and Power Company's Kansas City station had been in operation only a few months and consisted of a 200-horsepower B. & W. boiler and a New York Safety engine, to which were belted two No. 16 bipolar Edison dynamos. The connected load was then 2,600 16-candlepower lamps and 27 horsepower in Sprague, C. & C. and Eddy motors. Distribution was by the well-known Edison 110-220-volt three-wire system, with uninsulated overhead feeders, and all services were measured by Edison electrolytic meters. During the late '80's there was also built in Kansas City a Westinghouse alternating-current plant with all lighting services equipped with Shallenberger meters.

That the Western Electrician has lived in stirring times is shown by the fact that in the Kansas City of today the connected lighting and motor load is 11,788 horsepower in motors, 1,974 series arc lamps and 355,157 16-candlepower incandescent lamps or their equivalent, and the station capacity is over 10,000 kilowatts.

This springing up almost over night of an industry which brought forth each day some untried device of factory or plant made of manufacturer and central-station superintendent experimentalists mutually dependent and each deeply and interrogatively interested in the other's work. There resulted a *camaraderie* between them which showed itself in ways unknown to enterprises of slower and more certain growth.

Between the shareholders' demands for dividends and the consumers' demands for lower rates and extensions to plant the central-station man of pioneer times was frequently sore beset, especially for money with which to enlarge the plant, and the manufacturer had sometimes to fill the breach. I remember a successful negotiation at one such critical period with the Babcock & Wilcox Company for an indeterminate (!) loan of a new 200-horsepower boiler. Freedom from fixed charges for over a decade on so considerable a portion of the plant was a source of great satisfaction to me, and I still have a soft spot in my heart for the world's greatest boiler company for helping me keep up dividends, which had aggregated over 200 per cent. for ten years, while weathering our worst financial panic in multiple-arc, with cut-throat competition from two gas and two electric-lighting companies.

Comparatively little information on electrical practice was available in books 25 years ago, and station managers were obliged to learn from their own experience and that of others in the same line of work. Exchange of experiences had to take the place of systematized knowledge, for even the textbooks could not keep pace with discovery. Each of the pioneer manufacturing companies also was possessed with a religious zeal for converts to its own peculiar "system"—Brush, Edison, Weston, Hockhausen, Thomson-Houston, etc., which made each promoter deny that any virtue was to be found in the camps of his rivals. To afford opportunity to thrash out the problems of applied electricity the National Electric Light Association was therefore organized. Its programmes show the meager elementary knowledge available in the early '80's, and its records attest how eager was every central-station man and employe to know how the other fellow met this and that emergency. Very frequently there were signs that some feared losing the value of their experience by imparting it to others.

Master workmen and electrical trade schools were unknown in these recent pioneer days, yet the instant need for both was great. To fill this gap the writer organized what I think was the world's first mutual improvement society of electrical artisans. This organization, called the Gramme Society, was of value to both employer and employe. It established a most friendly relation between them and compensated in great measure for the lack of master workmen and trade schools, as well as for the absence of theoretical knowledge regarding this wholly new industry—knowledge now so abundantly furnished by books, the technical press, trade and correspondence schools and colleges.

From the slow spread of accurate information as to the results of the more or less chaotic experiments in actual practice with the numerous "systems" of the '80's has come the comparatively stable standardization of today. It is generally difficult to see the end from the beginning, and the applied electricity of 1882 formed no exception. It is therefore no small satisfaction to know that the three systems adopted and first installed by the Kansas City management formed the basis of the phenomenal success of the world's two greatest electrical manufacturing companies, and to reflect that the experience of Kansas City in applied electricity embodies so much of what has proved of lasting value in the development of this, the world's most pregnant industry.

The Chicago Electric Club.

No survey of the "Electrical West" for the last twenty years would be complete without an account of the old Chicago Electric Club, which came into existence in 1887, the year of the birth of the Western Electrician, and was disbanded late in 1893, after the World's Fair of that year and during the financial depression then prevailing. The club was noted alike for its high technical standing and for its pleasant social features.

In the spring of 1887 a number of well-known Chicago gentlemen held several conferences for considering the advisability of organizing an electric club "for the promotion of social intercourse, the diffusion of knowledge among those interested in electrical matters, and to provide members with the conveniences of a clubhouse." As a result of these gatherings a charter was applied for and on May 20, 1887, the Chicago Electric Club was formally incorporated with the following-named incorporators: Charles J. Van Depoele, Franklin S. Terry, Charles A. Brown, William J. Buckley, Aaron K. Stiles, W. J. Armstrong, W. A. Kreidler, F. G. Beach, John P. Barrett, Charles D. Shain, B. E. Sunny and Jos. Uhrig. Several meetings were held in the Lakeside Building to perfect the organization, and there the following-named were elected as the first officers of the club:

President, Gen. A. K. Stiles; vice-presidents, John P. Barrett, F. G. Beach, Charles A. Brown and B. E. Sunny; secretary, W. A. Kreidler; treasurer, Franklin S. Terry.

After a few meetings in the parlors of the Grand Pacific Hotel, the club established itself in its first home in an undecorated room at 225 Dearborn Street. These quarters being far from what a clubhouse should be, arrangements were soon made for removal to 122 Clark Street, and on October 17, 1887, the second home was occupied. A kitchen was established and the serving of the midday meal did much toward bringing the members together and creating the sociability so necessary to the life of the club. Billiard rooms and a library also helped in this line.

From the start the club filled an important place in the electrical field in Chicago as a gathering place for the fraternity, where all interests had a common ground for the discussion of technical and industrial subjects. Electrical men being quick to see the need and value of such a club, flocked to it with great enthusiasm, so that in the six months, to November 21, 1887, the membership had grown to 177, and by December 19, 1887, there were 201 names on the roll.

The first paper was read before the club on July 11, 1887, by the late C. C. Haskins, on "Unworked Territory." During the next month a paper was presented by F. B. Badt on the subject "The Danger to Human Life from Electricity." Each of these papers was followed by a liberal discussion. Other topics were taken up and their discussions began to create much attention outside of Chicago. By the end of the year 1887 the club had held 13 regular meetings and one banquet, and ten papers had been read.

In the early part of 1888 there was held a series of discussions on the "Relative Merits of Alternating and Direct Currents for the Commercial Distribution of Electricity." Papers on this subject were read by Messrs. H. Ward Leonard, F. B. Badt, M. M. M. Slattery, E. P. Warner, E. A. Sperry and George Cutter. That of the last-named gentleman was entitled "The Continuous Current, Limited, vs. The Alternating Current, Unlimited." In April the secretary reported "that the prophecy that the discussion of the subject would make valuable additions to the electrical literature of the day, is already fulfilled. The papers and discussions by members of the club have awakened widespread interest both in America and Europe."

In the latter part of 1888 there was a falling off in attendance and only three regular meetings were held. A deficit of $200 existed in the funds. By striking off the names of delinquent members the membership roll was reduced to 120. The falling off was also due to the dissatisfaction of many over the inadequate quarters of the club.

Mainly through the hard work of President S. A. Barton (who was elected early in 1888) a revival of interest was brought about and the club rented two floors of the High Block at 103 Adams Street, adjoining Kinsley's famous old restaurant and almost exactly where the offices of the Western Electrician are now located. These rooms included lecture, reading and billiard rooms and were handsomely furnished. They were connected with Kinsley's, so the members could enjoy good dining facilities without the trouble of operating a kitchen of their own. The formal dedication of this third home of the club took place on August 1, 1889, and was the occasion of a banquet and reception attended by a great many distinguished guests as well as a large percentage of members.

In the fall of 1889 President Barton decided to return to the East, and tendered his resignation on October 28th. The members were reluctant to see him leave, as he had done so much to increase the prestige of the club. A farewell reception was tendered him. Mr. F. G. Beach was elected on November 18th to fill the unexpired term and was re-elected the following year, 1890.

Among the papers read during the winter of 1889-90 were "The Use of High-tension Currents in Electric Lighting," by B. E. Sunny; "Theory of Compounding Dynamos for Constant Potential" and "Electric Motors in General Railway Work," by Dr. Louis Bell; "A Theory of Accumulators," by Dr. Paul Schoop of Zurich, Switzerland, who was then visiting America. The papers and discussions of the club continued to excite most favorable comment in all directions and were reprinted in the technical journals both here and abroad. Along about this time electrical men in Chicago began to appreciate more than ever that a membership in the club gave a technical man a standing not to be obtained on the outside.

During the next season discussions on underground conduits, rating and regulation of generators, incandescent lamps and electric railways created the most interest, and the substitution of electricity for steam on railroads was broached. Early in 1891 the club was complimented by the request of Chief Barrett of the Department of Electricity at the Chicago World's Fair that the club recommend to him the names of three members from whom he could choose one as the special electrical engineer for the exposition. At this time, also, a committee on World's Fair was appointed that from time to time conferred with the exposition officials and had much to say in the adoption of plans for the electrical features. It was this committee, headed by the president, B. E. Sunny (elected in 1891), that also aided in securing the International Electrical Congress at Chicago in 1893.

In the winter of 1891-92 the club was the scene of many spirited discussions on fuses, power transmission and allied subjects, and a particularly long series of debates on electric-railway topics. In February, 1892, the club started an agitation for the establishment in Chicago of a school of technology, which aided in the foundation of Armour Institute the next year. Mr. Sunny, who had done so much to make the club a potent factor in technical matters, was re-elected president for the ensuing year.

It became apparent to the members that it would be imperative to secure even better facilities than those afforded by the Adams Street rooms in order to be able to entertain properly the large numbers of electrical engineers, scientists and others interested in the electrical arts that were expected to attend the World's Fair in 1893. To secure these adequate quarters the club moved to the second floor of the northeast corner of Monroe and Clark streets and occupied the new rooms on May 1, 1892. These were fitted up as elaborately as any downtown business men's club ought to be and were the center of many pleasant social gatherings and receptions to distinguished guests during the continuance of the Fair. During this time the literary meetings became less frequent and entertainment was the order of the day. The president of the club in 1893 was John P. Barrett, chief of the Department of Electricity at the World's Fair.

The expenses of entertainment of visitors had been so great, however, that after the exposition closed the treasurer reported a deficit of about $3,000. Attempts were made to collect unpaid dues and assessments with incomplete success, and the club was therefore forced to close its doors. The last regularly recorded meeting was held on November 10, 1893.

Following is a list of the names of men who were active members of the club or who took part in its discussions:

Thos. Addison	C. J. Field	F. W. Parker
T. Ahearn	J. H. Gates	W. B. Pearson
W. H. Applegate	J. F. Gilchrist	D. P. Perry
C. G. Armstrong	C. K. Giles	F. L. Perry
W. J. Armstrong	E. R. Gilman	G. M. Phelps
Bion J. Arnold	H. K. Gilman	R. H. Pierce
Lieut. F. B. Badt	H. A. Glasier	H. R. Post
E. Baggot	J. H. Goehst	J. K. Pumpelly
Geo. C. Bailey	F. S. Gorton	Frank B. Rae
Theo. P. Bailey	Prof. Elisha Gray	J. H. Reid
Foree Bain	S. D. Greene	B. Rorison
W. E. Baker	Chas. E. Gregory	C. H. Rudd
C. M. Barclay	Thos. G. Grier	C. E. Sargent
J. L. Barclay	W. G. Hahn	Fred Sargent

Of the technical work of the club no one, perhaps, is better fitted to judge than Mr. George Cutter, long a Chicagoan but now of South Bend, Ind. Mr. Cutter says:

"I returned from Europe 20 years ago this fall. My position as chief engineer of the Thomson-Houston Company in Europe for two and a half years had brought me in contact with European engineers and their methods. This experience, I believe, caused me to appreciate very highly the value of work done in a technical way by the Chicago Electric Club.

"We had a pretty good coterie of technical men to steer this work. Amongst them I might mention offhand Mr. Van Depoele, who was then connected with his own company on the West Side, this being previous to his selling to the Thomson-Houston Company; Mr. Warner, the dynamo designer of the Western Electric Company; H. Ward Leonard of Leonard & Izard; E. A. Sperry of the Sperry Electric; W. S. Andrews, connected with Leonard & Izard, and Professor Badt. These men had considerable influence in the days of the Chicago Electric Club and have maintained important positions and influence in our loved profession ever since.

"We had before us at that time some interesting questions both as to their bearing upon the future of the business and their importance for the time being to the competing companies interested. It looks a little queer now when running back in the memory of those days that the question of "The Relative Merit of the High-potential Small-ampere or Low-potential Large-ampere Arc Lamp" should be considered a question of great importance. It seems to me right, however, to consider that these were important questions in a technical way, especially when taken in connection with another much more important and absorbing question before us at that time, namely, the relative merits of the constant-potential direct-current three-wire distribution system and the alternating-current system then just crowding its way upon the American market.

"The special value of papers and discussions upon these matters before an organization like our Chicago Electric Club was to be found in the happy mixing of technical and business men. This particular phase of these discussions is what impressed me so very favorably at that time, and the impression remains with me now as a correct one, especially when compared with the methods in Europe, where the technical men felt themselves to be in a class separate and distinct from the business end, and that is why so much work has been done in Europe in a technical way not in best relations to the business end of our industry.

"The technical men mentioned as leaders in this work for the Chicago Electric Club were well able to bring forth the possibilities of their own particular types of apparatus and systems, and the business men who took such active part in our discussions brought out in a forceful way the limitations in the business end of the undertakings. These discussions were considered important and indicative by the head men of the large manufacturing companies, because I well remember requests from Mr. E. W. Rice, Jr., and other leading spirits of the Thomson-Houston Company, with whose engineering staff I was connected, that certain phases of the business be brought before the Chicago Electric Club for consideration. Full reports of the papers and discussions thereon in the technical papers also evidenced the importance in which they were held, and very largely increased the value of the work done.

"On the whole, therefore, I feel that the opinion is justified that the technical work done by the Chicago Electric Club about 20 years ago was important and valuable to our profession."

Of the social features of the club Mr. Charles E. Gregory writes entertainingly as follows:

"My recollections of my associates in the Chicago Electric Club are as dear to me as those of my chums at school. It was organized at a time when Chicago's total investment in electrical apparatus did not total half a million dollars, when the industry was indeed a weakling, when underwriters' wire laid behind awnings and signs was considered a fine arc circuit, when shunt-wound arc generators were considered by many an economical means of producing current, when men representing the different lighting systems who disagreed with each other as to the merit of their respective systems found the need of social intercourse sufficient reason for the organization of a club where they could meet to apologize for the harsh criticism of each other in business competition—great days those.

"While not a charter member of the club, it is my recollection that early in 1888 I negotiated a loan of ten dollars and got on the waiting list, prepared to make good if elected to membership. I was elected, and I well recall the first meeting which I attended; I sat next to Mr. Aaron Stiles, who persisted in calling me 'sonny.' A paper was read by Mr. George Cutter on the 'Residual Magnetism in an Iron Dollar Spent Foolishly' was the event of the evening, and as I wended my way home I wondered if it would ever be my good fortune to become as proficient in the mystic as our chief entertainer of the evening.

"We enjoyed a hundred other delightful evenings during the life of the club, and among those that I remember best was a little social gathering of the friends of Mr. Kreidler to present to him a hall clock as a wedding gift. Congressman George Shaw of the National Electric Company of Eau Claire, Wis., was the toastmaster, and Mr. Fred Degenhardt made the presentation speech. Shaw was at his very best on this occasion, and we each told 'Bill' how much joy and happiness would be his if we could have our way. Fred, when called upon to make his speech, found us all in swaying humor, and we wept and laughed in turn, as he cared to sway us. Mr. Myron Knapp was the joyful surprise of the evening. He and his bosom friend, Mr. Harry Lucas, sat together at the table. Degenhardt by his eloquence had made them blue unto weeping, and as the toastmaster introduced Knapp as 'our handsomest, bighearted member,' and he arose in all his 'glad garments,' looking for all the world like a born orator, and, gazing steadily at the ceiling in an effort to recall the pleasant words he had thought of earlier in the day, we were warranted in expecting from him a fine oration. Well, he did not orate; he slid back into his seat, saying, 'Oh, pshaw! I can't talk.' Nothing could possibly have been funnier.

"Another pleasant evening was the one on which we tried Professor Badt for stealing some megohms from Fred Horne or some other fellow's field. Alexander Kempt was the judge, wearing the robes of a cardinal; W. J. Buckley was the prosecutor, I was clerk of the court, and the jury was made up of other members. After hearing all of the evidence, most of which was given in dialect, the court took the case from the jury, and fined each juror two dollars.

"At one of our meetings I recall that Mr. Grier put through a motion that all manufacturers of electrical machinery be requested to mark all generators with their kilowatt capacity, and all motors with their horsepower capacity, and we considered that if our request was complied with we had indeed spent a profitable hour in formulating, discussing and passing the motion.

"When the club gave a farewell dinner to S. A. Barton in 1889, nearly every member was present and each member exchanged photographs with Mr. Barton, and many pleasant inscriptions were written on them. Again, when Mr. H. Ward Leonard took his departure, to engage in business in New York, it was the occasion of another very pleasant evening spent in wishing him godspeed, and in singing many of the dear old songs that sound best when sung around the festive board.

"Our billiard and card rooms were the scenes of many contests for supremacy, and furnished much entertainment. Mr. A. L. Ide once told me that he preferred our little club because of the good billiard games we had. W. J. Buckley and George Cummings were our best players, and I have seen them play a great many match games that were really good. Our membership was not a cumbersome one, and an air of good fellowship seemed to prevail at all times.

"Our effort to provide club facilities for electrical men visiting the World's Fair was the beginning of the end of our little organization, and when the end came I was chosen to sell our personal property at an auction held in the club rooms. The proceeds of the sale and an assessment of $136 per member enabled Mr. James W. Johnson, acting as trustee, to pay all of our club debts, and we surrendered our charter to the state. Few technical clubs have had a longer life than ours, and I doubt if any produced more lasting friendships.

"Many of the members are still residents of Chicago, and without exception all have prospered."

Death of J. N. C. Shumway.

J. N. C. Shumway of Taylorville, Ill., died suddenly of paralysis at his home on September 22d. He was 57 years old. Mr. Shumway was a former state senator and, among other activities, was one of the best known and best liked central station men in the state of Illinois. Active in the affairs of the Illinois State Electric Association, he was elected president at the seventh annual convention in Springfield on September 20, 1906. His administration was a successful one, terminating in the recent pleasant annual meeting and outing at Peoria, at which he presided. At this meeting the association expressed its love and esteem for Mr. Shumway by presenting him a handsome gold-headed cane.

J. N. C. SHUMWAY.

For about twenty years Mr. Shumway has been identified with electrical interests. Never of very robust health, he abandoned a profitable law practice to engage in more active outdoor work. Since 1889 he has been secretary and manager of the Taylorville Electric Company, and at the time of his death was also interested in the electric plants at Pana, Jerseyville, Robinson and Mattoon. He was also active in many other business enterprises, having been at the time of his death secretary of the Taylorville Savings, Loan and Building Association and president of the national organization of building and loan associations.

Mr. Shumway was born in Illinois, and except for a few years spent in college and travel lived in Taylorville all his life. He was state senator and was a member of the Illinois commission to the Louisiana Purchase Exposition. Mr. Shumway was progressive and public spirited. He had a pleasing disposition and was a ready speaker and raconteur. He leaves a wife and two daughters and a large circle of sorrowing friends.

Chicago Electrical Show Officers Re-elected.

The annual meeting of the stockholders of the Electrical Trades Exposition Company of Chicago has been held and officers and directors elected. Mr. Homer E. Niesz, who so successfully managed the show at the Coliseum last January, has again been selected to manage the 1908 show, which will be held in the Coliseum on January 13th to 25th. Most of the exhibit space has already been applied for, and a larger and better show than ever is assured.

The officers and directors of the company were re-elected as follows: President, Samuel Insull; vice-president, E. B. Overshiner; secretary and treasurer, Stewart Spalding; executive committee, E. B. Overshiner (chairman), Louis A. Ferguson, Stewart Spalding; directors, Samuel Insull, G. H. Atkin, Stewart Spalding, E. B. Overshiner, George B. Foster, T. P. Gaylord, Louis A. Ferguson, H. B. McMeel, H. V. Bennis.

Arbitration Demanded in Telegraph Strike.

The strike of commercial telegraphers is still unsettled, to the detriment of business in some quarters. There are rumors of possible arbitration as the result of government solicitation. The Chicago City Council this week adopted a resolution calling upon President Roosevelt to use his influence toward an equitable settlement. The resolution says that for nearly seven weeks the telegraph companies have been so hampered that they have had to send messages by mail, and that the companies have expressed a determination to "starve the strikers into submission." It sets forth that the City of Chicago solemnly declares that it is the "duty of these great employers to meet representatives of the striking employes" in order that normal service may be restored.

The City Council of Portland, Ore., has appointed a special committee, with power to retain an expert consulting engineer, to consider the advisability of constructing a system of subways for holding all underground wires and pipes.

FALL TRADE PROSPECTS.

While business men in some branches of the electrical industry do not look for as much activity, possibly, this fall as last, others can see nothing ahead but continued heavy demand, so that the outlook for fall trade may be considered as satisfactory on the whole. Inquiry among the various interests reveals that nearly everyone is doing as much business just now as at this time last year. There are some, however, who feel that the close of this year and the beginning of 1908 will see some decline in the number of new enterprises to be launched and in the extension of present properties, bringing with it some falling off in the electrical business generally.

Several Chicago manufacturers, engineers and dealers when interviewed on the subject pointed to the recent unsettled condition of the copper market and the tendency of the banks to increase money rates as factors which are bringing on a more conservative spirit. Although the price of copper has fallen considerably recently, they say that many contemplated projects have been postponed to await developments in financial circles as well as a possible still further reduction in the price of the metal. One prominent dealer in electrical machinery could see some uneasiness in financial circles which might affect the electrical as well as other industries. The fall in the price of copper, he thought, was due to a lessened demand, brought on by the decision to wait in the construction of many new projects for which there is a good demand.

Public-utility properties, as indicated by the remarks of Mr. O. E. Osthoff and others, are producing more revenue at present than ever before, and there is a demand for bonds of going concerns. Nevertheless the properties of the H. M. Byllesby Company, as an example, will not be extended much for the present, and new construction contemplated will not be undertaken just now. The engineering end of this company's business, as also of other companies, is very active, due largely to the numerous waterpower projects which are being carried out and others in contemplation.

Following are some brief interviews and letters from men in various branches of the electrical industry bearing on the subject of fall trade prospects:

John W. Brooks, general sales manager, Pass & Seymour, Solvay, N. Y.: "We are looking forward to a very brisk and satisfactory business for fall, and while the percentage of increase may not be as heavy as last year, yet we believe it will be a more normal and healthier business."

W. W. Mumma, sales manager, the Robbins & Myers Company, Springfield, Ohio: "Prospects for fall trade in our line are good. The last fiscal year, which closed with us on September 1st, was very satisfactory, and we see no reason now why the trade should not keep up its progress."

A. H. Patterson, vice-president, the Phœnix Glass Company, New York: "Based upon the records of our business for the last eight months of this year and trade conditions at the present time, it is our belief that the closing months of this year will show good business conditions, and a volume exceeding that of last year."

H. G. Pratt, treasurer, Samson Cordage Works, Boston, Mass.: "We think our line is hardly a large enough one to be a very good index on the prospects of fall trade. We are glad to state, however, that we have never had so much business on arc-lamp and trolley cord as in the last few weeks, and we are not as pessimistic as some seem to be in regard to the future."

F. S. Hunting, sales manager, Fort Wayne Electric Works, Fort Wayne, Ind.: "The outlook for trade this fall seems very good in all electrical lines except new enterprises or extensive extensions to existing enterprises which require financing. We look for the business in the way of new enterprises to be rather dull until the financial situation in the country at large is considerably improved."

C. B. Humphrey, acting general manager, Westinghouse Lamp Company, New York, N. Y.: "We anticipate a very prosperous incandescent lamp business during the coming fall months, and, in fact, during the entire year. Our experience indicates that the lamp business is not seriously affected by the ordinary business depressions which apparently are being felt in certain other lines at the present time."

J. G. Ihmsen, general manager, American Electric Telephone Company, Chicago: "The telephone trade during the spring of 1907, both in magneto and common-battery equipment, has been the largest in the history of the Independent business. The spring trade opened in large volume over a month earlier than formerly and continued practically unabated until about July, which was three weeks or more longer than usual. In the months of July, August and September there has been the usual midsummer dull period in the magneto and farm-line departments, but the common-battery branch of the business has been exceptionally good. There are a large number of inquiries now for fall and winter delivery, and if 50 per cent. of the contemplated additions and improvements are consummated it will afford a very brisk demand during the next six months."

Walter Ramsey, manager, American Arc Lamp Company, Kalamazoo, Mich.: "The outlook for fall trade is exceptionally fine. Our August sales exceed the sales of corresponding months during the last nine years. September so far has exceeded by seven times the sales during the corresponding period of September last year. Every indication points to our doing a splendid business this fall and winter."

Charles E. Brown, president, American Electrical Supply Company, Chicago: "Our business, covering as it does both electrical machinery and all kinds of electrical appliances and supplies, should give a good indication of trade prospects. Never before have we done so large a business as at present, and the indications are that it will continue, resulting, of course, in a good fall trade. Our supply business is good and our factory is working to its full capacity."

Willard W. Low, president, Electric Appliance Company, Chicago: "From our viewpoint we cannot see anything but a good, healthy business for the coming fall season. Buyers of all classes of electrical material have been buying for the last six months from hand to mouth, the crops of the country are in elegant condition, and the metal and copper conditions, it seems, are adjusting themselves to a proper level, all of which, in my opinion, point to prospects satisfactory for business."

H. B. Vanzwoll, secretary, Sunbeam Incandescent Lamp Company, Chicago: "It is our opinion that the business in electric incandescent lamps this fall will show an increase of 20 to 25 per cent. as compared with 1906. Possibly the electrical business, as a whole, will not show the same increase as will be the case with incandescent lamps, but we believe there will be a substantial growth, due to several influences, notably the work of the Co-operative Electrical Development Association."

L. L. Brastow, the Trumbull Electric Manufacturing Company, Plainville, Conn.: "We take pleasure in saying that we can see only the best indications for a big fall trade. The volume of business has steadily held up to a month-by-month increase, and we expect 1907 to be by far the best year we have ever had. If the conditions in the money market hold good, as we believe they will, we can see no reason why next year should not be even better. In fact, we have included this expectation in our plans."

Thomas Duncan, manager, Duncan Electric Manufacturing Company, Lafayette, Ind.: "We take pleasure in advising that the outlook has never been better in the history of this company. If the indications of the last four weeks are to be taken as an omen for the coming fall and winter business, we will have to treble our output in order to cope with the demand for our apparatus. Our recent orders for meters call for more than we have been able to turn out; so we have every reason to believe that business is still on the boom."

H. Kimball Loud, H. M. Loud's Sons Company, Au Sable, Mich.: "We sell poles to the trade, and our view of the situation is that there will be a brisk demand for short poles during the closing months of this year. We base this partly on the fact that the summer trade has been very quiet, while now there is quite a demand and an increasing one. We also base this on our former experience in such cases. Cedar, outside of poles, has been in very great demand, our stock of cedar ties and posts being practically exhausted, although we generally have a large stock on hand at this time."

Julian Roe, Chicago manager, Crocker-Wheeler Company, Ampere, N. J.: "Judging from our own business, the electrical industry may look for good fall and winter trade. The month of September, as is always the case, has been rather quiet as regards the booking of orders, but the number of inquiries on hand is unusually large and gives promise of excellent business beginning with the first of October. Last year we did a very large business, but since June each month this year has surpassed the corresponding month in 1906. We would almost wish for a period of quiet so that we could catch up and readjust our forces so as better to meet the growing demand."

J. H. Clapperton, advertising manager, Minneapolis Steel and Machinery Company, Minneapolis, Minn.: "In our estimation, notwithstanding the Wall Street scare, the fall business looks very bright, and indications so far point to a good supply of orders for the fall months. The first eight months of 1907 have shown a substantial increase in our business over the corresponding months of 1906, and we see no indications of its letting up. We generally expect a slack period on the eve of a presidential campaign, but interviews with our trade in general indicate that the coming presidential campaign will not materially affect our line of business. Our different departments are at present well filled with orders for future delivery, and we have been obliged to turn down several orders on account of the crowded condition of our shops. Taking the general conditions all in all, would state that the condition of the western trade looks bright for the fall and winter months."

B. E. Sunny, vice-president, General Electric Company, Chicago: "The outlook for business in the electrical and allied interests for the closing months of 1907 is reasonably satisfactory, particularly when the financial situation is taken into account. There has been a slight falling off in the business during the past few months, and this may continue for several months until there is a market for bonds and other forms of securities. The public-utilities companies are all doing a satisfactory business and a large number of them are in need of additional facilities, orders for which are being withheld until the financial situation improves."

J. H. Parish, advertising manager, Kellogg Switchboard and Supply Company, Chicago: "There appears to be no disposition at present from any quarter to produce an unrest in business circles, except, perhaps, an occasional temporary financial agitation in Wall Street. Prosperity seems to reign supreme throughout the whole country. Collections are passably good, and the general money market, while a little unsettled at times, is firm and easy for all legitimate trade purposes. This favorable condition will, no doubt, continue for a long time, and the Kellogg Switchboard and Supply Company anticipates, as heretofore, a good strong fall business."

Joseph W. Marsh, vice-president and general manager, Standard Underground Cable Company, Pittsburg, Pa.: "Since copper and copper products have dropped in price to approximately the figures at which consumers (whether going concerns or new enterprises) can afford to make capital investment in extensions or wholly new constructions, we consider the outlook for the fall trade in our line at least, fair; and if the financial situation becomes easy we anticipate a very good fall trade. Much, however, depends upon the ability of new enterprises to market their securities at a fair price, and it is very difficult to forecast the future, for even three or four months, in this respect."

E. L. Clark, president, the Valentine-Clark Company, Chicago: "The writer is of the opinion that business is in a much healthier condition at the present time than it was six months ago. Copper is now getting to a point where construction will proceed provided we can get a little easier money market, which, in the writer's opinion, will exist some time about the first of November. There is any quantity of new work that should be done and will be done with an easier money market and copper at a price which will warrant the construction. In our particular line—cedar poles—prices are firm, the long poles holding well to last season's prices; the only instances of decreasing prices are in poles 25 foot and shorter. We are looking forward to considerable business yet this fall."

F. S. Terry, first vice-president, National Electric Lamp Company, Cleveland, Ohio: "If there are no large failures or new trust investigations started business will probably continue good up to spring or summer of next year, when there will perhaps be something of a depression in business, although probably not an actual panic. I believe, however, we are nearing hard times, which will probably be preceded by something of a panic, perhaps not as severe a one as 1893. We may reach it in two years, or it may be delayed four years. If I were to guess I should say that it would come in 1910. However, this is all a guess and may depend a good deal upon chance conditions. If an actual panic is avoided, I believe it will be due largely to the government investigations of railroads and large corporations, which are perhaps a little severe on those investigated and regulated, but such things really make for good, as they cause everyone to do business on more careful lines."

G. H. Rettew, general manager, Helios Manufacturing Company, Bridesburg, Philadelphia: "In general we find the volume of business to be good, but collections are unusually slow. Our opinion is that with some aid from the banks in the way of restrictions of loans the general financial conditions will be improved, and that, while this may restrict purchases somewhat, it will no doubt have a wholesome effect on the general business conditions. Our principal lines are arc lamps and storage batteries, and we find that the volume of trade in both is growing rapidly. We anticipate that the sales of lamps during the next three or four months will be very brisk. The arc-lamp business is growing rapidly, and we look for an increase of 20 per cent. in the value of lamps manufactured during the year 1907, that is, considering all of the lamps manufactured in the country. Of this increase we anticipate securing our share. The growth of the storage-battery business is probably due to the growth of the use of electric vehicles, and particularly vehicles used for pleasure purposes. The manufacture of batteries for this service has become one of our largest items and the department is still increasing in business, although the most active time is during the spring and summer."

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXXV. Electric Railways.

Controllers.

In order to operate a street car, controllers are used which have three functions, namely, to connect the motors into the circuit, to regulate the amount of current which passes through the motor and to govern the direction in which the car travels. Three different methods of control have been in use at different times for street cars, but two of these are now entirely obsolete, and what is known as the series-multiple method of control is now universally employed.

Of the two obsolete methods, one consisted in connecting car motors permanently in series with a special style of resistance box. With this method the speed of the car was varied by simply increasing or decreasing the amount of resistance in series with the motor. The other obsolete method consisted in winding the motor fields with a number of separate coils, which, by means of a controller, could be connected in various combinations from all in series, to all in multiple. This method was quite economical, as no external resistance was used in the circuit except on the starting notch of the controller; but the number of small wires and numerous connections required made this method subject to numerous derangements under the rough usage commonly accorded to street-railway cars.

The series-parallel control, which is now universally used, consists in connecting the motors on a car first in series and next in parallel. In the series position each motor receives half of the line voltage, and in this position the car runs at approximately half speed. In the multiple position each of the motors receives the whole voltage of the line, which therefore operates the car at full speed. The series and the parallel positions of the controller are called the running notches, or, in other words, these two positions of the controller are the ones on which the car can run for an indefinite length of time.

In addition to the running notches, there are seven or eight other notches on which the car should only be run for a few moments until it attains a speed corresponding to the notch in use. These intermediate notches are simply for regulating the amount of external resistance in the circuit. On the starting notch the full external resistance and all of the motors are connected in series. The next two or three notches simply cut out successive portions of resistance until all of the resistance is cut out and the motors are running in series without external resistance.

The resistances used are not of sufficient capacity to be used continuously, and therefore if they are used more than a few moments while the car is accelerating, they are liable to be burned out. Moreover, the continuous use of resistances in the main circuit of the motor is a very uneconomical method of regulation, as a large proportion of the energy consumed on a car would be wasted in heating up the resistances.

After passing the series notch on the controller the motors on the car are then connected in multiple, and all of the resistance is again connected in the motor circuit. During the next few steps of the controller, resistances are again successively cut out until the motors are in parallel without any external resistances in the circuit. This position gives the highest running speed of the car.

Street-railway controllers are made in a large variety of sizes to be used with various sizes of motors, and they may all be divided into four general types. Type R controllers are of the rheostatic type and are used on cars equipped with only one motor, as the series-parallel control is obviously possible only where two or four motors are used. The R controllers simply cut out the resistance gradually until the motor operates on the full line voltage. This controller is also supplied with a device whose function is to change the direction of the car travel. This reversing switch is provided with a separate handle, and its principle of operation will be explained later.

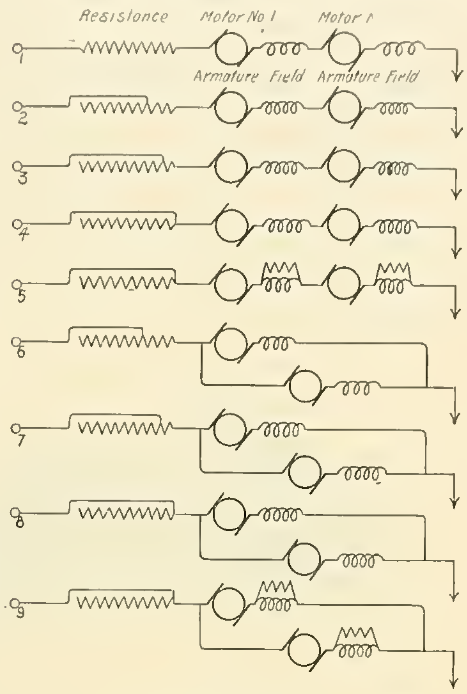
Type K controllers are of the series-parallel type and are the kind used on the great majority of electric cars. A distinctive feature of the type K controllers is shunting or short-circuiting of one of the motors, when changing from the series to the parallel connection, so that the power circuit through the car is not broken.

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

Type L controllers are of the series-parallel type, but differ from the type K controllers by completely opening the power circuit of the car when the change from series to parallel position of the motor is made.

The fourth type of controller is known as type B, which, in addition to its function of controlling the motors, has a number of additional contacts which operate an electric brake. The electric braking is sometimes accomplished by means of the ordinary brake-shoes electrically operated and in other cases by connecting the car motors so that they operate as short-circuited generators.

All of the series-parallel controllers are very similar in their general design, and consist of a vertical spindle which is revolved by means of the controller handle. Upon this spindle are mounted contact pieces in the shape of segments of circles. At one side of the controller is a row of contact



TYPICAL DIAGRAM OF CONNECTIONS OF A SERIES-PARALLEL CONTROLLER.

fingers to which the wires from the armature, field and resistances are connected. These fingers are connected in various combinations by means of the contact pieces upon which they bear.

Also contained in the controller is a second vertical spindle provided with contact pieces upon which another set of fingers bear, the object of which is to govern the direction of motion of the car. This is known as the reverser, and its function is to change the direction in which the current flows through the motor armatures. The reverser is operated by means of a small handle upon the top of the controller, which has three positions. When it is pushed forward the car runs in a forward direction. When it is pulled to its extreme backward position the car runs backward, and when it is in a position midway between these two, it opens the circuit of the car so that the motors cannot be operated at all. The main controller handle can only be removed when the reverser handle is in the "off" position, and an interlocking device is arranged so that the reversing handle cannot be moved except when the main controller handle is in the "off" position. The same interlocking device also prevents the main controller handle from being moved except when the reverser handle is fully thrown to either the forward or backward running position.

Cut-out switches are located in the lower part of the controller, so that in case of accident to either motor on the car the defective motor may be cut out of circuit and the car operated with the remaining motor. When operating with a single motor the car will reach its full speed on the full series position of the controller, and the cut-out is provided with an interlock which prevents the controller handle being moved past the series position when either motor is cut out.

The accompanying diagram shows the connections of the motors and resistance on each step of a series parallel controller having five series and four parallel running points.

In the first position the current passes through all of the resistance and through motors No. 1 and No. 2, all connected in series.

On the second notch the connections are nearly the same except that two thirds of the resistance is cut out.

On the third notch still more of the resistance is cut out, and on the fourth notch the resistance is entirely cut out, and the two motors are still connected in series.

As no current is being wasted in resistance on the fourth notch, the car may be economically run on this speed as long as desired, and it will run at a little less than half of its maximum speed.

On the fifth notch a connection is made which shunts part of the current around the field coils. This has the effect of weakening the field and increasing the speed of the motors, and in this position of the controller the car will operate at just half speed.

In passing from the fifth to the sixth notch the motors are changed from series to multiple connection, so that each motor receives the full trolley voltage, but in order that the change of speed may not be too abrupt, part of the resistance is introduced into the circuit with the two motors in parallel.

On the seventh notch most of the resistance is cut out of the circuit, and on the eighth notch the resistance is entirely cut out of the circuit, so that the motors receive the full line voltage and operate at nearly full speed.

On the ninth notch a connection is made similar to that on the fifth notch, that is, part of the current is shunted around the field of each motor and the car is operated on this notch at its highest speed.

This diagram is characteristic of all the series-parallel controllers, although some of them have two or three notches which cut out the resistance in smaller steps. In all of these controllers, however, the only points of the controller which should be used for continuous running are those points in which the resistance is entirely cut out of circuit.

The L type of controller is somewhat similar in appearance to the K type, but is considerably larger, and its handle operates in a counter-clockwise direction, which is just opposite to that of the K type. During the first half revolution the controller passes through the series points up to the full series position of the motors, and in order to throw the motors into multiple position the motion of the handle is continued in the same direction around past the "off" position, and again passes over what were the series notches on the first revolution. During the second revolution, however, the motors are connected in multiple, and after the handle has passed through one revolution and a half the motors are in full multiple connection and the car operates on its highest speed. An indicator on top of the controller shows whether the motors are in series or in multiple.

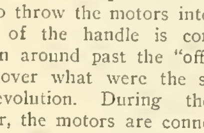
The B type controllers are those which are used in connection with electric brakes. Some of these controllers have two handles, one for operating the power and the other for the brake, while in others only one handle is used, which is moved to one side of the "off" position for operating the power and to the other side of the "off" position for operating the brake.

A feature of all of these controllers which has not been mentioned is the magnetic blow outs which are used to prevent the destruction of the contact by arcing. Arc shields are used, which extend between each row of contacts to prevent an arc from jumping from one row of contacts to the next. The action of the blowout coils was explained in the chapter on lightning arresters.

[*To be continued.*]

The "Chicago" Grip.

Mathias Klein & Sons, 81 West Van Buren Street, Chicago, have just placed on the market their new "Chicago" Grip, which is illustrated here-



"CHICAGO" GRIP.

with. This tool is made of steel throughout and is nickel plated. It is said to be just the right shape to handle quickly, is light, and when placed on the wire will hold itself in place. It can be pushed out on the wire so as to take up as much slack as necessary. It pulls strongly, leaving no kinks in the wire. It is said to cover all the essential points required of the grip to do good work on either iron or copper wire. This grip, as well as all the other well-known Klein products, is carried in stock by prominent supply houses.

Suction Producer Gas as a Means of Generating Power.

By J. H. Clapperton.

In 1881, at the York meeting of the British Association for the Advancement of Science, the late Sir Frederick Bramwell, a prominent member, made the prophecy that in 50 years the steam engine would have been replaced by the gas engine. This prophecy was based on the performance of a small three-horsepower gas engine exhibited at the meeting in connection with the first Dowson power gas producer.

Since that time, and particularly in the last few years, many important changes and improvements have been made in the gas engine as well as in the gas producer, bringing producer gas forward to become an important factor in the modern industrial life. Yet it would be venturesome to subscribe today to the memorable prophecy of 26 years ago, even in full view of the fact that the gas engine is speedily gaining ground on its more wasteful competitor.

What is likely to prove to be the saving factor in the future career of the steam engine is, curiously enough, its very wastefulness, because just as long as conditions prevail in which the waste during transformation of heat energy into power—the latent heat in the exhaust steam—can be continuously and fully utilized to advantage, just so long is the steam engine likely to find its peculiar field of usefulness. But whenever the main or exclusive object is the generation of power from available fuels, then the gas engine may be depended on to be the more efficient motor. To be sure, the heat in the exhaust gases from the gas engine can also be utilized for heating purposes, to a limited extent, either by heating from the gases directly or indirectly, by absorbing the heat value into hot water or steam. However, as the gases contain very much less heat value than the exhaust steam from a steam engine of the same power, they can of course not be counted upon to give but a small percentage of that obtained from the steam engine.

That in principle the transformation of heat into power is more efficient in the gas engine than in the steam engine is recognized and readily proved by the established absolute efficiency of a perfect heat engine expressed by the formula:

$$\frac{T_1 - T_2}{T_1}$$

T_1 and T_2 being the absolute initial and final temperatures of the working charge.

By inserting in the above formula the available extreme temperature limits, the numerical value of the absolute thermal efficiency becomes:

$$\text{For the gas engine } \frac{2{,}160 - 560}{2{,}160} = 74 \text{ per cent.}$$

$$\text{For the steam engine } \frac{872 - 560}{872} = 36 \text{ per cent.}$$

That is, assuming that the temperature of the working charge would be raised in the gas engine cylinder, as it normally is, through compression and combustion, from a temperature of 100° F. to an initial temperature of 1,700° and expanded in the cylinder until its temperature again becomes 100°, then the total efficiency of the heat transformation would be 74 per cent. Similarly, assuming that steam is raised in the boiler from water of a temperature of 100° F. to the initial temperature 412° (corresponding to a pressure of 250 pounds), and that it is expanded in the engine cylinder the entire range down to the temperature at which the cycle started, 100°, then the total efficiency of the engine becomes 36 per cent.

However, these ideal efficiencies of respectively 74 per cent. and 36 per cent., based on the assumption of a perfect heat transformation, can in reality never be obtained, and the object of their citation here is simply to show the comparative ultimate limit for the economy of the gas engine and of the steam engine, due to the difference in the range of temperatures between which they operate. But, should we reduce the above percentages to about one-half of their ideal value, then they will represent fairly the maximum thermal efficiencies that have been obtained in reality, or for the gas engine 37 per cent. and for the steam engine 18 per cent.

The combined efficiencies of the producer gas engine and producer and of the steam engine and boiler will, of course, be somewhat less than the percentages just quoted, which apply for the engines alone, and, as the process of gasifying the fuel in a good type of producer returns readily 80 per cent. of the heat value of the fuel, while an efficient boiler returns only a maximum of 70 per cent., the total useful effect obtainable from the coals consumed will be, for the gas engine 29 per cent. and for the steam plant 13 per cent. That is, the total returns in power from the heat value of the fuel are in the gas plant fully twice that of the most efficient steam plant, such a one we may say as includes in its equipment a compound or triple-expansion condensing engine. Furthermore, the efficiency of the gas engine varies very little with the power, size or type of the engine, whereas the efficiency of the steam engine varies considerably. On this account it will be found that the actual coal consumption per horsepower is in the gas plant often materially less than one-quarter of that of the average well-equipped steam plant.

The chemical reactions on which the operation of the gas producer is based are very simple and should be carefully considered by anyone wishing to obtain efficient results in its manipulation. The first reaction taking place in the lower part of the fuel bed is the combustion of carbon, C, into carbon dioxide gas, CO_2; the second is the reduction of this gas into carbon monoxide gas, CO, as it passes up through the incandescent fuel bed, and the third is the decomposition of steam in contact with carbon of high temperature, resulting in the formation of hydrogen, H, and carbon monoxide, CO.

The first reaction is expressed chemically by the formula:

$$C + 2O = CO_2.$$

The information conveyed by this formula may be expressed by stating that for the complete combustion of one pound of carbon there is required $2\frac{2}{3}$ pounds of oxygen, and the resulting carbon dioxide gas will weigh $3\frac{2}{3}$ pounds. During the complete combustion of each pound of carbon there is generated heat to the entire heat value of the fuel, or about 14,500 heat units.

The second reaction taking place in the producer is expressed by the formula:

$$CO_2 + C = 2CO.$$

That is, the previously formed $3\frac{2}{3}$ pounds of carbon dioxide takes up one pound more of carbon, forming $4\frac{2}{3}$ pounds of carbon monoxide, or per pound of carbon consumed we obtain $2\frac{1}{3}$ pounds of carbon monoxide gas.

The first two reactions in the gas generator, in combination commonly called incomplete combustion, result in the combustion of carbon to carbon monoxide gas, and during the process there is developed heat to the total amount of about 4,500 heat units, or less than one-third of the heat value of the fuel. This heat will appear as sensible heat of the gases and of the fuel bed. The carbon monoxide gas formed can at any time after it has left the furnace be made to again combine with oxygen to the same amount as that which it already contains, in doing which it will generate more than twice the heat developed at its formation in the furnace, or about 10,000 heat units.

The proportion of oxygen, O, to nitrogen, N, in the air being in the ratio of one pound of oxygen to 3.35 pounds of nitrogen, and as for each pound of carbon consumed there has been introduced in the furnace $2\frac{2}{3}$ pounds of oxygen, the $2\frac{1}{3}$ pounds carbon monoxide gas obtained from each pound of carbon must therefore be diluted by 4.46 pounds of nitrogen. But, nitrogen being an inert gas and carbon monoxide of low calorific value, it is evident that the gas mixture resulting from the first two reactions of the process in the generator and which is the main constituent of producer gas must be a lean fuel gas.

In the power gas producer the object is to generate combustible gas of as high heat value as possible, but any sensible heat is not required for the process, excepting to the amount necessary to maintain the temperature of the furnace at such a degree that the formation of gas takes place readily. All that is required, therefore, for the formation of combustible gas in the producer is to supply it with the amount of air only that is necessary for the combustion of carbon to carbon monoxide gas. As, however, during this gasification sensible heat is generated to the amount of 4,500 heat units per pound of coal, and as only part of this heat, about 2,000 heat units, is carried off with the gases, or dissipated through radiation, there will be a surplus of heat, about 2,500 heat units per pound of coal consumed, that must be carried off from the furnace in order not to overheat the same as the process of gasification proceeds. This surplus of heat can be utilized in a most effective and desirable manner simply by introducing steam in the furnace.

The circumstance that steam is subject to decomposition in its constituent elements, oxygen and hydrogen, when in contact with incandescent carbon of sufficiently high temperature, gives cause to the third reaction in the gas generator, which is expressed by the formula:

$$H_2O + C = 2H + CO.$$

That is, each pound of steam, when heated to a high temperature in presence of carbon, will liberate 1-9 pound of hydrogen, and the 8-9 pound of oxygen which it contains will combine with ⅔ of a pound of carbon to 1 5-9 pounds of carbon monoxide gas. It will be seen by the formula for this reaction that in the gasification of carbon by means of steam no inert nitrogen is introduced in the furnace, contrary to the occurrence in case that air is employed, and as the nitrogen, which dilutes the resulting gas, if of no value as far as the heat value of the gas is concerned, it is evident that the more oxygen that can be obtained for the combustion of carbon by decomposition of steam the richer in heat value will the generated gas be. However, as for the decomposition of each pound of steam there is required to be supplied heat to the amount of 6,800 heat units, which is absorbed into hydrogen liberated, and, as for each pound of carbon burned into carbon monoxide gas only a limited amount, about 2,500 heat units is available, it is evident that not more than about 0.36 pound of steam can be decomposed per pound of carbon without cooling the furnace unduly.

Now with 0.36 pound of steam yielding at its decomposition 0.32 pound of oxygen, which combines with 0.24 pound of carbon to carbon monoxide, we may say that somewhat less than one-quarter of the total carbon can be gasified by steam, using for the decomposition the surplus heat from the incomplete combustion only. The weight of hydrogen realized will be one-eighth of the weight of steam decomposed, or 0.05 pound per pound of coal gasified.

If a certain percentage of the carbon dioxide gas, at first formed in the generator, is not reduced by the incandescent fuel bed to carbon monoxide, but is allowed to escape with the fuel gases, then a greater amount of heat will be available for gasification of steam and for the formation of hydrogen, resulting in a gas in the same proportion richer in heat value. It is generally the case that some carbon dioxide will be found in the producer gas. In fact, it has, through experiments, been found impossible to reduce the last four to six per cent. of the carbon dioxide, excepting at extremely high temperatures and slow rate of gasification. A suitable amount of moisture must therefore always be supplied for decomposition and for the absorption of the surplus heat in the liberated hydrogen, as otherwise there will be a loss incurred on the account that the gases will pass off hot and the sensible heat be dissipated at the subsequent cooling of the gas. Too much steam must, however, not be admitted, as this will cool the fuel bed unduly and superheat, instead of decompose, the steam which will subsequently be condensed in the cooling process.

The percentage of fixed carbon, moisture, volatile matter and ash in coals varying considerably, it is evident that the amount of steam required to be supplied for different fuels must also vary to the same extent. In practice it is generally found that an anthracite suction producer requires 0.3 to 0.4 pound of steam per pound of coal gasified and that it gives a gas normally of a heat value of about 135 heat units per cubic foot of the average composition as follows:

	Per cent. volume.	Heat value per cubic foot in heat units at atmospheric pressure and 60 deg. Fahr.
Carbon dioxide CO_2	2.5	0
Carbon monoxine CO	28.0	96
Hydrogen H	9.0	31
Marsh gas CH_4	1.0	10
Nitrogen N	59.5	0
		137

The heat value obtained per pound of fuel gasified will be:

	Heat Units.
In the carbon monoxide gas	10,000
In the hydrogen reclaimed from the heat of gasification	2,500
Additional heat obtained if 1% of hydrocarbons are present in the fuel	100
Total heat value	12,600

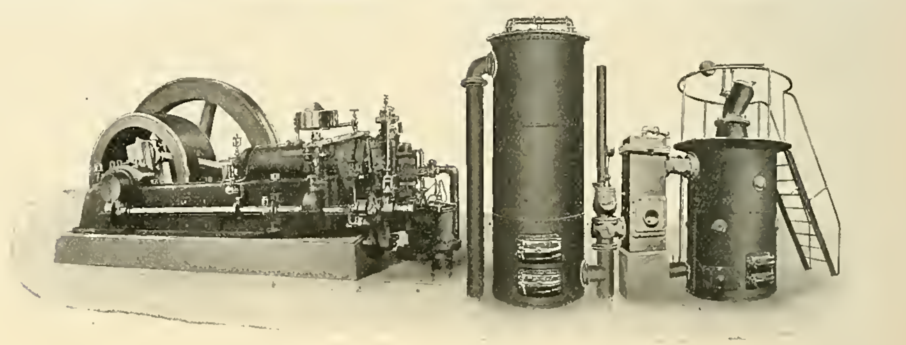


FIG. 1. MUENZEL SUCTION GAS PRODUCER AND GAS-ENGINE PLANT.

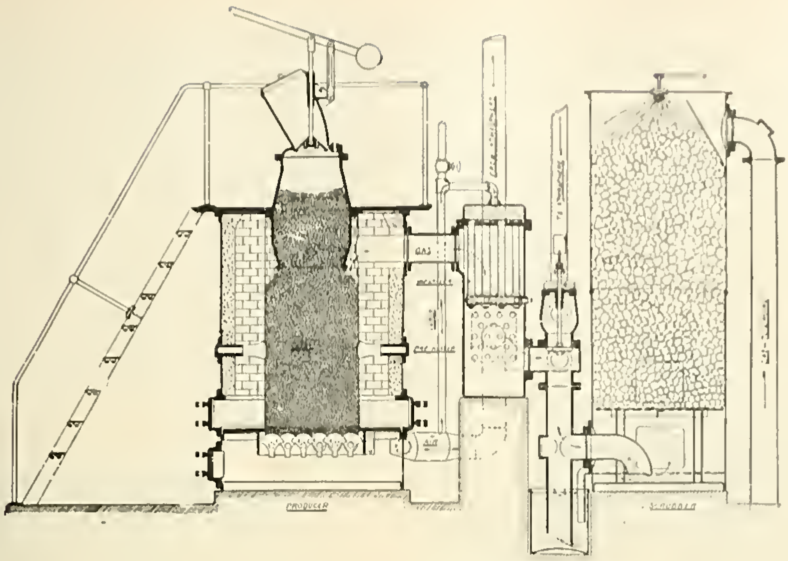

FIG. 2. SECTIONAL VIEW OF MUENZEL SUCTION GAS PRODUCER.

The actual heat value obtained in the gas is thus 87 per cent. of the heat value of the fuel, or if some waste of fuel through the grates and other minor losses are taken into account we may say that the actual efficiency of the producer is 80 to 85 per cent.

From the preceding detailed account of the processes taking place in the gas producer it may appear a rather difficult matter to control the various conditions that are required for an even and continuous formation of gas. This is, however, not so. A moderate amount of intelligent attention to the fire will keep it in a condition to permit the products of combustion to flow freely over the entire area of the incandescent fuel bed, which is one of the essential requirements for obtaining good gas. As to the adjustment of the proper amount of steam to be admitted to the fuel, this readily takes care of itself in a well-constructed apparatus, because the simple requirement that the vapor supply be increased as the sensible heat of the fuel bed increases is automatically filled by the tendency of the greater heat of the gases passing through the vaporizer to generate and supply a more plentiful allowance of vapor to the ash pit.

The construction of the suction gas producer, the type most frequently used at present for power purposes, may be seen by referring to Figs. 1 and 2, which represent the Muenzel suction gas producer, built by the Minneapolis Steel and Machinery Company. The producer is shown in a detailed sectional view in Fig. 2. The producer consists of a cylindrical air-tight steel shell, provided at the proper height with a rocking grate, and is lined above the grate level with a substantial fire-brick lining. At the top is the cast-iron feeding hopper and charging bell and below this the magazine in which the fuel is preheated by the gases before it descends upon the incandescent fuel bed.

The gases generated in the producer are discharged through a change valve into the scrubber, in the smaller sizes, and into the separate vaporizer in the larger sizes. The vaporizer in the smaller sizes consists of a steel pan forming the upper part of the producer body, but in the larger sizes it is found preferable to use the form shown in Fig. 1. This vaporizer consists of a proper number of water tubes connecting a steam heater and a waterlog placed in a suitable gas flue, which conducts the hot gases from the producer through the change valve into the coke scrubber. In this gas flue are also arranged heating tubes for preheating the air supply which is drawn from outdoors to be supplied to the ash pit. The change valve affords an outlet for the poor gases that are formed in the producer when blowing up and starting the fire. The scrubber, which has for its object the cooling and cleaning of the gases on their way to the engine cylinder, consists of a large cylindrical steel vessel filled with coke, over which water flows from the strainer nozzle above, while the gases ascend slowly from below and are, due to the large contact surface between them and the water, effectively freed from any dust or tar that they may carry over from the producer. After the gases have passed the coke scrubber they are sometimes, when generated from certain tarry and less suitable fuels, carried through a sawdust purifier for abstracting the last traces of tar. This is, however, not necessary when running on fuel of ordinary quality, but the gases are generally carried from the coke scrubber direct to the expansion tank and engine.

The expansion tank is simply a gas-tight vessel placed close to the engine for storing some volume of gas, thereby counteracting the pulsations in the gas line that in other cases would be noticeable, due to the periodical suction of the engine piston. The expansion tank serves also the purpose of effectively draining off any water that, in the form of vapor, may be carried with the gas.

The two-cycle engine, in the beginning of the gas-engine era, promising much, has more and more given way for the greater simplicity and compactness of the four-cycle engine. Even disregarding the greater complications of the former type of engine, and considering only the fact that in it the fluid velocity of the admission and exhaust gases are about eight times as great as in the four-cycle type, with consequently greatly increased fluid friction losses, it can readily be expected that the mechanical efficiency of the two-cycle type of engine should be considerably lower than that of the four-cycle type. That actually such is the case has also been satisfactorily proven by numerous records from gas-engine tests.

The Muenzel producer gas engine is of the single-acting four-cycle type for smaller or medium power and of the double-acting four-cycle type for large power.

The single-acting type is particularly suitable for engines of 25 to 160 horsepower in single units and for twice these powers for two engines connected in parallel to one shaft. The four-cycle double-acting type, in single or double units, is recommended for power requirements above those mentioned.

Fig. 3, representing a longitudinal section of the Muenzel gas engine, shows a very simple and compact construction in which it would appear that the various requirements for a successful service have been adequately filled.

The governing of the Muenzel engine, as in most of the modern engines, is accomplished by throttling a charge of constant mixture. Different methods of governing have been proposed from time to time, as, for instance, the varying of the gas mixture for different loads, the changing of the point of ignition, or the changing the point of ignition in combination with the throttling or varying of the cut off of the gas. All these methods have appeared very promising at first, but have failed to effect any marked advantage in the realization of a higher efficiency through the greater complications they involve.

Outside of the "hit-and-miss" governing, which has been found to cause serious fluctuations in the speed of the engine, any of the common devices for governing the gas engine may, in connection with a suitable flywheel, be relied upon to give a very close regulation, which is most important in connection with certain kinds of service, such as flour milling, electric-light service, etc.

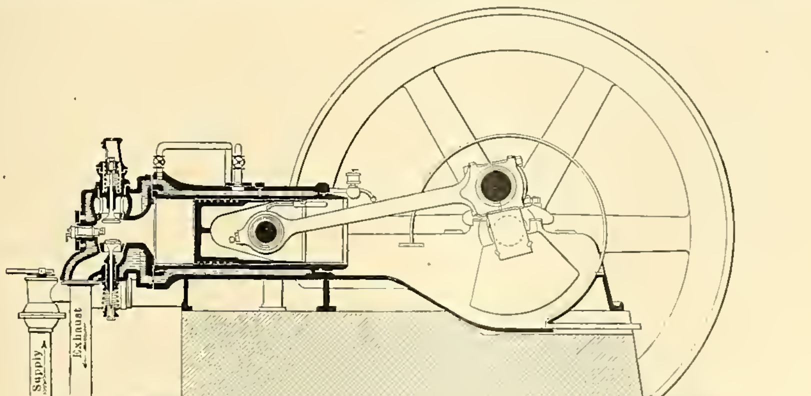

FIG. 3. LONGITUDINAL SECTION OF MUENZEL GAS ENGINE.

Suspension Insulator for High-voltage Transmission.

A suspension type of insulator, as shown in the accompanying illustration, has been designed and placed on the market by the Locke Insulator Manufacturing Company of Victor, N. Y. It was developed by J. V. E. Duncan, electrical engineer for Sanderson & Porter, New York, and W. T. Goddard, electrical engineer of the Locke company, and is believed to possess many advantages over the regulation pin-supported type of insulator for very high potentials, as used in modern power transmission.

NEW SUSPENSION-TYPE INSULATOR FOR HIGH-VOLTAGE TRANSMISSION.

The insulator is said to have an ultimate mechanical strength ranging from 10,000 to 12,000 pounds. The insulator element is made up of two pieces of porcelain—a short inner shell and an outer flaring shell. These shells are tested individually at a potential of approximately 60,000 volts before assembling, and the assembled element is tested at a potential in excess of 90,000 volts for a period of five minutes.

Great mechanical strength and low cost are claimed for the insulator. Being made up of a series of individual elements, it is extremely unlikely that the breakdown of one element will throw the line entirely out of service. The transmission line may be run with one unit, and the insulating element increased, at nominal erection expense, to at least 100,000 volts, as the increase in the transmission voltage may determine. In difficult localities one or more of the units can be carried about, thus taking advantage of the element of portability. The liability to puncture from damage is reduced, because of the wider separation between the earth and the conductors.

The Locke Insulator Manufacturing Company is just completing the engine and generator room of its 600-horsepower power house, brick and concrete; has just completed an addition to its testing facilities for cemented insulators, doubling the capacity, making it 1,800 terminals in all, and is building a brick fireproof transformer house in which will be installed, at the present time, five high-tension transformers, all of 200,000 volts and over.

Influence of Bearings on Accuracy of Integrating Watt-hour Meters.

By H. W. Young.

To the average purchaser or user of integrating watt-hour meters the subject of bearings is of keen interest in that it is quite generally appreciated that this element has a very marked influence upon the accuracy obtainable. Frequently, however, the subject is considered as being settled when it is learned that the meter to be purchased has a "jewel" bearing, and no effort is made to ascertain the kind of a bearing employed, its design, construction or arrangement.

The fact that a meter has a jewel bearing is far from being a guarantee that the accuracy obtainable is all that the purchaser has a right to expect, and it is the purpose of this article to point out some of the effects of imperfect meter bearings, their remedy, and illustrate a form of bearing which has proven to be eminently practical and reliable, a bearing which, with our present knowledge of meter designing, appears to offer a permanent solution of what has been a perplexing problem.

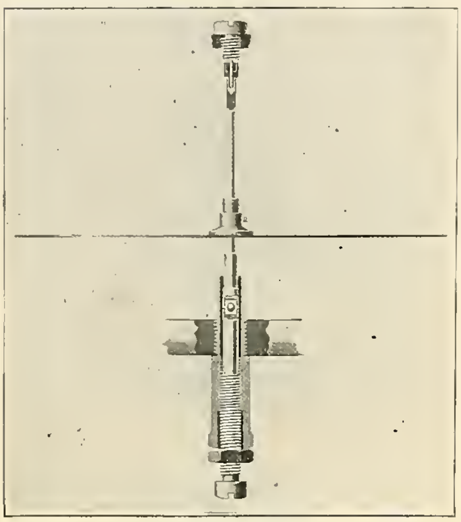

FIG. 1. COMPLETE MOVING ELEMENT OF SINGLE-PHASE INDUCTION METER.

In considering the possible effect of imperfect or improperly designed bearings it should be remembered that we are practically dealing with a miniature direct-connected motor-generator set in which the voltage and current elements of the meter are considered as the motor element, and the retarding disk and permanent magnets as a magneto-generator with a short-circuited disk armature.

The work expended by the motor is absorbed in two ways—first, in driving the generator, and, second, in overcoming friction. In a perfect meter or motor-generator, friction would be absent and all the work would be expended in driving the generator, in which case a direct ratio would exist between the disk speed and the energy passing through the motor system, thus insuring a meter accurate throughout its entire range.

Owing to the fact that a certain amount of bearing surface must necessarily be present in any meter design, it is impossible entirely to eliminate friction, but it will be seen that as the design becomes more perfect a meter is produced in which the ratio between the work expended usefully in driving the disk or armature of the generator and that expended in overcoming friction is high.

With a full knowledge that in order to produce an accurate meter it is necessary so to design and distribute the various elements as to secure a large expenditure of constant work or retarding torque in the disk, as compared to the variable or friction work, the designer has two courses open. The easier method is to increase the driving torque by using a heavier disk, thus decreasing its resistance to the induced current flow by expending a greater amount of energy, thereby increasing the watt losses in the measuring coils, or by employing both of these methods.

The second and by far the preferable method is refinement of design. This entails careful calculation and design of the measuring system, a light moving element, a light running register and a lower bearing of such construction that it will have a minimum amount of friction or wear.

Friction in meters has its greatest effect at the lower end of the calibration curve, or at light loads, and, as a meter is normally operating at this part of the curve for a large part of the time, it will easily be apparent that a commercial meter must be so designed as to give and maintain a high degree of accuracy at light loads.

In striving to secure the most efficient design of lower bearing, designers have experimented with practically every substance having a homogeneous hard composition and with pivots of various materials and forms. As a result of these efforts the "roller" or ball bearing has been developed to such an extent that it undoubtedly offers the least friction, has the largest useful life, and has solved what at one time seemed almost an insurmountable difficulty, namely, the production of an integrating meter which would hold its initial accuracy for a period of several years.

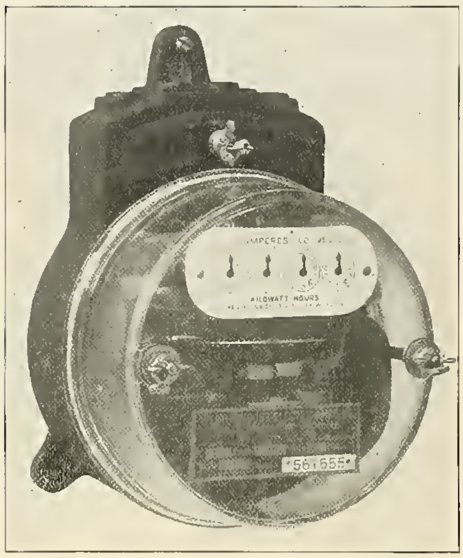

FIG. 2 SINGLE-PHASE INDUCTION METER WITH BALL BEARINGS.

Fig. 1 illustrates a complete meter movement provided with this improved form of bearing, which consists of a highly polished and hardened steel ball resting between two cupped sapphire jewels, one of which is mounted on a removable jewel screw and the other in a removable sleeve attached to the end of the disk shaft.

The action of the bearing is as follows: As the disk rotates the ball moves from its initial position, thus giving a rolling action rather than the straight rubbing action found in the older form of bearing. A changing point of contact between bearing surfaces is thus secured and insures minimum wear, a lower friction value and longer jewel life, than can possibly be secured by the older forms when combined with a light-weight rotating element.

To many unacquainted with the action of the improved bearing it may seem that this change of contact surfaces is questionable, and they may be led to believe that the action does not really occur but merely results in spinning of the ball on its jewel centers, thus giving two points of friction contact and in reality resulting in a greater total friction than would be found in the older form of bearing which had but one point of contact.

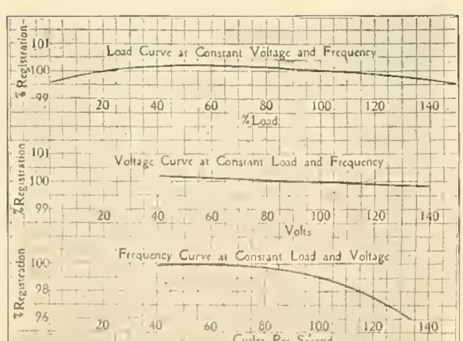

FIG. 3. CHARACTERISTIC CURVES OF INDUCTION METER.

Theoretically, a spinning rather than rolling action of the ball is possible, but to bear out this theory it is essential to have a condition impossible to obtain or maintain commercially, namely, an absolutely perfect alignment between the upper and lower jewel centers. This condition would hold the ball in practically its initial position, resulting in spinning on one or both of the jewel centers.

It is obviously impossible, however, to secure this condition of perfect alignment, owing to inevitable variations in jewels, screw threads, machine drilling of holes and magnetic side pull of the disk in seeking a magnetic balance. Any of these conditions will throw the jewels slightly out of alignment, and with centers a trifle off it will be seen that the ball must roll or revolve. Other factors which induce the rolling effect are external or internal vibration—external, from the support to which the meter is secured, internal, due to the slight disk vibration in the magnetic field. Examination of a ball which has been running in jewels containing a small quantity of dust or cutting material will show it to be surface scratched all over, another proof that it has rolled.

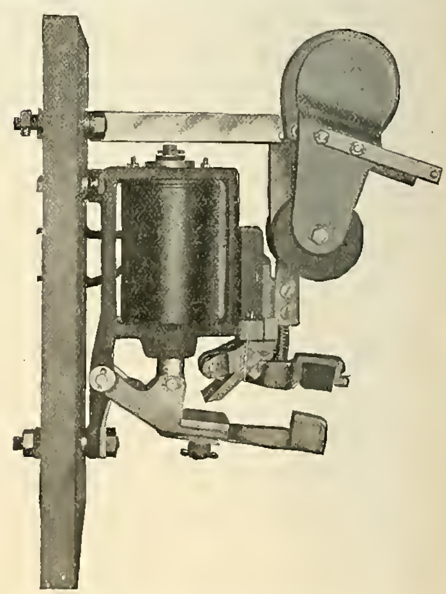
A large number of actual tests extending over a period of several years has fully demonstrated the superiority of this form of bearing. In one instance it was deemed advisable to secure absolute data on jewel life, and a considerable number of meters were put on jewel-life test, this test consisting of loading the meters slightly above full load and running them under actual service conditions over a period of three years, meaning approximately 10,000,000 revolutions of the disk (equivalent to 3,000 kilowatt-hours, or approximately 10 years of ordinary house service).

The meters were then tested and all found to be within two per cent. at full load; and one-half the meters within two per cent. at two per cent. of load. None of the remaining meters showed errors exceeding five per cent. at two per cent. load. This decided improvement in bearing construction with its attendant increase in meter accuracy means much to central stations, as it not only insures increased revenue but also effects a marked reduction in maintainance costs.

Fig. 2 illustrates a single-phase induction meter equipped with ball bearings and Fig. 3 illustrates the characteristic curves. As a matter of interest it might be stated that in addition to the refinement in bearing construction, the mechanical and electrical design is such that the moving element weighs but 15 grammes, the full load torque is approximately 42 gramme millimeters, the watt loss is but 1.6 watts and the ratio of torque to weight, 2.8.

A New Contactor for Heavy Duty.

The Cutler-Hammer Manufacturing Company of Milwaukee, maker of electric controlling devices, has recently placed on the market an improved type of contactor designed for handling main-line currents where the nature of the service is severe. In such cases, the company points out, controllers employing sliding contacts cannot be relied upon to handle the main-line current, and it is customary to employ a controlling panel consisting of a number of contactors, this panel in turn being controlled by a master controller designed to regulate the secondary current which energizes the solenoids of the contactors.



A NEW CONTACTOR FOR HEAVY DUTY.

The contactor here illustrated is a compact and strongly constructed piece of apparatus, and is provided with an exceptionally powerful blowout magnet. The main-line circuit is closed by the solenoid raising a pivoted arm carrying a thick copper plate to a point where contact is made with a pair of stationary, laminated copper brushes. Arcing on this contact is prevented by providing an auxiliary copper and carbon contact in the field of a powerful blowout magnet, which instantly extinguishes the arc incident to the breaking of the circuit. This auxiliary contact closes before the main contact is made and opens after the main contact is broken, thus effectually preventing any sparking on the main contact.

A noteworthy improvement is the pivoting of the blowout shields, permitting these to be raised (as shown in illustration), so as to expose the auxiliary carbon and copper contact. In earlier types of contactors these shields were rigidly fastened to their normal position, completely covering the copper and carbon contacts and rendering access to these difficult. The present construction makes renewal of either contact or of the coiled spring (visible just above the carbon contact) a matter of a few moments only. At a recent test at one of the largest Pittsburg steel mills a 220-volt circuit was opened and closed by a contactor of this type 88,000 times before renewal of the copper and carbon contacts became necessary, and—on a test to determine time required for repairs—the old contacts were removed and new ones inserted in less than two minutes.

A Clearing House for Second-hand Machinery.

A business which has sprung up in the West during the last 15 years and is now said to be the largest of its kind in the world, is that of the Gregory Electric Company of Chicago, a strictly Chicago institution, typical of Chicago methods and growth, able, through Chicago's central location and unequaled shipping facilites, combined with its own excellent methods and organization, to reach all over the continent and transact business with profit to itself and its customers. Speaking of the nature of the company's business, one of the officers called the establishment the "clearing house for America's second-hand electrical machinery."

Testing Department.

Machine Shop.

Warehouse.

Direct-current Motors.

A CLEARING HOUSE FOR SECOND-HAND MACHINERY.

Where does all the machinery sold by the company come from? For one thing, the company has been circularizing every central station in America, and practically every large manufacturing plant using electrical power, for years, and being a large and consistent general advertiser, the name "Gregory Electric Company" has become a household word in the electrical fraternity, identical with second-hand apparatus. Another source of supplies for the Gregory Electric Company is created when large installations are contemplated. In increasing the capacity of a central station, or changing over of an entire power circuit from one voltage to another, or from direct to alternating current, the Gregory Electric Company is frequently called upon to submit offers to competing manufactnrers on the present equipment, to be delivered as soon as the new apparatus is installed; and in this way the office of the company becomes a storehouse for information, and its works a genuine clearing house through which all of this apparatus passes, prepared for new purposes and new destinations, but cleared of defects in the meantime.

Accompanying are a few views taken in this company's works showng their size and the large stock carried. The works are well located in the heart of the shipping district of Chicago, with a branch of the Chicago, Burlington and Quincy Railroad running directly into the grounds and buildings. The works are equipped with powerful electric traveling cranes and a complete lighting, heating and power plant, thus reducing the cost of handling to a minimum.

The management of this company is in the hands of progressive and aggressive people, always on the alert for improvements and advancement. The officers are: President and general manager, A. Louis Kuehmsted; vice-president and manager of sales, A. O. Kuehmsted; general superintendent, J. D. Zook; secretary, George C. Besold. These gentlemen are favorably known wherever electrical current is used.

It has been a long step from the original small 20 by 150-foot shop at 47 South Jefferson Street, where every piece of machinery had to be moved by hand, to the modern equipment of the present works. It shows that this company has kept pace with the growth and importance of Chicago as the great central market, and as Chicago's business increases and expands, this company will no doubt continue an important factor in matters electrical.

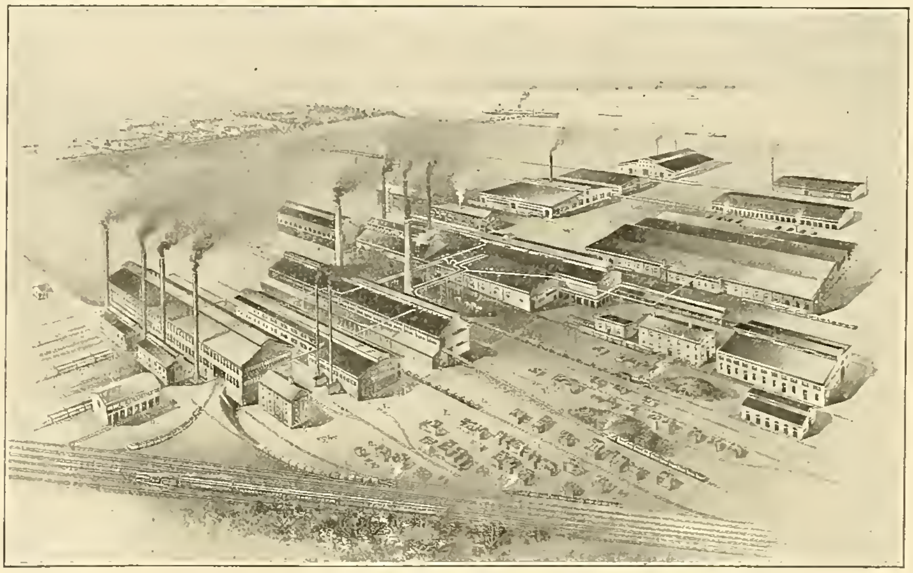
Kinkora Works of Roebling Company.

An important addition has recently been made to the works of John A. Roebling's Sons Company which will materially increase the company's facilities for the production of wire and wire rope. The addition, which is a complete plant in itself, is located about 10 miles south of the main works at Trenton, N. J., and is termed for convenience the Kinkora works, because of the proximity of a village of that name. Included in the buildings shown in the illustration are a thoroughly modern steel plant with four open-hearth furnaces, designed to produce the quality of steel suitable for high-grade wire, blooming and rolling mills, mills for drawing wire, shops for cleaning, annealing and galvanizing, and all the auxiliaries necessary for the production of wire from molten steel.

The additional works are on the line of the Pennsylvania Railroad, side tracks of which enter the yard. Rods which are not drawn into wire at the Kinkora works are loaded upon steel cars built for the Roebling company and taken to the wire mills at Trenton.

The village of Kinkora being too small to provide homes for the large number of men employed at the works, the company has built an entirely new town upon fields in the open country. This town, built of brick and stone, with wide streets and roomy houses, has its own waterworks and electric-lighting station, buildings for religious worship and secular entertainment, a schoolhouse, hotels, a public park, recreation grounds and all the conveniences of a thoroughly modern city. The United States government has established a postoffice in the town and officially named it Roebling.

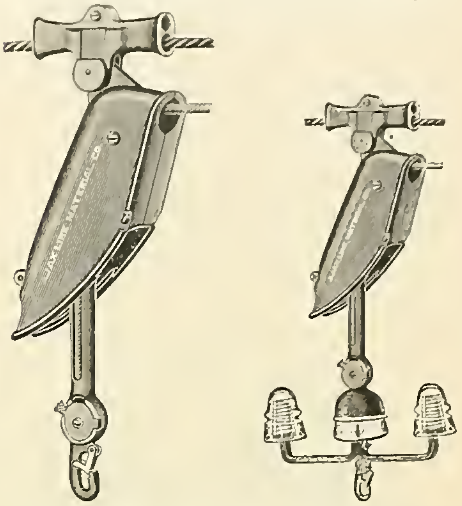
The additional works and their equipment, as well as the new town, were designed by the engineering force of the John A. Roebling's Sons Company and built under the supervision of Mr. C. G. Roebling, president of the company.



KINKORA WORKS OF JOHN A. ROEBLING'S SONS COMPANY, AT ROEBLING, N. J.

Safety Arc-lamp Pulley.

A new arc-lamp pulley is now on the market, being another product of the West. Three years after Fletcher (of Ohio) had introduced sleetproof pulleys, Lounsbury and Morgan (both of Chicago) perfected the first of the so-called lamp-supporting or safety pulleys, whose use has since become so general. Now another Chicago inventor, Albert Scheible, has brought out the new type illustrated here, which combines a smooth-acting safety arrangement with a weatherproof housing. It has only two moving parts, the sheave over which the rope runs and the hook-knob to which the lamp is fastened. When the latter enters the guideways in the pulley casing it first strikes an inclined guide, up which it climbs until the angle between the knob and the guide becomes too steep for it to move farther. There it is stopped by its own friction without striking any barrier which would halt it abruptly and jar the lamp out of adjustment. Slackening the rope allows the knob to slide to a seat, after which another pull automatically releases it. The knob part has a clamp for the rope, and the familiar Ajax snaphook for the lamp, and for series circuits it is fitted out with a high-voltage cross-arm as shown. Both types have been thoroughly tested in practice and are now offered to the trade by the Ajax Line Material Company of Chicago.



SAFETY ARC-LAMP PULLEYS.

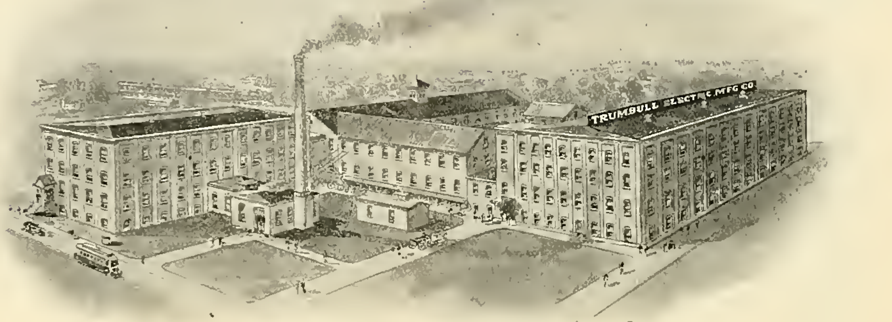
Growth of the Trumbull Manufacturing Plant.

In Plainville, Conn., on February 1, 1899, the Trumbull Electric Manufacturing Company was organized and began business in a very modest manner in the little factory building illustrated herewith. Frank T. Wheeler was elected president; John H. Trumbull, treasurer, and Henry Trumbull secretary. They occupy the same positions today,

ORIGINAL TRUMBULL FACTORY.

but now conduct an enterprise which is well known wherever electrical switches are used. The young men were practical mechanics, and had invented and perfected inventions of value. The early days were days of struggle and the patents had to be protected. This took a big part of the capital, but the fight was won, as well as recognition.

The plant and business of this concern has grown rapidly until now its territory not only covers the home country, but the trade-mark, "circle T," representing Trumbull materials, is known in many foreign countries. The recent completion and occupancy of the new factory building here illustrated has added materially to the equipment and producing capacity of the concern and makes the plant one of the most complete of its kind in the country.



THE TRUMBULL FACTORY OF TODAY.

The space originally occupied by the old factory is now used as a storeroom for copper and brass. There is carried on hand a supply of 200,000 pounds of copper and brass alone. In 1901 a building was added to the plant and the manufacture of type B switches was commenced. The second story is used for storing some of the porcelain, and in the attic are kept boxes and miscellaneous material for packing.

A large four-story brick factory was erected a year and a half ago and was promptly outgrown. At the same time there was erected a small brick building in which the enameling of the slate is done. Here the slate or marble, whichever is used in the switchboard work, is rubbed and polished. On the first floor of the large building are found the buffing rooms; also the plating and polishing rooms and those where the copper is dipped and lacquered.

The machine room is on the second floor. Here the copper is made into the various different parts. Here also are found a number of diemakers and toolmakers. This company makes practically all its own tools.

The third floor is given over entirely to the assembling of the switches, which at present is the largest line manufactured. The offices are on the fourth floor and they are equipped with every modern convenience.

The new large factory building just completed is a fine example of the modern mill construction. It about doubles the output capacity of the plant. In the basement is found a large supply of slates of various sizes used in the construction of switches. From 150,000 to 200,000 pieces are carried in stock. On the first floor are also machines for drilling the large slate and marble pieces for panel switchboards.

The second floor is devoted to the construction of switchboards and panel boards, and the construction of the iron boxes in which many of the panel boards are enclosed. The third floor is given over to the assembling of porcelain material, such as combination switches, plug cut-outs, new Code cut-outs, etc. Space is also here given to the cabinet department, where the wood panel boxes of various kinds with the doors and trims are made.

The fourth floor is at present used as a storeroom, but will probably be turned over for the making of the new lines that are contemplated.

The plant has its own sewer system, private wire connections, automatic telephone system and everything necessary for making high-class goods, which has made the concern prominent in the ranks of electrical manufacturers.

CORRESPONDENCE.

Continental Europe.

Paris, September 11.—Steps are being taken to adopt electric traction upon a certain number of sections of railroad in the north of Italy, in order to keep pace with the increase of traffic. According to recent reports coming from Rome, it appears that for some time past there has been agitation among the leading commercial houses of the Piedmont district in order to obtain from the Italian government an improvement upon the Frejus railroad line, seeing that it has now become quite insufficient for the needs of the Franco-Italian commerce. Senators and deputies from these provinces were at the head of the movement, and the result was the formation of a committee charged with obtaining the needed improvements from the government. The latter consist mainly in the establishing of a double track between Turin and Bussoleno and in the substitution of electric for steam traction on the section lying between Bussolcno and Modane. It is now announced that the government has decided to give satisfaction to the desire of the Piedmont inhabitants. Within a short time the work will be commenced upon a double-track line on the first section lying between Turin and Collegno, and all the details of the electric project have been decided upon. In this way the Piedmont region will be better able to compete with the Lombard district, since the latter now has the advantage of the Simplon Tunnel.

Somewhat of a stir has been caused by the disappearance of one of the special microphone signals which are placed off the harbor of Cherbourg. As this port is the headquarters of the northern section of the French fleet, comprising the naval construction docks and arsenal, it is desired to protect it in every way possible. To this end the Marine Department adopted a system of submarine microphone which was placed about five miles off the harbor and joined to the land station by a cable. In this way the presence of approaching ships could readily be detected, owing to the noise of the propeller, so that the system is a valuable one. It was found not long since that one of the microphone apparatus had disappeared, and the cable seemed to have been cut, so that many were of the opinion that it was carried off by a foreign vessel which wished to find out the details of the method. Others, however, claim that there is nothing especially secret about such microphones, and that they are of the usual kind, and that the disappearance is due to a simple accident. The matter stands in this way at present.

The question of the industrial use of alcohol, especially for motors, is coming specially into prominence of late in France, and the government is taking measures to promote such industries in order to give prominence to alcohol as a fuel, seeing that this is a national product, which is not the case with gasoline. From a technical standpoint, alcohol has been given a thorough test upon motors during the last few years, and is found to compete very well with gasoline for this purpose. Not long since the Chamber of Deputies appointed a special commission in order to find out the best measures to take in order to promote the use of alcohol, with M. Ribot as president. The commission is now engaged in preparing the technical data which are necessary and in drawing up the general programme to be followed.

Concerning the development of electric traction within a recent period, I may mention that a project is on foot in Sweden, which is due to Engineer Dahlender, for the application of the electric system in the southern part of the country upon no less than 1,000 miles of railroad. Not long since the Italian Parliament voted a credit of $10,000,000 for the construction of new electric railroads. The total length of lines which are to be built is nearly 200 miles. Upon the 12 new lines comprised in the project, eight will use the three-phase system, while there will be two upon the direct-current system and two using single-phase current. A. DE C.

New York.

New York City, September 21.—After several months of investigation of the New York Central's electric system Chas. F. Lacombe, chief engineer of the Bureau of Water Supply, Gas and Electricity, and Geo. F. Sever, consulting engineer to the city and a professor at Columbia University, have handed in a report setting forth that in the overhead transmission system, on which has been spent some three or five million dollars, some of the poles are not of sufficient strength to withstand the tensions which are brought to bear upon them; that some are set too close to buildings and that the building of the Kingsbridge section of the overhead line was an error in judgment and that it should be placed underground. Notice of the above decision has already been served upon the New York Central, but it is stated that the officials contend that they cannot maintain an underground system and that they will refuse to recognize any claim of municipal control over their private right-of-way. Although the Central crosses public streets, no thoroughfares are used for the right-of-way.

In the Belmont tunnel under the East River it was decided to install the third rail overhead so that any accumulation of water along the tracks would not impair the service. However, it has been found that water percolates through the roof of the tubes and in some cases has destroyed the insulation, thus delaying still further the time of completion. Although in the nature of an experiment, it was not thought that the plan would prove unsuccessful until it was noticed that moisture readily collected.

Owing to the inability of the Morris County Traction Company to obtain the necessary rights-of-way in and near Summit, N. J., work on the construction of the road in and near that city will have to be abandoned temporarily. This means that there will be no service to the center of the city this winter.

Coroner Julius Harburger, Senator William Sohmer and Alderman J. J. Haggerty, appointed as a sub-committee of the Committee of Ten named on September 3d to consider the speed of surface trolley cars through the city, have prepared an ordinance setting the limit in the Boroughs of Manhattan and the Bronx at ten miles per hour.

In the coming electrical show at Madison Square Garden, September 30th to October 9th, the Brooklyn Edison Company will exhibit a model apartment consisting of a kitchen, dining room, hall, bedroom and parlor, fully equipped with modern electrical appliances. The company is offering to supply to every customer who will drop the company a line two tickets of admission to the Garden. In addition to the exhibit itself, the company is preparing one or two contests to be carried on in connection with it. The name and address of every resident of the Borough of Brooklyn who attends the show is placed on a card and upon the last evening a drawing will be made and the lucky five will be given an order upon the Illuminating Company for the cost of wiring their homes, which in some cases amounts to as much as $250. Other contests will also be arranged for.

The first car which will be used in the Belmont tunnel, No. 601, was run through Jackson Avenue and Fourth Street, Long Island City, on its way to the incline leading down to the tunnel entrance of the north tube. It is essential to get the car through the tunnel as soon as possible in order to protect the franchise. E. H. S.

Southeastern States.

Charlotte, N. C., September 21.—The Americus Railway and Power Company of Americus, Ga., has been granted a charter; capital stock, $250,000. W. D. Dodson, A. W. Smith, E. B. Lewis and J. F. Lewis are the incorporators. This company will build a four-mile electric railway in Americus and furnish power and water to the city.

The Southern Power Company has completed its transmission lines toward Statesville, N. C., as far as Mooresville, about half way from Charlotte. The Statesville sub-station is being rapidly pushed to completion preparatory to the turning on of the current this week. The cotton mills of Concord, N. C., as well as those in Statesville and Lincolnton, N. C., will liberally patronize the company, together with many smaller industries. Concord, whither the current has been carried a distance of 40 miles, is now electrically lighted and the Carbarrus, Franklin, Young-Hartsell and other mills will also be driven by this current. The town of Mooresville is also lighted by the same system of transmission lines, which are now furnishing power to a large section of country north and northeast of Charlotte for a distance of 44 miles.

Superintendent of Lamps and Lighting McCuen of Baltimore is considering the substitution of the regulation arc lights for the incandescent lights now in use. These lights have been used in arches on Baltimore Street for some distance in the principal section of the city, and it is proposed to build a "Great White Way" in Baltimore by the use of arc lights. The cost of the change will be comparatively small.

The electric-lighting system of North Wilkesboro, N. C., is being rebuilt and otherwise improved by the owners.

C. R. Willard & Co. of Spartanburg, S. C., have been awarded the contract to build two dams for hydro-electric power development, one at Ware Shoals and the other at Brown's Mills, seven miles from Ware Shoals. Two hundred men have begun work on the plants, the first to approximate $75,000 and the second about $50,000.

The Raleigh (N. C.) electric railway has received a new 500-kilowatt generator from the General Electric Company, to be added to its equipment, while over four miles of new track is to be constructed. The power house and sheds are also being remodeled and the entire plant reconstructed on the most up-to-date plans. A new 400-horsepower boiler will also be installed.

A meeting of citizens of Washington, Ga., was held September 7th to discuss the building of an electric railway from Washington to Atlanta and to Augusta. About $100,000 has been subscribed by two counties toward this enterprise. A representative of the Atlanta and Carolina Railway was at the mass meeting in the interests of his company and the new enterprise. A second company, the Savannah, Augusta and Northern Railroad, is also interested in constructing a railroad to Washington. J. R. Dyson is president of the Washington Business Association, which is actively pushing the trolley projects, which promise to be realized soon.

The Horseford Power Company, Hickory, N. C., has gotten out its charter calling for a capital of $125,000. A. A. Shuford is interested. L.

Dominion of Canada.

Ottawa, September 21.—The deficit of the all-British Pacific cables for the year ended March 31st last was $335,340, which is considerably less than the deficit of the previous year. Canada's contribution to this deficit will be $93,150, as the Dominion is responsible for five-sixteenths of the undertaking.

Announcement is made of the issue of $1,000,000 stock by the Toronto Electric Light Company, which was ratified some time ago. The new stock is offered to shareholders at par, in the proportion of one new share to three of old. The stock is offered on the market at 150.

The town of Orillia, Ont., may make a profit this year of $9,000 from its light and power plant. The actual revenue from the enterprises owned by the town, including waterworks, is $34,500. Owing to the increased profits the Town Council has been enabled to reduce the tax rate.

The City Council of Sherbrooke, Que., refused to purchase the plant of the Sherbrooke Power, Light and Heat Company for $270,000, which was the amount demanded by the company. The city offered $250,000 cash, or $260,000 if the company would take 4 per cent. bonds of the city at par. The company has been given a limited time in which to accept or reject the city's terms, and failing to accept, work will be commenced immediately on a new power plant for the city.

A conference of managers of the electric development plants operating on the international boundary, extending from New Brunswick to the Rainy River country, will be held in Ottawa shortly. By the act of the Dominion Parliament, passed last winter, the export of electricity to the United States is now under federal control and companies supplying power for utilization across the line must operate under a Dominion license. Regulations have been prepared, but before their final adoption by the government the views of the electric interests affected by the new law will be heard by the government. The act goes into force on October 27th. W.

Winnipeg, Man., September 21.—After paying all expenses and interest the civic electric-lighting plant at Calgary, Alberta, has a surplus for the first seven months of the year of $9,469.

Notice is given in the Manitoba Gazette that the Brandon Electric Lighting Company of Brandon, Man., has increased its capital from $125,000 to $400,000.

A million dollars or more will be spent in the vicinity of Vancouver, British Columbia, by the British Columbia Electric Street Railroad Company. One large item is the Chilliwac line. About $70,000 will be spent on the equipment of the New Westminster-Eburne line. It is possible another 10,000 horsepower will be developed at Lake Buntzen to meet the growing demand for power.

It is expected that work will be commenced this fall on the Manitoba government's telephone system in Brandon, Man. The exchange will cost in the neighborhood of $15,000 and the conduits are estimated to cost about $20,000. Particulars may be obtained from Orrin F. French, superintendent of telephone construction, Winnipeg.

The civic board of control of Winnipeg has awarded several tenders in connection with the tramway to be built from the city to the power plant now being installed at Lac du Bonnet. The tenders awarded included a steam tug, flat cars and engine. Cecil B. Smith has charge of the development.

P. Cronin, Toronto, Ont., has made a proposition to buy the civic electric railroad now being built by the city of Edmonton, Alberta, and a number of aldermen are in favor of the sale of the line, owing to the failure of the city to dispose of the bonds necessary to complete the work. Mr. Cronin is representing George Balfour, an English civil engineer. R.

New England.

Boston, September 21.—The Boston and Northern Street Railway Company has filed petitions for the right to carry freight in the cities of Melrose, Lowell and Lawrence and the towns of Wakefield, Reading, North Reading, Andover, North Andover, Middleton, Danvers, Wilmington, Tewksbury and Dracut, Mass. The petition has been refused in Andover, but North Reading has granted the desired permission. After the municipal authorities have acted, the Massachusetts Railroad Commission will consider the matter. The Boston Elevated Railway Company's petition for a similar right in Boston, is pending before the aldermen. If it is granted the Boston and Northern company's freight can be brought into Boston over the Elevated company's tracks. This would allow the establishment of electric-railway freight service between Boston and Lowell and Boston and Lawrence. Lowell and Lawrence are important manufacturing cities.

The Berkshire Street Railway Company, which is controlled by the New York, New Haven and Hartford Railroad Company, has established an express service between Pittsfield and Great Barrington, Mass.

The firm of Conant, Whiting & Co. of Boston has been incorporated to do an electrical engineering business. It has a capital of $4,000, and George H. Conant, Herbert S. Whiting and Eugene H. Mahoney are the incorporators.

The Edison Electric Illuminating Company of Boston reports for the year ended June 30th as follows, the corresponding figures for 1906 being in parenthesis: Gross earnings, $4,020,620 ($3,780,911); net earnings, $1,428,797 ($1,337,625); total net earnings, $1,470,137 ($1,386,881); interest, etc., $1,406,700 ($1,227,776); surplus, $63,437 ($159,105).

The Boston Bakers' Union has voted that its members pay their fares in pennies to non-union conductors on the Boston and Northern Street Railway Company's lines.

The Massachusetts Railroad Commission has granted a certificate of "public necessity or convenience" to the Boston and Providence Interurban Railway Company, which proposes to build a fast electric railway between Boston and Providence. B.

Indiana.

Indianapolis, September 21.—The city of Logansport is rapidly developing into an interurban center. The Fort Wayne and Wabash Valley, the Indiana Union Traction, the Logansport and the Lafayette traction companies are already entering the city, while the Logansport and South Bend and the Logansport and Marion are seeking independent entrance to the city. The Board of Public Works is not inclined to grant any more independent routes, while the citizens have petitioned the board to let all come in upon favorable terms.

A contract has been entered into between the Chicago, South Bend and Northern Indiana Railroad Company and the St. Joseph Valley Traction Company for the exchange of track privileges in the city of Elkhart. Work on the Elkhart-Middlebury extension of the latter company's line is progressing rapidly, and through services will soon be afforded.

The first electric-railway express train operated by the United States Express Company out of Indianapolis was run out over the Northwestern Traction line to Lafayette during the last week, where connection is made with the Fort Wayne and Wabash Valley road, over which the company is also operating an express business.

A mortgage aggregating $4,000,000 has been filed in the recorder's office of Clark County at Jeffersonville by the Indianapolis and Louisville Traction Company in favor of the Colonial Trust Company of Pittsburg, Pa.

The Indiana Railroad Commission has decided that it has no right to compel electric-railway companies to protect crossings with streets in cities and towns by establishing and maintaining electric lights.

The Columbus Gas Light and Coke Company, a reorganization of the local company, is asking the City Council to grant to it a new and long-term franchise. The company contemplates the construction of a plant to furnish gas for heating and lighting purposes at a greatly reduced cost.

The Board of Public Works of Anderson has installed four new 310-horsepower boilers and an automatic stoker at the city waterworks and electric-light plant. The cost was $8,000. The new system consolidates the power for the two plants and discards six boilers and the services of four men besides making a decided reduction in amount of fuel required. The saving is estimated at $4,000 a year. S. S.

Mexico.

Mexico City, September 18.—The Mexican Light and Power Company is to have strong competition in supplying power and lights for Mexico City if the plans of a company which has been organized for the purpose are carried out successfully. The name of the new concern is Compania Electrica del Alameda. It will build a large hydro-electric plant at the waterfall of the Rio Alameda, situated about 40 miles from Mexico City, and will bring the power into the city by means of transmission lines. The company already has a power plant at the waterfall and it is to be enlarged. The new plant will have a capacity of about 8,000 horsepower. The firm of Donadiue & Veyan of Mexico City is largely interested in the new project. The new company claims that it will establish rates lower than those now in effect by the Mexican Light and Power Company.

A large electric power plant is to be erected at Sabinas, state of Coahuila, by Dr. Braulio Montemayor of Saltillo and associates. Sabinas is in the heart of one of the large coal fields of Northern Mexico and cheap fuel will be obtained for the plant. Transmission lines will be built to a number of industrial centers of that part of Mexico.

The Sultepec Electric Light and Power Company has completed the installation of its large power plant at Temascaltepec. The company has completed a 25,000-volt transmission line to Sultepec, and a sub-station has been built at the latter place. The company furnishes power to many mines and mills.

It is announced that more than $1,000,000 will be spent in constructing the new electric street-railway system in the city of Chihuahua and in building suburban lines to Santa Eulalia and to the new smelter of the American Smelting and Refining Company, 16 miles distant from town. The rails and other material for the new system have arrived. Enrique Creel, Mexico's ambassador to the United States, is the principal owner of the company which is to make these improvements. A. C. Nash is general manager.

Authoritative announcement is made that the Vera Cruz Electric Light, Power and Traction Company of Vera Cruz, which is owned by S. Pearson & Son, well-known English contractors, has completed arrangements to provide that city with electric traction in addition to the power and lighting service which it is now supplying. The power plant at Vera Cruz is being greatly enlarged and work of rebuilding the track will soon be started. W. D. H.

Illinois.

Peoria, September 21.—The street committee of the City Council that has been investigating the fenders submitted for use here on the street cars, met again this week, and, after considering the four kinds that were submitted by the railway company, decided in favor of the Providence. This type is in use in Chicago, and can be lowered by the motorman.

By January 1st the Illinois Traction Company will be connected with the Indiana electric railways. Congressman McKinley, while in Danville this week, said that the building of the connecting link between Ridge Farm and Clinton, Ind., would be commenced at once. This will be the first connection between the two systems by way of Terre Haute and the new line being built between that city and Indianapolis. Early in the spring another line will be built to Danville from Crawfordsville paralleling the Peoria and Eastern Railroad, making travel from St. Louis to points in Ohio and Pennsylvania a possibility.

A rumor that the Illinois Traction Company had purchased the Chicago, Peoria and St. Louis Railway was started in Springfield this week, but it is denied by the Traction Company.

An increase of $22,849.22 is shown in the net earnings of the Illinois Traction Company for the month of August over the corresponding month last year.

The new interurban road at Canton that has been using a gasoline car between Canton and St. David has decided to equip the road and use electricity for power. The Canton Electric Company will pay half the cost of the poles to St. David and use them to carry current to St. David for lighting purposes. The lighting company will also furnish the current to operate the cars. As soon as this part of the line is equipped the company will extend the lines north and south.

Damage suits aggregating $57,500 against the Central Illinois Traction Company, growing out of the wreck near Charleston on August 30th, have been filed.

The Litchfield Gas and Electric Company is installing a new equipment of machinery preparatory to the new lighting system that it will put in operation the first of October.

Henry H. Matlock, special agent of the Central Union Telephone Company, who has been away for a year on a vacation, has returned to Springfield.

A petition has been filed by the Mississippi Valley Electric Railway with the Warehouse and Railway Commission asking for permission to cross the Wabash and the Toledo, Peoria and Western railways at grade at Carthage and Elvaston. The road in question is proposed from Carthage west to Keokuk, Iowa, and from Hamilton, Ill., through Nauvoo, to Fort Madison, Iowa. V. N.

Pacific Slope.

San Francisco, September 18.—The Mono Power Company, on which Edson F. Adams has already spent $40,000 in preliminary work, has closed a contract for a temporary power plant to furnish electric lights and compressed air for completing the water tunnel leading to the initial generating plant of the company on the Owens River. Work is now under way on the diverting dam of concrete that will furnish power water for the plant. A three-mile road has been completed at an expense of $25,000 into the so-called "Impassable Canyon," where the hydro-electric plant is being constructed at a point 20 miles north of Bishop, Cal. Bids have been received on the three large generators which are to be installed in a chamber cut into the ledge of solid rock a short distance above the high-water mark in the canyon. The power will be transmitted about 100 miles to Goldfield and the other principal mining camps of Nevada.

The equipment department of the United States navy yard at Mare Island, Vallejo, Cal., has just finished the installation of a complete wireless-telegraph equipment on board the cruiser California. After three days' test it was pronounced satisfactory.

Bids are being received at Centralia, Wash., for furnishing the city with electric current for ten years.

The Seattle Electric Company of Seattle, Wash., has closed a contract with the Washington Coal Briquette Company of the same place which will result in the erection of a briquette plant at Renton, Wash., with a capacity of 125 tons daily.

E. P. Spaulding, vice-president of the Big Bend Light and Power Company of Spokane, Wash., has applied for a fifty-year light and power franchise in Spokane. The proposed ordinance provides for the construction of a power plant on the Spokane River capable of supplying the entire city, to be ready within three years.

Owing to the telegraphers' strike, the Southern Pacific has abandoned the use of its telegraph service for train dispatching at nine stations between San Jose and San Francisco, and now relies entirely on its recently installed automatic block system to keep its trains under control. Palo Alto, Mayfield and Sunnyvale are among the principal stations within the county that are affected by this new order. According to the head officials of this division, the system works out perfectly and is even more reliable than the old way.

The burning of a 50,000-barrel fuel-oil tank in the yard adjoining the main electric power plant of the Oakland Gas Light and Heat Company at First and Grove streets, Oakland, on September 18th, came very near destroying the entire works, but the actual damage was confined to the steel tank and its contents, about 5,000 barrels of crude petroleum. The report was current that the oil in the tank was ignited by the dropping of high-tension wires which melted the cover of the tank sufficiently to ignite the gas above the oil. The management is non-committal as to the short-circuit theory, however. A.

PERSONAL.

W. S. Powell, manager of the Wisconsin Telephone Company at Eau Claire, Wis., has been promoted to the management of the office at Stevens Point, Wis.

C. H. Edwards has become manager of the Citizens' Telephone Company at Mankato, Minn. He was formerly manager of the St. Paul office for the Northwestern Telephone Exchange Company.

Mr. James Lang died at his home in Chicago on September 10th at the advanced age of 84 years. Mr. Lang was the founder of the J. Lang Electric Company of Chicago some twenty-five years ago. He sold his interests about five years ago and retired.

Mrs. Marilla E. Chandler, wife of Albert B. Chandler, for many years president of the Postal Telegraph-cable Company, died at her country home in Randolph, Vt., on September 14th. She was 64 years old. Mr. Chandler is one of the best-known telegraph men in the country, having served in the military corps during the rebellion, and later as a superintendent for the Western Union Telegraph Company and the Atlantic and Pacific Telegraph Company.

The management of the United Railways of San Francisco announces that Charles N. Black, general manager of the Metropolitan Street Railway Company of Kansas City, has been appointed general manager of the United Railways of San Francisco to succeed George H. Chapman, who died some weeks ago.

H. C. Warren has resigned his position as superintendent of the Toledo, Port Clinton and Lakeside Railway in Toledo and will accept a similar one with the Toledo and Indiana Railroad, made vacant by the resignation of E. Darrow, who will accept a position as expert electrical engineer in New York.

F. J. Stout of Cleveland, Ohio, general manager of the Lake Shore Electric Railway Company and one of the best known electric-railway men in Ohio, died as the result of an operation last week. He had been prominent in railway affairs for several years and was among the first to introduce steam-railroad methods in the operation of interurban railways.

Mr. Francis E. Drake, managing director of the Société Anonyme Westinghouse of Paris, is in the United States on a short visit. Mr. Drake was in Chicago early in the week, and his old friends were delighted to see him. He is in charge of the Westinghouse interests in France, Italy and several other continental countries, and reports a good business.

Dr. Octaviano Pereira Mendes, president of Companhia Ytuana de Força e Luz, Ytu, Brazil, and Dr. Edgard Mendes of the same company have arrived in Chicago and are making their headquarters in the offices of Hays & Foster, consulting engineers. Dr. Mendes will purchase in this market additional American machinery for his power plant located on the Rio Tieta, state of Sao Paulo.

ELECTRIC LIGHTING.

Maryville, Mo., has granted a 20-year franchise to the Maryville Electric Light and Power Company.

Harley Russell is secretary of a newly organized company which is to install an electric-light plant in Ozark, Ark.

The Consumers' Electric Company, of which Atwood Benton is manager and engineer, will build a plant in Hot Springs, Ark.

The Ferris (Tex.) Light and Power Company has been incorporated with a capital stock of $4,000 by W. W. Batchelor and others.

The City Light and Power Company of Bruce, Neb., has been incorporated with a capital of $90,000 by R. C. Barney and others.

The Granite Electric Light and Power Company of Granite, Okla., has been incorporated with a capital of $10,000 by K. C. Cox and others.

The La Crosse Gas and Electric Company of La Crosse, Wis., has just been granted the right to increase its electric-lighting rates, which were declared to be so low as to be unremunerative. In accordance with the new Wisconsin public-utilities law, the company appealed to the state commission for relief and secured it.

At the meeting of the Chicago City Council this week Mayor Busse presented a message calling attention to the merging of the Chicago Edison Company and the Commonwealth Electric Company. The Commonwealth franchise has still 40 years to run and gives the city compensation of three per cent. of gross receipts, while the Edison franchise expires in a few years and pays no compensation. If the new Commonwealth Edison Company intends to operate under the Commonwealth franchise, the mayor thinks it probable that three per cent. should be forthcoming from the Edison business also. The proper committee was ordered to investigate the matter.

The corporation of East Toronto, Ont., during the summer of 1904 came to the decision that an electric power plant was needed to furnish electric light for the city and power for the electrically driven waterworks already owned by the municipality. With Mr. John Galt of Toronto acting as consulting engineer for the work, plans were drawn and contracts awarded for building the power plant and furnishing its equipment. The main generator selected is a 150-kilowatt 2,200-volt 3-phase 60-cycle machine of the revolving-field type furnished by Allis-Chalmers-Bullock, Montreal. This generator is operated at a speed of 150 revolutions per minute and has 48 poles. The exciter is a 15-kilowatt 125-volt machine of the same design.

ELECTRIC RAILWAYS.

The Snohomish Valley Railway Company of Snohomish, Wash., has let the contract to build 55 miles of road, to Renton.

The Milwaukee Northern Railway Company announces that it will sell mileage books as follows: 100-mile books $1.50, 500-mile books $7.00 and 1,000-1,000-mile books at $13. These books are to be transferable and interchaneable, their use not even being restricted to members of one family. For single-trip tickets the fare will be about 1¾ cents a mile. Cash fare paid on cars will be the legal rate, 2 cents a mile.

The Engineering, Construction and Securities Company of Chicago is just completing the third interurban electric railway in Iowa for which it has had the contract. The present road is for the Albia Interurban Railway and will be completed and in operation between Albia and Hocking by November 1st. The company has completed 11 miles of grade for the Atlantic, Northern and Southern steam road, which is to be in operation between Atlantic and Kimballton, Iowa, by January 1st. Messrs. C. B. Judd and C. A. Ross of the Chicago company are supervising the work in Iowa.

POWER TRANSMISSION.

M. H. Fiser is planning to establish a power plant at Alamogordo, N. M., to develop 600 horsepower for commercial purposes.

The Old Dominion Copper Mining and Smelting Company of Bisbee, Ariz., is about to begin the installation of a big central electric power plant, to be the largest in Arizona.

Work on the second hydro-electric plant of the Edison Electric Company on Kern River in the Sierra Nevada Mountains will soon be started. There will be five stations with an aggregate of 90,000 horsepower. V. P. Edmonson states that there will be a market for the company's power and for the city's power that may be developed in connection with the Los Angeles aqueduct.

The Falkenau Electric Construction Company of Chicago recently obtained the contract for installing a complete hydro-electric plant for the city of Paw Paw, Mich., a well known summer resort center. The electrical equipment consists of a 150-kilowatt and an 80-kilowatt Allis-Chalmers waterwheel type generator for direct connection to waterwheels, two nine-kilowatt belted exciters and a number of motors ranging from 15 to 40 horsepower.

It is announced that Helena, Mont., is to have a third great dam across the Missouri River for the development of electrical power, a portion of which will be utilized for a pumping plant to reclaim 10,000 acres of land in Prickly Pear Valley. The same interests which built the present dams are behind the new one and include the estate of Abram Hewitt, the Guggenheims, the Amalgamated Copper interests, Governor Hauser and A. M. Holter of Helena. The pumping plant will cost about $500,000 and the dam approximately $1,000,000. The power will be utilized to a great extent in the Butte mines, East Helena, the Anaconda smelters and minor industries. Already the horsepower development of Helena dams exceeds 35,000 and the new dam will swell this upward of 50,000 horsepower. Work will begin immediately on the new dam and ditches.

PUBLICATIONS.

The first number of Holophane, dated September, has been published and makes a creditable appearance. It is to be a monthly publication devoted to the Holophane system of illumination, and issued from the sales and engineering departments of the Holophane Company.

The latest bargain sheet of the Gregory Electric Company, Sixteenth and Lincoln streets, Chicago, is a booklet of 62 pages in which is listed a large stock of second-hand electrical machinery, including dynamos, motors, transformers, meters, arc lamps, instruments, repairs, etc.

The annual report of the Wire Department of the city of Boston has just been issued. The report gives interesting data on electrical properties and conditions in Boston, dealing especially with the removal of poles and wires from the streets. Patrick J. Kennedy is commissioner of wires.

All who have to do with the installation and care of electric meters will appreciate the efforts of the Fort Wayne Electric Works in publishing Instruction Book No. 3028, which thoroughly covers type K single-phase integrating wattmeters. The book is illustrated with halftones and drawings.

Two attractive bulletins just issued by the Fort Wayne Electric Works are numbered 1098 and 1100, respectively. The former goes into the details of type MPL generators for light and power, and includes some excellent illustrations. Likewise the latter treats exhaustively of small direct-current motors, type L.

The Sprague Electric Company, 527 West Thirty-fourth Street, New York, has just issued a number of handsome bulletins containing data and information on several subjects of interest to all electrical men. All are illustrated with half tones and drawings. Bulletin No. 108 goes into the subject of electric dynamometers for testing gasoline engines. Bulletin No. 229 is especially attractive, being an excellently printed book of 74 pages, going thoroughly into the subject of electric motor equipments for printing, electrotyping, sterotyping and binding machinery. Bulletin No. 230 is an interesting illustrated story, going into the general subject of the electric equipment of a modern factory. Direct-current motor equipments for single and double-magazine Mergenthaler linotype machines are well covered in Bulletin No. 231.

The story of how the New Bremen (Ohio) Electric Light Company sells $8.50 worth of electric current to every inhabitant in the town, written by Mr. F. H. Plaice for the Western Electrician, has been reproduced in pamphlet form by the Co-operative Electrical Development Association, with this recommendation: "Every man in the electrical business should read this story, whether interested as a central station, manufacturer, jobber, dealer, contractor, salesman or otherwise."

The Western Electric Company, Chicago, has just issued a little booklet describing the advantages of its "black enameled wire" as compared with the ordinary cotton or silk-covered magnet wire. A few of the good points of this wire are: Humidity and chemical reagents will not affect its insulating qualities, nor will heat up to 500° F.; it is a thinner insulation than cotton and even silk, and is yet so tough and elastic as to withstand ordinary handling. The company has used it on its apparatus for four years with very good results and is now ready to supply the market on a large scale.

"Curtis Steam Turbine Generator" is the title of a large pamphlet (No. 4531), issued by the General Electric Company, Schenectady, N. Y., that is a particularly complete and handsome publication. The printing and general style of the pamphlet are very attractive; it will be found of special interest to engineers on account of the information given with regard to superheat, vacuum, economy, etc., and the details of construction and operation of all parts of the Curtis apparatus. Under the heading of "Economy," detailed tests are given of 9,000-kilowatt, 5,000-kilowatt, 2,250-kilowatt and 1,000-kilowatt turbines, which show some remarkable high efficiencies. The advance made by this type of turbine is illustrated by the maker's assertion that nearly 1,000,000 kilowatts of Curtis steam-turbine generators have been sold. Special attention is called to the flat efficiency curve, giving high efficiency at overloads and light loads, the simplicity of design, the low maintenance, the economy in space, etc. This publication seems to be typical of the recent desire to have such information written by and to engineers, and the following synopsis of its contents will show the wide field covered: Advantage of vertical shaft type; economy of space, building materials and steam; clearances; flow of steam; balance; lubrication; the construction of buckets and governors; foundation; low pressure turbines; vacuum and regulation; parallel operation; ventilation, economy, etc. The illustrations are profuse and especially clear and good.

SOCIETIES AND SCHOOLS.

The articles of association, officers and committees, membership and general directory of the National Fire Protection Association have been published in book form from the office of the secretary, 382 Ohio Street, Chicago.

By the direction of the "Great Jupiter Fulminator" all faithful "Jovians" will meet in Dallas, Tex., on Jupiter's Day, October 15th, when the annual meeting of the order of Rejuvenated Sons of Jove will be held. Many important matters are to be considered, as well as the annual election of officers. The organization of the "Jovian Cloister," the second degree of Jovianism, will be perfected at this time. Mr. H. B. Kirkland, New York city, is Jupiter, and Mr. C. B. Roulet, Wilson Building, Dallas, Tex., is Mercury.

It has been decided to place Prof. Charles E. Lucke at the head of the Department of Mechanical Engineering of Columbia University. It was Professor Lucke who was chosen by the United States government to conduct the experiments with alcohol as a fuel. In addition to strengthening the regular teaching staff, the university is planning a series of lectures by prominent expert engineers. Part of Professor Lucke's plan is to require all the first, second and third year men to spend their vacations in practical engineering, the first vacation in the machine shops of some good manufacturing company, the second in the draughting rooms, and the third in the big power plants of the city.

MISCELLANEOUS.

The Copper Queen Consolidated Mining Company of New York city has recently concluded the purchase of some fifteen standard Allis-Chalmers induction motors for use on the properties of the Montezuma Copper Company, Nacozari, Sonora, Mexico. These machines are wound for 60 cycles, 3-phase, 220 volts and range from 10 to 75 horsepower. The mill where the motor will be installed is a new one just reaching completion.

In an agricultural machinery factory in Peoria, Ill., is an old Edison bipolar generator which has seen much service. The machine has been rewound and speeded up from about 900 revolutions per minute to 1,300 revolutions. It is carrying 400 lights. At the opposite end of the city is the latest type of generating machinery. Two 2,000-kilowatt turbine generator units installed at the power house of the Illinois Traction Company send their output almost to the Indiana state line, nearly 100 miles away.

BUSINESS.

The J. L. Hudson Company of Detroit, Mich., has let contracts recently covering a 20 by 36-inch Allis-Chalmers Reliance Corliss engine direct connected to a 250-kilowatt direct-current engine-type generator. The new equipment will be utilized to furnish light and power in the Hudson company's store. Messrs. Smith, Hinchman & Cryalls were the engineers and architects in charge of the work.

The Brilliant Electric Company of Cleveland, Ohio, is vigorously pushing the sale of its tantalum lamps. The company has just issued a circular showing how a 20-candlepower tantalum lamp effects a saving of $2.20 in the current charge in 1,000 hours' life as compared with the 3.1-watt carbon lamp. An interesting offer to prospective buyers is made that holds good till October 5, 1907, for a liberal allowance for every carbon-filament lamp replaced.

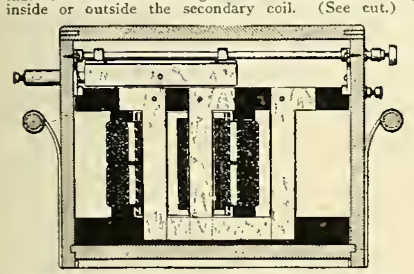
The Jones & Laughlin Steel Company is a recent purchaser of two 1,000-kilowatt Allis-Chalmers 6,600-volt generators wound for 25 cycles, 3-phase, and designed to operate at 94 revolutions per minute. These units, together with a 600-kilowatt direct-current generator, will be installed in the new Aliquippa Works near Pittsburg. A new 500-kilowatt motor-generator set, comprising a synchronous motor rated at 6,600 volts, wound for 3-phase, 25 cycles, and a 250-volt direct-current generator is also being added to the structural shop to carry a portion of the steel-mill load.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) September 17, 1907.

865,985. Variable-voltage Transformer. Thomas M. Bains, Jr., Philadelphia, Pa., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 8, 1907.

The transformer has a three-legged core; the primary winding surrounds the middle leg and the secondary winding surrounds the middle and one of the outer legs. An adjustable laminated armature is arranged so that it can shift the magnetic flux from a return path inside or outside the secondary coil. (See cut.)



NO. 865,985.—VARIABLE-VOLTAGE TRANSFORMER.

865,988. Electric Locomotive. Asa F. Batchelder, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed October 21, 1905.

An electric locomotive has a plurality of shafts, two armatures on each shaft, and field coils and cores for producing a magnetic flux through the armatures in series.

865,997. Electromagnetic Variable-speed Mechanism. Alexander Churchward, New York, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 20, 1902.

A controller is arranged for a nearly constant speed motor that drives a system of speed changing gears. A set of magnetic clutches connects the different gears to the motor. The controller successively connects the clutches and increases the speed of the motor to above normal after each change of gears.

866,001. Sparking Mechanism for Internal-combustion Engines. Leslie S. Cushman, Lincoln, Neb. Application filed June 3, 1907.

One terminal of the circuit is always in contact with a rocker arm that periodically touches the other terminal and thus closes the circuit. A casing surrounds the mechanism.

866,011. Method of Improving Vapor Electric Devices. Samuel Ferguson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 9, 1907.

This is a method of relieving a mercury-vapor rectifier from the dangers arising from mercury around or in the anodes and consists in initially operating the rectifier on a low-voltage current and distilling the mercury from the neighborhood of the anodes before the rectifier is put in service on high voltage.

866,012. Arc Lamp. Richard Fleming, Swampscott, and Cromwell A. B. Halvorson, Jr., Lynn, Mass., assignors to the General Electric Company, Schenectady, N. Y. Application filed March 12, 1904. Renewed April 7, 1906.

This lamp has its arc between a carbon and a non-consuming electrode. In feeding an auxiliary non-consuming electrode is oscillated to momentarily engage the carbon and strike the arc.

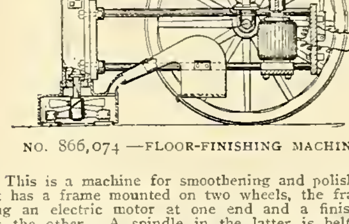
866,019. Rotary Vibratory Massage Brush. Jacob Handel, New York, N. Y. Application filed October 26, 1906.

An electric motor drives a flexible shaft that vibrates and rotates a massage brush.

866,036. Telephone Mouthpiece. Rudolf Knoll, Vienna, Austria-Hungary. Application filed August 11, 1905.

A tube having its outer end slotted and provided with an annular flange is screwed to the diaphragm box. The mouthpiece has a slotted inner end and is provided with spring tongues to fit over the flanged tube and to permit the mouthpiece to be readily removed or rotated.

866,074. Floor-finishing Apparatus. Eduard Schenk, Sheradan Borough, Pa. Application filed June 6, 1906.



NO. 866,074.—FLOOR-FINISHING MACHINE.

This is a machine for smoothening and polishing floors. It has a frame mounted on two wheels, the frame carrying an electric motor at one end and a finishing head at the other. A spindle in the latter is belted to the motor and carries the rotating finishing tools at its lower end. (See cut.)

866,075. Water-jet Grounder for Protection Against Excessive Potentials in Electrical Systems. Stephan Schneider, Berlin, Germany, assignor to the General Electric Company, Schenectady, N. Y. Application filed January 26, 1907.

A protective device against high potentials has a spark gap formed between a conductive plate and a grounded nozzle delivering a stream of liquid in proximity to the plate, but normally out of contact therewith, and projections from the plate and nozzle forming a horn gap.

866,076. Electric Self-winding Clock. Emil Schultz, Berlin, Germany. Application filed April 29, 1907.

This clock has a pivoted armature carrying an arm and contact piece and a pivoted lever contact near the first contact piece and held in its middle position by a spring.

866,081. Control of Separately Excited Generators. Georg Stern, Berlin, Germany, assignor to the General Electric Company, Schenectady, N. Y. Application filed January 23, 1907.

A controlling switch for connecting, varying and disconnecting the separate excitation of a generator and also for changing the field to connect it across the armature so as to annihilate the residual magnetism.

866,089. Combined Lamp Socket and Shade Holder. Julius C. Tournier, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed March 25, 1903.

The shade holder has a web with a central flanged opening to fit over the end of the socket shell, beads in the shell and a flange permanently holding them together.

866,090. Fuse Box. Lewis E. Troutman, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed November 11, 1905.

This fuse box consists of an insulating block having recesses in opposite sides and a handle at one edge, contact blades in the recesses on one side, an inclosed fuse in the recess on the opposite side, and bolts passing through the block and connecting the blades and fuse.

866,105. Flush Receptacle and Plug. George P. Whittlesey, Washington, D. C., assignor to the General Electric Company, Schenectady, N. Y. Application filed September 13, 1905.

A casing has a circular socket provided with shoulders, a face plate with a round opening and a circular shutter that has segmented flanges extending between the shoulders and the face plate, so that the shutter can be locked by turning.

866,128. Device for Transmitting Sound Through Water. Elisha Gray, Highland Park, Ill., assignor to the Submarine Signal Company. Application filed December 1, 1899.

A system of submarine telegraphy has a sounding plate in magnetic circuit or circuits, whereby it is maintained in a state of constant polarization and also adapted to be vibrated by magnetic lines of force, electrically induced in magnets in close proximity thereto, the polarity of which is alternately reversed.

866,138. Telephone System. Henry F. Joeckel, Clayton, Ill. Application filed February 23, 1904. Renewed March 11, 1907.

This system has two line circuits with the magnets and bell signaling instruments connected to one line circuit and the talking instruments connected to the other line circuit as they are usually connected in the common bridging system that has only one line circuit.

866,193. Trolley Guide. Frank G. Clark, San Francisco, Cal. Application filed February 20, 1907.

This trolley guide consists of a fork secured to the trolley pole near its upper end, each tine of the fork being made in three sections pivotally connected by two knuckle joints, and springs for maintaining the sections in a continuous line with each other, the springs permitting the sections to bend at the joints when passing a cross wire supporting the overhead or conducting wire.

866,212. Current Distributer for Sparking Devices. Montague S. Napier, London, England. Application filed September 26, 1904.

An ignition device has two shafts geared together, one operating the make and break in the primary circuit of an induction coil and the other closing the secondary circuit so as to distribute the induced current to the required sparking points.

866,224. Trolley Pole. Alexander Ross, Rochester, N. Y. Application filed February 5, 1906.

This pole has an outer tubular section and an inner section made of two pivotal connected members. A spring tends to force the inner section outward.

866,241. Ignition System for Explosion Engines. Richard Varley, Englewood, N. J., assignor to the Autocoil Company. Application filed November 13, 1906.

An auxiliary magneto generator is provided in this system, which is put in operation by the chauffeur depressing a pedal when he desires to start the engine. As soon as the pedal is released the auxiliary generator is cut out of circuit and the main generator operates the igniters.

866,261. Railway Traffic-controlling System. Clarence W. Coleman, Westfield, N. J., assignor to the Hall Signal Company. Application filed January 10, 1907.

This system has stationary and movable contact terminals, the latter being operated by an oscillating arm carrying a spring and a pawl to hold the arm while the spring is being put under tension.

866,262. Commutator. Clarence W. Coleman, Westfield, N. J., assignor to the Hall Signal Company. Application filed January 24, 1907.

The commutator is made of contact bars of nonmetallic material coated on their lateral surfaces with metal, and has means for engaging the ends of the bars and clamping them in place under pressure.

866,266. Telephone System. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed June 19, 1903. Renewed February 27, 1907.

This patent relates to a supervisory lamp signal in one of the talking strands of the cord circuit of a central energy system. While conversation is going on the current through the lamp is too feeble to light it. As soon as the subscriber's telephone is hung up, a relay in his circuit sends sufficient current through the lamp to light it.

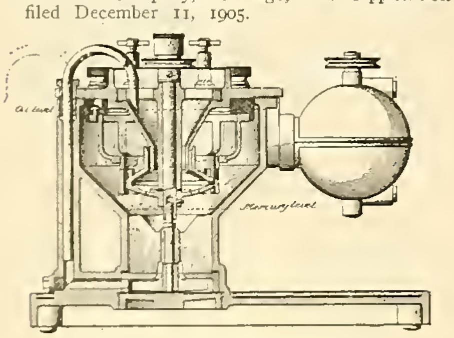
866,281. Railway Signal. William H. Jordan, Brooklyn, N. Y., and George T. Hanchett, Hackensack, N. J., assignors to the Jordan Automatic Signal Company, New York, N. Y. Application filed June 14, 1905.

A pair of opposed magnets has a plunger connecting their cores. The plunger has cylindrical teeth forming a circular rack. Pinions engaging with the teeth operate the signals.

866,286. Electric Generator and Motor. Alvaro S. Krotz, Springfield, Ohio, assignor of one-half to Paul A. Staley, Springfield, Ohio. Application filed January 12, 1905.

The field cores are in two sections, one thinner than the other. A special winding is placed on this thinner section and the main field coil about the entire core. The auxiliary winding is intended to overcome armature reaction.

866,289. Mercury Interrupter. August R. Luschka, River Forest, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed December 11, 1905.



NO. 866,289.—MERCURY INTERRUPTER.

A rotary shaft carries a mercury cup having a peripheral discharge opening. A stationary contact is so placed as to be struck by the jet of mercury from the opening when the cup is rotated. An inclosing vessel surrounds the parts and catches the discharged mercury, which is returned to the rotary cup by means of a centrifugal pump. (See cut.)

866,292. Ceiling Fan. Charles R. Meston, St. Louis, Mo., assignor to the Emerson Electric Manufacturing Company, St. Louis, Mo. Application filed June 2, 1906.

This fan has a hollow sectional frame of skeleton construction and a high-speed electric motor arranged inside of the frame and supported thereby and having its armature shaft disposed vertically. Fan blades connected to the armature shaft of the motor and located entirely within this frame are so formed that they dispel the air radially across the ceiling.

866,301. Method of Forming Seals and Terminals for Electric Apparatus. Henry N. Potter, New Rochelle, N. Y., assignor to the Cooper Hewitt Electric Company, New York, N. Y. Application filed November 19, 1903.

This method of sealing silicon within a tube of silica consists in passing an inert gas through the tube and fusing the silicon out of contact with gases active relative to it.

866,311. Electroplating Apparatus. Albert F. Schroeder, Cleveland, Ohio. Application filed March 18, 1907.

A tank is provided with removable castings which form the bearings for a tumbling drum and gearing to revolve it. The drum may be removed independently of the other mechanism.

866,327. Automatic Time Call. Jesse E. Boone, Almedia, Pa. Application filed July 2, 1906.

This is an annunciator with a signal operated by the hour and minute hands of a clock. The minute hand makes several short contacts while the hour hand makes one long one.

866,331. Railway Signal. Frederic B. Camors and Charles Pelletier, New Orleans, La. Application filed May 1, 1906.

This system employs the rails and auxiliary conductors insulated from the earth to form the circuits for a signal and a telephone carried in the car.

866,349. Trolley-pole Support. Hugh W. Fellows, Cahuenga, and Ira A. Cammett, Hollywood, Cal. Application filed September 15, 1905.

A spring working through a jointed brace is used in raising a rigid trolley pole. If the pole is raised above the wire, another spring causes it to drop to a point below the wire.

866,363. Trolley Wheel. Henry L. Humphrey, Monroe, Mich. Application filed October 12, 1906.

The hub of the wheel is parted on its middle plane, the two parts being flanged to fit and to be bolted together, and one of the flanges carrying the grooved rim of the wheel. The central part of the wheel journal is globular, so that the wheel can oscillate sideways through a small angle as well as rotate freely.

866,377. Push Button. George H. Mebold, New York, N. Y. Application filed March 16, 1907.

This push button has T-shaped contact plates attached to the base-plate and extending radially toward each other and a button provided with a shoulder and an interior metallic rim adapted to be placed in contact with the inner ends of the contact-plates, a helical spring being interposed between the base-plate and a cavity in the interior of the button.

866,387. Galvanometer. Jules Richard, Paris, France. Application filed January 27, 1905.

The galvanometer has two magnets with pole-pieces curved on concentric lines, the poles of one magnet being located within those of the other. The galvanometer coil is mounted on a V-shaped frame having one of its sides in each of the magnetic fields.

866,421. Process of Effecting Chemical Reductions and Producing Metals or Alloys. Frederick M. Becket, Niagara Falls, N. Y., assignor to the Electro Metallurgical Company. Application filed January 31, 1907.

This is a process for reducing vanadic oxide and consists in effecting reduction to vanadous oxide by the oxidation of carbon and reduction to vanadium by the oxidation of silicon and electrically supplied heat.

866,462. Selenium Cell. William J. Hammer, New York, N. Y. Application filed February 5, 1907.

A selenium cell of the incandescent lamp type comprises an inclosing envelope consisting in part of fused quartz and forming a vacuous inclosure for the selenium, screw-shell and central stud terminals upon the outside of the envelope, and means for connecting the selenium to the terminals outside of the envelope.

866,471. Electric Bell. Robert L. Hunter, Lakewood, Ohio, assignor of one-half to Don M. Osborne, Cleveland, Ohio. Application filed June 9, 1905.

This bell is of solenoid construction and has a casing of magnetic material inclosing the solenoid and provided with an integral pole-piece projecting within one end of solenoid and an insulating non-magnetic head inserted in the end of the casing opposite this pole-piece. A contact member is mounted in this head, and a plunger reciprocates within the solenoid and is resiliently held in contact with the contact member.

866,473. Electric Lamp Bracket. Daniel C. Keefe and Thomas M. Smith, New York, N. Y.; said Smith assignor to said Keefe. Application filed June 7, 1906.

This lamp support consists of an extensible lamp carrying tube having telescoping sections, the tube fitting into a cup which provides a receptacle wherein the wire automatically coils and uncoils.

866,484. Alarm. Thomas R. Kinsella and Christopher W. Hodgetts, Hartwell, Ohio. Application filed March 21, 1907.

This is an electric alarm for street cars. The top of the controller box has two adjacent arcs forming terminals of the alarm circuit. The controller handle has a button connecting by means of a flexibe shaft in a bore through the handle to a shoe adapted to bridge the terminal arcs and thus sound the alarm in any position of the handle.

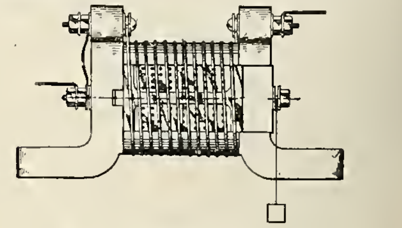
866,498. Method of Melting Through Masses of Material. Adolf E. Menne, Creuzthal, and Wilhelm Zollenkopf, Cologne, Germany, assignors to Cöln-Müsener Bergwerks Actien Verein, Creuzthal, Germany. Application filed August 27, 1906.

This method of perforating masses of metal and masses containing combustible parts consists in providing a pipe in an electric circuit, contacting it with the mass, and then withdrawing it to form an electric arc, permitting the arc to play for a brief interval of time only, and then admitting gases containing oxygen to the pipe, blowing out the arc, and burning out the required perforation in the mass.

866,521. Automatic Safety Apparatus for Railways. George E. Ryan, New York, N. Y. Application filed September 27, 1906.

A track device has a pin adapted to project into the path of a trip mechanism, a cam controlling the position of the pin, an electromagnet having a core connected with the cam, a catch for maintaining the cam in a set position, and an electromagnet controlling the catch to release the cam.

866,556. Lightning Arrester. Azel Ames, Jr., New York, N. Y., assignor of one-half to Asbury G. Wilson, Wilkinsburg, Pa. Application filed August 16, 1906.



NO. 866,556.—LIGHTNING ARRESTER.

This lightning arrester has a recessed body of insulating material open at one side, wire coiled around the body and extending over the recess, and a combined core and ground terminal within the body-recess and held therein by the pressure of the coil. (See cut.)

866,561. Process of Producing Alloys. Frederick M. Becket, Niagara Falls, N. Y., assignor to the Electro Metallurgical Company. Application filed December 22, 1906.

This is a process for producing ferro-vanadium and consists in reacting in an electric furnace upon vanadium oxide with ferro-silicon, the ferro-silicon containing not less than fifty per cent. of silicon.

866,577. Telephone-receiver Holder. Arlington D. Brittain, Youngstown, Ohio. Application filed December 15, 1906.

This holder consists of a number of connected levers for adjustably holding the receiver to the subscriber's ear.

866,590. Electrical Switch. Michael J. Kehoe, Fort Wayne, Ind., assignor of one-third to Benjamin Lehman, Fort Wayne, Ind. Application filed November 2, 1905.

An open-air high-tension switch has a horizontally movable frame carrying the contact blade. The frame oscillates on two long arms pivoted at their bottom ends.

866,596. Insulator. William A. Morton, Los Angeles, Cal. Application filed November 6, 1906.

This insulator comprises a body having a screw-threaded passage with a slot therein, and a screw-threaded part engaging in the passage, and having a longitudinal groove.

866,597. Process of Producing Manganese Silicide. Edgar F. Price, Niagara Falls, N. Y., assignor to the Electro Metallurgical Company. Application filed November 14, 1905.

The process consists in smelting a charge of compounds of manganese, silicon and carbon in an electric furnace and surrounding the zone of reduction and protecting the electrodes by a considerable body of the charge, the current being maintained at the lowest potential difference possible.

866,610. Massage Vibrator. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Samuel L. Kistler, Los Angeles, Cal. Application filed October 8, 1906.

This consists of an applicator driven by an electric motor through an eccentric. The vibratory stroke is adjusted by varying the eccentricity of the eccentric.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired September 23, 1907:

436,779. Electric-motor Car Truck. E. W. Goss, Amesbury, Mass.
436,814. Electric Arc Lamp. A. Wagniere, Los Angeles, Cal.
436,843. Electric Controller for Power Mechanisms. R. D. O. Smith, Mishawaka, Ind.
436,857. Coupling for Electric Wires. F. R. Jones, Kearney, Neb.
436,864. Electric Heater. E. Abshagen, Chicago, Ill.
436,874. Electric Contact Device. J. J. Hoppes, Springfield, Ohio.
436,895. Process of Electro-depositing Aluminum. J. A. Jeancon, Newport, Ky.
436,910. Electrical Weighing Machine. W. Snelgrove, King's Norton, England.
436,923. Electric Railway. H. W. Libbey, Boston, Mass.
436,952. Thermal Cut-out. G. H. Whittingham, Baltimore, Md.
436,961. Portable Electric Fire Alarm. F. R. Upton, Orange, N. J.
437,008. Holder for Electric-light Shades. L. J. Atwood, Waterbury, Conn.
437,010. Telephone Exchange System. E. M. Bentley, Boston, Mass.
437,011. Artificial Resistance. E. M. Bentley, New York, N. Y.
437,012. Telephone Exchange System. E. M. Bentley, Boston, Mass.
437,069. Electric Distance Heat Indicator and Alarm. F. W. Wieschrock, New York, N. Y.
437,111. Rheostat. J. H. Gunnings, New York, N. Y.
437,126. Underground Electric Conduit. C. E. Loth, Troy, N. Y.
437,158. Electric Railway. R. M. Hunter, Philadelphia, Pa.
437,160. Dynamo-electric Machine or Motor. M. Mayer, New York, N. Y.

20TH ANNIVERSARY AND FALL TRADE NUMBER.

Western Electrician

Vol. XLI. $3.00 Per Annum. Copyright, 1907, by Electrician Publishing Company, Chicago. CHICAGO, SEPTEMBER 28, 1907. Entered at Chicago Post Office as mail matter of the second class. 10 Cents a Copy. No. 13

ALPHABETICAL INDEX TO ADVERTISEMENTS.

For Classified Index of Advertisements See Page 6.

H-P Rustless Cable Hanger

For Suspending Telephone and Telegraph Cables

The hanger is made of one piece of zinc. This prevents any electrolytic action between separate parts, and there are no loose parts to become separated or lost. It will not rust, will not slip and is easily applied. The demand is constantly increasing — over 1,000,000 were sold during the past year. Cable chair passes over it without injury to either cable or hanger. Packs snugly 500 to a small box.

Samples and discounts sent on application.

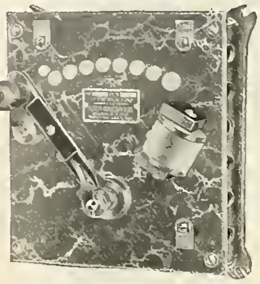
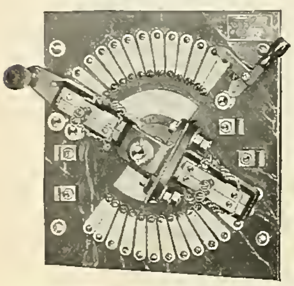
CUTLER-HAMMER

MOTOR STARTING RHEOSTATS

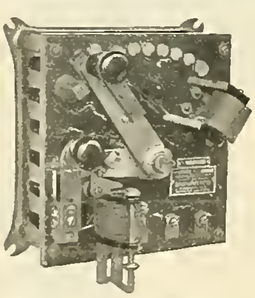
More than 300 Standard Types and Sizes



Motor Starting Rheostat with no voltage release. (Bulletin 10.)



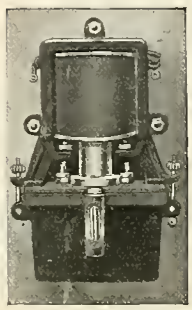
Starting Rheostat for induction motors —squirrel-cage type. May be used in place of auto-transformer or compensator with small motors. (Bulletin 18.)



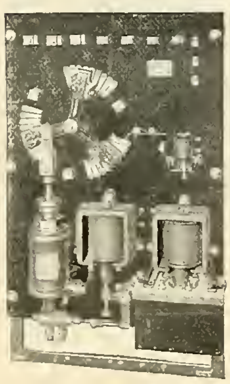
Double Lever Motor Starting Rheostat. Moisture proof Resistance. (Bulletin 17.)

A. C. SELF STARTERS

Controlling Apparatus for the automatic starting and stopping of motors operating on A. C. Circuits is one of our specialties



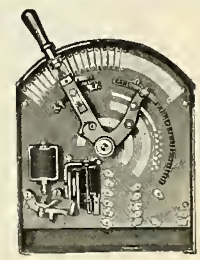
Self-starter for alternating-current motor—single, two or three phase. (Bulletin 33.)



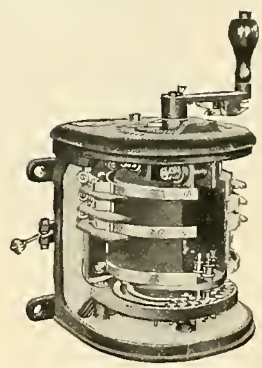
Self-starter for two or three phase A. C. motor—slip ring type. (Bulletin 35.)

MACHINE TOOL and PRINTING PRESS Controllers

Nearly 100 pages of our complete catalogue are devoted to descriptions of Cutler-Hammer Machine Tool and Printing Press Controllers



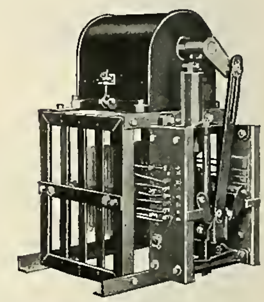
Printing Press Controller, "Carpenter" Type. (Bulletin 85½.)



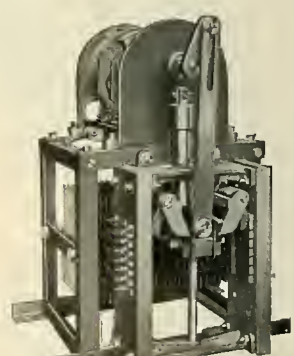
Machine Tool Controller. (Bulletin 78.)

Elevator Controllers

Our line of Elevator Controllers is now the most complete on the market



Elevator Controller, for use in connection with direct-current motors. (Bulletin 54.)



Elevator Controller for alternating-current motor—slip ring type. (Bulletin 56.)

THIS ADVERTISEMENT gives only an inkling of what we make. Our catalogue gives a better idea, for in it are listed no fewer than 2,500 types and sizes of STANDARD Cutler-Hammer controlling devices. Even the catalogue, however, does not tell the whole story for we make special apparatus as well.

WE DO NOT MAKE motors, nor generators, nor any appliances for electric lighting (except Theater Dimmers), but we DO make every conceivable device for CONTROLLING the electric current. Let us know in what line of controlling apparatus you are interested and we will gladly send descriptive Bulletins covering it.

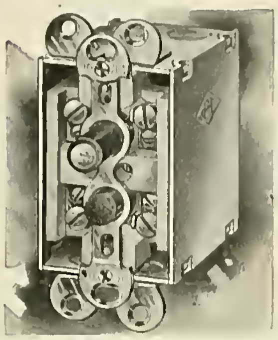
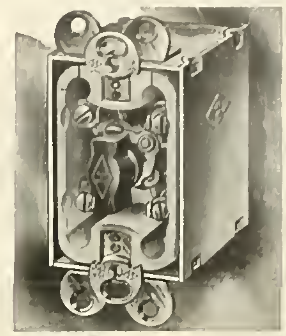
LARGEST MAKERS OF ELECTRIC CONTROLLING DEVICES IN THE WORLD

1897-1907



Push-Button Switch in Wall Case



Rotary Flush Switch in Wall Case

"DIAMOND H"

SWITCHES AND RECEPTACLES

Standard Switch without Dial

Standard Switch with Indicating Dial

When "Diamond H" Switches and Receptacles were first placed on the market in 1897 they were better than other makes. We have constantly strived to bring them nearer perfection, and they are today absolutely the best on the market. Slight improvements are always being made with the object in view to improve them faster than their new features can be copied by others. In simplicity of design, constructive strength and mechanical excellence they are unequaled.

"Diamond H" Steel Wall Cases are for "Diamond H" push-button and rotary-flush switches and for "Diamond H" flush receptacles. The reversible ear in these cases is a new feature and allows the case to be used in the regular way for old work, or for new work, by simply reversing the ear. The cases are made of cold rolled steel, eighty-five thousandths thick, and galvanized by the hot process to prevent rusting. They are made single and in gangs up to number ten. Made for flexible conduits and for iron pipes; provided with plug outlets.

"Diamond H" Switches are best because they are backed by seventeen years of practical experience in electric switch construction.

"Diamond H" Flush Receptacles are specified by exacting architects and contractors. They cannot ground or short-circuit. No lids to pry open, no broken finger-nails. Open or close alternately by inserting or withdrawing plug.

Write *to-day* for our new literature.

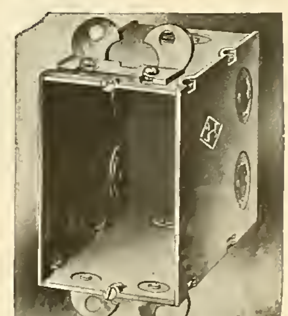
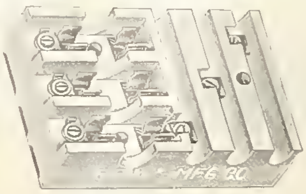
"Diamond H" Wall Case with Ears in Regular Position. To Use for Wiring Old Walls



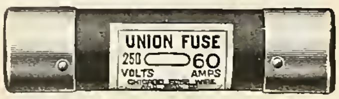
"Diamond H" Wall Case with Ears Reversed. To be Plastered in for New Work



From the first Fuse we ever made to the last Fuse finished today we have never lost sight of the principle that absolute perfection must prevail, in consequence of which our fuses are recognized to be scientifically constructed, accurately and carefully designed, perfect in operation, under all conditions.

The combined effect of these features makes the "Union" fuse the most accurate

"UNION" MEANS PERFECTION



Have you seen our new No. 19 Catalogue? Perfect in every detail giving all measurements of fuses and blocks. Write for one today.

100,000 VOLTS

THE WORD

For Decisions of great moment; for a crucial test; for installations demanding the avoidance of all questionable material and service, so far as possible and for great pioneer work, "VICTOR" Insulator quality and Victor service are demonstrated.

Stanisiaus Electric Power Co.
100,000 Insulator

THE DEED

This company has supplied the first

60,000-volt Insulators
The Bay Counties Electric Co., California
The Standard Electric Co. of California

66,000-volt Insulators
Grand Rapids-Muskegon Power Co., Mich.

75,000-volt Insulators
Edison Electric Co., California

and now has just been awarded the contract for 150 miles of 100,000-volt Insulators for the Stanislaus Electric Power Co., California; Sanderson & Porter, Engineers, New York City.

Your conclusions will satisfy us. "Victor" Insulators and service are insurance at 6,600 or 16,000 or 33,000 as well as at 100,000 volts.

The Locke Insulator Mfg. Co., Victor, N. Y., U. S. A.

WANTED, FOR SALE *and similar* **WANT COLUMN** *advertisements (50 words or less), $1.50 an insertion; additional words 3c each* **POSITION WANTED** *advertisements (50 words or less), $1.00 an insertion; additional words 2c each.*

POSITION WANTED

As manager of light and power plant in western state. Have been in present position four and one-half years, and can furnish splendid references from present employers. Have had fifteen years' experience in installing and operating plants. Have technical knowledge covering all the branches of steam and electrical business. Am familiar with office work, can secure and keep the good will of customers. Have been very successful in increasing the net earnings of the plants I have been connected with. Would expect a salary of $1,800 per year, and to be given full sway to manage plant to what I consider best advantage. Address Box 751, care of Western Electrician, 507 Marquette Bldg., Chicago.

POSITION WANTED

By an electrical engineer, technically educated and experienced in both operation and construction. Until recently employed by large power company on Pacific coast. Superintendent of plants in central states. Best of references, Asso. A. I. E. E. Prefer construction work, but will consider anything where ability and integrity will be appreciated. Address Box 750, care of Western Electrician.

WANTED

The Universal Mfg. Co. desires to enter into correspondence with reliable traveling salesmen who call on central stations, and who are in position to handle effectively an important and well-paying line. Liberal terms. Address The Universal Mfg. Co., 204-206 Illinois Street, Chicago, Ill.

WANTED

Line man for permanent position. Must be sober and a hustler. Reference required. State salary expected. Wabash Water and Light Co., Wabash, Ind.

WANTED

An up-to-date manager, capable in every way to take charge of an electric-light plant in central Wisconsin, in a city of 7,000 inhabitants. Address Box 749, care of Western Electrician Chicago.

FOR SALE

SPECIAL BARGAIN
Railway Motors

We have just closed out from the Westinghouse Electric and Manufacturing Co., East Pittsburg, Pa., their entire stock of No. "33 S," Walker railway motors. These are 30 H. P. brand-new motors complete with gears, pinions and gear cases—3¾-in. axles. We have 70 of these motors in stock in Chicago ready for immediate shipment.

Single-Phase—125-133 Cycle Motors

	H. P.		Speed.
1	¼	Holtzer-Cabot, 110 volts, self-starting	2500
1	½	Century auto., 110 volts	1940
1	1	Holtzer-Cabot, 110 volts	2500
2	1	Wagner auto., 208 volts, model B	1815
1	1	Wagner auto., 208 volts, model A	2000
1	1½	Holtzer-Cabot, 110 volts	2600

Single-Phase —60 Cycle Motors

	H. P.		Speed.
2	⅛	Emerson, 110 volts, class 3242 B. A.	1700
5	⅙	Emerson, 110 volts, class 3242 B. A.	1700
5	¼	Holtzer-Cabot, self-starting, 110 volts	1800
1	¼	Wagner, 110 volts, Model C.	1800
1	½	Gen. Elec., hand-starting, 110 volts	1800
1	½	Century, 110 or 220 volts	1750
1	½	Century, variable speed, auto., with controller, 220 volts	1750
1	½	Century, vertical type, 110 or 220 volts, automatic	1750
1	1	Stanley, type I, 220 volts, with condenser	1800
1	1	Century, 110 or 220 volts, auto.	1750
1	1	Century, vertical type, 110 or 220 volts	1750
1	1½	Century, 110 or 220 volts, auto.	1165
1	2	Century, 110 or 220 v., auto.	1750
1	3	Wagner, 220 volts, model B. auto	1750
1	3	Century, 110 or 220 v., auto.	1750
1	4	Century, 110 or 220 v., auto.	1750
3	5	Westinghouse, 110 volts, type C. C., with phase splitters	1120
1	5	Century, 110 or 220 v., auto.	1750

Single-Phase—40 Cycle

	H. P.		Speed.
1	¼	Emerson, 115 volts	740

Two-Phase—60 Cycle

	H. P.		Speed.
1	2	Gen. Elec., form K, 220 v.	1800
1	5	Gen. Elec., form K, 110 volts, with starter	1200
1	7½	Westinghouse, type C. X., 110 volts, with auto.-starter	1120
1	25	Gen. Elec., 220 volts, form K, with starter	1200
1	15	Gen. Elec. form L.	2200

Three Phase—25 Cycle

	H. P.		Speed.
1	3	Stanley 110 volts	750
1	10	Westinghouse, 440 volts	1420
1	10	Westinghouse, 440 volts	720
2	20	Westinghouse, 440 volts	1420
1	20	Westinghouse, 440 volts	720
2	30	Westinghouse, 440 volts	720

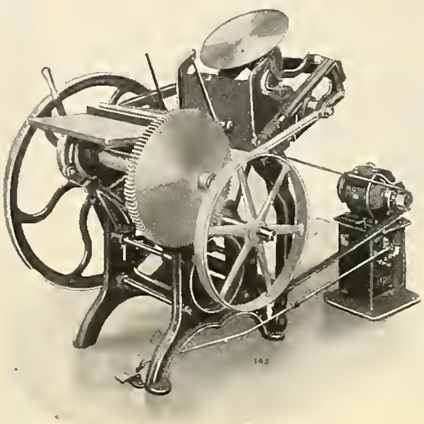
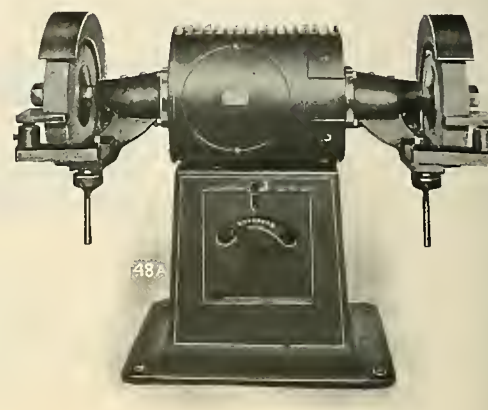
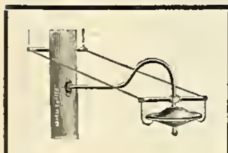
Electric Forge Blower

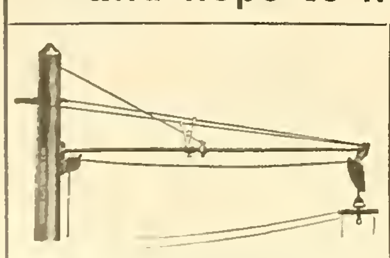


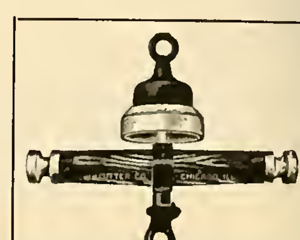
Printing-Press Outfit

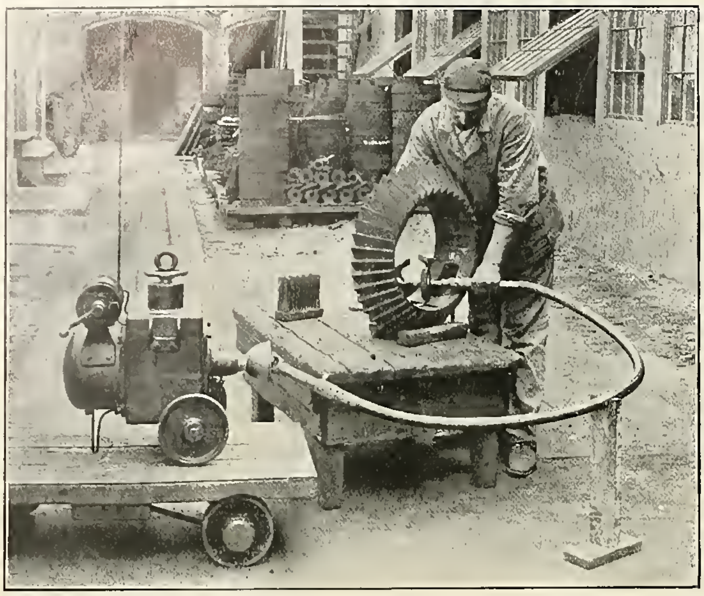


Grinding and Polishing Machine









Electric Emery Grinders

as manufactured by

STOW MFG. CO.

BINGHAMTON, N. Y.

General European Agents

Selig, Sonnenthal & Co.

85 Queen Victoria St., London, England

Portable Electric Grinders

We build these in four sizes:

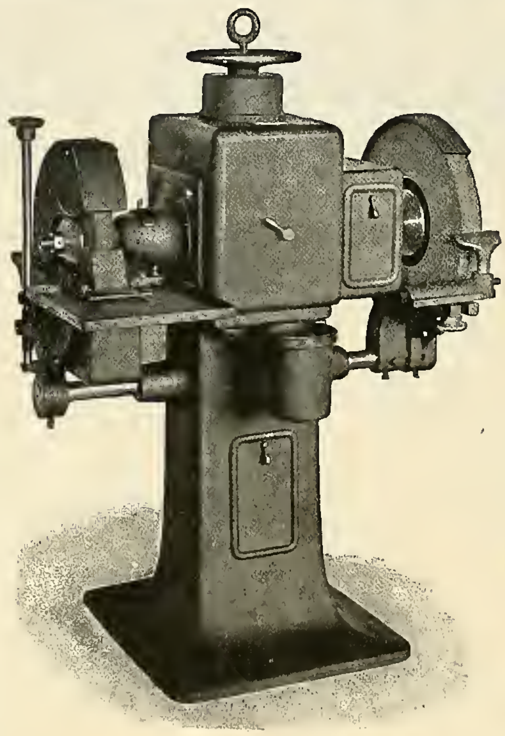
No. 4—¾ H. P. Motor
Emery Wheel capacity 6x1¼ in.

No. 5—1½ H. P. Motor
Emery Wheel capacity 8x1¼ in.

No. 6—2 H. P. Motor
Emery Wheel capacity 10x1½ in.

No. 8—3 H. P. Motor
Emery Wheel capacity 12x2 in.

For 110 or 220 volts they are furnished as shown in cut. For 500 volts with wood truck for better insulation. This latter is extensively used by street railways for grinding rails in bonding.



The Stow Multi - Speed Motor

is used in these machines.

RESULT:

Wide Range of Speed
Infinite Variation in Speed

A fraction of a turn of the regulating wheel on top of motor will make a corresponding change in speed of emery wheel.

Mechanical Regulation of Speed

No rheostats or controllers to fill up with dust and burn out.

Stationary Electric Grinders

Perhaps **Semi-Portable** would be a better name for this machine, because by loosening a few bolts it can be readily changed from place to place without regard to counter shafts or line shafts.

We build these machines in two sizes, the smaller taking two dry wheels, 2x18-inch or one 12-inch wet wheel and one 2x18-inch dry wheel.

The larger tool will carry two 3x24-in. wheels.

We build these machines for direct current only.

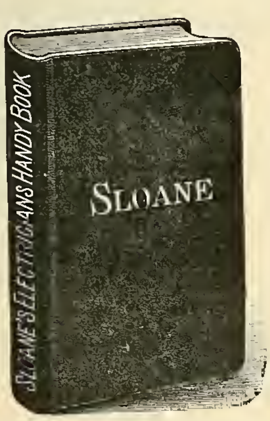
ELECTRICIAN'S HANDY BOOK

By Prof. T. O'CONOR SLOANE



Pocket Book Size. Handsomely Bound in Leather with Title and Edges in Gold. About 800 Pages. 500 Illustrations.

PRICE $3.50

THE latest, best and most complete book on Electricity, covering the subject of Practical Electricity in all its branches written by a well-known author in a manner that can be readily understood, and intended for the every day working electrician.

PARTIAL LIST OF CHAPTERS

Mechanics as Applicable to Practical Electricity—Electric Currents—Ohm's Law and Electric Energy—Alternating Currents—Direct-Current Dynamos—Care and Running of Dynamos—Direct-Current Motors—Alternating-Current Generators—Alternating-Current Transformers—Alternating-Current Motors—Distribution of Electric Currents—Arc Lamps—Incandescent Lamps—Electric Railways—Primary Batteries—Secondary Batteries—Central Station—Switchboards—Electric Heating and Cooking—Lightning Rods—Roentgen or X-Ray Work—Electric Elevators—Electro-Metallurgy and Electro-Chemistry—Electric Measurements, and Instruments used in Station Work—Miscellaneous Data, Formulas and Suggestions, etc., etc.

EVERY PROGRESSIVE ELECTRICIAN WHO WISHES TO KEEP UP WITH THE TIMES SHOULD HAVE THIS VALUABLE WORK

Send all orders to

ELECTRICIAN PUBLISHING COMPANY, 507 Marquette Building, Chicago, Ill.

PROPOSED RATES IN NEW TELEPHONE ORDINANCE

Single line nickel service,	20 cents;	now 30 cents a day.	
Two-party " " "	15 "	" 20 "	"
Two-party " residence "	10 "	" 20 "	"
Four-party " " "	5 "	" 10 "	"

Ten-party line abolished.

Single-line residence, unlimited service, $72 per annum; now $100.

Two-party line residence, unlimited service, $56 per annum; now $75.

Measured Rates for Business—

First 100 calls in month, $5.

Next 200 calls in month, 3 cents each.

Additional calls, 2 cents each.

Business users with 24 or more calls daily are furnished with two lines at $102 per annum each; additional calls, 2 cents each.

No charge for private branch exchange switchboards.

Trunk lines, $24 per annum; now $36.

The unlimited trunk line rate of $1 per day is to continue same as now for heavy users.

Extension telephones of all kinds, 50 cents per month.

The exchange limits cover the entire city without mileage charge.

No toll to outlying exchanges, such as Rogers Park, Austin, Pullman, South Chicago, etc. Toll from these neighborhood exchanges to other districts in the city, 5 cents; now 10 cents.

The reduction affects more than 95 per cent of the telephones in the city and provides a greatly improved service.

The right is reserved to the city to regulate rates, limit earnings and purchase the property after ten years.

The design of the ordinance is to provide the best possible service at the lowest possible cost.

CHICAGO TELEPHONE CO.

"We are in very great need

of telephone girls," wails a manual operating company, in a letter to us. "Can you advise us where you have recently replaced manual boards with automatic so that we can get in touch with them?

"We must have girls

from somewhere." We sympathized with the company, told them where we thought they might be able to get some girls, but we suggested the

Automatic System as the Solution

of their problem, which is becoming a common one among manual companies. Have you encountered it yet? When you do, remember that the Automatic dispenses with girls, saves money, makes money, and gives the best service. Automatic equipment has been adopted in the following cities:

Aberdeen, S. D.	Havana, Cuba.	Princeton, N. J.
Akron, Ohio.	Hazleton, Pa.	Richmond, Ind.
Allentown, Pa.	Holland, Mich.	Riverside, Cal.
Auburn, Me.	Hopkinsville, Ky.	Rochester, Pa.

Those who are most intelligent read most.

Those who read most are most intelligent.

The thinking man necessarily bases most of his thoughts upon the thoughts of others. The general growth and the specialization of the electrical business are such that it is absolutely necessary that a man should read the latest and best electrical books if he desires to keep abreast of the times. We are headquarters in the West for electrical books, and can fill orders for any work published, promptly on receipt of price.

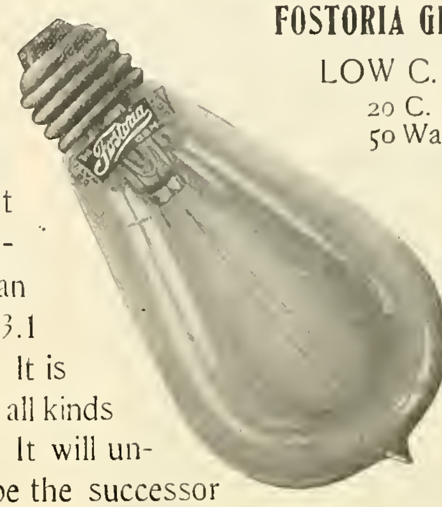
PEERLESS

FOSTORIA

FOSTORIA TANTALUM
22 C. P.
44 Watts

This lamp is 75 per cent. more efficient than the carbon filament lamps you have been using. It is the most economical electric lighting unit ever developed. We recommend it for either direct or alternating current. Life on former, 700 hours; on latter, 450 hours.

FOSTORIA GEM
LOW C. P.
20 C. P.,
50 Watts



The GEM low C. P. lamp is 25 per cent more economical than the carbon 3.1 watt lamp. It is adapted for all kinds of service. It will undoubtedly be the successor of the carbon filament lamp in all branches of electric lighting in a very short time. Try it now. This lamp is also made in high C. P.'s

---

No regular user of lamps can afford to procrastinate in the investigation of the modern high economy lighting units, of which two are featured above. We have complete bulletins on all of them. They will be mailed upon request.

However, we are still making the famous "Standard Fostoria" carbon filament lamp in ever-increasing quantities. Its quality is unexcelled. Its price the same as during the past TWELVE YEARS. We give you more for your money on carbon filament lamps than any other manufacturer.

FOSTORIA INCANDESCENT LAMP CO.

25c BOOKS

ELECTRICITY. The study of, and its laws for beginners, comprising the laws of electric current generation and flow, Ohm's law, galvanism, magnetism, induction, principles of dynamos and motors, wiring, with explanations of simple mathematics as applied to electrical calculations. By N. H. Schneider. With 55 original illustrations and 6 tables.

DRY BATTERIES. A practical handbook on the designing, filling and finishing of dry batteries, with tables, for automobiles, gas engine, medical and coil work, electric bells, alarms, telephones, experiments and all purposes requiring a first-rate battery. Fully illustrated with 30 original drawings.

ELECTRICAL CIRCUITS AND DIAGRAMS. Being a selection of original up-to-date and practical diagrams for installing annunciators, alarms, bells, electric gas lighting, telephones, electric power light and wiring circuits, induction coils, gas engine igniters, dynamos and motors, armature windings. By N. H. Schneider.

ELECTRIC BELLS AND ALARMS. How to install them. By N. H. Schneider. Including batteries, wire and wiring, circuits, pushes, bells, burglar alarms, high and low water alarms, fire alarms, thermostats, annunciators, and the locating and remedying of faults. With 56 original diagrams.

MODERN PRIMARY BATTERIES. Their construction, use and maintenance, including batteries for telephones, telegraphs, motors, electric lights, induction coils, and for all experimental work. By N. H. Schneider. 94 pages, 55 illustrations. The best and latest American book on the subject.

EXPERIMENTING WITH INDUCTION COILS. H. S. Norrie, author of "Induction Coils and Coil Making." A most instructive little book, full of practical and interesting experiments, fully explained in plain language with numerous hints and suggestions for evening entertainments. Arranged under the following headings: Introduction; The Handling of Ruhmkorff Coil; Experiments with Sparks; Effects in the Vacuum; Induction and Wireless Telegraphy. With 36 original illustrations. [In the press.]

SMALL ACCUMULATORS. How made and used, by P. Marshall. Giving full descriptions how to make all the parts assemble them, charge the cells and run them, with examples of their practical application. Useful receipts and memoranda and a glossary of technical terms. 80 pages, 40 illustrations, paper.

ELECTRIC GAS LIGHTING. How to install electric gas igniting apparatus including the jump spark and multiple systems for all purposes. Also the care and selection of suitable batteries, wiring and repairs, by H. S. Norrie. 101 pages, 57 illustrations, paper.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, OCTOBER 5, 1907. No. 14

The Schaffhausen-Schleitheim Electric Railway.

By Dr. Alfred Gradenwitz.

Cars of the Schaffhausen-Schleitheim Electric Railway of Switzerland are designed for two operating voltages, the lower tension being that of the municipal tramways of the city of Schaffhausen (the tracks of which the railway uses), with a higher tension for the interurban section. The construction of the motors, as well as the arrangement of the car-lighting plant, had accordingly to be adapted to these two voltages.

Starting at the Rheinhof terminal at Neuhausen, the railway goes through a number of towns and terminates at the station of Oberwiesen situated behind Schleitheim on the frontier of Switzerland and Baden. From its present terminus the railway is to be continued on Baden territory as far as Stühlingen, connecting with the strategical railway.

The road, 17.17 kilometers in length, with a gauge of one meter, runs on the public roads throughout its length and has a maximum gradient of 60 per 1,000 over a length of 50.39 meters. The difference in altitude between Schaffhausen and the highest point on the line, viz., Siblingerhöhe, is 149.26 meters. The track construction is of grooved rails on village streets and road crossings, with Vignole rails on other portions. The roadbed is 2.1 meters in breadth and 30 centimeters in height, consisting of crushed stone covered with gravel. The rails are placed on ingot-iron sleepers 1.6 meters in length, weighing 15.3 kilograms per meter. The grooved rails are 12 meters in length and have a weight of 30.8 kilograms per meter. The Vignole rails have the same length and a weight of 24.2 kilograms per meter. The minimum radius of curvature is 12 meters.

The electric works of the city of Schaffhausen has two 150-kilovolt-ampere transformers, raising the tension of the current supply to 10,000 volts. The high-tension line leading to the transformer station consists of three wires five millimeters in cross-section, while six-millimeter wires are used only at railway crossings. The line is carried on wooden poles and crosses the Rhine River on iron framework towers. After repeatedly crossing the municipal tramways and the Swiss and Badenian railways, it terminates at the converter station of Siblingen. The high-tension wire is protected at both ends by lightning arresters, in the earth conductors of which are inserted water resistances. Three-pole circuit-breakers are arranged at both ends.

The converter station comprises the high-tension transformer room, the engine room (containing the converter set and switching plant), the battery room, car shed, painting and other shops, and the offices and accommodation for the superintending staff.

The shed contains three tracks, with two cleaning pits in which the tracks are supported by concrete pillars. One of the tracks leads to the workshop containing two lathes, one drill, one planing machine and a forge, the ventilator of which is operated by hydraulic vanes. All the machine tools are operated from a main shaft run by an electric motor.

The transformer room is planned for receiving three transformers, and at present contains two of the Oerlikon type. These transformers, of 150-kilovolt-ampere capacity each, will reduce the tension from 10,000 to 380 volts, their number of periods being 50 per second. They are placed in oil baths without any artificial ventilation, which, owing to the intermittent operation, was not found necessary. The three high-tension cores have each a coil of 780 windings of a wire 2.6 to 3 millimeters in thickness, and the low tension cores a coil of 30 windings of 40 by 3 millimeters copper tape. The housings are grounded. The efficiency of the transformer is 97 per cent. in the case of full load, 96.5 per cent. on three-fourths load and 96 per cent. on one-half load.

For each transformer there has been provided an iron frame carrying the three-pole high-tension train switch and three tubular fuses designed for being cut out. The lightning arresters are arranged on a special frame. The five-kilowatt station transformer, mounted on a bracket, and which supplies the lighting current, will reduce the high tension to 125 volts.

The engine room, which is served by a three-ton hand-operated traveling crane, is designed for three motor-generator sets, two of which have at present been installed. Each of these sets comprises an asynchronous motor connected by an insulating flexible clutch to a four-pole direct-current dynamo.

The motors, giving an output of 165 horsepower under a tension of 380 volts with 735 revolutions per minute, are designed as double-bearing machines, with stationary primary windings and rotating induced windings. The iron body of the rotating and stationary parts is laminated.

The dynamos are designed on the external-pole type for a capacity of 110 kilowatts, and will

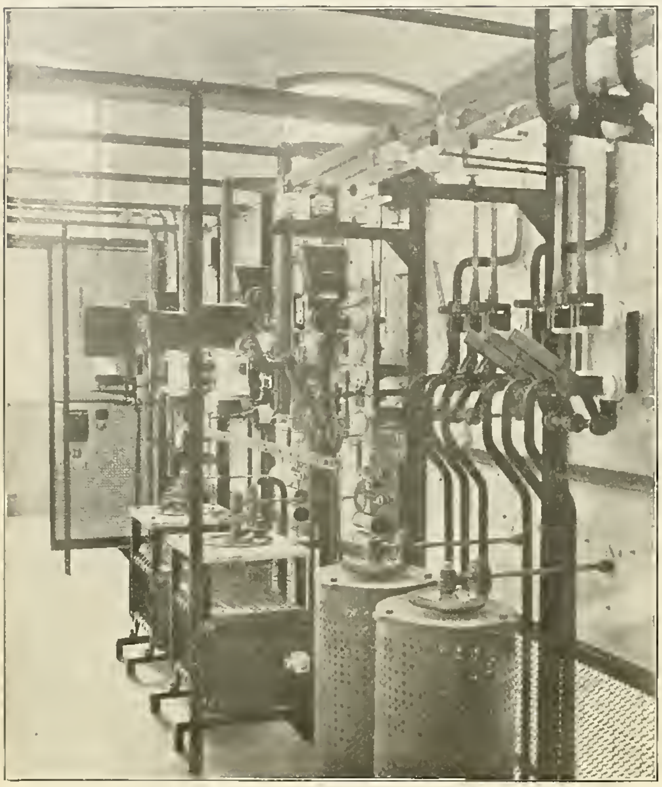
Transformer Room in Sub-station.

SCHAFFHAUSEN-SCHLEITHEIM ELECTRIC RAILWAY OF SWITZERLAND.

generate direct current at 800 volts and 138 amperes with 735 revolutions per minute. The commutator is made of hard-drawn mica-insulated copper, and the brushes of carbon. The exciter windings are arranged in shunt and are fed from the bus-bars. The dynamos are assisted by a storage battery consisting of 390 cells, which is able to yield 200 ampere-hours with a one-hour discharge.

Two triple pole switches, six single-pole safety fuses and two amperemeters are inserted into the circuit leading from the secondary terminals of the two transformers to the bus-bars of the switchboard. For the secondary bus-bars of the transformer is further provided a voltmeter. The stator coils of the two converters are connected to the secondary bus-bars of the transformers. An amperemeter is arranged for each motor to control the current input. The rotor circuit comprises the starter, which is used both for regulating the speed in starting and for switching out of circuit. When the rotor circuit is short-circuited the brushes are lifted off the slip rings, that is, during the operation of the motor the starter is switched off the rotor circuit.



DIRECT-CURRENT SWITCHING PLANT OF THE SCHAFFHAUSEN-SCHLEITHEIM ELECTRIC RAILWAY.

The trolley-wire circuit comprises a ground-circuit tester, two automatic maximum cut-outs, two amperemeters and two lightning arresters with magnetic blowouts. The ground-circuit tester consists of two push-buttons (one for each trolley wire), an intermediary resistance, an amperemeter and a small battery. In the case of short-circuit in one of the lines, the automatic switch of the latter being thrown out, the corresponding push-button of the ground-circuit tester will be first actuated, so that, on inserting the automatic switch, no short-circuit can be produced, the current being compelled to traverse the resistance. In the case of a continued short-circuit, the amperemeter will indicate the maximum current consumed by the resistance.

The trolley line consists of two shaped-copper wires 80 square millimeters in cross-section, suspended from wooden outriggers, partly by means of span wires. The feeder consists of a copper wire 34.48 square millimeters in cross-section, carried partly on the trolley poles and partly on span wires.

The rolling stock comprises four four-axle passenger cars (gross weight, inclusive of electrical equipment, 19,450, electrical equipment 6,060 kilograms), three passenger trailers (gross weight 5,510 kilograms), three enclosed freight cars for five tons effective load (gross weight 3,550 kilograms), and three open freight cars for the same effective load (gross weight 3,220 kilograms).

The motor cars are of the four axle type and are 15 meters in total length across buffers, the [illegible] center being 8.6 meters from each other.

Access to the interior of the car is obtained at the head ends through enclosed platforms. While the latter can be locked laterally by sliding doors, provision has been made for maintaining these doors in the open position or for replacing them by safety bars, which may be bolted. At each car head there is a rotary door giving access through an iron hinging bridge to the trailer. Connection between the platforms and passenger compartments is likewise obtained by sliding doors. Each motor car contains a passenger compartment for smoking and one for non-smoking, with 18 seats each. The compartments are separated by a baggage compartment with postal outfits.

The bogeys are provided with double springs, so as to insure a perfectly smooth running of the cars. The brake generally used is a compressed-air brake of the Böcker system, combined with a hand spindle brake. Electric braking has likewise been provided for.

The four car motors are designed on the Oerlikon type for an output of 45 horsepower each at a tension of 750 volts. The ratio of transmission to the running wheels has been chosen as 1:5. The motors, wound on the lattice drum type, are entirely enclosed.

According to contracts, the rise in temperature of the car motors after one hour's operation was not to exceed 75° C. with 45 horsepower, and this limit is far from being reached.

The mean output of the motor will be found at

$$\frac{748.8 \text{ volts} \times 55.3 \text{ amperes} \times 84}{746}$$

$= 47.2$ horsepower, allowing for the measuring instrument correction, 0.84 being the efficiency corresponding to 55.3 amperes. The energy input of the motor, corrected, thus works out at $748.8 \times 55.3 = 41.5$ kilowatts, while the energy output of the generator, corrected, is $450 \times 67.3 = 30.28$ kilowatts. The efficiency of the motor is thus 0.854.

The controllers are arranged on the series-parallel system, magnetic blowing being provided for. The arrangement of connections allows of both forward and backward traveling, with on or two motors, one motor being in each case replaced by a set of two motors connected up in parallel or in series. The motor cars are further equipped with maximum-current circuit-breakers, designed also for hand operation, as well as with lightning arresters and electric heating and lighting.

All trailers are of the double-axle type, with free guiding axles. The capacity of the passenger trailer cars is 24 seated and eight standing passengers.

Proposed Railroad Electrfications in Idaho.

Plans are under consideration for the electrification of the Bitter Root Mountain Division of the Chicago, Milwaukee and St. Paul's extension to the Pacific Coast. The section of the line, which it is planned to operate by electricity, is about 54 miles long and includes 8,000 feet of tunnel through the Bitter Root Mountains of Idaho and grades on both sides of the mountain. Considerable interest is being taken by railroad men in the fact that the St. Paul is considering the electrification of a protion of its new line, for all railroad plans for electrification are now being watched closely.

Writing under date of September 25th the San Francisco correspondent of the Western Electrician says:

"There is no further doubt as to the intention of the Southern Pacific Company to electrify its transbay lines in the immediate future, as it has closed contracts to the value of nearly $900,000 for the Fruitvale power house. The central power house will serve the lines in Oakland, Berkeley, Alameda and Fruitvale. The entire cost of changing the motive power from steam to electricity is estimated at $3,000,000, of which $900,000 will be for the power house, $500,000 for the cars and the remainder for track and other expenses. The portion of the Fruitvale plant already contracted for includes two 5,000-kilowatt turbo-generators and ten boilers. A third generating unit of 5,000-kilowatt capacity is to be ordered later. The cars will have overhead trolleys and direct-current motors, will be 71 feet long and will have a seating capacity of 64 in the motor cars and 80 in the ordinary cars. They will be run in solid trains."

This is the Oakland terminal electrification which Mr. Bion J. Arnold mentioned in his article on "The Rise of the Electric Railway" in the Western Electrician of September 28th.

Three-wire Direct-current Generators.[1]

By B. T. McCormick.

It is the purpose of this paper to give briefly the principles of operation of three-wire generators and to call attention to some of their advantages. The three-wire generator is the outgrowth of the well-known Edison three-wire system, in which two direct-current generators are connected in series, with a line known as the "neutral" tapped into the point where the machines are connected together. A load, usually light, is fed between each outside wire and the neutral. If the load is balanced on either side, no current will flow in the neutral, while in the event of an unbalanced system the neutral will be required to carry the current corresponding to the amount of "unbalancing." The main lines must be of sufficient capacity to carry current corresponding to the combined output of the machines at a voltage equal to twice the voltage of one machine, while the neutral need be only large enough to take care of the unbalancing. Such an installation when applied to a well-balanced 120-volt incandescent lighting load combines a saving in copper as a result of transmitting at the higher pressure of 240 volts, together with the advantage of a 120-volt installation for supplying the lights. It also possesses the advantages of a 240-volt system for power purposes, the motors being connected across the outside lines.

The three-wire generator is designed to accomplish the same results as the Edison three-wire system. It is more efficient, and not nearly so cumbersome, as only one generator is required instead of two generators of half the capacity.

The three-wire generator consists of a direct-current generator of the standard type, but provided with slip rings to which are attached taps from the armature winding, as in a rotary converter. A transformer known as the "balancing transformer" is mounted behind the switchboard or in some convenient position, and connected across the slip rings. A tap is brought out of the center of the transformer winding, to which the neutral wire is connected. Fig. 1 shows diagrammatically a three-wire generator in its simplest form, the two-pole diagram being used for simplicity. (A) and (B) are the main leads and (N) is the neutral. So long as the loads on each side of the neutral are equal, the balancing transformer (T) takes only the magnetizing current for which it is designed, but where one side is loaded more heavily than the other, the excess of current flows through the neutral into the middle tap of the transformer, and divides, as shown by the arrows (P) (P), half flowing to one ring and half to the other. In so dividing, the ampere turns in one-half of the transformer, due to the direct current, exactly balance the ampere turns in the other half, thus the magnetic flux in the balancing transformer remains constant regardless of the amount of direct current flowing. From the above it is evident

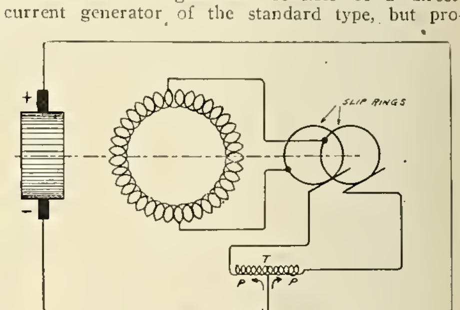


FIG. 1. DIAGRAM OF THREE-WIRE GENERATOR IN ITS SIMPLEST FORM.

1 Paper read at the annual convention of the Canadian Electrical Association in Montreal, September 12th. Mr. McCormick is electrical engineer for Allis-Chalmers-Bullock, Limited.

that the requirement for a balancing transformer is, that it shall have sufficient current carrying capacity to carry the unbalanced current and a sufficient number of turns and core area to generate a counter-electromotive force, the effective value of which is $\frac{E}{\sqrt{2}}$ where E is the normal direct current voltage between brushes.

A core-type of transformer is admirably suited to such service, and the coils on either side of the neutral tap are comprised of sections staggered from one leg of the core to the other, in order to reduce the magnetic leakage to a minimum.

Probably the most efficient three-wire outfits consist of a generator as described above but provided with a two-phase combination of balancing transformers, as shown in Fig. 2. The center taps are tied together and the neutral wire joined to the point of connection. Two pairs of slip rings are used, connected to taps in the armature winding situated 90 electrical degrees apart. Such a combination of two transformers results in a more even current distribution in the armature than can be secured by the use of a single transformer.

The cost of the balancing transformer is a very small part of the total cost of the apparatus, and depends, of course, upon the amount of unbalancing to be allowed. Ordinarily an allowance for about

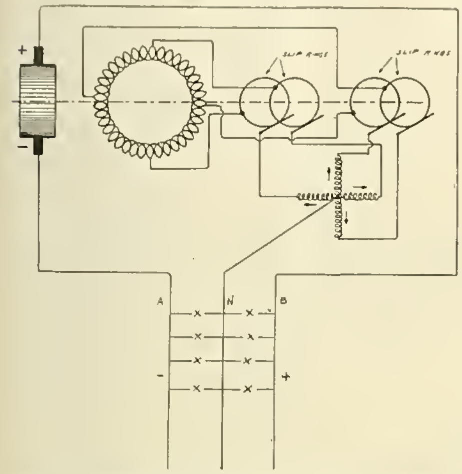

FIG. 2. THREE-WIRE GENERATOR WITH A TWO-PHASE COMBINATION OF BALANCING TRANSFORMERS.

25 per cent. unbalancing is sufficient. A concrete case will serve best to illustrate the size of transformer required. Suppose we wish to design a two-phase combination of balancing transformers for a 100-kilowatt 250-volt machine to take care of 25 per cent. unbalancing. The amount of current taken by two transformers is that corresponding to 25 kilowatts, or 100 amperes, and for one transformer, 50 amperes. As the current divides on entering the center tap of the transformer, the copper sections need be made only large enough to carry 25 amperes. The number of turns and core area must be such as to give a counter-electromotive force of $\frac{250}{\sqrt{2}}$ The volt-ampere capacity must therefore be $\frac{250}{\sqrt{2}} \times 25$. As a balancing transformer has but one winding, whereas an ordinary transformer has both a primary and a secondary, the above value must be divided by two to get a basis of comparison with a standard transformer $\frac{250}{\sqrt{2}} 25 \times \frac{1}{2} = 2.2$ kilowatts. Roughly speaking, therefore, the transformer should be about the size of a 2.2-kilowatt lighting transformer.

The generator, if shunt-wound, differs from standard generators only by the addition of the slip rings, while, if compound-wound, the alternate poles are connected so that half the poles receive their series excitation from each of the main leads. In this way the corresponding characteristics are still maintained even if one side of the system is completely unloaded.

Three-wire generators can be operated in multiple with one another, or in multiple with two-wire generators, and it is often convenient to operate a 120-volt machine in multiple across one side of 240-volt three-wire systems, to maintain a better balance, in case that side is unloaded.

The two-wire generator with rotating direct-current balancers, as a competitor of the three-wire generator, possesses a great many good points, but the cheapness, simplicity and compactness of the three-wire generator are points not to be overlooked in deciding on a three-wire system.

The world's production of coal in 1906 amounted to about 1,106,478,707 short tons, of which the United States produced 414,157,278 tons. Since 1868, during a period of 39 years, the percentage of the world's total coal produced by the United States has increased from 14.32 to 37, and this country now stands far in the lead of the world's coal producers.

Measuring Total Output of Station.

In the Question Box of the September Bulletin of the National Electric Light Association the question was asked:

"In registering the total output of the station, which will give you the more accurate record: wattmeters on the feeders or wattmeters on the generators?"

Answers to this question were as follows:

T. O. Ripley: This company follows the practice of placing wattmeters on feeders, thus obtaining the total output of the station, and at the same time obtaining information regarding the amount of current consumed by the various sections of the city supplied by the various feeders. The character of the load carried by various feeders, particularly the light-load conditions, should be considered before discussing the accuracy of the two methods mentioned.

Robert J. Clark: You will find in a great many stations that the day load is very light, and if this load is distributed over several circuits with a meter on each feeder the load will be so light that the meters will not run up to efficiency, as we all know that meters with a light load on do not run as well as with a heavy load. I would therefore say install one meter on the generator, which will give a more correct record of your output.

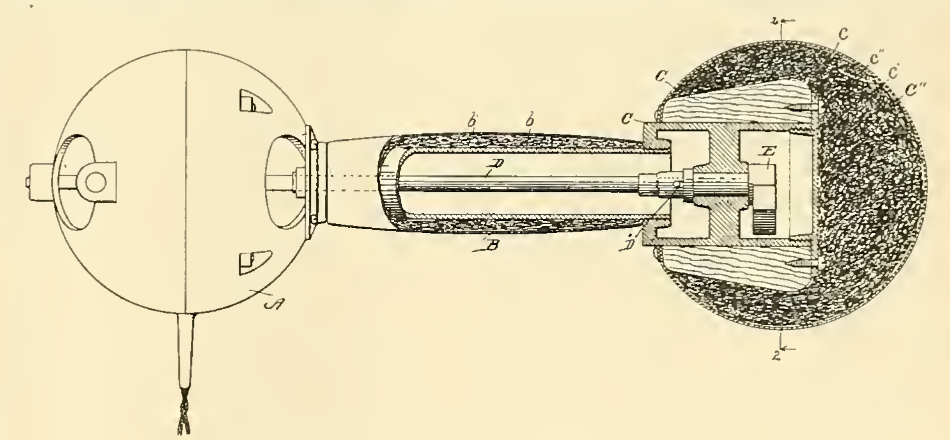
Alex Dow: The less the number of wattmeters the more accurate will be the record. Therefore, if there are few generators and many feeders it is best to put the wattmeters on the generators. If there are few feeders and many generators the wattmeters should be put on the feeders. Of course, in both cases, provision must be made for metering the current used in the station.

J. L. Moore: Wattmeters on the feeders will probably be more accurate, as they will be smaller capacity and more accurate on light loads. Have wattmeters on both generators and feeders, and, as soon as the output recorded on one set does not agree with the other, look up the reason. Test meters at regular intervals.

Vibratory Dumb-bell.

The popular demand for vibrators has brought out many new inventions in this line. One that was recently patented was devised by John H. Kellogg of Battle Creek, Mich. The main object of the invention is to provide an improved dumb-bell adapted to vibrate when in use.

Referring to the drawing, (A) is an electric motor inclosed in a suitable casing forming one of the dumb-bell balls. A hollow handle or grip (B) is secured to the motor casing. This handle consists of a tube (b), of metal, having a suitable covering (b'), preferably padded, as illustrated. The other dumb-bell ball preferably consists of a metal core (C), which is threaded upon the end of the tube (b). A plate, as (c), having an inwardly projecting annular threaded flange (c'), is threaded into the outer end of the core (C). About the core (C) is a wood ring or covering (C'). This is secured upon the core by screws, as (c''), arranged through the plate (c). The padded covering (b')



DUMB-BELL ADAPTED TO VIBRATE WHEN IN USE.

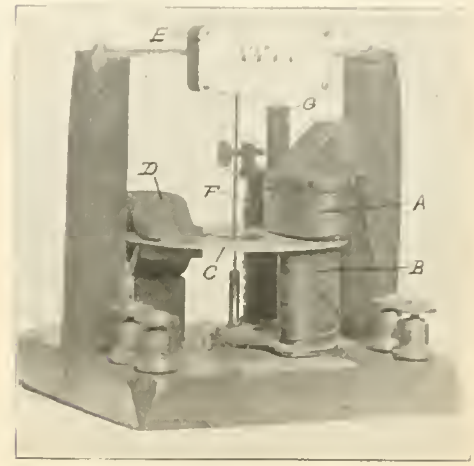
is secured over these parts, preferably by tacking to the inner end of the wood ring (C), as illustrated. Within the core (C) is a bearing for one end of the shaft (D). This shaft is preferably made up of sections secured together by a slip-joint (D') for convenience in assembling the structure.

An eccentric weight (E) is arranged upon the shaft (D) in a manner to throw the same out of balance, so that when the shaft is rotated by the motor the dumb-bell is vibrated. This is said to be a valuable exercising device, as the muscles, in addition to the benefit of movement secured by the use of the dumb-bell, are vibrated in an effective manner.

The First Induction Watt-hour Meter.

The accompanying illustration will be of interest to electrical engineers, and particularly to users of induction meters. It shows the first induction watt-hour meter made in which a single armature was used for both the motor part of the meter and the magneto-electric drag.

This model was made by Thomas Duncan (now manager of the Duncan Electric Manufacturing Company, Lafayette, Ind.) in 1891 and embodies



THE FIRST INDUCTION WATT-HOUR METER.

many features still incorporated in meters of the present day.

Referring to the illustration, (A) represents the current field coil in series with the load, (B) the shunt or pressure coil, (C) the aluminum disk armature, (D) the permanent magnet, (E) the registering train, (F) the impedance coil, and (G) an adjustable iron core for regulating the speed.

The operation of the instrument is similar to that of all induction watt-hour meters in use today, even to possessing a high torque.

At the time this instrument was built, only commutator watt-meters and induction lamp-hour and ampere-hour meters were used; and although this model is now sixteen years old, Mr. Duncan says that its design, involving the aluminum armature common to both motive and retarding elements, has been followed by all makes of induction meters to the present day.

No Lighting Wires on Telephone Poles in Fort Wayne.

A decision of considerable importance has been rendered by Judge Heaton of the Superior Court in Fort Wayne against the city of Fort Wayne in a suit to restrain the Home Telephone Company from interfering with the city's purpose to use the top cross-arms of the company's poles on which to string electric-light wires. The city is proposing to build a municipal light plant, and asserts the right to use the telephone company's poles for its wires under the clause in the franchise which purports to give the city the right to string wires for police and fire-alarm purposes. The court held that the franchise reserves no right to the city to string wires of such a disturbing character on the telephone poles as those for the conveyance of current for electric lighting. While the decision will greatly increase the cost of the city's plant, it is gratifying to the telephone company and to telephone men generally throughout Indiana, where conditions of a similar character exist.

New Patents for Motor-controlling Systems.

On September 10th the United States Patent Office granted 12 patents on systems for motor control that were assigned to the Allis-Chalmers Company. William H. Powell of Norwood, Ohio, was the inventor of nine of these; Walter J. Richards, also of Norwood, invented two, and Louis E. Bogen of Cincinnati one.

The first patent covers the idea of a combined starting box and speed-regulating field rheostat. A generator and a motor have their armatures connected together through a starting resistance. The fields of the machines are of the shunt type, one terminal of each field being connected to one pole of the generator, the other field terminals end on opposite sides of two separate adjustable resistances arranged with contact buttons in two adjacent concentric arcs. An adjacent continuous metallic arc connects with the other pole of the generator. A contact arm swings over the three arcs, cutting resistance out of the generator field circuit and thus raising its voltage and cutting in resistance into the motor field circuit, each of these actions increasing the speed of the motor. The armature resistance is arranged to lie in the same circle as the field resistances, so that the same contact arm is used to start the motor and then to regulate its speed. The buttons in the field rheostat arcs are staggered so as to get a still more uniformly varying and wider range of speed.

In the next patent a motor-control system is referred to that consists of a number of machines. An induction motor having a flywheel on its shaft is direct-connected to a generator supplying the armature current for the motor to be controlled. The last two machines have separately excited fields, that of the generator being reversible so as to reverse the polarity of its electromotive force and thus the direction of the motor's rotation. The field rheostats of these two machines are of the type covered by the first patent, with reversing device for the generator field just referred to. Reversing is brought about by first strengthening the motor field and weakening that of the generator. The speed of the generator and its driver is allowed to vary in an inverse manner as the load on the motor varies, and a flywheel is provided on the generator shaft to take up the load fluctuations.

The third patent covers a system similar to the previous one, but with the added feature that a single controller is so arranged that, as its arm is moved from "off" position, the generator field circuit is first closed and its resistance gradually decreased to a minimum, and then the resistance of the motor field circuit gradually increased to a maximum, both operations increasing the motor speed. In reversing, a high resistance connected across the generator field circuit prevents arcing at the contact points when that circuit is opened.

The fourth patent relates to substantially the same system as the two preceding, the new feature being that the controller simultaneously and inversely varies the field strengths of the motor and generator.

In the fifth patent a motor-control system is treated of that has an induction motor supplying mechanical power to a main generator and an auxiliary generator or exciter, the main shaft carrying a flywheel. The armature of the working motor is connected across the main generator. The armature of the auxiliary generator is connected in series with that of the main generator. The field of each of these three machines is supplied by the two generators in series, one field terminal being in common and connected to the remote pole of the exciter armature. The other terminal of each field circuit ends in a separate set of resistances on a single rheostat, and these resistances are so disposed that a contact arm can cut resistance into the field circuits of the working motor and of the exciter and at the same time cut resistance out of the field circuit of the main generator.

A working motor with two windings is covered by the sixth patent. One winding is separately excited and of practically constant value and the other is a variable and reversible shunt winding supplied, along with the motor armature, from a generator whose field is variable, reversible and separately excited. The two motor field windings normally oppose each other. The motor shunt field and the generator field are varied separately or at the same time, either correspondingly or inversely.

The next patent relates to the use of two generators in series to supply the armature of the working motor, the field of which is a separately excited one of practically constant value. The fields of the generators are also separately excited, but are variable and reversible either separately or together. The electromotive forces of the two generators are normally equal and opposed, the algebraic sum being impressed on the motor.

In the eighth patent the generator has its field excited jointly from its own armature and from a separate source, such as an exciter, the two sources being in series. The excitation from its armature is the main one and is varied by a rheostatic controller. The separate excitation is nearly constant in value, but is reversible by the controller at a time when the self-excitation has been reduced to a minimum. This reverses the polarity of the generator and the direction of rotation of the working motor to which it supplies armature current. The field of this motor is separately excited and is regulated by the controller at the same time and inversely as the main generator field.

The feature of the ninth patent is the use of a main generator and a working motor supplied by it, each of which has two distinct field windings, one self and the other separately excited. An auxiliary generator or exciter supplies the separate excitation, and this is controlled by resistance in the exciter field. For the generator both excitations are varied in an inverse manner and the separate excitation is reversible as in the previous patent. For the motor the self-excitation alone is variable.

The patents granted to Messrs. Richards and Bogen relate to still other methods of regulation of the generator and motor, with the object of getting complete and wide control of the latter. The entire set of 12 patents gives a multiplicity of systems of motor control, such as are particularly adapted to the operation of motors for rolling-mill work.

Mexican Mining Progress Due to Electricity.

Applications of electric power in the operation of the mines in the Guanajuato district, Mexico, and the wonderful development of that district as a direct cause of this cheap power, have caused steps to be taken to supply the same power to many of the other leading mining camps of the country. The districts of El Oro and Pachuca are already being supplied with the cheap power, and the same stimulus of development is witnessed in those places.

American capital and American engineers are back of most of the electric power projects in Mexico. The big generating and transmission plant which supplies Guanajuato and a number of other towns and districts with electric power and lights is owned by a syndicate of Colorado men. The name of the company is the Guanajuato Light and Power Company. A Canadian syndicate, known as the Mexican Light and Power Company, is not only supplying Mexico City with electric power and lights but has reached out to El Oro, Puebla, and will probably extend its transmission lines to other more remote places.

Mexico is abundantly well supplied with waterfalls from which the initial power for the hydroelectric plants may be obtained. These waterfalls, which are mostly situated in remote parts of the mountains, were formerly considered to have little value. With the use of electric power and the knowledge that it could be transmitted long distances, a value came to be fixed upon the waterfalls, and some of them which have been sold recently have brought good prices. It is said that there is hardly a mining camp of importance in Mexico which cannot be easily reached by transmission lines from some one of these waterfalls. The general introduction of this cheap power means that many low-grade mines which cannot now be worked profitably will be opened and become paying producers of ore.

An X-ray Outfit for Country Doctors.

The use of X-rays for medical purposes has been extended to such an extent in the course of the last few years that even ordinary practitioners at present cannot do without an X-ray apparatus. But in many cases difficulty is experienced in obtaining the electric current for operating the tube. This applies particularly to country doctors, who often live far away from any generating station capable of supplying the required "juice."

FIG. I. CAPSTAN-DRIVEN DYNAMO IN OPERATION IN THE COUNTRY

Primary cells, Leclanché elements, dry batteries and the like, which may be used for this purpose, are hardly convenient, owing to their short life and small capacity. Storage batteries might be employed, but in many cases there is no opportunity for charging them.

These drawbacks to the use of X-rays by country doctors have been done away with by a capstan-driven dynamo which has been recently constructed at Berlin, and which can be used practically anywhere. This small machine does not require any superintendence worth speaking of in comparison with a dynamo driven by a gas engine or small steam engine. The current generated by the machine is sufficient to operate a small X-ray outfit, while also ample to charge a storage battery of a size convenient not only for the operation of X-ray apparatus but of nearly any other electrical apparatus used in medicine or surgery.

Figs. 1 and 2 show, respectively, the capstan-driven dynamo and X-ray outfit in operation, while Fig. 3 represents a machine with the protective hood removed.

The dynamo is designed for 10 amperes at 30 volts and is driven by two horses through a toothed wheel gearing fitted in an angle-iron frame. Two extensible steel-pipe poles, which are taken apart for transportation, are attached to the upper and projecting end of the dynamo, as shown in Fig. 1. The gearing is so designed that the required speed of rotation (1,000 revolutions per minute) will be obtained with five revolutions of the horses. Four pegs bolted to fishplates secured sideways to the ground surface are used to attach the iron frame to the ground. In order to protect against moisture, dirt, etc., the frame is surrounded with a readily removable water-tight canvas cover.

The outfit also includes a marble switchboard, an ammeter and a voltmeter, two fuses, switches and plugs. Two of the plugs are used for connecting the two conductors starting from the dynamo, and two others for connecting the X-ray apparatus or for charging a storage battery.

When the capstan-driven dynamo is used for the direct operation of an X-ray outfit a convenient portable apparatus has been especially arranged for this purpose. It is shown in Fig. 2 and includes an induction coil for 25-centimeter spark length, fitted with a regulating resistance, a controlling switch, a fuse, a platinum interrupter (with condenser), a connection box inclusive of a cable four meters in length provided with pole tips, an X-ray bulb-holder and two insulated conductors for connecting the X-ray bulb to the inductor.

Portable X-ray outfits of the kind described have the undoubted advantage of being independent of the electrical facilities at the place at which they are to be used, whether at the doctor's house or at the house of the patient, which is specially important in the case of patients whose removal is difficult. A portable storage battery, charged by the capstan-driven dynamo, may then be used as source of current.

Similar X-ray sets operated by capstan-driven dynamos are constructed for military purposes, and Fig. 4 illustrates a military X-ray car of the type used in the German Army. G.

Central Electric Railway Association.

The fall meeting of the Central Electric Railway Association was held in the assembly room of the Chittenden Hotel, Columbus, Ohio, on September 26th. This being the first meeting after the summer vacation, the attendance was unusually large. The members of the association came to the meeting in special trolley cars from all parts of Ohio and Indiana. The meeting was called to order by the president, H. A. Nicholl, at 10:30 a. m. A committee was appointed, with E. E. Spring, chairman, to draft resolutions relative to the death of Mr. F. J. Stout. President Nicholl announced the meeting of the American Street and Interurban Railway Association to be held at Atlantic City October 14th to 18th, and Messrs. Nicholl, Wilcoxon and Sloat were appointed delegates. The report of the secretary-treasurer showed the association to be in an excellent financial condition.

Under head of reports of committees the report of the committee on train rules was presented by F. D. Carpenter, general manager Western Ohio Traction Company, who said that the committee, having familiarized itself with the rules now in vogue on the electric railways, had drawn up what it believed to be a practical set of rules which can be used upon all interurban railroads with satisfaction and uniformity. The report of the committee was adopted without being read in entirety, and the delegates to the national convention were instructed to present it to the Atlantic City meeting with a view of having it adopted by that association as well.

The first paper on the programme was read by

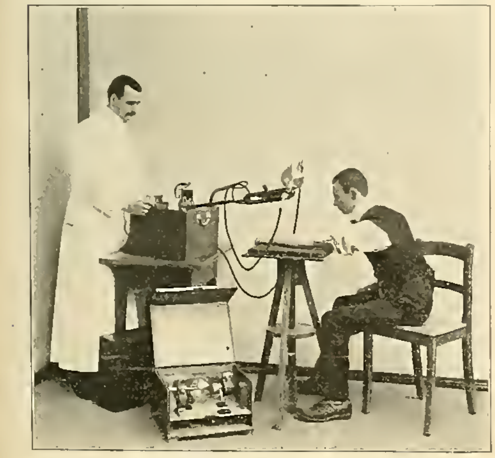


FIG 2. PORTABLE X-RAY OUTFIT IN USE.

G. D. Nicholl, electrical engineer on the Indianapolis and Cincinnati Traction Company of Rushville, Ind., on "Single-phase Catenary Line Construction." The paper is given in full elsewhere.

Henry N. Statts of Cleveland, chairman of the committee on fire insurance, presented a long report showing that the movement for the better protection and insurance of the properties of street and interurban railways and lighting companies was progressing successfully. After careful consideration on the part of the executive officers of a number of leading electric railway and lighting companies as to the best plan for producing lowest cost of insurance, it has been deemed advisable by the companies to perfect their own organization and to surround themselves with the best methods of safeguarding their property against loss by fire. Mr. Statts next outlined the organization and incorporation of the American Railway Insurance Company and the Electrical Mutual Insurance Company of Ohio, which co-operate with each other in writing insurance at a rate, it is said, not to exceed one fourth of that charged by old line insurance companies. Mr. Statts stated that the committee had communicated with 420 companies and their reports show that they paid during the last 10 years for fire insurance premiums to old-line companies $6,400,641.45, while during the same period the amount returned to the 420 electric companies for fire losses amounted to $1,073,336.27, leaving a balance to the credit of the insurance companies of $4,376,305.18. These figures, Mr. Statts said, prove beyond question that electric traction companies of United States and Canada have been paying excessive rates, and the leading electric railway companies are now quite willing to join in the movement to establish an insurance fund to carry their insurance on a co-operative plan. The report of the committee was adopted and a further discussion of it will be taken up at some future time.

The report of the express committee, with reference to the best manner of handling express matter, was presented by J. S. Starkey of the Indiana Union Traction Company of Anderson. Mr. Starkey said that the committee sent out inquiries to 80 interurban roads of Indiana, Ohio and neighboring states, with a view of learning what roads have contracts with express companies, and asking for opinions as to the advisability of entering into contracts with the old companies or of organizing an independent express company. The report gave considerable detailed information as to the terms of contracts where they exist, and the replies received indicate that only a small proportion of the lines have as yet

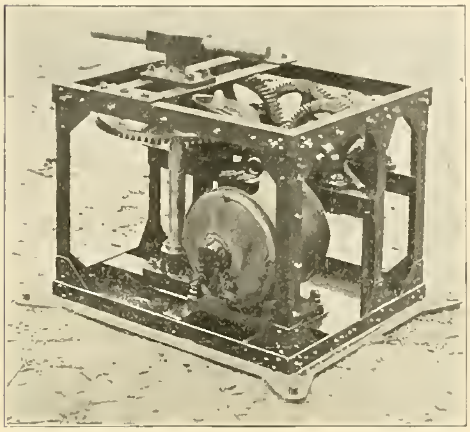

FIG. 3. CAPSTAN-DRIVEN DYNAMO WITH CASING REMOVED.

contracted with express companies to handle their business over their lines.

The report is quite complete, giving many experiences of electric railways relative to the methods of handling express matter, but on the proposition as to the advisability of contracting with old-line companies, the organization of independent companies, or handling of express as they do now along with their freight matter, the companies seem to be equally divided on the several propositions. A number of companies expressed the belief that they could do better than to go in with any old-line company; while other companies said that the laws of the states would soon compel them to deliver express in the towns and cities, and it is necessary to make arrangement for that contingency either through contracts, the most favorable that can be made with old-line companies, or organize an interurban express company, which some of the companies believe can be operated successfully. The committee, however, reports that its conclusion, from information obtained, is that the contracting with old-line express companies has a little advantage, and for this reason the committee recommends this course.

The next paper on the programme was read by E. H. Anderson of the General Electric Company of Schenectady, N. Y., on the "1,200-Volt System." This paper consisted in showing the General Electric Company's commutating pole motors ranging from 600 to 1,200 volts direct-current, and explaining each in the form of a lecture that was exceedingly interesting to members of the association. At the conclusion of Mr. Anderson's lecture and description of the illustrations he answered many questions of the electricians present, who were greatly pleased with the information obtained along these technical lines.

The Central Electric Railway Auditing Association, which is an adjunct of the railway association, was also in session, but made no report to the meeting. The work of the auditing association is to adopt and maintain uniform methods of keeping accounts. In addition to a large representation of the members of the association there were present traction men from Illinois, Michigan and West Virginia. The next meeting will be held in Indianapolis on November 28th.

British Postmaster-general Reports on the Telephone, Telegraph and Radio-Telegraphy.

London, September 20. The annual report of the postmaster general naturally has a good deal to say concerning the radio-telegraphic convention, but it cannot be said that it adds much to our existing knowledge on the subject, beyond stating quite

FIG. 4. MILITARY X-RAY WAGON FOR GERMAN ARMY.

finally, if this were needed, that the government intended to ratify.

The report, however, contains one or two other items of interest in relation to wireless. During the year covered by the report, viz., to March 31, 1907, 45 new applications for licenses were made under the wireless-telegraph act, of which no less a proportion than 36 were for experimental purposes. These 36 licenses have all been granted, but the other applications have been held over pending the consideration of the whole question of the use of wireless telegraphy in the United Kingdom for commercial communication with ships. This, in its turn, depends largely upon the ratification of the Berlin Convention, and as the government has announced its policy in regard to this, we should soon hear all about the attitude of the government concerning competitive licenses for commercial ship and shore work, for, whatever the views of the Marconi company may be, there is no doubt that the hesitancy on the part of the Postoffice to grant such licenses in the past has been no mean factor in building up the Marconi company's present position.

During the last year the Postoffice has continued to collect and deliver Marconi company's telegrams to and from ships at sea under the agreement of 1904, and it may be noted that the inward messages amounted to 15,853, as against 11,094 in the previous year; the outward messages increased from 558 to 1,140.

As usual, the telephone system monopolizes the greater portion of the report, and in the present position the letterpress concerning this is more than usually interesting. Apart from the question of mere figures of capital expenditure and new lines, etc., it tells a story of great efforts at development in face of difficulties more or less peculiar to this country. The most important of these latter is the inherent objection to overhead wires, and in the linking up of sparsely populated areas overhead wires are a sine qua non. Yet we read of the use of wires, primarily intended for telegraphic purposes, for telephonic purposes in rural districts. These, of course, are what might be termed local trunk messages, i. e., communication between the central town and the postoffices of surrounding villages.

The capital expenditure upon the British trunk telephone system to March 31, 1907, amounted to roughly, $10,000,000, the expenditure during the year being $2,000,000. The total number of conversations during the year were 19,803,000, an increase of over 1,000,000. In connection with the London telephone service, carried on in co-operation or competition with the National company, it is interesting to note that new subscribers are being added at the rate of about 150 per week, the total number now standing at 45,000. Five new exchanges were opened during the year under review, and 65,000 miles of new wire was laid.

Another interesting figure is the cost of constructing an exchange circuit in the Metropolitan area; this has been reduced from $175 to about $163. These figures include instruments and exchange apparatus, and the anticipations of previous reports have been amply realized, inasmuch as the average for the whole system, including spare plant, is $250, as against $270 and $320 in the two years previous. After payment of working expenses, depreciation and interest, there is a balance of, roughly, $100,000.

The record for the year in relation to the telegraph service deals with considerable extensions to the underground trunk lines, in connection with which there are increasing complaints year in and year out. There has, however, practically been no increase in the number of telegrams sent, due, in the main, to the increasing use of the telephone.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the **old** address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

New York Electrical Show, Madison Square Garden, September 30th to October 9th.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

Western Association of Electrical Inspectors (annual meeting), Hotel Ryan, St. Paul, Minn., October 22d, 23d and 24th.

THE SUCCESS of the Chicago Electrical Show has resulted in a number of other electrical shows in other cities. The Canadian show at Montreal was a pronounced success. The New York Electrical Show was begun on September 30th and is to last until October 9th. This also, from early accounts, seems to be "making good." The electrical show seems to have made a hit, and the result is largely due to the prestige which attaches to these exhibitions since the Chicago show blazed the way to popular favor.

IN HIS instructive article on "The Industrial Uses of the Electric Motor" in the Western Electrician of last week Mr. E. W. Lloyd set forth in a very convincing way the reasons why manufacturers should use electric power. One of these is of particular interest. Not only may the output of machines be doubled in many instances by equipping them with individual motors, but "the cost of labor for a given amount of work is materially reduced, notwithstanding the fact that it has been possible to increase the wages of the men operating motor-driven tools by offering them a premium for the extra output." It will be seen by this that not only the employer but the workman may benefit in pocket by the use of the electric motor, and thus the modern method of power application has a sociological bearing which not many persons have suspected.

FALL TRADE prospects in the electrical field may be described as "reasonably satisfactory," in the language of Mr. Sunny as given last week in the Twentieth Anniversary and Fall Trade Number of the Western Electrician. The views of a number of other gentlemen well qualified to judge were given at the same time, and on the whole there was a cheerful tone in the review of the business situation. A quieting of the bounding pulses of industrial activity is not dreaded; on the contrary it will probably make for the health of the body politic in the long run.

The general situation seems to be well described by the 1907 edition of "Crop Reports and General Business Conditions," recently issued by the Commercial National Bank of Chicago. This compilation is based on nearly thirty thousand replies from banking, manufacturing and merchandising correspondents throughout the country. The consensus of opinion is that the financial situation is sound and satisfactory. We quote three extracts from the general summary:

"The overwhelming preponderance of evidence is that the business situation is sound and satisfactory. Not one of the thousands of replies negatives this conclusion in definite terms. That there has been a marked easing down from the tension of the spring and winter months of the year is generally admitted, but it is admitted without a trace of regret or misgiving. The country had been rushing ahead at a whirlwind pace until the tax on credit and capital accumulations compelled a respite. The demand for goods to meet instant needs, or to replace other goods destroyed by wars and calamities, or to provide for the certain needs of the future, has been unprecedented. To meet this it has been necessary for the manufacturers and distributive agencies of the entire world to employ almost every available unit of money and to put into action every potentiality of credit. The result is too familiar to all men of affairs to need exposition."

"Business is generally reported to be good in volume, making an exception for the great hesitancy in the metal markets, especially in copper and the alloy metals. Voluntary concessions in the prices of these materials have made buyers wary, and they are generally waiting in the hope of further forced declines. The iron and steel industry is going ahead under the pressure of orders previously booked for fall delivery; but it is conceded that the current inquiry is lighter, leading to shading of prices in pig and billets—the basic articles of the industry. The demand for consumption has been steadily in advance of production for many months, hence a slight relaxation in the demand is regarded with favor."

"In general, it seems justifiable to conclude from the data at hand that any further slowing down of business will be accompanied by moderate recessions in the prices of raw materials without any serious decline in consumption due to decreased purchasing power, and that the recessions in prices will prove to be encouraging rather than discouraging factors in the trade situation."

We believe that the above outlines existing conditions with accuracy and also that it is a judicious forecast of the probable business situation during the next three or four months. Conditions in the electrical industry are no less sound than in other branches of trade.

EXTRAVAGANTLY worded claims for alleged electrical cure-alls have not disappeared by any means, although it does seem that the crop of "electric" belts, hair-brushes, insoles and the like is somewhat less plentiful than in former years. As showing some of the things that electrical men themselves do not know about electricity and as of curious interest, the following extracts from a recent circular are given:

"It has been demonstrated that electricity is the most natural of all remedies for the cure of ailments that inflict the human body. What steam is to the locomotive, electricity is to the human body. It stands first in the list of positive and wonderful cures. It is the infallible conqueror of pain and disease, and the only permanent cure for rheumatism and all nervous ailments." If the foregoing is true, it will be of importance to know how best to secure the advantages of electricity, "the greatest blood purifier and nerve builder in the world." This point is not neglected, for we are told of certain devices which "are worn in the heels of the shoes with no inconvenience to the wearer and nobody knows you are wearing them. They differ from all other electrical appliances, as they are not batteries and make no electricity until in contact with the body; then they make a battery out of the body, for one foot rests on the positive magnet and the other on the negative. So the nerves themselves become the connecting wires, and the blood, nerves and tissues of the body are fed with new vitality, life and power the whole day, and all weakness, pain and disease are banished."

We do not quite understand the process of generating the current and should think the shoe-heel magnets rather diminutive affairs; but nevertheless we are boldly told that they banish "all weakness, pain and disease." If there should be some mistake about this, and we fear there is, it would seem to be a cruel thing to raise false hopes in the minds of the suffering for motives of gain, for pain and disease are very real and very grim to most of us in this old world.

A DECISION of much importance to the electric-railway interests of Indiana has been rendered by the Indiana Railroad Commission in the case of the Farmland Stone Company of Farmland, Ind., against the Big Four Railroad Company and the Indiana Union Traction Company to compel them to interchange traffic at Winchester, about eight miles from Farmland. The evidence showed that the stone company had been getting coal over the Big Four railroad, which was transferred in carload lots to the electric-railway company at Winchester and brought to Farmland to the stone company over the electric road. Recently this exchange of traffic and transfer was stopped, and the stone company was compelled to haul by wagon its coal from Winchester. The stone company petitioned that the previous interchange of freight be resumed.

The railroad company in its answer alleged that the stone company was not entitled to the relief demanded and that the railroad commission had no jurisdiction in the matter, thus attacking the constitutionality of the law passed by the last session of the Legislature giving the commission jurisdiction in cases of this kind. After hearing the evidence the commission ordered the interchange of traffic to be resumed, since it was found that the physical condition of the electric-railway line was amply sufficient to carry the loaded coal cars, while both steam and electric roads were common carriers, belonging to the same class and amenable to the same general rules and regulations.

The case is the first in which an interchange of traffic between the steam and electric roads has been raised in Indiana, and therefore sets a precedent. Chairman Hunt of the Indiana commission stated, however, that this ruling pertained to this particular case only, and that the exchange of such freight depended upon the merits of each case and the physical conditions and capacity of the interurban lines to carry freight turned over to them in carload lots by the steam lines.

The Large San Francisco Gas-engine Electric Power Plant.

[From the San Francisco correspondent of the Western Electrician.]

The California Gas and Electric Corporation—now a subsidiary of the Pacific Gas and Electric Company—has been doing some remarkable pioneer work in the suburbs of San Francisco in the installation and operation of very large electric generating units with direct-connected gas engines to supply current for operating electric cars. Over a year ago the Snow Steam Pump Works of Buffalo erected at the San Mateo power station near San Francisco three horizontal, duplex, double-cylinder gas-engine generator sets. The engine capacity was rated at 5,400 horsepower and the generator capacity at 4,000 kilovolt-amperes for each unit. Each engine has the revolving field of a Crocker-Wheeler three-phase 25-cycle 13,200-volt generator on its main shaft next to its flywheel. At the time the engines were constructed they were the largest gas engines in the world, and the generators were, of course, the largest to be driven by gas engines.

The erection of these engines and the subsequent modifications in the details of operation were under the personal supervision of Mr. Aue, the mechanical expert of the Snow Steam Pump Works, who is still in the city watching the performance of the big plant. His painstaking study of the large units may result in the adoption of some further refinements in gas-engine practice. Before this plant was started there was some uncertainty in the minds of some electrical engineers on the successful operation of three such large gas-engine units when two or more of the big generators were connected in parallel. The test proved that the engines regulated satisfactorily under these conditions.

The plant was intended as a relay station to be held in reserve in case of interruption of the current transmitted 140 miles from Blue Lakes to San Francisco for the operation of the electric cars of the United Railroads of San Francisco under a 20-year contract, commencing with June 1, 1906. The engines were built about two years ago.

The unusual conditions prevailing for some time after the disaster of 1906 had something to do with the delay in the placing of the new gas engines in commission, although the large gas generating plant with its gasholders was completed and undamaged. On account of shortages in the supply of current available for use in San Francisco, it was found necessary to operate the three gas engines regularly during the peak load and at other times early in the year 1907, and they have been in almost continuous operation for a number of months.

The engines are of the twin-tandem double-acting four-cylinder side-crank type, operating on the four-cycle principle. The 5,400-brake-horsepower rating of the engine is only on an overload of 35 per cent. The usual overload rating is 15 per cent. for brief periods. The engine delivers 4,600 horsepower at this rating, but normally the engine will deliver 4,000 brake horsepower.

The cylinders are made in two parts, with a circumferential joint in the center, which is covered by the removable part of the water jacket. The water jackets are cast solid with the ends of the cylinders. The explosion chamber is cast to one side of the cylinder, this making very strong construction.

The pistons are made of cast-iron and bolted together on a circumferential joint. Six concentric cast-iron piston rings without keepers are used. Both the piston rods are 15 inches in diameter and made of two parts—the sleeves, made of nickel steel, and the bolt which extends through the whole length of piston and sleeves. The piston rods are hollow and conduct water to the pistons for cooling purposes.

The cylinders are supported on the bedplate in such a way that they can slide in grooved guides in the longitudinal direction only to allow for expansion or contraction caused by changes in temperature. The bedplates are held down to the foundation with foundation bolts running clear through to the top of the bed. The weight of the crank shaft is 99,734 pounds. Its diameter at the rotor fit is 37 inches, with a journal bearing 30 inches in diameter by four feet eight inches long. The crank-pin bearing is 19 by 19 inches. The wrist-pin is 17 inches in diameter and 18 inches in length.

The design follows the steam-engine practice by using two overhung crank pins, thus avoiding the trouble of keeping more than two main journals on one engine in line. The crank arms are provided with heavy counterweights to partly counterbalance the momentum of the heavy reciprocating parts.

The 23-foot flywheel weighs 97,000 pounds—a rather small weight for such a large engine, but the weight of the rotor has been considered. Although the weight is less than some electrical for mulae would give, it has been found that lighter wheels, when their weight was chosen correctly, have given better results. When the wheel has not the proper weight, parallel operation becomes difficult.

The weight of the main engine frame is 170,000 pounds. It contains the bored guides for the main cross-head and the main bearing.

For ignition, the electric make-and-break spark is used in connection with a storage battery, discharging at about 10 volts and one ampere. Each igniter is supplied with a spark-coil indicator. This indicator will indicate constantly the condition of each circuit. When the indicator swings with the igniter, the igniter is in order; when it stays drawn up against the core, the igniter is short-circuited.

The engines are started by compressed air, through valves which are operated from the cam shaft in such a way that the air enters behind the piston, which is starting on its expansion stroke, acting in the same way as steam in a steam engine. At the end of the stroke, the exhaust valve opens and the air escapes. Some of the cylinder ends, during this time, take in a charge, and, when this is ignited, the pressure holds the check valve closed so that the air cannot enter the cylinder. After a few explosions the air is shut off and the engine soon reaches its full speed.

The valves, all of which are located on the same side of cylinder, have a positive motion, imparted through cams, vertical rods and rocker arms from a common lay-shaft geared to the main shaft. There is, of course, an inlet valve and an exhaust valve at each end of each cylinder. The valves are water-cooled.

The speed of the engine is regulated by the governor working on the compression and also on the mixture. A Lombard governor regulates indirectly, with the aid of pistons, moved by oil under pressure. This governor is very powerful, yet still very sensitive, and can be easily adjusted to give a slow regulation, which is suitable for parallel operation.

Oiling systems facilitate the lubrication of crank-bearing, crank and cross-head. The oil is fed to the bearing through sight feeds. It then runs through filters and is pumped up to the storage tank. The cylinder oil is necessarily of a different quality from the oil used in a steam cylinder. The oil must have a high flash point, and must not carbonize. The oil is forced into the cylinder on the inhalation stroke, when the oil hole is covered by the piston, and is forced on the piston between the rings. The oiling of the gas-engine cylinder is not nearly as difficult as it appears, because the piston is cooled by water. Too much oil is detrimental and causes carbon deposits.

The total weight of each twin engine is 600 tons, of which 186 tons represents the weight of the two main-frame castings. The frame carries the main-bearing block and the slides for the large main crosshead. The floor space occupied by each engine is 35 by 74 feet, which is not very large, considering that there are four double-acting cylinders of 42 inches diameter and 60 inches stroke.

These engines have been started and gotten up to speed in the short time of from 55 seconds to two minutes. This means the time required to bring the engine fully up to service from a standing condition, carrying any quantity of load, and synchronized with other engines and hydro-electric plants. This also includes the time required to turn on air, gas, electric current for the igniter, and synchronizing at 88 revolutions per minute.

The three engines have been running about eight months, driving three 25-cycle three-phase generators. The fourth unit, which is under construction, will be installed in the same station, to generate 60-cycle three-phase current, which is the standard on the California Gas and Electric Corporation's transmission lines. It is of practically the same design as the other machines, but the flywheel weighs 19 tons more, and the speed will be two revolutions greater, or 90 revolutions per minute. It is the intention to increase the installation, in time, to six units, aggregating over 24,000 kilowatts in capacity. It has also been planned to install one 4,000-kilowatt 60-cycle gas-engine generating unit in the company's Oakland power station.

Turning to the generator, the stator frame, which is approximately 26 feet in diameter, is of cast-iron, provided with ventilating openings to allow a free circulation of air around the ends of the windings and through the ventilating spaces in the core. It supports the stator laminations and winding. It is of the box-girder type, designed so as to be strong enough to prevent distortion due to its own weight and the magnetic pull. The laminations of the stator are securely clamped together by end flanges and provided with a sufficient number of ventilating ducts to insure a uniform and low temperature throughout the core.

Each slot of the stator is lined with a tube of insulating material possessing high dielectric and mechanical strength. There is, the usual ventilated type of shield to protect the ends of the coils of the windings. The rotor, which is designed for great strength and simplicity, is of cast-steel, made in two sections and bolted together. The pole and pole shoe are cast in one piece and bolted to the rim. There are 34 poles.

The rotor coils consist of strip copper wound on edge, each turn being properly insulated from the others, and the whole coil is compressed and baked into a compact unit. The oblong coils have no sharp corners and are held securely in position by the pole-shoes.

The exciting current is conducted to the field windings through carbon brushes. The collector rings are supported on a cast iron hub, from which they are very thoroughly insulated.

Although the Crocker-Wheeler Company had built no alternating-current generators prior to 1904, the engineering corps secured the benefit of the data and experience of Brown, Boveri & Co., who had made an enviable record in three-phase work in Europe. The California Gas and Electric Corporation accepted and paid for the three Crocker-Wheeler machines in full several months ago, showing complete satisfaction with their performance.

The Stanley Electric Manufacturing Company furnished the special exciter sets, which include several different motor-generator sets, of various types and capacities. One of the exciters has a capacity of about 340 kilowatts. This flexible system of independent excitation is so designed that quite a wide range of voltages and wattages can be supplied to the main field circuits, according to the varying conditions under which the large generators are to be operated.

The Stanley company also built two large frequency changers for this station, which take the 60-cycle high-tension current from the 142-mile transmission line of the California Gas and Electric Corporation, and, in turn, supply 13,200-volt current at 25 cycles for the use of the United Railroads. While this apparatus is installed in the same power station, it is operated independently when the gas-engine generators are not running.

Under the original plans the current for the electric railroad was to be supplied from the transmission line extending from the hydro-electric power station at Electra, and the gas-engine units were to be held in reserve in case of emergency. Since the gas engines were placed in commission the demand for power has exceeded the capacity of the company's other plants, so that it has been necessary to run the gas engines almost continuously.

A prominent engineer recently said that he had rarely seen large generators operate so well in parallel as these gas-engine-driven Crocker-Wheeler machines.

The gas plant, which was built especially to supply these gas engines, produces gas of a quality high enough for illuminating purposes. The surplus gas is turned into mains connected with the city lighting system of San Francisco and used whenever needed. There are two standard gas-generating units, each having a capacity of 400,000 cubic feet per day, constructed in accordance with the Lowe crude-oil, water-gas system. The gasholders, which are located within a few hundred feet of the power station, include, one with a capacity of 1,000,000 cubic feet, and two holding 200,000 cubic feet each. Mains of ample size furnish connection with the gas engines.

This gas contains from 45 to 55 per cent. of free hydrogen. Its heat value averages about 630 British thermal units per cubic foot. In the Lowe crude-oil, water-gas process the crude oil is heated to a temperature of 300 degrees, being vaporized, and is then mixed with superheated steam. The excess of water is taken out and the vapor and steam pass into a hot chamber, being superheated to 600° F. This high temperature turns the mixture into a fixed oil-and-water gas, which is then purified and passed on to the engines.

When the engines were originally designed, the initial pressure of the gas in the main cylinder was estimated at about 150 pounds per square inch.

A.

Industrial Progress in Germany.

Reviewing the commercial and industrial situation at Frankfort-on-the-Main, Consul-general Guenther says that the year 1906 was a continuation of the great industrial activity of the previous year, and was even more marked, although the prices for labor, raw materials, interest on capital, and the cost of living have been almost steadily advancing, which, in spite of the increase of trade in nearly every branch, reduced the profits, since prices could not be obtained for the manufactured articles commensurate with the advance in the cost of production.

Another considerable increase was witnessed in the production of the electrical industry, although the previous year had been remarkable in this respect. Prices, however, could not be raised in proportion to the enhanced cost of manufacture. The chemical industry was very lively during 1906, and in some instances the demand was so enormous that it could not be met. Copper has not been as high in forty years, and although the production has been largely increased, consumption of this metal has been even larger. Frankfort is a center of the German metal trade, and its prosperous condition has resulted in the establishment of a mining and metal bank with a capital of $9,520,000.

Single-phase Catenary Line Construction.[1]

By G. D. Nicholl.

The object of this paper is merely to promote a general discussion of the characteristics of catenary construction for the operation of high-voltage electric railways. While there are some high-voltage direct-current railways under construction, I believe none is in commercial operation at the present time, and these remarks will bear particularly on line construction for alternating-current railways.

The introduction of the single-phase alternating-current railway motor brought about the possibility of delivering energy to the car equipments at high voltages and decreasing the investment necessary in copper for the distributing system.

It has also been a problem to collect the current for heavy equipments at high speeds with the ordinary type of wheel trolley, and considerable experimental work has been done to develop a current collector of the sliding type.

There is a difference of opinion among engineers as to whether the current collector should be of the underrunning type or make contact with the conductor on the side or top. In this country, however, the general practice has been to use the underrunning type of current collector, with the trolley wire over the center of the track. In order to operate the sliding current collector successfully at high speeds it is necessary that the trolley wire have a practically smooth and even surface, free from kinks that might cause the sliding current collector to break contact.

Various types of catenary construction have been proposed for different classes of railway service. For trunk-line railroads having two or more tracks the double catenary will undoubtedly be used, the messenger wires being supported from steel bridges spanning the tracks. This class of construction has two messenger wires spreading at the points of support and converging at the center of the span, the trolley wire being supported from both messenger wires by means of hangers of various lengths; a tie also being used between the messenger wires at each trolley support. This type of construction has been used by the New York, New Haven and Hartford Railroad on its electrification near New York city.

This type of construction is expensive, and the cost of it is not warranted for the average interurban line of the Middle West.

Single catenary consists of a single messenger wire with the trolley supported directly underneath by means of hangers of various lengths. Different engineers have different ideas as to the best method of supporting the trolley wire from the messenger wire, also as to the number and length of hangers used. The lines of the Indianapolis and Cincinnati Traction Company, with which the writer is particularly familiar, have single catenary construction. The line from Indianapolis to Rushville was built in the fall and winter of 1904-5 and was, I believe, the first single-phase alternating-current railway in commercial operation using the catenary trolley construction and the bow or sliding trolley.

On the portion of the line from Indianapolis to Rushville the trolley poles are spaced 100 feet apart. From the experience gained on this portion of the line, it was decided to increase the distance between the trolley poles, so that on that portion of the line constructed during the year 1906 the spacing of the trolley poles was increased to 120 feet on tangent track, the distance between poles on curves depending on the degree of curvature. The shortest curve being of three degrees radius, the poles are spaced 50 feet apart, the center of the poles being located seven feet from the center of the track.

The trolley brackets are made of 2 by 2½ by ¼-inch angle iron, the outer end of the bracket being drawn into a loop to form a support for the messenger-wire insulator.

The loop in the trolley bracket is 16 inches long, allowing an adjustment of eight inches on each side of the center line of the track for staggering the messenger and trolley wires and for aligning the trolley wire due to the unevenness of pole diameters and adjustment of messenger wire on curves. The inner or pole end of the bracket arm is bent at right angles to the arm and is fastened to the pole by two through bolts, the outer end of the bracket arm being supported by a ⅝-inch brace rod.

The messenger wire is supported on an especially designed porcelain insulator, the insulator being cemented into a cast-iron base which is fastened to the bracket arm by means of four hook bolts. The messenger wire, which is composed of seven-strand steel cable having outside diameter of 7-16 inch, is supported in the groove of the porcelain insulator and tied to it by a steel tie wire.

The trolley wire, which is of the No. 000 grooved section, is supported from the messenger wire by steel hangers spaced 10 feet apart. Five different lengths of hangers are used, 12 hangers being used between two poles on a 120-foot span, as follows: Two of 11-inch, two of 9 inch, two of 7¾-inch, two of 6¾-inch and four of 6-inch. The hangers are fastened to the messenger wire by means of a "U" clamp and a through bolt, and to the trolley wire by a clamp that fits into the groove, this clamp being held by screws. On curves the trolley wire is held directly under the messenger wire by means of steady strains, one end of the steady strain being clamped to the bracket arm and the other end to the trolley wire; these steady strains are made of treated hickory.

The messenger wire is anchored every mile, a pole being set on the opposite side of the track from the trolley poles and well anchored. A 7-16-inch steel cable is stretched diagonally across the track and securely fastened to the messenger wire. Extra heavy wood strain insulators are placed in this anchor wire to insulate it from the poles, and the ends made up into turnbuckles so the anchor cable can be easily adjusted.

Section insulators are installed about every 11 miles; these section insulators are made of treated hickory. Connection is made to the trolley wire at each end of these section insulators by a knife-blade switch. Normally, this switch is open, but in case of trouble it can be closed, and two sections of the line fed from one transformer station.

In towns span-wire construction is used, extra heavy wood break insulators being placed in the span wires. The messenger wire is fastened to the span wire by special clamps that permit of easy adjustment for aligning the messenger wire with the track, the same style and length of hangers being used on span construction as on bracket arm construction.

Lightning arresters are installed three to the mile, the ground connection being made to a galvanized iron pipe driven 10 feet into the ground.

On private right-of-way the trolley wire is supported approximately 18 feet from top of rails.

In building this line both messenger and trolley wires were run out at the same time and both pulled to the same tension, an equalizer being used between the two wires.

With the length of hangers noted above the trolley wire is supported at an almost uniform distance above the track rails, the successful use of the bow or sliding trolley at high speeds requiring this type of construction.

The insulation of these lines was designed to withstand 3,300 volts of alternating current, and no trouble has been experienced with this voltage. On several occasions the lines have been covered with sleet and wet snow but no trouble developed.

The operation of the bow trolley has proved very satisfactory with this type of construction, there being no difficulty in collecting current at speeds of 65 miles an hour.

1 A paper read before the Central Electric Railway Association at Columbus, Ohio, on September 26, 1907. The author is electrical and mechanical engineer of the Indianapolis and Cincinnati Traction Company at Rushville, Ind.

The Street-railway Conventions.

The American Street and Interurban Railway Association, with the allied bodies of street-railway accountants, engineers and claim agents, will hold its annual convention in Atlantic City on October 14th to 18th, inclusive. The Central Passenger Association has granted a uniform rate of two cents a mile in its territory; the Western Passenger Association grants special one-way rates to its eastern terminals and the Southwestern Passenger Bureau grants reduced one-way rates to St. Louis. Some of the eastern passenger associations have made rates of a fare-and-a-third. The railroad arrangements are somewhat complicated, and persons in doubt should address Mr. B. V. Swenson, secretary of the association, 29 West Thirty-ninth Street, New York city, at once, for full particulars. From Chicago the Pennsylvania Railroad announces that it will run a special train leaving the Union Station at noon on Sunday, October 13th, arriving in Atlantic City about noon the next day. C. L. Kimball of No. 2 Sherman Street, Chicago, can give further information in relation to this train.

The convention meetings and exhibition will be held on the Steel Pier. Hotel headquarters will be as follows: American and Manufacturers' associations, Marlborough-Blenheim; Accountants, Chalfonte; Engineers, the Dennis; Claim Agents, St. Charles.

The exhibit of the Manufacturers' Association on the Steel Pier promises to be larger and more comprehensive than ever before. More than two-hundred different exhibitors have been assigned space.

In general outline, the Engineers and Claim Agents' convention will be begun on Monday afternoon, October 14th, and last through Wednesday afternoon. The Accountants will begin on Tuesday morning and last through Thursday morning. The American or parent association will begin its sessions on Wednesday morning and conclude on Friday morning. On Wednesday morning there will be a joint session of all associations. There will be no banquet. There will be sessions on Monday afternoon; morning and afternoon of Tuesday; morning and afternoon of Wednesday; morning of Thursday and morning of Friday.

More detailed reference to the programme will be made in the Western Electrician next week.

Chicago Street-railway Situation.

As planned, default was made this week by the receiver of the Chicago Union Traction Company on the semi-annual interest due to holders of the $1,614,000 North Chicago Street Railroad refunding bonds. Interest on the bonds, at 4½ per cent., is due April 1st and October 1st, in equal amounts. This makes the amount defaulted $36,315, which, under the promise of Receiver Sampsell to the city when the extension of time for reorganization to February 1, 1908, was secured, will be applied to rehabilitation expenses. Formal protest may follow from trustees of the bonds that get no interest.

The Chicago City Railway Company has made a statement of earnings since the lines came under the new settlement ordinances. The gross earnings from passengers, rent, sale of power, etc., was $4,057,336. Operating expenses and maintenance amounted to $2,840,135, leaving an excess of $1,217,201. Fixed charges, such as taxes and interest, being deducted left the net earnings for the six months, $503,566. This amount is divisible on the basis of 45 per cent. to the company and 55 per cent. to the city, the amounts being $226,605 to the company and $276,961 to the city. Interest on bank deposits amounting to $1,257 is deducted from the company's share and goes to the city.

The Chicago City Railway Company is planning a new system of car dispatching from a central headquarters on each line. This system, which will be tried first on the Cottage Grove line, will, it is said, not only permit of the supervisors notifying the dispatcher and receiving instructions from him in case of trouble or delay, but will also enable the dispatcher by signal to call one or all of the supervisors to the signal telephones located upon the street, so the whole movement of the cars may be intelligently governed by one mind, which directs the movements of the subordinates.

A summary of the recent report of the board of supervising engineers to Mayor Busse, giving the progress of traction rehabilitation work, shows that the Chicago City Company has spent $3,500,000 and the Union Traction Company $1,500.000. The latter company has promised to spend $1,000,000 more before January 1st and the former will add $4,000,000 more if the weather permits late fall work. An estimated total of $10,000,000 for both for the year's work.

The Chicago City Company will have delivered to it within two months 300 new cars. If the experiment is found to work they will be operated on the "Montreal plan" of having the conductor collect the fares when the passengers enter the car, and allow no one to enter after the car is comfortably filled. The company now has 100 more new cars of a similar type, 205 cars of a trifle larger size, of which 90 have been remodeled to conform to the standard, and the remainder will be remodeled shortly, and 110 single-truck cars for cross-town work.

The Union Traction Company has 118 new cars and has contracts for 400 more.

If the weather permits, 62½ miles of new track will be laid this year, 39⅛ by the Chicago City company, and 23⅜ by the Union Traction. With bad weather it is expected at least 50 miles will be completed.

Western Electrical Inspectors' Meeting.

The third annual meeting of the Western Association of Electrical Inspectors will be held in St. Paul, Minn., on October 22d, 23d and 24th. The sessions will be held in the assembly room of the Hotel Ryan. An instructive programme has been prepared for the meeting, and there will be six trips of inspection for those desiring to see up-to-date installations of wiring.

Tuesday, the 22d, besides the president's address and the transaction of preliminary business, will be devoted to reports on uniformity in ruling, National Electrical Code, outside wiring, and theater wiring and show equipment. On Wednesday there will be addresses on the following-named subjects: "Approved Electrical Fittings," by Dana Pierce, Chicago; "Joint-construction Pole Lines," by H. B. Gear, Chicago; "Electrical Inspection from the Viewpoint of the Central Station," by Paul Doty, St. Paul; "Electrical Inspection from the Viewpoint of the Telephone Exchange," by C. M. Manseau, Minneapolis; "Flexible Cord for Pendants," by Hugh T. Wreaks, New York. In the evening there will be a discussion of difficulties arising in electrical inspection work by members.

Thursday will be devoted to hearing reports of committees on these subjects: Grounding of conductors for safety construction and installation of electric signs; show-window and display lighting; instructions to the public concerning the safe operation and maintenance of electric wiring and apparatus; underground systems; installation and operation of induction motors; wiring for electric cranes; laws and ordinances; architects' specifications.

Mr. Waldemar Michaelsen of Omaha, Neb., is president of the association and Mr. William S. Boyd, 382 Ohio Street, Chicago, is secretary.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXXVI. Electric Railways.

Multiple-unit Control.

The types of controllers described in the previous chapter are generally used where cars are operated singly, but where a number of cars are connected together and operated as a train some method of control must be employed in which the train can be operated from the front end of the forward car. Moreover, when very large quantities of current are to be handled it necessitates the use of a very large controller if the K or L type of controller is used, and a very large controller is undesirable on account of the great muscular effort required to operate it.

In the multiple-unit systems the main control switches are placed under the car, or under the car seats, and the master controller which the motorman handles is comparatively small, as it handles only a small amount of current necessary for the electrical operation of the main controller.

There are two general methods of multiple-unit control, one of which is purely electrical and the other electro-pneumatic. One feature is common to both, namely, each car of a train carries its complete equipment of remote-control switches which open and close in various sequences which are determined by the position of the master controller. The main switches operate to produce the same combinations of the motors and resistance as is effected by the type K controllers, that is to say, the first step puts all the resistance and the motors in series, and the last step puts the motors in parallel, with the resistance all cut out. Each car is also supplied with a master controller on each platform, and all the master controllers on a train are connected together in multiple by means of a train line, which is connected from car to car by means of jumpers. In this manner each car is a complete and independent unit whose switches, however, can be operated from any master controller on the train.

The purely electrical system of multiple control is known as the type-M control. The switches which govern the combinations of the motors are electrically operated switches and are called contactors. These contactors can be placed below the car floor in any convenient position, and all of them taken together constitute a series-parallel controller. The different combinations of the contactors are indicated by the positions of the master-controller handle. The contactors consist of a removable arm with a renewable copper contact at one end, which makes contact with a similar fixed contact piece, and a magnet coil, which actuates the movable arm when energized by current from the master controller.

In addition to the contactors, each car is equipped with an electrically operated reversing switch, called a reverser, and a cut-out switch, by means of which all of the control-operating circuits on the car may be cut out. The contactors are provided with a blow-out coil, which prevents arcing when the switches open. In their closed position the contactor contacts are held together by the action of an electromagnet, and when the energizing current is cut off the contacts on the movable arm fall by gravity, cutting off the current supply to the motor.

The master controller is a drum-type switch somewhat similar to the ordinary car controller, but smaller, and is provided with magnetic blowouts. It also has separate handles for the power and the reverser. The power handle is generally provided with a push-button, which must be held closed by the motorman all the time the car is in operation. This attachment is known as a "dead man's handle," for the reason that if the motorman should fall dead or faint or remove his hand from the push-button for any reason the current would be at once shut off from the motors, no matter what the position of the master-controller handle.

From what has been said, it is evident that there are two principal circuits on each car equipped with multiple-unit control. First, there is a pilot circuit, so called, which passes from the line through the master controller which happens to be in use. This circuit carries a comparatively small current, which is only used to energize the contactors. Second, there is the main circuit, which passes from the line to the contactors and thence through the motors. This main current does not pass through the master controllers, and therefore the latter can be made of relatively small size. The master-controller handle has a number of different positions similar to those of the type K controller, and each position corresponds to a certain combination of contactors.

With this system of control each car can be run alone, or any number of motor cars and trail cars can be coupled together and operated as a train, and the cars can be connected together in any order. Where trail cars are placed between motor cars it is necessary to provide them with a train line for connecting the master controllers and reversers throughout the train. The trail cars can also be provided with master controllers from which the train can be operated if desired.

The electro-pneumatically operated system of control is known as the unit-switch system of multiple control and differs in some important respects from the method described above. The main switches in the motor circuit are operated by compressed air, while the valves which govern the admission of compressed air to the main switches are electrically operated. There are thus two entirely distinct circuits on each car.

The operating or control circuit extends throughout the length of the train and receives current from a small storage battery. This is a low-voltage circuit of about 14 volts, and is the only circuit which is brought above the floor of the car.

The motor circuit is confined entirely to each car, and is a 500-volt circuit. This main-motor circuit is located entirely beneath the car floor.

This system, like the one previously described, is designed to operate any combination of motor cars and trailers. The motors throughout the train are operated simultaneously, and each takes its proportionate share of the load. The control is effected from a master controller on the forward platform.

The control apparatus on each motor car comprises the following principal parts: Line switch, switch group, limit switch, reverser, resistance, master controller, plug cut-out, storage battery, battery-charging relay, besides other minor accessories. The functions of these various parts are briefly given below.

The line switch is a circuit-breaker for the protection of the apparatus on the car and is provided with an overload release.

The switch group is a row of unit switches of the same style as the line switch, which are grouped together on a frame forming an air reservoir. Blow-out coils are placed between each of the unit switches.

The limit switch is a solenoid switch operated by the current of one motor. Its function is to give a uniform accelerating current. When the current for which it is adjusted is exceeded, the limit switch opens the operating circuit so that no more unit switches can close until the accelerating current is reduced, when the circuit is again closed.

The reverser is a switch which reverses the armature connections, thereby reversing the direction of the car travel.

The master controller is a small switch located in the motorman's cab, the handle of which has seven positions—the center "off" position and three running positions for each direction of the car. The three positions are "switching," "series" and "parallel." The operation of the master controller will be described later.

The plug cut-out is a plug switch with two sockets. One position of this switch permits the line switch to be closed. The other position resets the overload release of the line switch.

The storage battery is composed of seven cells, and is installed in duplicate on each car, so that one set may be charging while the other is being used.

The battery-charging relay keeps the batteries automatically charged. They are connected in the circuit of the air-compressor motor, and the relay opens the battery circuit except when the battery is being charged.

All of the apparatus is provided with interlocks, so that it is impossible for any of the switches to operate out of their proper sequence. In operating a train, first insert the plug in the cut-out receptacle of the plug cut-out and then move the master-controller handle in the direction corresponding to the desired direction of motion of train. If it is desired to make a slow start, the master controller should be advanced to the switching position only, but this position should not be retained longer than necessary, as it is not a running position. If this does not start the train, or the speed is not high enough, the switch group can be made to advance one switch at a time by repeatedly moving the master controller handle to the series position and returning it promptly to the switching position. In making the ordinary starts in service, throw the master controller handle to the "series" or "multiple" running position, according to the speed desired.

When the handle of the master controller is thrown over without stop to any position, e. g., parallel running, the switches close automatically in such sequence that the car starts and is brought up to full speed at uniform acceleration, until full voltage is applied to the motors.

[*To be continued.*]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

QUESTIONS AND ANSWERS.

Electric Elevators.

Mr. Harrison W. Craver, technology librarian of the Carnegie Library, Pittsburg, kindly contributes the following:

"In your issue of September 14th, page 201, you inquire concerning books on electric elevators. A search of some extent has not given us anything better in English than the volume on Steam Engines and Elevators in the International Library of Technology. This is published by the International Textbook Company, Scranton, Pa."

Operation of Motor Generators.

P. L., Kenora, Ont.: Is the efficiency of a motor-generator set changed if the direction of rotation is reversed?

Answer.

The efficiency of such a set should not be affected by reversing its direction of rotation, for the efficiency of a motor or generator is independent of that feature, other things being equal. In direct-current machines you must make sure that the angle of brush lead is not changed after reversal, and in any machine connections must be correctly made.

Motor Troubles.

F. M. M., Duluth, Minn.: I recently rewound a Westinghouse alternating fan motor. It is wound with four square-shaped coils of 528 turns of No. 25 double cotton-covered wire. There are also four solid pieces of copper, oblong in shape, placed on one end of the pole-pieces, to give it the direction to rotate. I am sure I have the coils connected right, or rather, I think I have, but I can't make the motor run full speed. If I run it half an hour, the rotor gets very hot and the coils commence to smoke. I also have trouble with two Crocker-Wheeler motor-generator sets. They don't seem to want to carry their full load. I recently rewound the armatures, but it doesn't help any. I'm obliged to replace the brushes every other day. If I roughen the commutator they run away above their voltage. I then cut in resistance in the field and bring it down to normal. But the voltage varies continuously. The brushes seem to me to be very thick for a four-pole machine of five kilowatts, but if I use thinner brushes they spark badly. Could I remedy the trouble by taking the armature core to pieces and anneal the laminations? The machines are not grounded. They are 500 to 110-volt, and I tested them with 1,000 volts; neither is there any short-circuit in the winding.

Answers.

1. If the coils of the fan motor as rewound are identical with the original coils, and if the voltage and frequency of the service are those for which the motor is designed, then the connections between the coils are incorrect.

2. The information is too incomplete for a proper diagnosis of the trouble.

Copper Market.

The copper market continues in an unsettled state. The prices have declined to 15¼ to 15½ cents a pound for Lake copper and 15 to 15¼ for electrolytic. There is no telling whether these are bottom prices or whether a further decline may be expected. These low values are being quoted to stimulate a more brisk demand, but up to the present this has not materialized to the extent that was anticipated. The uncertainties in both the copper and money markets have brought about a more conservative attitude on the part of backers of large new projects and, therefore, of large buyers of copper, with the result that the copper trade is quiet.

SELLING ELECTRICITY.

Under this heading will appear, from time to time, articles, suggestions and examples which will be of assistance in the constant effort to increase the existing demand for electric current and to create new demands.

Electricity as a Factor in Advertising.

At the recent convention of the Pacific Coast Advertising Men's Association at Sacramento Mr. Bury I. Dasent, advertising manager of the Portland (Ore.) Railway, Light and Power Company, gave an address in which he made a strong plea for a greater use of electric signs. Some of his suggestions will be valuable to central-station men in their effort to sell current.

Mr. Dasent said:

The relation of electricity to advertising in its most utilitarian aspect is not intricate, nor does it involve abstruse considerations such as are ever present in the mental processes of the ad-writer in the preparation of copy for even the most simple five-line "want ad;" but it is, however, well worth studying. The science of advertising changes rapidly to meet the varying conditions of supply and demand, of media, of environment, of trade relationships and of exigencies of business requiring immediate and forceful publicity, but the art of employing materials at hand to produce desired results follows lines which are to a very considerable extent subject to fairly well-defined laws which are framed inevitably for appeal to that court of last resort, the human eye. In other words, the fundamental law with respect to all forms of advertisement is based upon its appeal to the vision.

That this deduction is correct is amply proven by the enormous increase in the use of illustration in advertising, as well as the universal recognition by advertisement writers that much depends upon the display, form and effective typographical setting of the advertisement. It will thus be seen that consciously, or unconsciously, the appeal of the writer of advertisement is not primarily to the quality of reason but to the sense of sight, and continuing in sequence still farther along this line of reasoning we find the fundamental bases of all advertising to be optional, physiological, æsthetic and utilitarian. This brings us logically to the illuminated advertisement, par excellence, i. e., the electric sign, the electric lighted show window, the electrically illuminated store and the electric lighted street.

Curiously enough, this selection of the human vision upon which to concentrate the appeal of the advertisement, like most rules of human conduct, finds its justification in a law of nature. It is stated by a German scientist in regard to the sensitiveness of the eye that the persistence of visual impressions tends to form a retinal image which is transferred to the brain centers. Optically, this statement is not of startling novelty, for the eye is an organ that has been developed through ages of evolution, but physiologically it is of deep significance in any consideration of the relation of electric light to advertising.

The ultimate aim of any advertiser is to make the name of his product as nearly standard as possible, so that when you think of that particular article or experience a desire for it you will recollect his brand, the kind he makes—and to attain this end most readily his advertising must be so devised that a retinal image of this particular product, or of its name or brand, is readily transferred to the brain of the public.

What devotee can readily forego the spell cast by the electric time-recording sign with its direct command "Time to Take a Wilson High Ball" when seated in club or cafe, after watching the marvelous working of its electric mechanism and play of light—all-powerful in the formation of a retinal image.

A retinal image is instantly gained by a glance into a brilliantly illuminated show window radiant with electric light. Displayed thus favorably, the merchant's wares take on a new character. Under the well-diffused illumination afforded by electricity the various articles are seen "true to life" as to color, size and shape, while every minute detail of texture and of fabric is revealed in the beautiful, soft, unobtrusive light, sunlight in character and brilliancy, but infinitely more dependable. Here you have the zenith of cumulative visual impression, the absolute perfection of the art and theory of illustrative advertising—the one perfect appeal to the eye, to the senses, to the fancy, to the humor, to the reason!

The enormous increase in the use of electric signs in Portland, and indeed throughout the United States, simply means that merchants have begun to realize their tremendous possibilities as trade-bringers. Frank R. Woodard, director of publicity for the Gunning System of Out-Door Advertising, said in a recent address, "The test of the pudding is in the eating, and there is but little question that of all forms of out-of-door advertising none has stood the test so well as the electric sign. The rapid increase in their use, the comparative low cost of operation and maintenance, has made them exceedingly popular, and the man who is bidding for the public's patronage and fails to use the electric sign is not improving his opportunities. It is [illegible] statement and entirely within reason that [illegible] people see an electric sign at night where one [illegible] sees an ordinary sign in daylight

The business men of Portland who employ electric signs are up-to-date and keenly alive to their opportunities and necessities. Advantageously located in the shopping district, these electric signs are seen by thousands of pairs of eyes during the daylight hours; but it is at night, when the electric current illumines the many lamps of which they are composed, that these silent salesmen accomplish the most good.

Electric signs have assumed such importance in the business-getting plans of progressive merchants that even staid and conservative concerns such as banks have been brought to a realization of their value. A prominent banking institution of Portland last winter broke away from its hide-bound traditions of conservatism and installed an electric sign of the "flasher and chaser" variety, bearing the legend, "We Pay Four Per Cent." It was something unique for an establishment so dignified, but what was the result? The day after its installation a stranger entered the bank and, depositing $10,000, remarked, "I don't reside in your city—but I happened to see your electric sign last night, and was so impressed that I decided to open an account with you."

This sign is a large and expensive one, but I have been assured by an officer of the bank that the profits traced directly to its influence paid for the sign within eight days after its installation. Looking between the letters of the electric sign one always reads "Prosperity."

It must not be forgotten that practical needs must be considered quite as seriously as æsthetic aspirations, especially in a domain of so great and general importance as advertising.

The advertising man must, of all men, be free from the fetters of convention. We are some of us fettered by training, by tradition, by precedent, and venture too little beyond our immediate conditions to be able to rise to the portrayal of images of individual originality. We must not forget that just so long as life lasts and impressionability and plasticity remain, humanity is always adapting itself to its environments and seeking—originality!

Let us be honest with ourselves—with our clients! Throw tradition to the winds and break loose from the fetters of custom. If we find that the electric sign is the best media for our client, let us recommend its use. Nothing can ever replace the newspaper as the logical medium of publicity. Its position is unassailable, but there is a place for the electric sign, a most important place—and one of no mean proportions. We all realize the importance of the selection of the right media to national advertisers.

Is it not significant that the national advertisers have taken up the electric display signs and are rapidly installing them in all the larger cities of the country as well as in their factories and salesrooms? The railroads with all their advantages in the distribution of literature concerning their systems are yet liberal users of electric signs. I tell you seriously that there is absolutely no business, no attraction, that appeals to the public that cannot be intensified, built up and advanced by the proper use of display electric-sign advertising. Even the churches are installing electric signs, as we find in the cities of Brooklyn, N. Y., and Cleveland, Ohio, where electric signs have been installed by houses of worship with gratifying success.

In Denver, Colo., the citizens have erected a great arch, which stands inside the grounds of their Union Railway Station, and which bears a monster electric sign with the word "Welcome"—a perennial smile upon the face of their city, and a blazing salutation to the stranger at their gates. This is municipal advertising of a high order, and the fame of Denver's electric "Welcome" has spread throughout the United States.

In many cities throughout the country enterprising merchants have combined to secure the effective advertising of particular sections and streets by the adoption and installation of an especially efficient scheme of special street illumination, using incandescent lamps of high candlepower. Experience has shown that where a street, formerly dark and unattractive, has been so illuminated a business reanimation has speedily followed. The city of Portland is now experiencing this renaissance of street illumination. The transitional movement in streets and sections so lighted is characterized by an unquestioned business revival, and as a result the Portland Railway, Light and Power Company is now engaged in the installation of these lamps in various sections of the city for business men who are interested in the stimulation of trade and the improving of the lighting in the vicinity of their places of business, and for the further purpose of beautifying and advertising the streets in which their stores are situated. It has been realized by the enterprising business men of Portland that this plan of special illumination forms an advertising feature of tremendous value, and one that is absolutely necessary if they would keep abreast of the times.

The great increase in the use of electric signs, and the ever-widening utilization of electric light for purposes of advertising in Portland is not surprising. Wide-awake communities throughout the United States have all adopted this powerful means of publicity, and the public has come to look upon these messages written in electric light as convincing evidence of the enterprise and up-to-date character of the business houses which utilize them.

Perhaps no feature has contributed more largely to the growing popularity of this means of advertising than the easy adaptability and flexibility of the electric sign in fulfilling the requirements of advertisers, while the low cost which attends even a lavish employment of electric current, for purposes of advertisement, forms an additional reason for its universal use.

The sign of the times in Portland is, beyond doubt, the electric sign. At least that is the impression gained during a stroll through the streets of the business district after nightfall. On every side are seen electric signs of all shapes, sizes and colors, advertising every kind of business, and not only branding their legends upon the brains of the multitude, but proclaiming that here is an up-to-date banking establishment, there a progressive clothier, here a furniture store that has forged to the front, there a business man who believes in modern methods of merchandising.

To the electric sign Portland owes its brilliant thoroughfares, and its air of metropolitan gaiety throughout the hours of the evening. With shops and streets ablaze with electric light many more people venture out at night, and, if anything, the throngs are now greater after nightfall than in the daytime.

The electric illumination of Portland's shopping district constitutes a spectacle that is free for the enjoyment of all, and the great public loves spectacular effects, and will go a long way to see and enjoy them. Until this electric era began the merchant put up his shutters or pulled down his shades when he closed the doors of his store. His expenses—rent, salaries, insurance—all went on, but his business stopped. That was the ancient way. With the modern way—the electric way—business no longer slumbers, for the store keeps glittering eyes open for trade throughout the lingering hours of the night, and whets the desires of the multitude by tempting displays under the glittering rays of the electric lamps.

Trade follows the light, wherever that light may be placed, and the allurements of electric light and electric signs are but the working out of the same natural law that draws the moth to the lighted candle.

Electric signs are all conspicuous in the daytime, but, brilliantly illuminated at night by electric light, they compel the attention of the evening crowds upon the streets.

Why One Man Patronizes the Electric-light Company.

"Tactful relations with customers," as Mr. J. W. Ferguson phrases it, pay. This seems to be shown by the following communication recently printed by the Chicago Daily News:

"Will someone please tell me what scheme the gas company uses to increase the size of the bills of its patrons? Can a 'gas inspector' with a monkeywrench so manipulate a meter as to increase the register to whatever size the company thinks is normal?

"Yesterday my wife was in the basement of our flat building when a gas inspector came in. My wife asked him what he wanted. He said that his company had an idea that the bills for illuminating gas from the flats in the building were not big enough, and for that reason the company feared there was something wrong with the meters. He acknowledged that the readings from the cooking-gas meters were all right.

"My wife then explained that we used electricity for illumination, as did nearly all the tenants in the building, and she went on to explain that they patronized the electric company rather than the gas company principally because the officials and agents of the electric concern were quicker to respond to 'kicks' and were more polite in their treatment of patrons. After confessing that perhaps this was so, the man said that perhaps the falling off in gas consumption would explain why the employes of the company had been granted only one week's vacation this summer.

"Then he set to work with his monkeywrench, and I suppose that next month our bills will be increased to a size that will please the company. But what right has any gas inspector to 'monkey' with the meter?"

Something Doing in The Bronx.

It is not so long ago that tradesmen in The Bronx had to be urged to make great use of electric light in shops and show windows and to use electric signs for the kind of advertising that "keeps everlastingly at it." They seemed to think the outlay high and approached the problem with unusual reluctance. Those unacquainted with The Bronx do not know how different is some of its ways from those of Manhattan.

Each has its own commercial problems, and each its own excellent way of solving them. An increase of 44 per cent. in its electrical development during the last 12 months is one of the ways of The Bronx.—Bulletin of New York Edison Company.

Portable Wattmeter Calibrators.

The importance of calibrating meters in service at regular intervals is recognized by all central station men and a means by which this periodical calibration may be done quickly, without in any way impairing the accuracy of the result, is received with favor. In the type KM 1 calibrator, made by the Fort Wayne Electric Works, and illustrated herewith, no stop watch is required in calibrating meters, except in standardizing the instrument itself, nor is it essential that the load be constant. It is only necessary to observe the revolutions of the meter under test and the pointer indications of the calibrator before and after test, from which, by the use of the proper constants the watt-hours registered by the meter under test and the calibrator may be determined. The calibrator is so designed that it covers the range of most meters in service from light to full load, for either 110 or 220 volts, two or three-wire circuits. This is a very desirable feature in that it saves carrying more than one standard.

The calibrator is enclosed in a mahogany carrying case provided with a carrying strap for use in transportation. The cover is hinged and provided with a lock which prevents tampering by unauthorized persons. The case is of a convenient size, the over-all dimensions being 8 by 8 by 10¼ inches high.

The register is located on the top of the calibrator so that the pointer indications can be read by the operator at a distance if necessary, as in

PORTABLE WATTMETER CALIBRATOR.

checking a meter installed close to the ceiling with the calibrator resting on the floor. The dial is 2¾ inches in diameter and provided with three pointers, the larger of which reads directly in revolutions, being connected directly to the shaft, and which in turn drives the units and tens pointers through the medium of two 10:1 reductions. The periphery of the entire dial constitutes the tenths circle and is divided into ten large divisions which in turn are subdivided into ten smaller divisions so that the pointer indications may be easily read to one-hundredth of a revolution. The units and tens circles are within the large circle, the former reading one revolution per division and the latter reading ten revolutions per division.

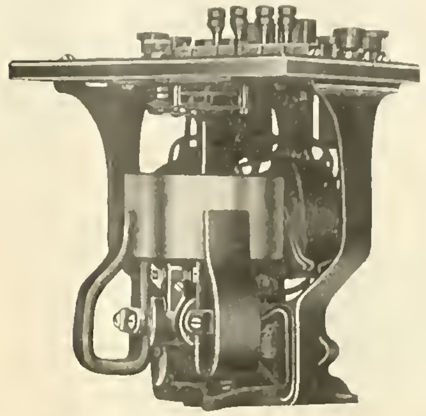
The dial is covered by a suitable glass held in place by a spring brass ring.

Directly in front of the dial is located a small knurled thumb-screw by means of which the rotating element may be raised from the jewel and locked firmly in transportation.

The rear section of the top of the calibrator constitutes the terminal plate to which all connections are made. On this plate are located four current binding posts to which the current coils of the calibrator are connected. On this plate are also located plug switches by means of which the current capacities of the calibrator may be changed. The current coils (two in number) are wound in sections which may be connected in series or series parallel with the plug switches and in parallel with the plug switches in conjunction with the cable connectors on the current leads. Directly behind the plug switches are located the potential receptacles, one for use on 110 volts and the other for use on 220 volts. These receptacles are provided with caps to prevent dust entering the interior of the calibrator when not in use. On this plate are also two one-ampere fuses to protect the one-ampere winding from possible injury due to improper connections.

Each calibrator is furnished with a set of current and potential leads. On one end of each of the current leads is a small punched terminal for connection to the binding posts of the calibrator. The potential leads are provided with a plug at one end for connection to the calibrator. The other ends of these leads have spring clips for connection to the line.

The top bearing is located in the top plate of the register and is easily accessible by removing the glass and pointer over the dial. The top bear



CALIBRATOR REMOVED FROM CASE.

ing may then be readily unscrewed for inspection. The lower bearing consists of a cup diamond jewel mounted in a post set on a carefully selected spring to take up sudden jars which might be caused by setting down the instrument while the pivot rests on the jewel. The lower end of the shaft is provided with a removable pivot in order that the lower bearing may be replaced without replacing the entire shaft.

The entire calibrator may be lifted out of the case by removing the screw under the strap in the bottom of the case. The top plate is made of hard rubber in two sections, all of the connections being made on the rear section. This feature permits the removal of the register and rotating element without interfering with the connections. The shaft is made in three sections: the top bearing pivot, the shaft proper and the jewel pivot.

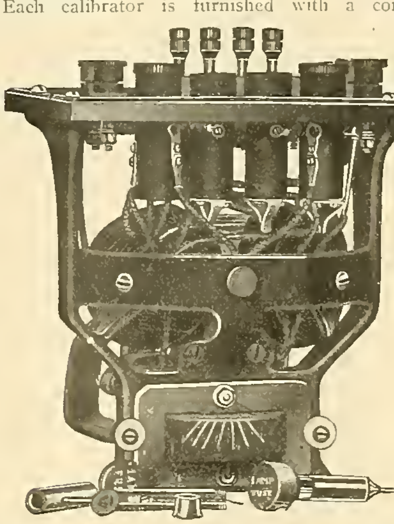
The windings selected as most suitable for meter testing are 1, 2, 5, 10 and 20 amperes and 110 and 220 volts. With these windings meters up to and including 25 amperes, two-wire, either 110 or 220 volts, and up to and including 12½ amperes, three-wire, 220 volts, may be tested. The ampere turns of all the windings are equal, therefore the torque is constant when the meter is operating on a given percentage of full load for any of the different windings.

In checking the calibrator the same rules are followed as in testing standard type K meters with the possible exception of the formula which with the constants furnished with the calibrator becomes:

$$\frac{3{,}600 \times \text{revolution} \times \text{calibrating constant}}{\text{seconds}} =$$

watts registered by calibrator.

Each calibrator is furnished with a complete



BACK VIEW OF CALIBRATOR REMOVED FROM CASE.

list of calibrating constants (reading in watt-hours per revolution) corresponding to the different capacities.

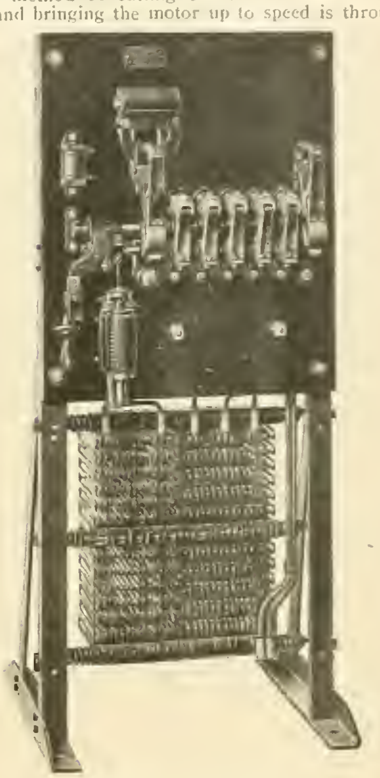
For operation the calibrator is placed in a level position and the rotor is lowered by means of a knurled thumb-screw on the top. The rotor should always be raised in transportation. The current lead terminals stamped A, B, C and D should be connected to correspond with the stamped binding posts on the calibrator, these connections to remain the same for all circuits. The other terminals of the current leads are connected to the meter under test and the line, according to instructions furnished with each calibrator and pasted on the inside of the lid. Different current capacities are obtained by plug switches, which are also fully explained in the instructions.

After making the proper connections for calibrator and meter under test, a reading of the dial should be taken. The calibrator should then be started simultaneously with the counting of the revolutions of the meter under test and stopped after the desired number have been taken. The difference between the first and last reading of the calibrator gives the total number of revolutions. The watt-hours registered by both meters is the product of the revolutions and their respective calibrating constants. These constants being the watt-hours registered per revolution, therefore, the relative accuracy of the meter under test is shown by the ratio of the watt-hours registered by the two meters.

A New Combination Starter.

The J. L. Schureman Company has recently placed on the market a combination starter (type EH), which can be operated automatically or by hand. This has been designed chiefly for the control of motor-driven fire pumps, but will probably be used for a great many other purposes, as the additional charge over that for an ordinary automatic starter is not great.

The method of cutting out the armature resistance and bringing the motor up to speed is through



A NEW COMBINATION STARTER.

a series of cam-operated switches, the shaft on which the cams are mounted being revolved in one case by a solenoid through the medium of a rack and pinion, and in the other case by a hand-operated lever.

An overload device is used which breaks the circuit of the solenoid under an overload condition and also breaks the mechanical connection between the lever and the cam shaft so that the entire bank of resistance is cut into the armature circuit, whichever method of operation is being used. This is of particular value when the apparatus is being started by hand, as it prevents the operator from cutting out the resistance too rapidly and makes the apparatus "fool-proof."

The type EH starter is mounted in panel form, so that all wiring is accessible from the back of the controller. The resistance is ordinarily made of cast-iron grids, and is mounted at the base of the panel and to the rear.

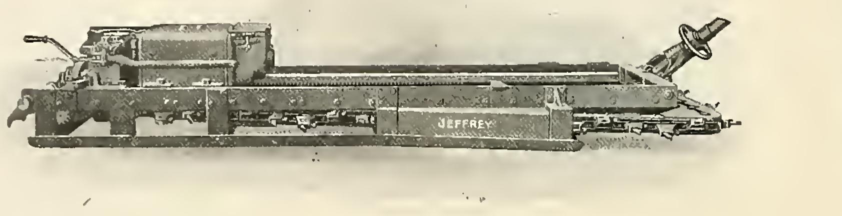
The Chicago City Railway Company has recently placed an order with Yeomans Brothers of Chicago for a fire pump complete with "Schureman" 100-horsepower 550-volt type EH starter for one of its power houses.

The Evansville and Southern Indiana Traction Company in an answer to a suit for damages growing out of an accident to a child during the recent street-railway strike denies all liability, asserting lack of police protection. Strikers and their sympathizers are said to have overpowered the conductor and motorman, and while in possession of the mob the car was run so fast that it left the track, ran into a house and injured a child. At the trial the company expects to show that it is not responsible for the accident.

Electric Coal-mining Machines.

The Jeffrey mining machines with flame-tight motors and starters, shown in the accompanying illustrations, were brought out almost simultaneously with the publication of the British Departmental Committee's report upon the use of electricity in mines. This report, which embodies rules for the use of electricity in mines, recommended the adoption of entirely enclosed motors and auxiliary devices, such as starters, terminals, etc., for all mines coming under general rule No. 8 of the Coal Mines Regulation Act of 1887.

Mining machine motors of necessity have to be designed to be very compact. It is therefore necessary that every advantage be taken of space, so that the motors will not heat excessively under their regular duty. In this country, where the mines are very free from gas, the open type of motor has found favor on account of its accessibility, and on account of the fact that the same motor capacity can be put into smaller space in the open type than in the enclosed type. By careful designing, however, the Jeffrey Manufacturing Company of Columbus, O., says that it has been able to put upon its mining machines motors of the enclosed type which are of equal capacity to those of the open type formerly used, while the enclosed motors occupy practically no more space than those of the open type.



ELECTRIC COAL CUTTER WITH ENCLOSED MOTOR.

Mining-machine service is probably the most severe of any service which electric motors are called upon to perform. The insulation has to withstand both oil and moisture, as well as heat, and infinitely more dirt and less attention than in any other service known. The motors illustrated are provided with self-oiling ring-oiling bearings, which are so arranged that the oil hermetically seals the motor so that any gas which may accumulate about the motor cannot be ignited by sparking at the brushes, or any interior trouble with the motor. Over the commutator of this motor is a plate glass door, protected by a heavy malleable iron lid. Through the plate glass door the brushes may be observed without opening the motor to mine gases.

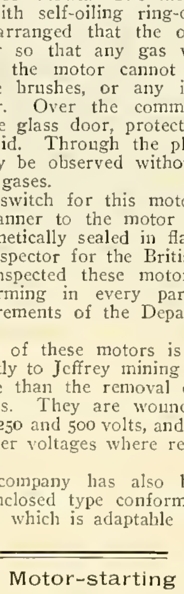
The starting switch for this motor is protected in a similar manner to the motor itself, all contacts being hermetically sealed in flame-tight metal casings. The inspector for the British Government who recently inspected these motors, pronounced them as conforming in every particular to the rules and requirements of the Departmental Committee.

An advantage of these motors is that they can be applied directly to Jeffrey mining machines with no other change than the removal of the existing open-type motors. They are wound for standard voltages of 220, 250 and 500 volts, and may be wound specially for other voltages where requirements demand it.

The Jeffrey company has also brought out a motor of the enclosed type conforming strictly to the mining laws, which is adaptable to low or thin vein machines.

Security Motor-starting Panels.

A new form of motor-starting unit combining all the safeguards required by the National Elec-



SECURITY MOTOR-STARTING PANEL.

trical Code has just been brought out by the F. Bissell Company of Toledo, O. As shown by the accompanying illustration, the Security motor-starting panel is of compact and neat design. The automatic circuit-breaker takes the place of the main switch and fuses, although these are furnished when desired. These units provide protection for both over and underload, and are fire and fool-proof. The panels can be obtained without the starting rheostat when so ordered. This panel has been brought out to meet the demands for an efficient self-contained motor-starting panel.

LEGAL NOTES.

In a case in equity on final hearing before the United States Circuit Court, District of New Jersey, the question presented was whether the defendant (Prudential Insurance Company of America) has infringed complainant's (Westinghouse Electric and Manufacturing Company), patent No. 582,481, dated May 11, 1897. The patent was issued to the complainant as assignee of Edwin E. Nolan, and is entitled "Fastening Means for Core-Plates of Electrical Machines." Judge Lanning says: "In my opinion the complainant's patent is good as to claims 2 and 4 and invalid as to claims 1 and 3, and that the defendant's device is an infringing one as to claims 2 and 4. There will be a decree according to these views."

A suit in equity was brought by the General Electric Company against Corliss-Coon and Company to restrain alleged infringement of the Carl Eickemeyer patent No. 677,308 for an alternating-current motor. Claims 1, 2, 9 and 16 only were at issue, covering what is known as the Eickemeyer squirrel-cage winding. Judge Ray's opinion is that the claims in issue are valid and infringed by the defendant.

In the case known as the self-regulating transformer case involving the Stanley patent No. 469,809, the United States Circuit Court, Southern District of New York, has ordered a preliminary injunction restraining until further notice the defendant, the Wagner Electric Manufacturing Company, from directly or indirectly manufacturing or selling or using any system of electrical distribution or other apparatus containing or employing the inventions or improvements described in the patent named, particularly the first and third claims and that it desist from making alternating-current transformers substantially like those referred to in the complainant's affidavit. The Westinghouse Electric and Manufacturing Company as assignee of William Stanley, Jr., is complainant.

In the United States Circuit Court, District of New Jersey, the General Electric Company was complainant against the Bullock Electric Manufacturing Company, defendant. The complainant is the owner of the Morrow patent No. 504,401 and of the Reist patent No. 559,910, each for an armature for dynamo-electric machines. They are capable of conjoint use. Each patent was issued to the complainant as assignee of the inventor. The defendant was charged with their infringement and the defense set up as to each patent was invalidity of the patent and non-infringement. The final conclusion reached by Judge Lanning is that the complainant is entitled to a decree adjudging the defendant an infringer of Claim 2 of the Morrow patent, but not of the Reist patent, Claim 2 of which is anticipated by Crompton.

A motion for preliminary injunction was brought in the United States Circuit Court for the Middle District of Tennessee by the General Electric Company against the city of Nashville, Tenn., to restrain the city from the further use of some alternating-current generators manufactured by the Bullock Electric Manufacturing Company of Cincinnati, O. These generators have laminated pole pieces attached to the revolving field spider by means of bolts from the spider engaging a transverse bar embedded in the pole piece, a construction said to be covered by the Parcelle Patent No. 463,704, granted November 24, 1891, which has been heretofore sustained by the courts. Judge Clark holds that the defendant has not produced any new matter tending to invalidate the patent and that, therefore, there is no reason why injunction should not issue, this patent having previously been held valid by the Court of Appeals for the Sixth Circuit of Cincinnati.

A Large Roof Sign.

An electric sign 100 feet long by 50 feet high has been placed on the roof of the Colgate factory in Jersey City. Each letter is 10 feet high and the words are in three lines. It is intended to increase the size of the sign to 200 feet long by 50 feet high, when it will contain about 2,500 lamps.

The New Canadian Tariff.

The new Canadian tariff, which went into effect last May, provides for the assessment of three rates of duty: First, the "British preferential," the rates of which apply to goods produced or manufactured in certain-named British possessions, including the United Kingdom; second, the "intermediate," applying to goods of any British or foreign country to which its benefits shall have been extended in a manner prescribed when imported direct from such foreign country or from a British country; and third, the "general tariff," applying to all goods not entitled to admission under either of the foregoing classes. Following are some items of interest to electrical men:

	Br. Pref.	Interme.	General.
Carbons, over 6 inches in circumference	Free	Free	Free
	Pr. Ct.	Pr. Ct.	Pr. Ct.
Electric light carbons and carbon points, of all kinds, not otherwise provided for	22½	32½	35
Incandescent lamp bulbs and glass tubing for use in the manufacture of incandescent lamps	5	7½	10
Wire, single or several, covered with cotton, linen, silk, rubber or other material, including cable so covered	20	27½	30
Electric light fixtures or metal parts thereof	20	27½	30
Motor cars and motor vehicles of all kinds	22½	30	35
Telephone and telegraph instruments, electric and galvanic batteries, electric motors, dynamos, generators, sockets, insulators of all kinds; electric apparatus, not otherwise provided for	15	25	27½
Electric or magnetic machines for separating or concentrating iron ores	Free	Free	Free
Brass caps adapted for use in the manufacture of electric batteries	Free	Free	Free

The Great Proportion of Central Stations in Small Towns.

Mr. J. Robert Crouse of the Co-operative Electrical Development Association has caused to be prepared some interesting statistics of the central stations of the United States, showing the number that give night service only and those that supply 24-hour service. Excluding municipal plants, and classifying the stations by the size of the towns in which they are located, the figures are as follows:

Population of Cities:	Night Service Only.	24-Hour Service.	Total.
1,000 and under	730	554	1,284
1,000 to 5,000	1,158	1,000	2,158
5,000 to 10,000	69	365	434
10,000 to 25,000	21	310	331
25,000 to 50,000	5	119	124
50,000 to 100,000	1	56	57
100,000 to 250,000	6	40	46
250,000 to 500,000	1	23	24
500,000 to 1,000,000	....	13	13
1,000,000 and over	1	14	15
Total	1,992	2,494	4,486

Including municipal plants, the grand total of central stations in the United States is given as 5,577, and of these 1,466 are in places of less than 1,000 population. Of the private-owned central stations 75 per cent. are in towns and villages of less than 5,000 population.

Electric-railway Extension in Northern California.

The filing of incorporation papers of the Northern Electric Railway Company indicates the consolidation of electric-railway interests in Northern California and a plan to extend the system to make it one of the most comprehensive in the state. It is said that the Western Pacific Railroad and the Gould interests are interested. The objects of the company are said to be to acquire the properties of the Northern Electric Company and the Shasta Southern Railway Company, and to build other electric lines in Northern California. The Northern Electric Company, which is to be acquired by the new company, owns the railway running from Chico, Butte County, to Sacramento, by way of Oroville, Yuba City and Marysville. The Southern Railway, whose properties are also to be acquired, operates the electric line from Chico to Hamilton. Lines are to be built by the Northern Electric Railway Company as follows: Chico to Redding, through Red Bluff, 76 miles; Sacramento to Folsom, 20 miles; Sacramento to Hamilton, 108 miles, with a branch 28 miles long from Colusa to Yuba City.

Proposed Code of Ethics.

At a meeting of the board of directors of the American Institute of Electrical Engineers held on August 30th these resolutions were adopted:

"Resolved, That it is the opinion of the board of directors that the American Institute of Electrical Engineers should adopt a code of ethics.

"Resolved, That the draft of the code of ethics as presented at this board meeting be submitted to the membership as the preliminary draft of the proposed code, and that suggestions for alterations or amendments be invited to be sent promptly to the code of ethics committee."

The draft of a code of ethics referred to was presented at the Niagara Falls convention of the Institute last June and was printed in full in the Western Electrician of July 6, 1907.

Statistics of Street-railway Car Manufacture.

The most recent statistics of street-railway car building indicate the large growth in street railways since 1890, since there has been an extraordinary growth in the industries engaged in the construction and repair of street-railway cars. The value of the products of car manufactories has nearly quadrupled during the last fifteen years, increasing from a total value of $6,268,462 in 1890 to $24,281,317 in 1905. The increase from 1890 to 1900 was $10,407,717, or 166 per cent., and that for the five years from 1900 to 1905 was $7,605,138, or 45.6 per cent.

Street cars are manufactured by two classes of shops, one being independent of the street-railway companies, and the other being operated by the companies, and doing repair work.

Of the 100 establishments engaged in the street-car industries at the census of 1905, 80 were street-railway repair shops. Notwithstanding the fact that there were six times as many repair shops as establishments engaged primarily in the manufacture of street-railway cars, the latter represented an investment of $12,975,703, or 50.1 per cent., of the capital employed in the combined industry, and manufactured a product valued at $10,844,196, or 44.7 per cent., of the value of products for the two branches of the industry.

The repair shops employed 11,052 wage-earners and paid in wages $7,012,798, which constituted 70 and 71.2 per cent., respectively, of the totals for the combined industries. Less than five per cent. of the value of the products of the street-railway repair shops resulted from the manufacture of cars. On the other hand, with the car-construction shops 76.6 per cent. of the value of the output was represented in the building of cars.

The number of street-railway cars built during the year 1905 was 4,694. These cars were valued at $9,902,316, and practically all of them were electric. No cable cars were reported, and only 42 were cars for horse lines. Of the electric cars built in the shops independent of the railways, 2,621 were closed, 554 open and 502 were of the combination class, leaving 251 of other varieties.

Ohio was the leading state in the value of products, so far as the independent shops were concerned, furnishing $1,828,326, or 16.9 per cent., of the total value of products for such shops. New York ranked first in the value of the products of the repair shops, with $3,879,933. The other states with products valued at more than $1,000,000 were Pennsylvania, with $1,258,542; California, $1,228,443; Missouri, $1,210,961, and Illinois, $1,142,562.

Canadian Telephone Items.

The Saskatchewan provincial government has decided upon a system of government-owned long-distance telephone lines similar to those now being completed by the province of Alberta and about to be commenced by Manitoba. With the object of ascertaining the feelings of the people on the question, circular letters were sent out to each municipality asking the name and strength of the operating company and for any other information available. Francis Dagger, Regina, Sask., telephone expert for the province, has received replies from 36 towns. It is understood that the Saskatchewan government, in which province all the towns are located, will give every assistance possible to towns and municipalities wishing to install municipal systems, and small Independent companies can be started to advantage in the majority of the towns where there are no telephones.

A Bell Telephone Company's exchange has just been opened at Battleford, Sask., with 135 subscribers.

The Manitoba government will install an automatic telephone system in the provincial buildings, Winnipeg, in the near future. This announcement was made by Hon. J. H. Howden, minister of telephones. The system will include the courthouses, parliament buildings, old and new land titles buildings, jail, etc. There will be between 60 and 70 telephones in the system, and these will be placed in every office connected with the civil service. Work will be commenced shortly and will be completed this winter. The exchange will be in the parliament buildings, and the other buildings will be connected by subways.

All the subways and pipes have been laid south of Portage Avenue in connection with the government telephone system in Winnipeg, Man. The pipes are laid in cement, and cables will be run through from manhole to manhole. Orrin F. French is superintendent of telephone construction, Winnipeg, Man.

The provincial government's telephone lines have been completed in several parts of Alberta, and work is proceeding briskly on the unfinished sections. When the Alberta government promised 500 miles of government line in operation before the end of 1907 there were a number of scoffers, but from the progress made by the various gangs it is evident that some 600 miles will be in working order before the arrival of 1908. It is said that the government mileage will exceed that of the Bell company by at least 200 miles before the end of the year. R.

Indiana Telephone Items.

The Home Telephone Company of Waterloo is preparing to install a modern telephone plant and establish toll line connection with all the surrounding towns and cities, including Fort Wayne and its toll-line connection. The Home Telephone Company has been reorganized.

The citizens of Dale and vicinity, in Spencer County, having grown dissatisfied with the telephone service of the Cumberland and the Home Telephone companies, have organized a mutual company of their own and will install a new plant with the principal exchange in Dale.

The annual meeting of the stockholders of the Lafayette Telephone Company, held recently, resulted in the re-election of all the old officers. The report of the secretary showed that more than 200 telephones were added during the last year. The company has expended over $150,000 in construction and equipment at the new plant, which is valued at $500,000. The new building soon to be occupied is now being installed with a new switchboard by the Sterling company. By November 1st the company will be operating from its new building, which, together with its equipment, will be one of the most modern and complete in the country. William Horn is president and O. B. Friberg, secretary.

At a recent meeting of the directors of the Goshen Telephone Company plans were approved for the erection and equipment of a new exchange building. A new common-battery switchboard, with an ultimate capacity of 3,000 lines and a present equipment of 1,200 lines, will be installed.

R. R. Faulkner, general manager of the Newcastle Telephone Company, denies the truth of the report that the company is to go out of business. On the contrary, he said, the company has decided to extend the city lines, not only in and about the city, but to construct toll lines to Middletown, Anderson and Muncie. The company is now in the market for material for these extensions.

The Central Union Telephone Company of Indianapolis has just issued from its own printing plant a new directory—the most complete ever issued by the company. In addition to the city telephones, suburban telephones in 60 towns within easy access of Indianapolis are listed. The service indexed in the directory includes over 12,000 telephones in the city and 8,500 suburban connections. S.

Telephone News from the Northwest.

The Wisconsin Telephone Company is about to erect an exchange building at Neenah, Wis.

The Turtle River Co-operative Telephone Company of Mekinock, N. D., has filed articles of incorporation with a capitalization of $50,000. A. J. Ulvedal heads the list of stockholders.

The Greaves Telephone Company of Kenmare, N. D., has been incorporated with $150,000 capital.

The Nicollet County Telephone Company's exchange at St. Peter, Minn., was damaged by fire, the loss amounting to about $1,500.

D. N. Tallman of Willmar has been granted a franchise to build a telephone line into Granite Falls, Minn.

E. E. Thompson has resigned as superintendent of the Iowa Telephone Company's exchange at Des Moines.

The King Mutual Telephone Company has incorporated at Thompson, Iowa, with $2,500 capital. F. J. Brooker is president and H. H. Mattison, secretary.

M. M. Head of Jefferson, Iowa, and associates are planning the formation of a company to have control of a system of telephone lines through Nebraska, Iowa, Kansas and Missouri. The company will have its headquarters at Omaha. R.

Important Consolidation of Telephone Companies.

The consolidation of the Bell Telephone Company of Philadelphia, the Pennsylvania Telephone Company and the Chesapeake and Potomac Telephone Company, all licensees of the Bell company, operating in Southern New Jersey, Eastern Pennsylvania, Delaware, Maryland, the District of Columbia, Northern Virginia and West Virginia, was announced recently at the offices of the Chesapeake and Potomac Company in Washington, D. C. The companies involved operate more than 300,000 telephones, but are not competitors, as they do not operate paralleling lines. The authorized stock of the new company will be $60,000,000, which is less than the combined capital and outstanding indebtedness of the old companies.

GENERAL TELEPHONE NEWS

The Del Rio Telephone Company of Del Rio, Tex., has been incorporated with a capital stock of $30,000.

The Edmond (Okla.) Southwestern Telephone Company has been incorporated by F. M. Pettigrew and others.

The Norfolk (Neb.) Long-distance Telephone Company has been incorporated with a capital of $200,000, of which $50,000 is paid up.

CORRESPONDENCE.

Continental Europe.

Paris, September 18.—One of the most important of the electrical contracting firms of Paris, the Giros and Toucher Company, has lately founded a syndicate whose field of operations will be quite extensive. This firm has already installed a number of hydro-electric stations of considerable size in different parts of France. The object of the present syndicate is stated to be the operation of central stations in general, as well as the erection of hydraulic plants or steam plants, and in general all enterprises having for their object the production and distribution of current in different forms for commercial purposes. Owing to the well-established reputation of the founders, there is no doubt that the new syndicate will rank among the most extensive commercial enterprises of Paris.

While passing through Bordeaux not long since I had occasion to visit the new city electric plant which is now being erected. This large station is located in the suburbs just outside the city and covers an extensive tract of ground lying upon the Garonne River. It is built by the Bordeaux Gas and Electric Light Company and will give a supply of current which has been needed for some time, owing to the small capacity of the present plant, which is situated in the center of town. The new station will rank among the largest in France, and owing to the large amount of ground which the company possesses adjoining the gas works the buildings can be disposed in the best possible manner. Coal is to be brought at present by the line of railroad which now supplies the gas works, but at the same time arrangements are being made so that it can be brought by river and unloaded from barges upon the company's ground. The main building of the station comprises a boiler room of large surface, with a dynamo hall adjoining it. At present the boilers are being erected, along with feed-water heaters, pumps, etc. In the dynamo room there are three main alternator groups, which are now being set up. These groups consist of cross-compound engines of 1,500 horsepower each, built by the Carels firm of Ghent, such as are used to a considerable extent in France. On each engine shaft will be mounted an alternator. The latter machines are furnished by the Havre works of the Westinghouse Electric Company.

Professor Mora of the Milan University lately made a comparison between the high-voltage direct-current and the three-phase system as regards efficiency and cost for long-distance power transmission. The direct-current method is now used on a number of power lines on the Continent which are operated on the constant-current system, with generators connected in series, and it is found to work very successfully. The Geneva Electric Company has been one of the most active in promoting the direct-current system. Professor Mora compares the two methods, taking as a base a 40,000 horsepower transmission line, covering a distance of 90 miles from a hydro-electric station. According to his calculations, the three-phase system has a certain advantage from the standpoint of efficiency, this being about three per cent. in its favor, but, on the other hand, the first cost of the plant on the direct-current plan is found to be 1.6 per cent. lower. Using the direct current, the cost of erection is estimated at $2,000,000 comprising $600,000 for the power line and $1,400,000 for the machines. As to the three-phase system, the total plant will cost $2,032,000, counting $1,282,000 for the line and $750,000 for the machines.

Among the new companies which have been formed at Paris are to be noted the Paz and Silva Company, especially devoted to electric wiring, signs and special illumination; also the International Patents Company and the Economic Lighting and Heating Company. At Marseilles the Continental Electric Company is of recent formation.

Great Britain.

London, September 21.—The British Thomson-Houston Company, agent here for the Curtis turbine, recently supplied a 1,000-kilowatt turbo-alternator of this class to the Lancashire United Tramways Company. Tests of the turbine were carried out by Prof. E. Wilson, F. R. S., head of the Siemens laboratory at Kings College, London (which post he succeeded to after the lamentable death of Dr. John Hopkinson in the Alps some few years ago), on behalf of the Thomson-Houston Company, and by Mr. J. P. Salter, chief engineer to the tramway company. The speed of the set was 1,500 revolutions per minute, the alternator being two-phase and giving 1,000 kilowatts with 80 per cent. power factor. The voltage was 7,500 volts and the periodicity 50 cycles per second. The full-load figures worked out to 18.5 pounds of steam per kilowatt-hour, or four per cent. better than the guarantee. The tests are in every way absolutely reliable, all the electrical measuring instruments being calibrated by the Board of Trade after the tests. The regulation was well within the specified limits, while the temperature rise was even more so. Wave forms obtained with an ondograph show that the deviation from a sine curve is not beyond the limit given in the specification.

An inquiry is being conducted into the boiler explosion which took place early this year at a London electric power house, where, as the result of an explosion, the end of a thermal storage drum was blown a considerable distance away.

The adoption of the Griffiths-Bedell surface-contact system by the London County Council in the East End of London, as I reported a few weeks ago, has been the subject of a memorial to the Board of Trade by several tramway authorities outside London working the trolley system, who wish to secure intercommunication by the line of least resistance. Having received the memorials, the board is asking for the comments of all interested. The London County Council and the Poplar Borough Council, two of the partners in the scheme, are willing to adopt the overhead system, but the Stepney Borough Council, thanks to a foolish parliamentary agreement by the London County Council a few years ago, refuses and is able to defy even the Board of Trade. If, in view of the strong expression of opinion by the outside authorities, the Board of Trade deems it expedient to withhold its consent to the adoption of the surface-contact system, the only remedy is for the London County Council to go to Parliament for permission to use the overhead system, and this will delay matters for quite 18 months.

The government, through the Irish Board of Works, is about to erect a new wireless station in Cork Harbor.

Workmen's unions are very keen just now on the question of fair-wages clause in municipal contracts. Both the British Westinghouse Company and the British Insulated and Helsby Cables Company have come under the ban recently in connection with contracts at Manchester and St. Helens, respectively. In the case of the former, the allegation is denied and in the latter instance the reply of the company has not yet been received.

Advices from South Africa indicate considerable activity in electrical circles there. Large extensions are contemplated to the municipal electrical plants at Johannesburg and Pretoria, while extensions of some magnitude will shortly take place in several other towns. Harbor extension works are also to be made at Laurenco Marques.

The general adoption of the common-battery system of telephony throughout the provinces has called forth such an amount of criticism and comment on the part of the local papers that, if it were taken seriously, it would almost hold the British nation open to ridicule. Unfortunately the spirit of the comments has been to a certain extent upheld and fostered by an exceedingly lengthy, and at times far from courteous, discussion in almost every paper, except the electrical journals, between two well-known telephone men. The purport of this is difficult to conceive, remembering the fact that the government is bound to take over the National company in 1911, and that meanwhile the system of the company is being developed in cooperation between the technical officers of the company and the Postoffice. I do not think the user is so much concerned with the technical side of the question as with the financial. The new measured-rate system will bring a host of small users over to the telephone, while the larger existing users will have to pay more than usual when the unlimited-service rate is abolished. Times change, and we not always with them, but that is no argument for continuing a system which is hopelessly out of date. G.

Dominion of Canada.

Winnipeg, Man., September 28.—The system of inspection of houses by the city electrician's department of Winnipeg proves very unpopular. Under the existing by-laws an electrician is obliged to take out a permit before installing fixtures. Upon completion of the work it has to be inspected, and the inspector often causes a delay of several days when people are anxiously waiting the turning on of their lights.

F. E. Cambridge, city electrician of Winnipeg, has issued his annual report, which shows that the use of the street-railway power for only four months has cut down the expenses of lighting for the year. By the moonlight schedule the cost per lamp for street lighting was $57.06, against $75.65 for the previous year. The cost per light on the all-night schedule amounted to $73.40, against $91.88 last year.

The City Council of Port Arthur, Ont., has decided to offer the electric street railway to the sister town of Fort William for $250,000. The people of the latter town consider this figure to be just twice the value of the street railway, and will make an offer of $125,000. The system operates in the two towns.

A limited company has been formed at Kenora, Ont., for the purpose of building an electric street-railway system from that town to Keewatin, a distance of about seven miles, and from thence to the Grand Trunk Pacific Railroad. The route to be taken will be along the Winnipeg River, and application has already been made to the government for the necessary land. As a commencement the municipal power of Kenora will be used, and if the traffic warrants the outlay, power will be developed along the Winnipeg River, where there are several excellent power sites.

The Edmonton City Council has been negotiating with the sister town, Strathcona, Alberta, for electrical power. At a meeting of the Strathcona Council it was decided to sell Edmonton power at seven cents per kilowatt-hour, the latter city to provide transmission.

F. E. Cambridge, city electrician of Winnipeg, does not approve the rail bonding done by the Winnipeg Electric Company. He presents a long report to the council, with figures prepared by a special inspector, and shows that a large amount of damage has been done to the city water mains through electrolysis, and in places the pipes are so badly damaged that they will have to be replaced. R.

New England.

Boston, September 28.—The Minneapolis, St. Paul, Rochester and Dubuque Electric Traction Company has been organized in Portland, Me. It has an authorized capital of $25,000,000 and it proposes to build and operate electric railways in Minnesota and Iowa. Eben W. Freeman of Portland, Me., is president, and M. H. Boutelle of Minneapolis, Minn., is secretary.

The statement of the earnings of the Boston Suburban Electric Companies for the quarter to end September 30th (this month's earnings estimated) has been made public. It is as follows: Income from subsidiary companies, $110,801; expenses, $13,591; net, $97,210; dividend, preferred, $35,339; surplus, $61,871; previous surplus, $40,101; total surplus, $101,972.

The Meriden Light and Equipment Company of Meriden has been organized to manufacture and deal in electrical supplies. The capital stock is $25,000.

The Loomis-Pettibone Company of Hartford, Conn., has been incorporated under the laws of Connecticut. It is authorized to construct and operate railways and telegraph lines. It is capitalized at $100,000. The incorporators are Burdett Loomis of West Hartford, Hawley Pettibone of New Rochelle, N. Y., and Harrison B. Freeman, Jr., of Hartford.

The statement of earnings of the American Telephone and Telegraph Company for the nine months ending September 30, 1907, has been made public. It is as follows: Balance earned for dividends, $10,960,000; increase over same period of last year, $1,385,000; dividends paid, $7,893,000; increase, $329,000; surplus, $3,067,000; increase, $1,056,000; outstanding stock, $142,514,000; increase, $10,962,600.

A new schedule of wages has been prepared by electrical workers in Boston. They ask that after October 1st their pay shall be 50 cents an hour for 44 hours a week. Under such a scheme they would work eight hours a day with a half-holiday on Saturday.

The selectmen of Great Barrington have imposed a peculiar restriction on the Berkshire Street Railway as a condition for allowing that company to act as a common carrier in the town. They require that the company shall carry packages of less than 25 pounds anywhere in the town for five cents and that the cars of the company shall take up and deliver trunks and other baggage along the line wherever signaled by passengers. These restrictions will have to be approved by the railroad commissioners. The company has asked for this approval. Besides asking for the local rights in Great Barrington, the company has also asked the commissioners to approve its location through Lee to the town of Becket boundary. B.

New York.

New York City, September 28.—Overwhelmed by obligations amounting to millions, which it was unable to meet, the New York City Railway Company, the Manhattan and Bronx surface-line end of the Belmont-Ryan "traction trust," has gone into the hands of a receiver. Similar action is expected on the part of the Metropolitan and Third Avenue companies, which are controlled by the New York City company. It is alleged that the present receivership was due to the investigation of the Public Utilities Commission, through its counsel, William H. Ivins. The appointment of a receiver will relieve the commission of a large amount of the burden of looking into the financial relations existing between the three companies.

The construction of a new electric-traction system on Staten Island is projected by New Yorkers, who plan to build and operate a standard-gauge line in a section of the island which is now being served by stages. The line will be known as the Richmond and Tottenville Railway and it will connect Richmond, Rossville, Kreischerville, and Tottenville. It will be about 10 miles long. The overhead trolley will be used, and the cost of the construction of the line and equipment will be about $400,000. Among those interested are Thomas B. McGovern of the firm of McGovern & Donnell and Cornelius G. Kolff, 50 Broadway, city.

Columbia University's 154th year was begun on Wednesday, the 25th, by exercises held in the gymnasium on Morningside Heights. This promises to be the largest year in the history of the institution. Already the registration shows an increase of 150 over last year and the total enrollment in the university will be over 5,000. President Butler has adopted the preceptorial system similar to that in force at Princeton and other universities. It consists in assigning each student to some professor, who becomes a sort of "father confessor." To him the student must come and plan out his course of study. This gives a chance for closer relations and for the personal element to enter largely into the instruction. A number of the older professors are retired and are replaced by younger men who will come into closer touch with the students.

The Electrical Show to be held at Madison Square Garden will be opened at 7 p. m. on September 30th. Already the work of putting the different booths in shape preparatory to opening is well along. E. H. S.

Ohio.

Toledo, September 28.—Local conditions are somewhat improved the last week or two. A number of lettings have been made for structures recently, carrying with them electrical equipment, and building business generally is on the advance. It now looks as if the late fall building operations will be fairly active. While the local conditions have not been all that might have been desired this summer, the large electrical concerns have not suffered materially, as their business has not been limited to the local field. There are a number of concerns which do a handsome business all over the United States, and these have not felt the depression of local conditions. The smaller concerns and the local electrical workers are feeling much elated by the present promise of improved conditions in the near future.

The Citizens' Lighting and Heating Company will ask the council of Toledo for a franchise to do a general lighting and heating business in the city. Its present franchise is limited to a small territory.

The sum of $1,021,755 was added to the appraisement of the interurban railroads of the state by the board of equalization at Columbus on Tuesday of this week. The total appraisement now amounts to $12,605,796.

An ordinance has been introduced into the Dayton City Council providing for a bond issue of $500,000 for the purpose of building an electric lighting plant for the city.

The Seaman Bell Telephone Company has been incorporated at Seaman, Ohio, with a capital stock of $5,000. The incorporators are L. W. Sprague, C. E. Kirkpatrick, J. O. Wickersham, Frank G. Young and W. H. McCreight.

The Radio Telephone Company has arranged for a test of its wireless system between Toledo and Fremont, Ohio, using the top of the smokestack of the Yaryan power house for its mechanism at Fremont, which will be the first test between inland cities. The passenger steamer Greyhound, plying between Toledo and Detroit, is being equipped with this service.

The Toledo, Ann Arbor and Detroit electric railway, which is partially constructed, was offered at sheriff's sale recently. The Ohio and Michigan ends were offered separately, but not a bidder could be found for either end. It will be re-advertised.

Thirty-five electrical contractors, supply dealers and sign builders in the territory of the Canton Electrical Company were entertained at a banquet given by that company at the Courtland Hotel, Canton, recently. An elaborate and interesting programme was carried out.

The main building of the Power Electric Company at Canton is fast nearing completion. It will be 53 feet by 260 feet. The machinery is ready for installation, and the plant will be in operation in October.

The Ohio Manufacturing Company of Upper Sandusky will remove to Columbus about November 1st. A rush order for 200 motors detained the company in its old location longer than was intended.

Charles E. Ashley, W. B. Walbridge, G. W. Kinney, J. F. Shaufelt and J. W. McMahon constitute the incorporators of the Citizens' Lighting and Heating Company of Toledo, recently organized with an authorized capital of $200,000.

The Delta Electric Light Company has made application for a franchise to put in a waterworks plant for the city of Delta, Ohio, asking the town to take 25 plugs at $40 each per year for five years.

A franchise has been granted to the Toledo and Delphos electric railway to use the streets of Neapolis and cross county roads in Lucas County. When completed this line will give Toledo trolley communication with Fort Wayne.

A new ordinance in Toledo requires all street cars, interurbans or locals, to stop on signal at all street crossings. In blocks more than 500 feet long cars must stop in the middle of the block. H. G. S.

Indiana.

Indianapolis, September 28.—The Evansville, Petersburg and Vincennes Railroad Company has filed articles of incorporation. The company proposes to construct an electric railroad from Evansville through Vanderburg, Warrick, Gibson and Pike counties to Petersburg. It also proposes to furnish light and power to the inhabitants along the line.

By unanimous vote the City Council of Terre Haute killed the interurban franchise that the Mc-

Gowan syndicate has been seeking to obtain for six months. The proposed franchise gave the traction syndicate the right to occupy every street and alley in the entire city for interurban purposes. The demand of the people was that the city receive pay for the use of its streets in the same manner as Indianapolis and other cities.

The Indianapolis, Huntington, Columbia City and Northwestern Railroad Company is in hard straits. According to the report of the appraisers, Charles L. Henry and Edward Hawkins, the property is worth, as it stands today, a little less than $10,000. One mile of line ready for operation has been leased to the Syracuse and Milford Railroad Company. The property has been ordered sold by the receiver.

The City Council of Seymour, Ind., is advertising for propositions from any corporation, person or firm to furnish the city and its inhabitants with artificial gas for light and fuel and electric light for street lighting and for private use, and also electric power for persons desiring it. The proposition will remain open for 60 days from September 2d.

The Clay City Lighting Company has been incorporated with a capital stock of $10,000. This company proposes to build and equip a plant for electric-lighting and power purposes in Clay City, Ind. The directors are B. M. and W. H. Guirl, J. M. Long and H. R. Vandever.

The Citizens' Electric Light and Power Company of Lebanon has been incorporated, to construct and operate an electric-light plant for use of the citizens of Lebanon and surrounding country and towns. The capitalization is $25,000. Richard A. Edwards, M. A. Edwards and George R. Chamberlain are directors.

The International Engineering Company of Fort Wayne has been incorporated with a capital stock of $200,000. According to the articles of incorporation, the company proposes to manufacture machinery and mechanical and electrical appliances. The incorporators are F. L. Jones, Charles H. Doebler and George H. Loesch. S. S.

Illinois.

Peoria, September 28.—The Hinsdale Electrical Supply Company of Hinsdale has been incorporated with a capital of $2,500 to manufacture electrical devices. The incorporators are Arthur W. Morrow, John B. Hess and E. I. La Plant.

The Warner Electrical Engineering Company of Rockford has been incorporated to manufacture and deal in electrical instruments and machinery. The capital stock is $5,000 and the incorporators are Romaine Warner, E. M. St. John, Carl Spalding.

Work has been begun on the steam-heating system of the Canton plant of the People's Gas and Electric Company. Mains are to be laid to the business section this fall, and if the idea proves all that is expected of it the mains will be extended next summer.

Gasoline motor cars are in use on the Aurora, De Kalb and Rockford interurban railway. The motor car weighs about ten tons and is equipped with a four-cylinder four-cycle 60-horsepower engine with 7 by 7-inch cylinders. It is 36 feet over all, with a seating capacity of 32 persons.

The Illinois Traction Company is replacing the insulators it first put up on the long-distance transmission lines. The new ones are much larger and heavier and of the triple-petticoat variety, and will withstand the voltage of 33,000 now in use. The line between here and Bloomington is equipped with them, and so far they have given no trouble. In all the company will change about 70,000. Four new refrigerator cars are expected this week and will be put on as soon as received.

The ordinance now before the City Council of Springfield for the electric plant to be constructed by John Brinkerhoff has been reported back to the council for certain changes, the principal of which are that the company should pay to the city five per cent. of the gross proceeds, ordinance to expire in 1927 instead of 1937; that the wires be placed underground, work to be commenced as soon as the franchise is passed, and that the maximum rate to be charge be named. V. N.

Northwestern States.

Minneapolis, September 28.—The Great Northern Power Company has completed its work on the St. Louis River near Duluth, Minn., and is now supplying electric power for commercial purposes at the head of the lakes. The company is in a position to generate 40,000 horsepower and is already furnishing power for the Duluth-Superior Traction Company, the Duluth Edison Company and other large concerns.

A company is being formed for the purpose of building a trolley line from Superior to Ashland, Wis. It is proposed to have the road financed by people along the line, which will be about 100 miles long.

A franchise has been granted at Prentice, Wis., to the Prentice Light, Water and Power Company. A. F. Zeigler is president of the company. Plans are being prepared for a plant. It will be completed by November 1st.

The Burkhardt Milling and Electric Company of Hudson, Wis., has incorporated with a capital of $50,000. C. Burkhardt heads the list of incorporators.

The electric light plant at Waterloo, Wis., may be sold to the village.

The Osage (Iowa) Electric Light and Power Company has asked for permission to raise its dam on the Cedar River.

It is reported that Robert Thompson will take up the project of building an interurban line between Grand Forks and Carrington, N. D.

The Mankato (Minn.) Gas and Electric Light Company has ordered new machinery for its plant to enable it to furnish power for the new street railway system.

The City Council at Eveleth, Minn., has finally granted a franchise to the Mesaba Traction Company.

A 20-year franchise has been granted at Northfield, Minn., to the Northfield Light, Heat and Power Company.

A franchise for an electric-light plant has been granted at Northome, Minn., to E. E. Bigham of Minneapolis.

The Fort Madison (Iowa) Street Railway Company has sold its system to the Mississippi Valley Electric Railway Company.

Fire destroyed the car barns at Waterloo, Iowa, of the Waterloo, Cedar Falls and Northern Railway Company, the loss being $20,000, which is covered by insurance.

It is proposed to issue $25,000 worth of bonds for the purpose of building a municipal light plant at West Bend, Wis.

The proposition to vote bonds for a municipal electric-light plant at Ashland, Wis., has been defeated and the matter will be abandoned. R.

Pacific Slope.

San Francisco, September 25.—There is some friction between the electric companies of which Sam. Naphtaly of San Francisco is manager and the union electricians, and a vote is now being taken by the members of the union to decide whether or not a strike shall be declared. The companies concerned are the City Electric Company, the Truckee River General Electric Company, the Reno Water Light and Power Company, the Central Traction Company and the American River Electric Company.

The rumor is current here that the plant of the City Electric Company in San Francisco, which has been completed at a cost of about $1,000,000, will be bought by the Pacific Gas and Electric Company for $1,500,000. The management of the City Electric Company announces that it will be ready to begin operations about October 1st.

J. Downey Harvey, president of the Ocean Shore Railroad, states that it is now doubtful whether the company will be able to commence the operation of its road within the coming year, as much difficulty is experienced in floating the bonds of the company. A small portion of the line is already in operation, and through service could be given in a short time if the bonds were taken.

Richard Phelan of Sierra County, Cal., is planning to run an electric power line into Reno, Nev., from several points in California, where he is erecting large power plants run by water. He states that he intends to cut the rates of the present companies which are supplying Reno.

The question of a municipal lighting plant is occupying much attention at present in San Jose, Cal. The contract for lighting the streets has been held for some years by the United Gas and Electric Company, but the contract expires next June, and there is much discussion in regard to the expense of lighting under the terms of the contract. The city council has been strongly urged to make appropriations for a municipal plant, and, while no action has yet been taken upon the matter, a favorable opinion has been expressed by members of the council. The mayor has appointed an engineer to make an estimate of the cost of a plant.

The supervisors of Ventura, Cal., have received an application from J. P. Jones and F. M. Packard of Los Angeles for a franchise to build and operate an electric railway from Ventura to Nordhoff, Cal.

The electric train service between San Rafael and San Anselmo, Cal., will be greatly improved within the next few months, according to the statement of the North Shore Electric Company. The electric cars from Sausalito will extend their runs to Fairfax. The trains between San Anselmo and San Rafael will be run at much greater speed and will be better lighted. Over $30,000 will be spent in providing new machinery and enlarging the power plant, and the storage batteries at San Anselmo will be abandoned for two 500-kilowatt motor-generators. The latter will develop the same potential as the power house. Trains will be operated by electricity as far as Fairfax as soon as the generators are installed and the necessary rolling stock arrives. Four additional motor cars will be provided.

The Central California Traction Company wishes to get certain new franchises in Stockton, Cal., to enable it to land its passengers at the depots of the Southern Pacific and Western Pacific railroads.

The railroad from San Diego, Cal., to La Jolla is to be operated by electricity soon. The plant of the Los Angeles-Pacific system at Sherman has already been purchased and, with new machinery, will be set up in San Diego.

A special meeting of the Pacific Gas and Electric Company is to be held in San Francisco on November 20th to take action on a proposition to increase the bonded indebtedness of the company from $10,350,000 to $14,350,000.

The City Council of Los Angeles, Cal., has amended an ordinance granting to the Los Angeles Pacific Railway Company (electric) permission to construct a brick and concrete subway under private property on Hill and Temple streets. The subway shall not be more than 28 feet in width and 24 feet in height.

The Northern California Power Company has begun work on its new power plant on Battle Creek near Red Bluff, Cal.

The Tejunga Water and Power Company has been incorporated in Los Angeles by C. F. Hunter and others with a capital stock of $250,000.

The California Gas and Electric Company will shortly erect a transformer house at its works in Santa Rosa, Cal.

An electric light and power franchise has been advertised for sale in the first township of San Mateo County, Cal.

The Huntington-Kerchoff syndicate will put its lighting wires underground in the business district of Fresno, Cal.

The town of Placerville, Cal., is planning to install a municipal electric-light plant. The cost is estimated at about $20,000. A.

PERSONAL.

Mr. H. McCullough has accepted a position as electrical engineer for the Pittsburg and Montana Copper Company of Butte, Mont.

O. R. Sturinger of Toledo, Ohio, has been appointed superintendent of the Toledo, Port Clinton and Lakeside Railway, to succeed H. C. Warren, resigned.

Edward W. Clark, for five years in the employment of the Boise Electric Company of Boise, Idaho, has accepted the position of superintendent of the electric-light plant at Ellensburg, Idaho.

Mr. H. S. Rush has left the testing department of the General Electric Company, Schenectady, N. Y., and is now in the inspection department of the North Shore Electric Company at Evanston, Ill.

Jere T. Burke of the Southern Pacific Railroad Company has been elected president of the Peninsula Electric Railway, running between Mayfield and Los Gatos, Cal. Mr. Burke succeeds the late O. A. Hale of San Jose.

Mr. E. J. Cook has been appointed general manager of the Rochester Railway Company, Rochester, N. Y. Mr. Cook is a graduate of Stevens Institute of Technology, and has been chief engineer of the Consolidated Street Railway properties in Cleveland, Ohio, since 1903.

A. J. Campbell, treasurer of the territory of Hawaii, has come to the mainland to float over $300,000 worth of bonds issued by Hawaii for public improvements, a large part of which will be the completion of the Nuuanu dam, which will furnish waterpower for the generation of electricity for the city of Honolulu.

Andrew Boughan, 77 years old, who is said to have helped to construct the first telegraph line from Chicago toward the Pacific Coast, died in Chicago on September 25th. Mr. Boughan was for 44 years in the continuous employment of the Western Union Telegraph Company. When he retired four years ago he was a department manager. He worked for the old Illinois and Mississippi Telegraph Company before the Western Union was formed. He leaves a widow and five children.

Mr. Arthur S. Merrill, who has been identified in the electrical business for the last ten years, most of the time in New York city, and who has been assistant western sales agent for Pass & Seymour, Solvay, N. Y., with headquarters at 130 West Jackson Boulevard, Chicago, for over a year, has tendered his resignation in order to carry out plans which he has had in mind for some time. He is a brother of Mr. Wm. W. Merrill, secretary of the Chicago Fuse Wire and Manufacturing Company, Chicago.

ELECTRIC LIGHTING.

The city of Blackshear, Ga., contemplates building an electric-light plant.

W. L. Underwood and others have been granted an electric-light franchise in Childress, Tex.

The Texhoma (Okla.) Electric Light, Water and Ice Company has been incorporated with a capital stock of $15,000.

The E. S. Cowie Electric Company of Kansas City, Mo., has been incorporated with a capital of $10,000 by Ernest S. Cowie and others.

The Sacramento Power Company of Alamogordo, N. M., has been formed with a capital stock of $1,000,000, to operate power and electric-light plants.

The McVeytown (Pa.) Electric Light, Heat and Power Company has been incorporated to build and operate a plant. The incorporators are J. E. Rupert, James and George Macklin, J. S. Lefford, J. T. Rogers, McVeytown, and William Atkinson, Mattawana.

By a decisive vote the citizens of Canton, Ga., voted for the issue of bonds for the establishment of electric lights, waterworks and a sewerage system in the town.

The Cottonwood Water and Light Company has been incorporated at Cottonwood, Idaho, with a capital stock of $20,000 by H. Huxoll, W. H. Schiller, Samuel Goldstone and A. L. Creelman.

The Mt. Union Light and Power Company, of Mt. Union, Huntingdon County, Pa., has been granted a charter. Thomas N. Kurtz, Scott Dibert and John L. Dickson of Mt. Union are identified with it.

The state of Pennsylvania will soon ask bids through its Board of Public Grounds and Buildings for changing electrical work so that the library and other buildings as well as the Capital Park in Harrisburg can be lighted from the power plant in the state capitol.

A lamp-renewal plan has been adopted by the municipal electric-lighting system of Lansing, Mich., to go into effect October 1, 1907. The first installation of lamps must be purchased by the consumer. Incandescent lamps of 2 to 24 candlepower will be sold for 20 cents each; 24 to 32 candlepower lamps will cost 25 cents each. All burned-out lamps will be exchanged, but broken bulbs will not be replaced without payment.

San Antonio and Southwest Texas men will build a plant at the Rio Grande coal mines to furnish motive power for irrigating several thousand acres of land between the mines and Laredo, Tex., 26 miles distant. It is planned to construct an electric transmission line to Laredo, where a substation will be built for furnishing the city with electric lights. About $100,000 will be expended. Construction work will begin within two months under the supervision of Samuel Kahn, chief engineer of the San Antonio Traction Company, San Antonio, Tex.

ELECTRIC RAILWAYS.

The Tulsa (I. T.) Electric Light Company has been incorporated for $15,000 by R. D. Campbell and D. M. Martindale of Tulsa and H. F. Burt of Oklahoma City.

The city of Findlay, O., is advertising for bidders to construct, maintain and operate a street railway over certain of its streets. Particulars can be obtained from J. E. Edie, city clerk, Findlay, O., and proposals must reach him by noon on October 26, 1907.

The Oklahoma City Street Railway Company has increased its capital stock from $1,000,000 to $3,000,000 for the purpose of extending the interurban line to Guthrie and adding several local lines. A new terminal station will also be erected as soon as the location has been secured.

The little town of Dover, Ark., has raised a bonus of over $5,000 to secure the building of the interurban line from Russellville to that place. It is said that considerably over $15,000 has been raised in different quarters as a bonus to help out this line and that the prospects for its construction are very good.

Seven companies controlling the electric lines in and near York, Pa., were merged on September 26th into a single corporation, which will be known as the York Railways Company. The capitalization of the new corporation is $3,397,000. Of this amount a large proportion will be available for improvements and extensions.

The recently incorporated Norwich, Colchester and Hartford Traction Company of Connecticut has organized with Costello Lippitt as president, Lucian Brown, secretary, and H. W. Tibbits, treasurer, all of Norwich, Conn. The company has a capital stock of $1,000,000 and is empowered to construct an interurban line from Norwich to Hartford, Conn. The length of the proposed road is 38 miles, which is 11 miles shorter than the steam railroad now connecting these cities.

The Brooklyn Union Elevated Railroad Company has sought permission from the New York Public Service Commission for the issuance of $20,000,000 of bonds. Recent improvements costing $7,000,000 are to be paid for and $8,000,000 is to be used for constructing an elevated extension on Flatbush Avenue, to bring the road to the terminal of the new Manhattan Bridge. About $2,500,000 will be needed for new rolling stock and the balance of the bond issue for general improvement. The application will be granted.

The city of Little Rock, Ark., has for some time sought to purchase West End Park from the Little Rock Railway and Electric Company, but refused to pay the sum of $40,000 which the company demanded. The company has now made an offer to give the city immediate possession of the property on condition that the annual compensation the company must pay the city be withheld till it aggregates $40,000, when the city will be given the full title to the park. This proposition will probably be accepted, as no city funds will be required and no interest called for.

POWER TRANSMISSION.

The Altoona Construction Company has been given the contract for the big dam of the Roystown Power Company which will be built on the Juniata River in Central Pennsylvania.

Messrs. Wallace Wilson and W. P. Woods, who have been taking out Pennsylvania charters for various towns in the Juniata Valley which can be reached from several of the proposed big power dams, have secured a franchise for the Mapleton Electric Company of Mapleton.

The North Georgia Electric Company has been placed in the hands of a receiver. Samuel C. Dunlap of Gainesville, Ga., was appointed to act in that capacity temporarily. The company has a 50,000 horsepower hydro-electric plant on the Chattahoochee River and sells its power in and about Atlanta, Ga. The authorized capital stock is $7,500,000, of which $1,000,000 has been issued.

The German Transatlantic Electric Company is said to have a concession to erect a hydro-electric power and lighting plant on the River Maipo, above Santiago, Chile, at an estimated cost of $4,015,000 United States gold, of which about $1,295,040 will be for materials and machinery that must be imported. It is estimated that it will take about five years to complete the undertaking. The company has petitioned the government of Chile for the free entry of its machinery and material for a period of five years.

PUBLICATIONS.

A little pamphlet published by Harvey Hubbell, Inc., Bridgeport, Conn., tells of the simplicity and economy of the Hubbell Guard for incandescent lamps.

The H. W. Johns-Manville Company has undertaken the exclusive sale of Morris' Metallic Packing and has just published a booklet describing this packing for rotary-valve stems and reciprocating rods.

The National Battery Company, Buffalo, N. Y., has published a new bulletin on "Storage Batteries for Isolated Plants," wherein it offers complete generating units for this service, including gas, gasoline or alcohol engines, dynamos, switchboards and storage batteries of the Unit Accumulator type manufactured by this company.

The Gail-Webb Manufacturing Company of Buffalo, N. Y., is sending out literature descriptive of some of its products of interest to users of incandescent electric lamps. Among the articles to which it calls attention are the Gail-Webb lamp guard, adjustable wall fixture, adjustable electric portable, adjustable ceiling fixture and the Universal electric-light holders.

A convenient and serviceable catalogue, No. 2, has just been issued by the Pringle Electrical Manufacturing Company, 1906-08 North Sixth Street, Philadelphia. A thumb index enables the reader quickly to turn to switches, panel boards, iron and wood boxes, switchboards, accessories, receptacles, specialties, etc. The book is profusely illustrated and in the back are given a number of handy tables of various kinds. A copy will be sent to anyone upon request to the company.

SOCIETIES AND SCHOOLS.

The next meeting of the American Institute of Electrical Engineers to be held in New York city will be at the Engineering Societies Building on the evening of October 11th.

A number of new subjects have been added to the course in electrical engineering at Armour Institute of Technology, Chicago. The junior students are now required to make a study of illumination in the first semester and the senior students will add electric railways to their programme in the second semester. Additional quarters for drafting rooms, physical laboratories, and student organizations have been opened. The evening classes were begun on September 30th with an attendance much larger than ever. A new feature of this evening work is the addition of college preparatory courses. The total number of evening courses offered at the Institute is now over 70. A bulletin describing them can be had by writing to Dean H. M. Raymond, Armour Institute of Technology, Chicago.

The American Society of Mechanical Engineers will hold the first monthly meeting this fall on Tuesday evening, October 8th, in the main auditorium of the Engineering Societies Building at 29 West Thirty-ninth Street, New York. The subject will be "Industrial Education." The college technical courses and the student apprenticeship courses will be discused at length by men who have been in charge of theoretical and practical institutions. Prof. John Price Jackson has written a paper on the college technical courses and apprenticeship courses offered by manufacturing establishments. He gives data in the form of letters from several of the largest manufacturing establishments in America in which they outline the courses offered by the factories and explains the manner of conducting the same. Dr. Henry S. Pritchett and Prof. Dugald C. Jackson will deliver short addresses. Manufacturers have been invited to speak informally at the meeting of their experiences, and altogether it is expected that the meeting will prove interesting and instructive.

MISCELLANEOUS.

Prof. G. M. Minchin, observing with a selenium cell of special design at the Daramona Observatory, Westmeath, Ireland, has reported that the electromotive force generated by starlight was sufficient for observation in stars of the first and second magnitudes.

A new textile factory is to be erected by Oscar Heineman, a silk manufacturer of Chicago, along the most modern lines. All the machinery will be electrically driven. The new plant will be located on the Northwest Side and will cover an entire city block. The building will be a three-story structure, with saw-tooth roof, and is estimated to cost $135,000. Paul Gerhardt, 109 Randolph Street, Chicago, is the architect.

The St. Louis, Iron Mountain and Southern Railway Company will establish a power plant to furnish heat and light for the Union Station at Little Rock, now under construction, light for passenger yards, heat for passenger equipment and compressed air for cleaning and brake testing. Building will be of brick. Equipment to be installed consists of two 240-horsepower water-tube boilers, two 75-kilowatt direct-connected generators, two exciters, one small generator and one air compressor. E. F. Mitchell of St. Louis is engineer of construction.

TRADE NEWS.

The London office of the Western Electric Company announces the removal on September 30th to its new address—Norfolk House, Victoria Embankment, W. C.

Manager of Sales Frank Warren of the Warren Electric Manufacturing Company of Sandusky, Ohio, was in Chicago last week. The Warren company is now very busy, as it is increasing its line of apparatus.

At a meeting of stockholders of the Johnston Electric Machine Company of Charleston, W. Va., the capital stock was raised from $20,000 to $100,000 to permit enlargement of the plant to a capacity sufficient to meet the demand for the electric coal-mining machinery that the company manufactures.

The entire business of the Beck Flaming Lamp Company of 30 Greenwich Avenue, New York city, including manufacturing and selling, is now conducted in the name of that company, the selling organization known as the New York Beck Lamp Company being no longer in existence. The company has an extensive exhibit at the New York electrical show, and in addition the New York Edison Company has adopted the Beck flaming lamp exclusively for the illumination of the interior and exterior of Madison Square Garden.

Syles R. Fralick, whose offices are located at 161-163 South Canal Street, Chicago, has taken the agency for the Premo and Star knife switches made by the Barkelew Electric Manufacturing Company, Middletown, Ohio. He also represents the Clark Electric and Manufacturing Company of New York city, manufacturer of insulator clamps for insulated wires; W. J. Jackman of Lima, Ohio, maker of the Jack guy anchor; Blake Signal and Manufacturing Company of Boston, Mass., manufacturer of saddle staples and solder flux; Horton-Morehouse Company, knife switches, and the Chance Manufacturing Company, manufacturer of the Sky-rocket lightning arrester.

Mr. Charles Blizard, third vice-president of the Electric Storage Battery Company of Philadelphia, says that the demand for storage batteries is, within certain limits, independent of extensions in the electrical field. During periods when the lighting and railway companies are postponing enlargements of their plants batteries are largely used to provide for immediate demands for increased power; the batteries are bought with a view of being later fitted in with the new plants or extensions. For this reason the business of the company during the current year has been uniform and satisfactory, and the indications point to a material growth as soon as funds become more plentiful.

Eugene Munsell & Co., well-known dealers in mica, and the Mica Insulator Company, manufacturer of micanite and other high-grade electrical insulators, for many years located at 218 Water Street, New York, have removed to 68 Church Street, corner of Vesey Street. Owing to the increase in business, more commodious quarters were required. The new location is one of the most central in the downtown business district, being only one block west of Broadway and within five minutes' walk of the principal railways and ferries. Four floors are used, the second floor being devoted entirely to offices, while the other three are used for stock and shipping departments, for the preparation and assorting of mica and for the manufacture of mica specialties.

Sealed bids will be received by the secretary of the Board of Public Works of Los Angeles, Cal., up to October 7th, for furnishing hydraulic and electrical machinery and material for equipping one hydro-electric generating plant and 90 miles of 30,000-volt transmission line and transformers, bidders to state the earliest date on which delivery can be guaranteed. This apparatus is to be used in connection with the building of the Owens River aqueduct.

Referring to the outlook for fall trade, V. R. Lansingh, general manager of the Holophane Company, New York, says: "On the whole, it seems to me that the electrical business this fall will be very good. There has been, generally speaking, a little tightening up along the lines of credit, but on the whole the industry is growing so rapidly that the demand for good articles will, in our opinion, increase rather than decrease. If we should judge the outlook by the increase in the Holophane business, we would hardly get a fair comparison, inasmuch as this business is growing remarkably, the increase this year being 79 per cent. over the corresponding period of last year. On the whole, we look for an increase in electrical business this fall, with, however, a little more care with reference to credits."

BUSINESS.

The Bristol Company, Waterbury, Conn., announces that it is about to erect another addition to its present plant. The addition, which will be 53 by 170 feet, three stories high, is made necessary by the increased demand for Bristol's recorders and Bristol's patent steel belt lacing.

The Nernst Lamp Company, Pittsburg, says that the increasing demand for Nernst lamps, coupled with the closing of several large contracts during the last few weeks, necessitates its appealing to customers to anticipate their requirements for lamps and renewals for the lighting season, to avoid delays in delivery. Delivery of material is assured by sending requisitions through the district offices, or direct to Pittsburg, marking on same date of shipment desired and spreading same over a period of several months, if preferred.

In the purchase of a spark coil that will give good results, it is necessary to have a coil giving a hot, bright spark which will never fail to ignite the explosive mixture in the combustion chamber and never cause the motor to miss an explosion. A low internal resistance requiring a comparatively small amount of current is necessary. The Edison spark coil in connection with the Edison primary battery is said to require less than half the current used by many other coils. Three times as much copper wire is put into them as in many in general use, the company says, and the high ampere power is not wasted by unnecessary resistance in parts of the circuit other than the spark [illegible] Manufacturing Company of 10 Fifth Avenue, New York, making both battery and coil, has an interesting little booklet, "Battery Sparks," which goes deeply into the details of its product. On receipt of a postal the company will forward this to any address.

The Electric Storage Battery Company of Philadelphia will have an interesting exhibit at the convention of the American Street and Interurban Railway Association at Atlantic City, beginning October 14th. Among other material will be shown one element of type 71-R in a containing tank sufficiently large to hold 83 plates of this type, the tank showing the standard method of reinforcement used on cells at the end of rows. A 12-pole carbon regulator, recording hydrometer, recording and signaling hydrometer, automatic cell filler and compensating hydrometer will be shown, with examples of positive and negative plates of the different types. The representatives who will be present are Messrs. Charles Blizard, third vice-president; Albert Taylor, manager New York office; G. H. Atkin, manager Chicago office; E. L. Reynolds, manager Pennsylvania sales office; H. B. Gay, manager Cleveland office, and Robert C. Hull, district engineer. A cordial invitation is extended to members of the association to visit the booth, where a number of recent publications of the company of interest to railway officials will be distributed.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) September 24, 1907.

866,618. Electric Water Filter. Melvin A. Brannon, Grand Forks, N. D. Application filed April 11, 1906.

This filter has two chambers, one above the other with the filtering medium between. This consists of a sand tray and an unglazed earthenware partition on one side of which lies a layer of zinc fragments and on the other is supported a similar layer of copper turnings, the two metals forming a short-circuited electric couple that is acted on by the salt content of the water passing through the partition.

866,631. Sparking Plug for Explosive Engines. William Diebel, Philadelphia, Pa. Application filed July 13, 1906.

A cylindrical casing has a small aperture at one end into which extends a small sparking point from the casing wall. A porcelain insulator fits into the bore and has an asbestos washer at its end and a conductor with the other sparking point passing through its center.

866,636. Vibrator. Charles R. Elliott, Rochester, N. Y. Application filed February 11, 1907.

The particular feature of this patent is that the vibrator has a flexible coiled wire handle through which the wires pass to the electric motor in the casing.

866,639. Automatic Telephone Release. Edward D. Fales, Chicago, Ill., assignor to the Automatic Electric Company, Chicago, Ill. Application filed February 9, 1907.

In this automatic telephone system, there is in combination with the selector switches, a set of trunk lines and trunking switches, a connector and a trunk release circuit controlled at the connector and extending through all of the trunking switches.

866,643. Pressure Controller. James H. Glenn and Michael Reule, Lafayette, Ind. Application filed April 10, 1907.

This device is intended to work in connection with an electrically driven air compressor. A cylinder is connected with the receiver of the compressor. A plunger in this cylinder has a stem, whose motion is governed by a set of springs, and which carries a circuit closing device at its end.

866,645. Anti-hummer for Telephone and Telegraph Lines. Nels O. Hagen, Pekin, N. D., assignor of one-half to Ole O. Forde, Pekin, N. D. Application filed May 4, 1907.

A pliable tube is bent about a support to a form like the letter J. The line wire is wrapped about, and fastened to the longer stem of the tube. The house wire is connected to the line wire and then passes through the tube, which has a stopper with a hole in each end.

866,646. Contact Device. Clarence J. Harter, Ilion, N. Y. Application filed December 3, 1906.

This is a trolley wire contact shoe. It is supported in a contact head at the top of the trolley pole and is provided with an adjustable hanger adapted to engage the guy wire of the trolley wire or cable.

866,667. Means for Fastening Collector Leads. Emil Mattman, Norwood, Ohio, assignor to the Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Application filed January 31, 1907.

The shaft of a dynamo-electric-machine has a cone-shaped portion over which fits a collector ring. The collector lead has a wedge-shaped terminal fitting into a slot between the collector and shaft.

866,709. Support for Electric Conductors. William W. Benson, Philadelphia, Pa. Application filed August 14, 1905.

The body has a section like molding, the channels of which have corrugated sides for holding the conductor. A groove makes one of the sides flexible so it can be sprung for the insertion of the wire. A cap fits over the channels.

866,714. Telephone System. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company, Chicago, Ill. Application filed October 25, 1901.

This patent has 158 claims. One of the features of the common-battery system covered is a normally open low-resistance connection across the terminals of the subscriber's line at the exchange, which short-circuits the line and lights a signal lamp, when the subscriber calls.

866,716. Manufacture of Enclosed Fuses. Robert C. Cole, Hartford, Conn., assignor to the Johns-Pratt Company, Hartford, Conn. Application filed June 23, 1906.

The fuse is provided with an indicator wire which is fastened to the ferrules at the end of the case independently of the terminal contacts.

866,729. Trolley. William Moeckel, Jersey City, N. J. Application filed June 12, 1907.

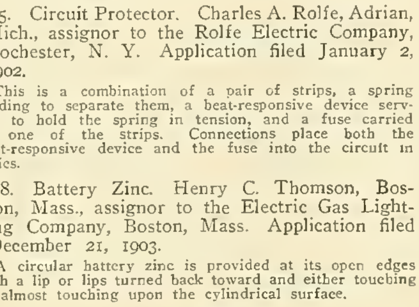
On each end of the shaft of the main trolley wheel is pivoted a U-shaped side frame carrying a vertical spindle on which revolves a guide wheel engaging the side of the trolley wire. These lateral guide wheels are held to the wire by a spring, but can be freed from it by pulling a rope.

866,735. Circuit Protector. Charles A. Rolfe, Adrian, Mich., assignor to the Rolfe Electric Company, Rochester, N. Y. Application filed January 2, 1902.

This is a combination of a pair of strips, a spring tending to separate them, a heat-responsive device serving to hold the spring in tension, and a fuse carried by one of the strips. Connections place both the heat-responsive device and the fuse into the circuit in series.

866,748. Battery Zinc. Henry C. Thomson, Boston, Mass., assignor to the Electric Gas Lighting Company, Boston, Mass. Application filed December 21, 1903.

A circular battery zinc is provided at its open edges with a lip or lips turned back toward and either touching or almost touching upon the cylindrical surface.



NO. 866,751.—METHOD OF EXHAUSTING INCANDESCENT BULBS.

866,751. Method of Exhausting Incandescent-lamp Bulbs. Frank L. O. Wadsworth, Pittsburg, Pa. Application filed February 28, 1906.

This method of exhausting bulbs consists in causing the flow of a liquid under the action of pressure to control in succession the several steps in the operation. (See cut.)

866,760. Polarized Ringer Magnet. Francis H. Whitman, Cambridge, Mass. Application filed December 31, 1906.

Two electromagnets have cores which project at one end of the magnets, the projecting ends being formed with transverse grooves to engage and be clamped to a yoke having slotted ends. An armature is supported by a bridge which has adjustable means for securing it to the yoke, whereby the bridge may be adjusted to vary the distance between the armature and the magnet cores.

866,770. Electric-conductor Molding. Sidney M. Burk, Philadelphia, Pa. Application filed February 9, 1906.

This molding has thin grooves adjacent to the sides of the conductor channels. The tongues left between these grooves and the channels thus make flexible sides for the latter.

866,781. Trolley. George R. Forster, Fithian, Ill. Application filed April 27, 1907.

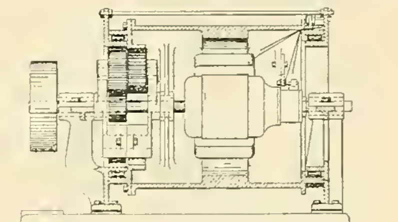
A mechanism is provided at the base of the trolley pole which automatically lowers the pole when the trolley wheel leaves the wire. The mechanism comprises a cylinder with fluid operated piston, trip devices and springs.

866,794. Intercommunicating Telephone. Charles E. Lee, Chicago, Ill., assignor to the Electric Goods Manufacturing Company, Boston, Mass. Application filed February 28, 1906.

This patent covers a special form of hook switch for a local telephone system. It consists of a set of circuit springs, a push-button in connection therewith, and a latch at the end of the hook arm for engaging the springs when the receiver is removed.

866,810. Electric Laundry Iron. Earl H. Richardson, Ontario, Cal. Application filed October 10, 1906.

The body of the iron has resistance wire wound into a recess in its top. A detachable cover lined with heat insulating material is provided with binding posts and fuses that connect with the terminals of the resistance wire.



NO. 866,820.—ELEVATOR MACHINE.

866,820. Elevator Machine. George L. Smith, Chicago, Ill. Application filed August 11, 1906. Renewed July 12, 1907.

This machine has a drum revolving on roller bearings. The motor is mounted within the drum on the central shaft and is geared to the drum. (See cut.)

866,838. Apparatus for Firing Explosives in Wells. Luke H. Broadwater, Findlay, Ohio, assignor to the E. I. du Pont de Nemours Powder Company, Wilmington, Del. Application filed June 24, 1907.

The apparatus consists of a chamber containing the firing fuse and a chamber containing an explosive, there being a space between these chambers. Firing wires, adapted to be ruptured by the explosive, are provided with an electrical connection between the firing wires and the fuse and explosive.

866,846. Electric Locomotive Controller. Charles O. Dayton, Washington, Iowa. Application filed October 8, 1906.

This is an electric block signaling system for railroads. The locomotive engages road-bed contacts at the ends of each block. A step by step controller is arranged in each block and this opens the circuit in the block which the train is approaching and thus operates an electromagnetic signal in that block.

866,849. Method and Process for the Recovery of Copper and Other Metals from Their Ores. Charles H. Ehrenfeld and Jacob R. Grove, York, Pa. Application filed September 7, 1906.

This process is particularly adapted to sulphide ores of copper. The ore is first heated in the presence of a limited supply of oxygen to expel the sulphur and convert the copper of the ore into the lower oxides of copper. The metal is then dissolved out by electrolysis into an aqueous solution of ammonium chloride, and finally electrically deposited therefrom.

866,858. Apparatus for Depositing Metals. Wilbur A. Hendryx, Denver, Colo. Application filed June 30, 1905.

Any apparatus for recovering metals has a tank and a depositing cell therein, the cell comprising electrodes adapted for connection to an external source of current and a filtering medium.

866,859. Apparatus for Depositing Metals. Wilbur A. Hendryx, Denver, Colo. Application filed June 30, 1905.

This apparatus for precipitating metals consists of an anode separated by a filtering medium from a cathode. The latter is composed of an amalgam of mercury and zinc, and is supported by a permeable casing surrounding the anode.

866,920. Perforating Machine. Lewis B. Doman, Elbridge, N. Y., assignor to William C. Ranney, trustee, Elbridge, N. Y. Application filed March 7, 1899.

Punches are arranged on opposite sides of the path of the article to be perforated. Electromagnets are arranged so as to control the operation of the punches.

866,945. Electric Signaling on Railways. William J. MacKenzie, Dunmurry, Ireland. Application filed December 13, 1905.

This system requires one or two insulated conductors laid between the rails on the track. Trolleys on the engine make contact on these conductors and enable signals to be transmitted from the engine man to the signal tower man or the reverse.

866,959. Electroplating Apparatus. Louis Potthoff, Flushing, N. Y. Application filed May 1, 1906.

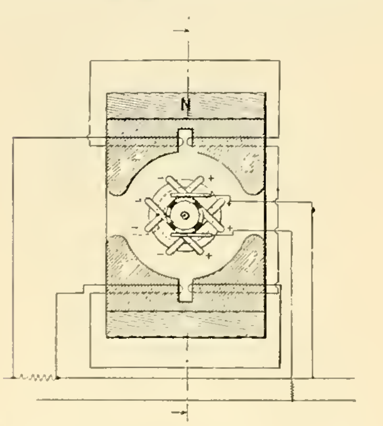
A galvanizing tank is arranged in the form of a tumbling barrel for shaking the material while being galvanized. Connections for the anode and cathode are brought into the barrel through the shaft bearings. Means are provided whereby the material is retained within the barrel when it is rotated in one direction, but discharged from the barrel into a washing tank, when the barrel is rotated in the other direction.

866,977. Cut-out. Joseph G. Swallow, New York, N. Y., assignor of one-half to Frank W. Smith, New York, N. Y. Application filed April 4, 1907.

The base of this cut-out has a receptacle for a fuse plug. The cover has a hole through which the fuse plug may be inserted. When the cover is turned about, the fuse plug and the electrical connections are entirely covered.

866,983. Railway Switch. Guy M. Thompson, Seattle, Wash., assignor of one-fourth to Charles S. Follett, Seattle, Wash., and one-eighth to Samuel E. Lancaster and one-eighth to Jacob A. Meyer, Le Claire, Iowa. Application filed November 26, 1906.

This is an electrically operated track switch. On each side of the switch are arranged casings containing electromagnets, the cores of which are connected to a bar fastened to the movable tongue of the switch.



NO. 866,990.—ELECTRICAL MEASURING INSTRUMENT

866,990. Electrical Measuring Instrument. Thomas W. Varley, New York, N. Y. Application filed September 7, 1905.

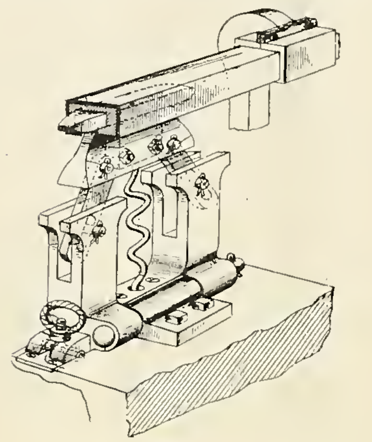
A wattmeter has a permanent magnet with pole pieces. The pressure coil is wound so as to form a two-pole armature rotatable within the pole pieces, but remains balanced when the permanent magnet's field alone is acting. The series coil is wound around the pole pieces and its current tends to distort the magnetic field in a diagonal direction and thereby cause rotation of the pressure coil. (See cut.)

867,014. Telephone-exchange System. Edward E. Clement, Washington, D. C. Application filed December 10, 1904.

This patent relates to a common-battery system having a signal relay normally connected to the line, a cut-off relay controlling the connection of the signal relay and means controlled by the latter for connecting the cut-off relay. Further means are provided for energizing the cut-off r[illegible] circuit.

867,021. Electric Contact Rail and Shoe. George Drawert, Chicago, Ill. Application filed May 14, 1906.

The rail has an undercut groove along the lower surface, in which fits a contact shoe flexibly mounted over, and connected to, a car running under the contact rail. (See cut.)



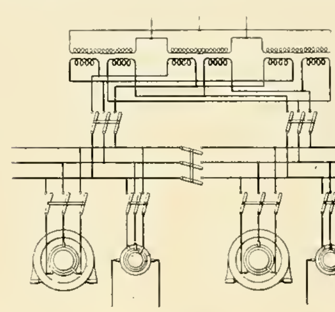
NO. 867,021.—CONTACT RAIL AND SHOE.

867,046. Electro-metallurgical Process for Extracting Copper from Its Ores. Lucien Jumau, Paris, France. Application filed December 29, 1905.

The ores are first roasted to drive off the sulphur and to reduce the metal to oxide. This is next leached with an ammoniacal solution to dissolve out the copper. Sulphur dioxide gas is then passed into the solution to reduce cupric to cuprous salts, which are finally electrolyzed.

867,065. System of Electrical Distribution. Louis C. Marburg, Norwood, Ohio, assignor to the Bullock Electric Manufacturing Company, Cincinnati, Ohio. Application filed August 30, 1905.

This system consists of a plurality of independent alternating-current generators, a transformer having a high-tension winding and a plurality of low-tension windings, means for connecting each of the generators to one of the low-tension windings, a plurality of converters, and means for connecting each of the converters to one of the generators. (See cut.)



NO. 867,065.—SYSTEM OF ELECTRICAL DISTRIBUTION.

867,085. Fare-register Attachment. John R. Scott, Oakland, Cal. Application filed December 12, 1906.

The operating lever of the register when moved in one direction closes a switch in the lighting circuit and lights up a lamp near the register. When ringing up fares of another denomination, the lever is turned in the other direction which does not affect the lamp.

867,095. Circuit Closer. Thomas A. Bemus, Boston, Mass., assignor to the T. Alton Bemus Company, Incorporated, Boston, Mass. Application filed March 2, 1905.

A casing with a circumferential wall has contact plates on the inner face of the wall. A rotary shaft passes through the center of the casing and carries a contact brush with a ball at its end.

867,125. Trolley-wheel Support. George W. Grisdale, Jr., Philadelphia, Pa. Application filed March 5, 1906.

A hinged sleeve at the top of the trolley pole contains a shaft with a forked head carrying the journals of the trolley wheel. In the sleeve there is also a spring acting at nearly right angles to the trolley wire to hold the wheel tightly against the wire.

867,140. Molding for Electric Wiring. William H. G. Kirkpatrick, Philadelphia, Pa., assignor to the Kirkpatrick Manufacturing Company, Philadelphia, Pa. Application filed April 27, 1906.

This molding has a number of dovetailed grooves diagonally crossing the partition between the main channels. In these grooves are keepers that can be moved either way a distance equal to one-half the width of the main channels.

867,147. Rail Magnetic Brake. Victor L. Ochoa, New York, N. Y., assignor of one-half to Benjamin A. Jackson, New York, N. Y. Application filed January 5, 1907.

A magnet core consists of a tube, divided longitudinally at one side and having projecting poles. A longitudinal winding of exciting wire is placed within and without the tube which is suspended from a car in close proximity to the rail.

867,150 to 867,152. Railway Signaling Apparatus. Vincent L. Raven, Darlington, England. Application filed April 18 and 23, 1907.

These three patents relate to a system that makes audible and visual signals on the moving vehicle, which are under the control of the signal man. The vehicle carries means for contacting on bars along the track that are electrically connected with the signal tower where duplicate signals appear.

867,154. System of Motor Control. Walter J. Richards, Norwood, Ohio, assignor to Allis-Chalmers Company, Milwaukee, Wis. Application filed September 29, 1906.

This system has a separate generator supplying current to the armature of the motor to be controlled. The fields of these machines are energized by two separate exciters, the fields of which are parallel and connected across one of the leads running from the generator to the motor. The exciter fields are adjusted inversely by rheostats and are reversible.

867,155. Motor-control System. Walter J. Richards, Norwood, Ohio, assignor to Allis-Chalmers Company, Milwaukee, Wis. Application filed March 1, 1907.

This patent relates to a controller in the armature circuit of a motor, the controller contact arm being operated from a number of distant points through a set of levers connected by a rod to it. This mechanism is governed by a dash pot and springs causing a slow movement "on" and a rapid movement "off."

867,168. Controller Regulator. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company, jointly. Application filed March 30, 1907.

The controller handle carries a pawl which engages a notched ring on top of the controller box when the handle is moved forward, but releases when the forward pressure on the handle is relieved. This is accomplished by a shifting of the center of gravity of the pawl and results in permitting a forward movement of intermittent character only.

867,180. Vehicle-controlling Apparatus. Granville T. Woods, New York, N. Y. Application filed September 23, 1899.

This is a system wherein a number of electrically driven vehicles are run in a contest on separate tracks and individually controlled by a master controller.

867,197. Block-signal System for Electric Railways. Clayton W. Hamm, York, Pa., assignor of two-fifths to Robert S. Beard, York, Pa. Application filed December 19, 1906.

A rotary switch controls the signal circuit. This switch is moved by oppositely disposed ratchet wheels on its shaft and a pawl on each wheel, the pawls being actuated by electromagnets that are energized by the passage of a car.

867,211. Circuit Making and Breaking Device. Andrew L. Riker, Bridgeport, Conn., assignor to the Locomobile Company of America, New York, N. Y. Application filed January 18, 1904.

This device contains a contact member and a resiliently mounted armature member having a vibratory movement on either side of its normal position. Impact means are provided for forcibly making and breaking the circuit.

867,212. Electrical Circuit Protector. Charles A. Rolfe, Rochester, N. Y., assignor to the Rolfe Electric Company, Rochester, N. Y. Application filed September 18, 1905.

A pair of metallic supporting strips holds a heat cartridge which is provided with self-soldering circuit-opening mechanism, and means extending through the cartridge for returning the mechanism to normal position.

867,220. Circuit-closer for Door Alarms. Louis E. L. Themke, Strathcona, Alberta, Canada. Application filed March 14, 1907.

The door carries a battery concealed in a recess. The stem of the door knob is provided with a contact, closing the battery circuit and sounding the alarm, when the knob is turned.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired September 30, 1907:

437,183. Electric Meter. R. N. Dyer, East Orange, N. J.
437,210. Electric Street Car. L. H. Leber, Pittsburg, Pa.
437,226. Electric Illuminated Sign. J. A. McEntee, Chicago, Ill.
437,272. Distribution and Regulation of Electric Currents. F. Wilking, Berlin, and H. Muller, Nuremberg, Germany.
437,293. Coin-operated Telephone Attachment. H. F. Dugan, San Francisco, Cal.
437,307. Automatic Telegraphy. D. Kuihardt, Aachen, Germany.
437,311. Artificial Ground and Compound Metallic-circuit System. C. E. McClure, Richmond, Va.
437,324. Electric Cut-out. E. E. Bailer, Everett, and G. J. Galbraith, Boston, Mass.
437,352. Electric Hand Switch. J. W. Battershall, Attleborough, Mass.
437,358. Electric Railway System. C. K. Harding, Atlantic, Iowa.
437,359. Electric Snap Switch. W. Hochhausen, Brooklyn, N. Y.
437,360. Dynamo-electric Machine. W. Hochhausen, Brooklyn, N. Y.
437,362. Electric Cut-out. W. J. Jenks, Nyack, N. Y.
437,363. Lightning Arrester. H. M. Kalbach, Ashland, Pa.
437,369. Electric Alarm. A. Tschira, Freiburg, Germany.
437,393. Galvanic Battery. E. H. Crosby, Boston, Mass.
437,422. Telegraphy. T. A. Edison, Menlo Park, N. J.
437,428. Propelling Device for Electric Cars. T. A. Edison, Menlo Park, N. J.
437,469. Galvanic Battery. G. A. Liebig and C. Willms, Baltimore, Md.
437,512. System of Electrical Distribution. F. B. Rae, Chicago, Ill.
437,513. Electric Switch. F. B. Rae, Detroit, Mich.
437,570. Welding Metals Electrically. C. J. Coffin, Detroit, Mich.
437,654. Electric Forging Apparatus. G. Lauder and J. H. Simpson, Pittsburg, Pa.
437,662. Automatic Switch for Stationary Motors. F. B. Rae, Detroit, Mich.
437,663. Armature for Dynamo-electric Machines and Motors. F. B. Rae, Detroit, Mich.
437,668. Fire-alarm-signal Box. J. Young, Chicago, Ill.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, OCTOBER 12, 1907. No. 15

An Aerial Electrically Operated Tramway Over Lake Michigan.

Aerial tramways, electrically operated, while not common, are in use for various purposes in this and other countries. Akin to them are the suspended electric railways, of which notable examples exist in Germany. A similar project for a passenger cableway for hanging cars has been talked of in New York and Long Island City for some time.

An interesting and novel application of the aerial tramway, although only for temporary use, is to be found in Chicago, where, for the first time, such a line is being operated over water for such a considerable distance as a mile and a half. In constructing what is to be known as the southwest land and lake tunnel, which is to furnish from Lake Michigan the water supply for a large area in Chicago, some means had to be supplied for conveying construction material to, and later excavated material from, the site of the new crib and shaft far out in the lake.

After careful consideration Mr. George W. Jackson, the well-known contractor and engineer, who has the contract for driving the tunnel, decided that the work could be done to great advantage by the aid of an aerial tramway, instead of by boats. Plans were at once made for the steel tower line and cableway shown in the accompanying pictures.

The tunnel, as stated, is to be for water supply, and will extend from the end of the steel tower line, about a mile and a half from shore, to a considerable distance inland. It will be built in three sections, two on land and the present lake section, No. 3. The terminal of the aerial railway, where operations for the construction of this section of the tunnel are carried on, is at the corner of Seventy-third Street and Bond Avenue. At this point and located about 50 feet inland from the tower shown in Fig. 5 is being completed a three-story frame structure known as the terminal building. Here is to be found the electric motor and mechanism for operating the aerial tramway, also "side track" space for the traveling buckets and cars.

In Fig. 1 is given a good general view of the tramway structure. The two heavy cables at the top are the carrying cables on which the cars travel, suspended as shown in Fig. 5. These cables are 1⅜ inches in diameter and are capable of supporting cars as fast as they can be loaded and sent out. The cable to the right in the picture carries the inbound cars and the one to the left the outbound.

On the lower cross-arm will be noted another set of cables, which, however, is one continous cable for pulling the cars. This steel traction rope is always moving, being driven by a large beveled gear sheave in the terminal house and revolving on a plain sheave at the crib end. The traction sheave is driven from a shaft belt-connected through reduction gearing to a 25-horsepower induction motor—a 60-cycle, 35-ampere, 440-volt machine—revolving at 600 revolutions per minute. Current for the motor is taken from the Edison mains.

Two kinds of cars are in use, the workmen's and material type shown in Fig. 3 and the bucket type shown in Fig. 4. A good idea of the carrying and pulling operations may be gained from Fig. 5, showing a workmen's car returning from the crib.

At each end of the line the carrying cables terminate in steel tracks like those shown in Figs. 3 and 4. When a load is to be sent over the tramway the car is pushed by hand from its position on the main steel track or side track to a point near the flush connection of the track with the cable, at the exit of the terminal, where a clutch on the car is automatically thrown, gripping the traction rope. The traveling mechanism of the cars is simple and is clearly shown in the pictures When no cars are in transit for a considerable distance the traction cable is permitted to drop into a series of guides on the lower cross-arms of the towers.

The tower line, while for temporary use, is of substantial construction. The towers, 26 in number, are of steel, 30 feet high, and set on steel piles of the kind designed and used for various purposes by Mr. Jackson. The details of the towers are clearly shown in Figs. 1, 2 and 5.

A feature of this new application of the aerial tramway lies in the building of the foundations and placing of the towers. That efficient and safe operation of the cars might be assured it was necessary that the towers be in perfect alignment. To accomplish this result over water required considerable engineering skill, and several methods were tried. Finally an elevated platform was built on shore and from this the piles for the first six towers were driven and the towers erected by a transit line. The platform was then moved to the last completed tower and the next six were built by the same method. In the next shift six more were constructed, and eight in the last shift. This method naturally consumed much time, as progress could be made only when the lake was smooth, giving no motion to the vessel from which the work of placing the towers was conducted. Frequently it was necessary to be idle several days at a time, but every calm was promptly utilized. That the line is true and the work well done is apparent from the picture.

The crib, shown floating to the right in Fig. 1, was built at South Chicago and towed to its destination at the end of the tower line. Here a

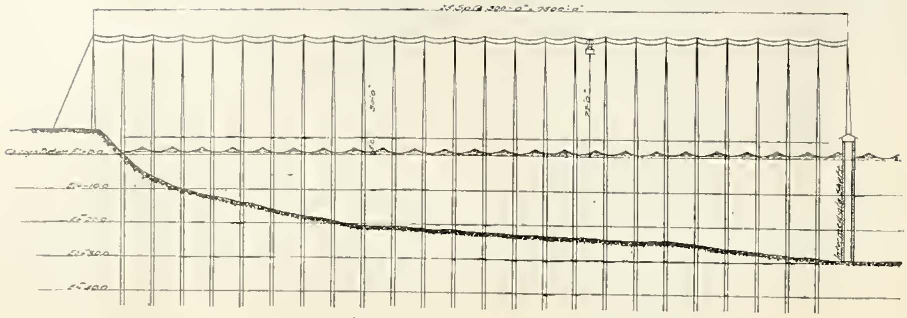

FIG. 2. PROFILE OF AERIAL TRAMWAY OVER LAKE MICHIGAN.

deep shaft is to be sunk, from which the work of driving the tunnel will be begun. Through this shaft also compressed air will be supplied as the tunnel work progresses.

It may be said that the towers will also support the pipes from the compressor plant to the shaft. These pipes are now being suspended from the towers. Telephone wires and electric-light wires for crib, shaft and tunnel service are also carried on the towers.

The diagram, Fig. 2, shows the conditions met

FIG. 3. PASSENGER CAR OF AERIAL TRAMWAY, SHOWING METHOD OF OPERATION.

with in building. The towers reach 30 feet above the waterline and are spaced 300 feet apart, making the aerial tramway over the water nearly 1½ miles long. The last tower is in 30 feet of water.

This enterprise, aside from the aerial tramway, will consume considerable electric current in the shops and compressor plant located directly across the street from the terminal building at Seventy-third and Bond streets. Here a large building has been erected to accommodate the temporary shops and air compressor plant.

Three Ingersoll-Rand air compressor units are being installed. The compressors are belt-connected to three 150-horsepower induction motors taking current from the Edison mains. There is also a motor-generator set for supplying direct current for various uses in the machine and blacksmith shops. This set consists of a 360-horsepower three-phase synchronous motor direct-connected to a 250-kilowatt direct-current generator. A substantial slate switchboard for controlling the current throughout the plant has been erected.

Applied Electrochemistry in France.

Consul William H. Hunt, in a report from St. Etienne, states that the electrochemical industries of France can be divided into three classes, which he names and describes: First, industries utilizing electrolysis; second, industries utilizing the heat produced by the current, either from the arc or from a conductor; third, industries utilizing the electric spark.

To the first class belongs galvanoplasty, used for coating metals with silver, gold or nickel, and is employed all through France. An important application of this industry is the electrolytic refining of copper, of which there are several examples in France, and notably at Eguilles, near Sorgues, in Vaucluse, belonging to the Société de Cuivre de France, producing two tons a day, and at Givet, in Ardennes, with a production of seven tons daily. There are also several minor factories. All these factories produce copper in a very pure state, but it has to be always melted on account of its physical conditions. At Dives, in Calvados, however, this operation is rendered unnecessary by the Emore process, producing directly plates and tubes of copper by electrolysis 12 tons daily.

The decomposing of water into hydrogen and oxygen is exploited by several concerns. The establishment of St. Vrain, near Ballancourt, employs the Hazard-Flamand process, and produces 200 cubic meters (one cubic meter = 35.3 feet) of hydrogen, and 100 cubic meters of oxygen per day. La Société Oxydrique Française utilizes in its factories at St. André, near Lille, and Villeurbanne, near Lyon, the Garuti process, in which the cathodic and anodic compartments are separated by an iron partition pierced with a multitude of small holes. The daily production of these works is about 400 cubic meters of hydrogen and 200 cubic meters of oxygen.

The Electrochemical Company furnishes hydride of lime (CaH), which gives off hydrogen in contact with water. This body, which sells at present at $1.93 per kilo (2.2 pounds), is commercially known under the name of "hydrolith."

In the manufacture of soda by the electric process, the Volta Company, whose works are situated near Moutiers, utilizes the Outhenin-Chalandre process, and turns out 800 tons of soda and 2,000 tons of chloride of lime per year. About 4,000 tons of caustic soda are manufactured annually by this method in France. Chlorate of potash is manufactured at St. Michel de Maurienne by the Gall process, and at Chedde, near Chamonix, by the Corbin and Lederlin method. The total production is about 7,000 tons annually.

Aluminum is produced principally by three companies. The total annual production is estimated at 6,000 tons.

Carbide of calcium is already manufactured on a very large scale in France. It furnishes not only acetylene gas, but also cyanide of calcium, much spoken of today as a fertilizer and as an agent for producing ammonia.

Numerous companies employ electricity in the production of ozone, used as an oxydant in the preparation of certain organic products—vanaline, heliotropine, essence of hawthorn, etc.

It may be said in concluding that the electrochemical industry has developed considerably within the last few years in France, and the amount of horsepower used in the different manufactories is estimated at 100,000.

Single-phase Operation on the Rochester Division of the Erie Railroad.

By W. N. Smith.

One of the most important electric-railway developments of the present year is the change from steam to electric motive power on a portion of the Rochester division of the Erie Railroad, which took place on June 18, 1907. This is the first installation of a single-phase alternating system of electrical motive power upon a steam railroad to go into commercial operation.

This electrification can justly claim the priority of application of several important features which are of interest in connection with the discussion now prevailing upon systems best suited for steam-railroad electrification. This line was the first to operate electric cars on the single-phase system over the tracks of an operating steam railroad; the first to use 11,000 volts working pressure commercially on a trolley in this country, and the first instance of a heavy electric traction system receiving power from the 60,000-volt transmission line.

FIG. 5. TOWER AND CABLE CONSTRUCTION OF AERIAL TRAMWAY.—FIRST CAR RETURNING FROM THE LAKE.

All of the construction described below, except that of the 60,000-volt power transmission line and the car bodies and trucks, was designed, executed and placed in operative condition by Westinghouse, Church, Kerr & Co., engineers, through whose courtesy the photographs were furnished which illustrate the article.

The section of track equipped is 34 miles long, extending from Rochester, N. Y., over the main line of the Rochester division to Avon, a distance of about 19 miles, thence 15 miles over the Mount Morris branch. The railroad is entirely single track, with sidings at way stations averaging three to four miles apart. The grades are light, and the curvature for the most part quite easy, the line being relatively quite straight.

The line was originally laid with 68-pound rails, but was relaid with 80-pound rails taken from another division just prior to the electrification. The roadbed is ballasted with gravel, and the joints are of the Weber type. A single No. 00 protected rail bond is applied to each rail joint under the plate, one of the advantages of the high-tension single-phase system being that the relatively small current, combined with the high impedance of the main circuits, renders it unnecessary to resort to heavy bonding.

The line crosses a number of bridges, the longest one, that over the Genesee River, about a mile and a half south of Rochester, being 780 feet long, comprising seven spans. There are also through truss bridges at Rush and at Canaseraga Creek, near Mount Morris, and a stone arch bridge over Conesus Creek, a short distance south of Avon.

The electric service is devoted solely to passenger traffic, which is of the local interurban type. The freight service is handled exclusively by steam as heretofore, as are also the through trains operating between Rochester and Corning, over the main line of the Rochester division, a distance of about 94 miles. Instead of three round trips a day, the electric service has introduced six complete round trips between Rochester and Mount Morris, and three more between Avon and Mount Morris.

Four-car Elect ic Train at Avon, N. Y.

SINGLE-PHASE OPERATION ON ROCHESTER DIVISION OF ERIE RAILROAD.

Power Supply.

The power is generated at Niagara Falls, in the plant of the Ontario Power Company, and is transmitted at 60,000 volts, three-phase, over the lines of the Niagara, Lockport and Ontario Power Company. The Iroquois Construction Company constructed a branch line from Mortimer, a little over four miles south of Rochester, to Avon. The pole construction used upon this branch transmission line is of the A-frame type, using two 40-foot cypress poles, set abreast of each other, and inclined so that their tops are framed together, the butts being joined by horizontal plank braces underground. The insulator pins are grounded by copper wire. The conductors are of No. 4 hard-drawn, stranded copper cable. The standard length of span between poles is 220 feet, which is shortened at curves where necessary.

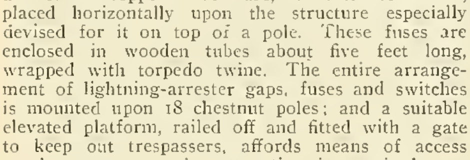
Sub-station.

The sub-station building is located in the Y formed by the railroad tracks at Avon, and, together with the car shed, is adjacent to the roundhouse and division repair shop. The building is absolutely fireproof, the doors and windows being of kalomein construction, and fitted with wire glass. In the basement are located one of the transformer oil tanks and the oil pump. The main floor is divided into three rooms, the main transformer room being 43 by 17 feet, and extending the full height of the structure to allow room for the high-tension bus-bars, which are carried over the transformers. The remaining space on the main floor is divided into a high-tension room (through which the 60,000-volt wires enter, and which is the location of the high-tension circuit-breakers, 16 feet 8 inches by 19 feet 8 inches), and the operating room, where is located all the 11,000-volt switching apparatus and the measuring instruments.

Directly over the operating room is a mezzanine floor, reached by an iron staircase, in which are located the 11,000-volt lightning arresters, the 60,000-volt choke coils, and the 60,000-volt series coils. The high-tension connections enter through the high-tension room, which runs from floor to floor, and pass through the choke coils and series coils, on the mezzanine floor, and then turn through a wide opening in the wall to the 60,000-volt bus bars, which are located in the upper portion of the transformer room.

The transmission line terminates at the lightning-arrester yard in the rear of the sub-station. The arrangement of the 60,000-volt lightning arresters consists of three horn gaps, arranged one behind the other, on each of the three conductors, the first gap being 4¾ inches across, the second five, and the third six inches. A concrete column is in series with the first gap, an electrolytic arrester in series with the second, and a five-foot fuse of No. 18 copper wire in series with the third, that is to say, between one horn and the ground. Both horns of each gap are of one-half-inch round iron. Between the line and the first arrester there is a hook-type knife switch, and between the last arrester and the lead into the sub-station, there is a No. 18 copper wire fuse, in each conductor, placed horizontally upon the structure especially devised for it on top of a pole. These fuses are enclosed in wooden tubes about five feet long, wrapped with torpedo twine. The entire arrangement of lightning-arrester gaps, fuses and switches is mounted upon 18 chestnut poles; and a suitable elevated platform, railed off and fitted with a gate to keep out trespassers, affords means of access to the apparatus when attention is required.

Within the sub-station the wires first pass through three 60,000-volt stick-type circuit-breakers, mounted directly inside of the rear wall. Thence, over bare copper conductors, to the three oil-insulated choke coils, situated on the mezzanine floor, thence to three oil-insulated series transformers, also on the mezzanine floor, from which connections are taken to the power measuring instruments in the operating room. The main connections finally terminate upon a set of copper bus-bars in the transformer room, which are run upon porcelain insulators mounted on wooden cross-arms and placed at a convenient height directly over the line of transformers.



100-HORSEPOWER SINGLE-PHASE RAILWAY MOTOR.

The 60,000 three-phase current is rendered available for single-phase distribution by means of three transformers of the Westinghouse oil-insulated water-cooled type, each of 750 kilowatts capacity. For the present installation, two transformers only are used at one time, the third being a spare. The low-tension windings can be so connected that either 11,000 volts or 22,000 volts can be obtained, so that in case it should ever be desired to transmit railway current for an extension of 40 or 50 miles, to another sub-station, it could readily be done without adding transformers to this equipment.

One end of each low-tension winding is directly grounded to the boiler iron case, which in turn is, by means of a No. 0000 stranded copper cable, directly connected to the track-return circuit.

The necessary transformation from three-phase to two-phase fits in very well with the natural subdivision of the electrified line, into two sections, one of which is about 19 miles in length, north of Avon, the other, about 15 miles in length, being to the south of Avon. The connections were therefore laid out to operate the sections upon separate phases of the two-phase secondary system. Either the T or V connection can be used, the latter method being employed at present. Each one of the active transformers therefore feeds a separate section.

The low-tension bus-bars run along the wall of the operating room, and directly beneath them are three type E Westinghouse automatic oil circuit-breakers, one on each of the two trolley feeders, the third breaker, which is situated between the other two, being a spare. One pole of each of the three oil breakers is connected to the center pole of a double-throw hook-type knife switch, by means of which it is thrown upon either bus bar. The other pole of the oil breaker runs directly to the feeder. The outgoing lead from the middle or spare circuit-breaker can be thrown upon either one of the feeders, should the breaker usually controlling that feeder be temporarily disabled. The system of connections is simple, compact and flexible, and has admirably fulfilled the conditions for which it is intended.

The outgoing 11,000-volt feeders run up to the mezzanine floor directly over the operating room, where they emerge from the building through perforated glass disks.

The station itself does not require the continuous presence of an attendant, which is needed in the case of a rotary-converter sub-station. The working force is so organized that the car-repair men are always available for manipulating the sub-station circuit-breakers, and the cost of attendance is thereby reduced to a minimum.

Catenary Trolley Construction.

The overhead trolley construction is in many respects unique. It was the first of all catenary installations to operate regularly at 11,000 volts. There were very few precedents to follow; many of the details of the overhead work are entirely original, and nearly all of them were specially designed for this installation by the engineers who planned the work.

The poles are of chestnut, averaging 25 inches in circumference at the top and about 42 inches at the butt. Most of them are about 35 feet long, but 40-foot poles were used where the embankments were narrow and steep, and in span construction. Nearly all of the construction is of the bracket type, except at the railroad yards at Rochester, Avon and Mount Morris, and for some distance at Mortimer, where there is a siding on each side of the main track, which prevented the use of bracket construction there.

The insulator is of the R. Thomas & Sons manufacture, 6⅞ inches in diameter, and 6 inches high, made in two parts, but of the three-petticoat type, and known as the No. 3029. It was designed by the engineers especially for this installation.

The messenger wire is of "extra high-strength" steel, furnished by the American Steel and Wire Company. It is of seven strands, and is seven-sixteenths inch in diameter. The trolley wire is No. 000 grooved copper, the lengths being spliced with the usual type of soldered splicing sleeve.

The spans on the straight-line track are 120 feet in length, and as much shorter than this on curves as required by the radius of the curvature. The maximum deflection from the center line of the track on curves is seven inches each way.

The Rochester yard was a different piece of construction, on account of the distance between supports (which reaches a maximum of 94 feet, where spanning seven tracks, four of which are electrified), and also on account of the uncertain nature of the soil, which on the bank of the Genesee River is filled in with gravel and cinders. For these long spans, where it was impossible to use guys of the usual type (the river bank being on one side and the main high highway which gives teams access for loading and unloading of freight cars on the other side), it became necessary to use self-supporting span construction, and this was done by using the "tripartite" type of steel pole, set in concrete. This type of pole being constructed of rerolled Bessemer steel rails, is less subject to rust, and consequently more durable than any other available type of metal pole, and all of its surfaces are always open and easy of inspection.

The span wires consist of the regular messenger cable, fitted with cable sockets sweated on at each end, the same being fastened to turnbuckles and pole collars at the tops of the poles. There are two span cables at each pair of poles, the upper one being used to carry the weight, the lower one acting to steady the arrangement and also to act as a relay in case of an accident to the upper span. Similar construction was also used at Avon, where guying of side poles was not always possible.

Nearly all the telephone and telegraph wires which cross over the 11,000-volt trolley wire have been put underground, particularly in the case of the leads composed of only a few wires; but where the line is crossed by heavy telephone trunk lines they have been protected by the basket type of construction, so designed as to effectually prevent a broken telephone wire from falling across the messenger or trolley wire.

Lightning protection for high-tension single-phase railway lines not having as yet been standardized, only a part of the line was equipped with line lightning arresters, which are of a swinging-fuse-gap type of construction, made by the Westinghouse Electric and Manufacturing Company. On the other half of the line lightning arresters were not installed. During the summer two of the poles were struck by lightning, but the metal work of the brackets and truss rods being entirely grounded, these poles were not damaged below the topmost point of attachment of the truss rods, which is generally not over 18 inches from the top of the pole. In a number of instances the lightning-arrester fuses have blown, but it is not known how many of them have blown simultaneously. Although the extent to which this type of arrester is fully protective is hardly established as yet, it can be stated that at no time since regular operation started has any injury to the car equipment resulted from lightning, though there were several severe storms during June and July.

The conditions of electric traction upon this line are such that no feeder is necessary besides the trolley wire, and consequently there is no necessity for feeding the seven sections separately.

Overhead Construction at Rochester Terminal.
SINGLE-PHASE OPERATION ON ROCHESTER DIVISION OF ERIE RAILROAD.

Rolling Stock.

The cars equipped with electric apparatus are six in number, and, together with their trucks, were furnished by the St. Louis Car Company. The electrical apparatus was installed upon the cars and trucks by the engineers at the railroad company's car shops in Buffalo, N. Y. The cars are 51 feet 4 inches over bumpers, 43 feet over corner posts and 29 feet 4 inches between truck centers. They are 8 feet 9 inches wide over sheathing, and 13 feet 8⅝ inches in height above the rail. Four of the six have two passenger compartments, the other two having a baggage compartment about 14 feet long, and a small smoking compartment with six seats, besides the regular passenger compartment.

The trucks are both alike, wheel base being 6 feet 8 inches. The axles are 6½ inches in diameter. The trucks are of the standard M. C. B. swing bolster type, with heavy framing. The brake shoes are inside-hung.

The heating equipment consists of 32 of the Consolidated Car Heating Company's electric heaters of the truss plank type, 450 watts capacity each in the main portion of the car, and two "No. 192 M. S." heaters in each cab.

Electrical Equipment of Cars.

The electrical equipment of the cars consists of four No. 132-A Westinghouse single-phase railway motors, with a nominal rating of 100 horsepower each, the gear ratio being 20:63. The suspension is of the nose type, and solid gears are pressed upon the axles.

The control system is of the Westinghouse electro-pneumatic type and includes three distinct circuits—the high potential, the low potential and the control circuit.

The high-potential circuit includes the pantagraph trolley, line switch and the transformer. The pantagraph trolley mechanism is operated by a pair of springs and by an air cylinder. The trolley is raised and held against the wires by means of springs against its own weight, and it is lowered by the application of air pressure to pistons working in cylinders that form part of its base. When down it is automatically locked, and the latch of this lock can only be withdrawn by applying air pressure to another small piston which then unlocks the pantagraph, allowing the springs to raise it. This trolley mechanism is so connected with the control circuit through the line relay that any interruption in the supply of high-tension current through opening of the line switch or main circuit-breaker immediately causes the trolley to be lowered by applying the air to the main cylinders in the trolley base.

The control circuit includes a master controller in each vestibule, the train-line wires and their connections to the valve magnets and interlocks a storage battery supplying current for these wires, and a motor generator set, which is used either to charge the batteries or to actuate the control system. The master controller makes the proper connections by means of which the 15-volt storage battery actuates the valve magnets which control the action of the air-operated main contactors in the switch group and the reversers. The controller handle is normally held in a vertical central position by springs unless it is moved to one of the running points by the motorman. When released from the grasp of the hand it flies to the vertical position, cutting off the power and enabling the emergency application of the brakes by means of a brake relay valve alongside of it.

In one vestibule there is located in an asbestos-lined compartment enclosed with steel doors, a slate switchboard panel upon which are carried all the switches and fuses for the control of the battery and motor-generator set, the lighting circuits and heaters, and also the main connection from the low-tension side of the transformers to the auxiliaries.

Operation.

The equipments above described were intended to be sufficient for operating single-car trains with one stop per mile over the entire road at an average schedule speed of 24 miles an hour, or to haul one trailer making stops about 2½ miles apart at the same schedule speed. The company has furnished shelters where the public highways cross the line, there being 22 of these flag stations besides the regular intermediate way stations at which steam trains stop, six in all, or a total of 28 stations at which electric cars may be required to stop. A single passenger coach is frequently attached to a motor car, and on some trains baggage, milk or postal cars are required, making a four-car train, as shown in an accompanying picture. The service has proved immensely popular throughout the Genesee Valley, through which it passes, and it is intended to increase the number of motor cars in order to handle the business a little more comfortably next season. It is found that the electric trains on their 34 miles of line can be depended on to keep to their running time rather better than the steam passenger and freight trains operating over the main line.

Telegraph and Telephone.

As is well known, the single-phase trolley system causes interference with telegraph lines along the right of way, and unless both the electrostatic and electromagnetic induction are properly compensated there is always danger of telegraphic communication being seriously affected. The static effect is particularly annoying, as it is absolutely continuous as long as the trolley line is charged, whether or not there are any cars moving. Various means were proposed and tried by the Western Union Telegraph Company for the elimination of the "static," which always causes the telegraphic relays to chatter, but the most successful thus far known is that due to the inventive genius of Mr. E. W. Applegate, quadruplex expert for the Western Union Telegraph Company, who has developed a very simple means for overcoming static interference. Mr. Applegate worked upon the theory that it was useless to try to compensate for the static, and that the thing to do was to "pacify" the instrument by additional devices. The Applegate "static pickup," for which a patent has been applied, comprises a back contact relay and a high-resistance shunt. By this arrangement all the telegraph wires are "singled," and metallic circuits, the necessity for which was at one time pending, were discontinued. The repeater service which they necessitated was also discontinued, and there is now a spare wire between Rochester and Mt. Morris through the entire zone of static interruption.

Speech over the telephone line along the road is very clear and distinct, and although the wires and instruments have a heavy static charge a few simple precautions enable it to be of great use to the operating department. It is intended to carry portable telephones upon the cars.

Organization.

The single-phase system was recommended for the electrification of this division by the Electric Traction Commission of the Erie Railroad, and after authorization by the company was installed under the general direction of Mr. J. M. Graham, vice-president and head of the construction department of the Erie. The engineering work and the construction work were carried out and the system brought into operative condition by Westinghouse, Church, Kerr & Co., who designed and erected the buildings and the catenary trolley construction, bonded the track and installed the electrical apparatus in the sub-station and on the cars. The adjustment of the telegraph system was carried out jointly by the Western Union Telegraph Company and the telegraph department of the railroad company.

The Erie is one of the oldest steam railroads in the country, but that it is also one of the most progressive is demonstrated by its policy of giving a thorough trial to a system of electric traction whose characteristics of simplicity in construction and economy in operation make it so eminently fitted to replace steam motive power wherever the economic conditions point to the desirability of its substitution for the betterment of either passenger or freight service.

A Case of Fruit-stand Lighting.

The ordinary Italian or Greek fruit stand offers an excellent field for the sale of central-station current on a small scale. The load is not large, of course, but it is good for at least a dollar or two a month if properly handled in most cases. In the summer the electric fan finds almost continuous use at a fruit stand, but in the winter the lighting demand of a number of stands is a most desirable load, being of the long-hour variety. It ought not to be difficult to drive the gasoline torch out of business in this field, for the electric lamp of high efficiency is much cleaner and also cheaper to operate. In one case a Greek fruit vender stated that in the darkest winter months his maximum bill for operating a single-glower Nernst lamp at a point nine feet above his fruit display and out of doors came to $2.58 a month, whereas it cost him formerly using gasoline at least $3 per month, with the added disadvantage of oily drippings on his fruit. The central station supplied the lamp, which easily gave the best out-of-door illumination in the block where several other stands were situated. The gasoline torch burned five gallons of gasoline per week at a cost of 15 cents per gallon.

Extension of Wichita's "White Way."

Mr. H. Almert, consulting engineer for the Edison Light and Power Company of Wichita, Kan., announces that by November 1st Wichita's "White Way" will be extended so as to include eight city blocks. At the present time the "White Way" consists of one block on North Main Street brilliantly lighted by arc lamps. The extension will be from First to Second streets on North Main and from Main to Santa Fe on Douglas Avenue. In these seven blocks there will be placed 359 additional 2,000-candlepower arc lamps. They will be operated, as the present ones are now, every evening till 10:30 o'clock except Saturday, and till midnight on that day. Mr. Almert, who has charge of the work, declares that, when completed, these streets will be the best lighted in the world. The citizens of Wichita, and business men particularly, are taking an active interest in the project.

Employes' Lecture Course of New York Edison Company.

For the benefit of its employes the New York Edison Company has inaugurated a course of lectures on electrical engineering to be delivered weekly at its auditorium, 44 West Twenty-seventh Street, throughout the coming fall and winter. The first lecture was given on Tuesday evening, October 1st, to an interested audience which taxed to the utmost the seating capacity of the spacious auditorium.

Mr. Alexander Maxwell, chairman of the lecture committee, called the meeting to order and introduced Mr. John W. Lieb, Jr., who spoke on behalf of the management of the New York Edison Company. Mr. Lieb, in his opening remarks, dwelt especially on the deep interest manifested by the company in the educational welfare of its employes, describing the successive steps in its welfare work, such as the building of the auditorium, the equipment of an employes' library, and the institution of these experimental lectures.

Prof. Sydney V. Ashe was then presented as the lecturer conducting the course. In his address he emphasized the fact that there is an imperative demand for technical training in preparing to enter the engineering profession today. The subject of his lecture was "Magnetism," and dealt with the fundamental principles governing the magnetic properties of iron. He laid great stress upon the necessity for a thorough knowledge of these peculiar characteristics of iron in order that the effect upon the growth of the electrical industry may be comprehensively grasped by the student. Lantern slides and numerous experiments illustrated the particular points of the lecture, which terminated at 10 o'clock. Professor Ashe was assisted by Mr. C. S. Kern of the Brooklyn Polytechnic Institute.

Electrical Exports for August.

Electrical exports from the United States for the month of August, 1907, were the largest of any month this year except June, and show an increase of $371,714 over August, 1906. The total value of such exports for August, 1907, was $1,740,793. There was an increase over the corresponding month of 1906 both in electrical appliances and electrical machinery, as shown by the following figures: Electrical appliances—August, 1906, $744,775; August, 1907, $810,301. Electrical machinery—August, 1906, $624,304; August, 1907, $930,492.

Following are the countries which made the largest purchases of electrical goods from the United States in August, 1907, the value of the goods being given:

Electrical appliances (including telephone and telegraph instruments)—Brazil, $167,869; British North America, $162,495; United Kingdom, $135,873; Germany, $47,806; Japan, $44,440; Mexico, $37,133; Cuba, $36,483; Argentina, $23,462; Central American States and British Honduras, $21,713; British Australasia, $11,120; Belgium, $8,763; British Africa, $7,415; France, $5,102; West Indies and Bermuda, $3,718; Philippine Islands, $2,051; other South Africa, $79,259.

Electrical Machinery.—Brazil, $210,670; Mexico, $162,196; British North America, $151,406; Japan, $121,407; United Kingdom, $86,140; British Australasia, $82,863; Argentina, $29,878; France, $28,991; British East Indies, $12,624; British Africa, $9,957; Cuba, $8,056; Central American States and British Honduras, $6,320; Germany, $2,435; Philippine Islands, $1,166.

Is Wireless Power Transmission Possible?

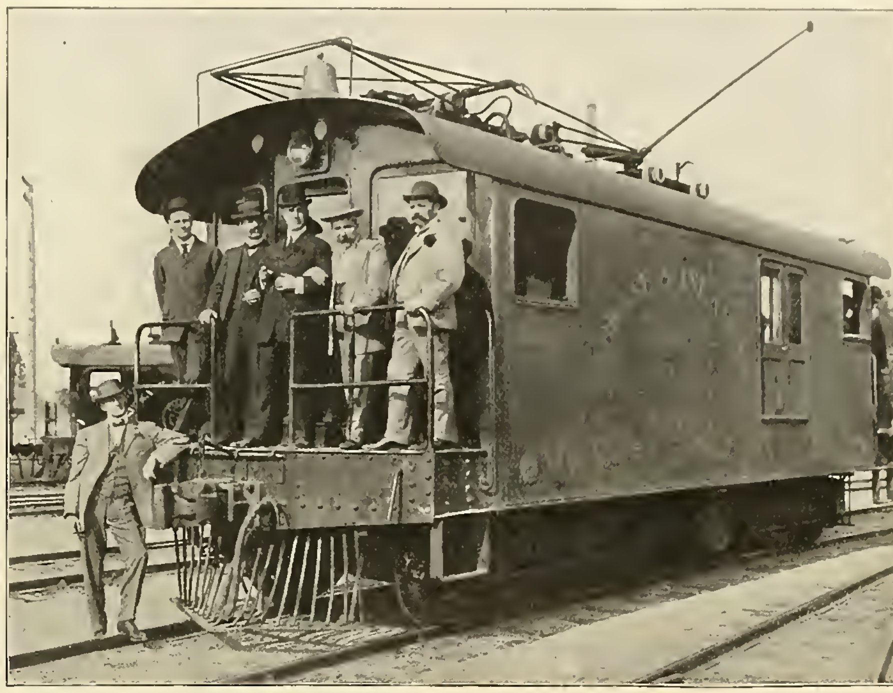
A cable dispatch from Paris of September 26th announces that "Mr. Young, a Lyons scientist," has conducted some experiments in the transmission of electric power without wires. These experiments were carried out in the grounds of the Chateau du Cret, belonging to Auguste Villy, a Lyons manufacturer. It is said that a miniature car was run a distance of 200 yards along rails without any tangible connection with the stationary electric transmitter or source of power. The details are withheld. According to the account, patents were applied for and a syndicate of bankers formed to promote the scheme.

What credence is to be given to this statement it is too early to say. At present it belongs to the "important-if-true" class. In view of the fact that radio-telegraphy on land is not as successful as over water, the probability is that radio-power transmission (if that term is permissible), if ever used, will be more successful as an aid in navigation of the air and water than for transmitting large amounts of power over land. Further, it is not at all likely that the power transmission and electric trolley lines of the present day are doomed to an early disappearance as was stated by some newspapers in considering the results of these French experiments.

German Electric-railway Commissioners in Spokane.

By August Wolf.

That was an interesting and significant announcement in Spokane, Wash., by Geheimrath Wittfeld, confidential adviser and counsellor to the German government, heading a royal commission appointed by Kaiser Wilhelm of Germany, when he said that the single-phase alternating-current system will be employed in electrifying 400 miles of railroad in the German empire. The commission, composed of Frederich Jordan, director of the Felton-Guilleaume Company; Emmerich Frischmuth, director of the Siemens-Schuckert Company, and Philip Pforr, director of the Allgemeine Company, engineers connected with three electrical manufacturing concerns employing 65,000 men, and Dr. Ing. Walter Reichel, engineer and professor of electricity in the Berlin Polytechnic school, inspected the Spokane and Inland Empire Railroad Company's system of 200 miles the last week in September and expressed themselves satisfied with what they had seen on this important single-phase railroad.



Reading from left to right: J. B. Ingersoll (on the ground), manager of the Inland Emp're System; M. R. Randall, local agent for the Westinghouse Company; Director Frederich Jordan, member of the German imperial commission; William F. Zimmerman, hydraulic engineer for Spokane and Inland; Geheimrath Wittfeld, head of commission and adviser of the kaiser, and Director Philip Pforr, member of the commission.

GERMAN ELECTRIC-RAILWAY COMMISSIONERS IN SPOKANE.

Mr. Wittfeld said in the course of a conversation that the royal commission was appointed to examine and report on all single-phase electric railroads in the country with the view of determining whether this system should be used for equipping the Berliner Stadtbahn railway lines, which have between 300 and 400 miles of road, owned by the government. The undertaking of electrifying the road, he added, means an expenditure of 200,000,000 marks, and for this reason a nonpartisan commission was named to make a thorough inspection. Before coming to Spokane the party investigated the New York, New Haven & Hartford and the Erie railroads in the East, and after leaving Spokane the Pacific Coast's systems will be visited. Speaking for the commissioners, he added:

"We were very agreeably surprised in Spokane and the surrounding country. It seems almost incredible that all these fine buildings could have been built and the city grown to nearly 100,000 population in twenty-five years. We have read much about the success of the new Spokane and Inland railroad, the articles appearing in the American technical journals being widely commented upon by the German press, and what we have seen here has more than repaid us for coming across the continent. The substantial and permanent construction of the road, especially the overhead work, and the completeness of detail in the frequency of sub-stations is also a surprise to our party. Taken altogether, the Spokane and Inland is undoubtedly the best equipped electric railroad of equal mileage in the world."

While in Spokane the commissioners were entertained by A. L. White, second vice-president of the Spokane and Inland Empire Railroad Company; J. B. Ingersoll, manager of the system, and F. H. Shepard, special representative of the Westinghouse Company. The party was taken in President Jay P. Graves' special car forty miles south to Spring Valley Junction, the round trip being made in a little more than two hours. Upon the return the visitors inspected the Inland's 50 and 72-ton electric freight locomotives, which have a capacity of from 500 to 700 horsepower each. A train of fifteen standard freight cars was attached to one of the electric locomotives and taken as far south as Moran Prairie on a two per cent. grade. Several stops were made and the members of the commission expressed surprise at the ability of the locomotive to stand the heavy overload without the least strain on the apparatus. The party also visited the big power plant now being constructed at Nine Mile Bridge, where apparatus is being installed to develop 20,000 horsepower.

Radio-telegraphy in France.

In regard to wireless telegraphy in France the following information is transmitted by the French director of posts and telegraphs: "We possess actually two stations for wireless telegraphy, one at Ouessant and one at Porquerolles. These two stations are prepared to handle private messages, to which may be added the station at Dieppe, which belongs to the Western Railway Company. Two other stations are about to be opened, one at Saintes-Maries-de-la-Mer (near Marseille) and the other in the environs of Algiers. It has been at last determined, according to an agreement reached between the interested departments of the government, to establish stations at Boulogne, Havre, St. Nazaire, La Coubre, Nice and Cape Corsica. This programme has been established tentatively and is susceptible of modifications."

A Wireless Police Patrol Signal System.

According to report, Assistant City Electrician Charles N. Farmenter of Berkeley, Cal., has invented a system of wireless telegraphy for transmitting signals to patrolmen while on their rounds. The plan consists in the erection of an antenna at or near the station house and furnishing each policeman with a small portable wireless receiver, so that signals can be given by the sergeant on duty for any particular patrolman to report to the nearest police telephone for instructions. It is reported that police commissioners in other cities are much interested in the invention.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, • CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

 This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome: and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

DATES AHEAD.

American Street and Interurban Railway Association and affiliated societies (annual convention), Atlantic City, N. J., October 14th to 18th.

Western Association of Electrical Inspectors (annual meeting), Hotel Ryan, St. Paul, Minn., October 22d, 23d and 24th.

ATLANTIC CITY will witness the meeting of the electric-railway clans next week, and there is no doubt that the attendance will run up into the thousands, with a display of appliances of unequaled magnitude.

CHANGING TIMES demand new conditions, as somebody has said before. In the telephone field the altered situation has brought about the unusually interesting announcement, made last week, that the Bell interests will now sell telephone apparatus to all buyers, irrespective of previous condition of opposition. Hitherto this privilege has been strictly restricted to companies operating under license from the American Bell Telephone Company or its successor, but now, it seems, anyone with the price can buy Bell telephones as easily as he can a push-button. This is indeed a significant change. It may be viewed in several ways, and is no doubt a shrewd business move; but in any case there seems to be a somewhat formal recognition of the importance of buyers of telephone appliances who are not Bell licensees.

MUNICIPAL OWNERSHIP appears not to be very successful in Indiana, particularly when applied to electric-light plants in the smaller cities. Thus the municipal lighting plant of English was sold for 35 per cent. of its cost because of financial loss to the city. The depreciation of the plant was 13 per cent. a year. The plant at Linton was sold to private persons, the city management having resulted in a cost to taxpayers of from $200 to $500 a month more than the income. The plant as now operated by a private corporation is said to be making money and giving good service. Dunkirk tried the experiment for a time, and unloaded the plant at a considerable loss to the city. The city of Washington is about to vote, or has just voted, on the proposition either to sell the municipal plant or to expend a considerable sum in improvement and re-equipment. These examples speak for themselves. A system that provides for a reasonable reward for private enterprise, with honest and efficient municipal regulation for the public good, is best.

AN IMPORTANT educational movement of the last decade is the engineering apprenticeship courses of great industrial companies in the United States, and particularly of the larger electrical manufacturing companies. It is the link, in many cases, between the technical schools and the industries. In his recent paper before the American Society of Mechanical Engineers, entitled "College and Apprentice Training," Prof. J. P. Jackson of State College, Pennsylvania, considers these apprenticeship courses for students, and he finds them to be decidedly beneficial. Indeed, the author speaks of this connecting link in technical training as probably the greatest advance in useful education which the world has ever seen accomplished in the same space of time. "In the old days the boy who graduated from a literary or classical college and who found himself unfitted for the learned professions was apt to become a pauper and a burden upon the community, and even the technical graduate had great difficulty at first in making himself useful and valuable. Today, on account of this new type of post-graduate industrial education, every young man who has received his bachelor's degree, and who has a fair modicum of brains and common sense, has fields innumerable open to him which lead, possibly by slow steps, but surely, to positions of responsibility and usefulness which carry with them in the end excellent rewards to men who give energetic and studious service."

These student-engineer courses extend over two years usually. The students are paid for their work, beginning at perhaps 15 cents an hour, the rate of pay being advanced as experience warrants. The young men are not asked to enter into contract to remain with the company for any specified time, although it is rather expected that the students will not withdraw until they have finished the course. However, it usually happens that no opposition is made in the case of a man who has an opportunity to secure a good position outside if he has been with the company a reasonable length of time. As one employer of students expressed it, "We are just as anxious to have good men with our customers [say, electric-lighting and railway companies] as we are to retain them in our employment." The courses are laid out by practical men for the purpose of training the young graduates for positions of responsibility. The movement is not philanthropic, and it seems to achieve the desired end with a great degree of success.

AS WAS to be expected, the Board of Supervising Engineers, Chicago Traction, has begun its important task of directing the rehabilitation of the street railways of Chicago with an intelligence, comprehensiveness and energy which are worthy of praise. The work is being laid out on broad lines and is in thoroughly competent hands. Moreover, the traction settlement provided or will provide sufficient funds so that, with the judicious expenditure which may be looked for, there will undoubtedly be sufficient money to build a really first-class system of electric street railways (including eventually a system of subways) for the city of Chicago. The prospect is a pleasing one. Perhaps the Board will make mistakes, but at any rate the enterprise is in the hands of men who are honest, who have the requisite engineering and administrative ability and who have also the "Chicago spirit."

NEW YORK has a street-railway "situation" which threatens to become almost as complicated as that in Chicago. In both cities "high finance" has figured conspicuously in the management of street-railway properties with rather unfortunate results. The era of mergers, of floating new bond and stock issues and of "underlying securities" has been succeeded in each case by receiverships and the assemblage of eminent legal counsel, with satisfactory retainers, summoned to the unraveling of the skein. One result of the condition of affairs in New York has been the resignation of Mr. H. H. Vreeland from the operating management of the Metropolitan company. Mr. Vreeland is a former president of the American Street Railway Association, as it then was, and is known throughout the country as a street-railway man of ability and prominence. He began at the bottom of the ladder, but attracted the attention of the late William C. Whitney, who recognized his executive capacity, and thereafter his advancement to the presidency of the most important surface street-railway system in the country was rapid.

AN INTERESTING plan to facilitate the securing of new business has been put in effect at Minneapolis in connection with the starting of the Taylor's Falls electric transmission plant. As noted by a contributor, the Minneapolis General Electric Company made a careful canvass of the manufacturing districts prior to the completion of the first 12,500-horsepower installation at Taylor's Falls, securing data as to the hours of work and horsepower utilized. This information was then classified and maps were made showing the location of the different plants and the company's power lines. Letters were then sent to different firms on the distribution system asking them to allow the company to make power tests on their premises without cost with the object of being able to supply these houses with electricity at a lower cost than obtained with their existing equipment.

Upon receiving permission to make the tests, complete data of the installation were recorded, giving all the particulars of the machinery, location and use, size and arrangement of shafting. All engines were tested and the total and friction loads obtained. Four indicator cards per hour were taken for the full time of daily operation. The maximum load of the plant, with all machines running at full output, and the minimum friction load, with all machines running empty, also the friction load of the line shafting alone, were taken. In some cases the larger machines were taken individually with the rest of the plant shut down. Coal and water records were taken in the longer runs. The returns showed where motors could be used to advantage, and while somewhat expensive to secure, enabled the agents of the company to talk much more intelligently about the conditions, and resulted in a large addition to the connected load on the system.

New York Electrical Show.

By Edwin H. Seaman.

New York, October 5.—The first annual New York Electrical Show is now being held at Madison Square, as already announced in the columns of the Western Electrician. This show differs from all the previous shows which have been held in New York in that the exhibits there displayed well illustrate the hold that electricity is obtaining upon the commercial world. The exhibits of the Edison Illuminating Company of Brooklyn, the New York Edison Company and the United Electric Light and Power Company, the three largest electric-light and power supply companies in New York, in their displays of the uses to which electricity may be applied in the purely domestic affairs of the home, are surprising to those not familiar with the art.

In connection with the extensive advertising campaign, which it is now carrying on, the Brooklyn Edison Company fitted up a model apartment exhibit, consisting of six rooms, the decorations being furnished by Abraham & Straus of Brooklyn. In the kitchen and laundry we find a small electrically driven refrigerating machine, supplying to the apartment sanitary refrigeration and hygienic ice. A clothes-washing machine, consisting of a tub, in which the wash is placed, and driven electrically by a special mechanism, which gives to the tub a half rotating motion, is to be seen and also a dish-washing machine, in which the finest china may be placed without the least fear of its being broken. Water, boiled by the heat derived from a set of coils, supplied with electricity, is circulated through the china by means of a small circulating pump, also driven by an electric motor. An electric range, provided with utensils, including broiler, griddle, pots and warming plate, is of great attraction, and is without question the acme of convenience in cooking, and of course sanitary, reliable and instantaneous. There are four positions indicated on the snap switch—"off," "low," "medium" and "full." Electric grinders, either for coffee or meats, polishing and buffing machines are also displayed.

In the dining room, artistically arranged, are to be seen coffee percolator, tea kettle, chafing dish, small plate warmer and vacuum cleaner, all operated by electricity. The lighting of each of the rooms was planned by V. R. Lansingh, with the double purpose of securing economy and efficiency. In the parlor the "smelly" gas-log is superseded by the cheerful electric grate. A piano, operated by a telelectric piano player, gives music for any occasion. In the bedroom electric heating pads, radiator, baby milk warmer and massage outfit are displayed, and in the office an electric fountain, sewing machine, sterilizer, cigar lighter and many other useful articles make this exhibit one of the most attractive to be found at the Garden.

A general view of the Garden, taken from the rear promenade, is here shown.

The exhibits of the General Electric Company and of the Roger Williams and Simplex apparatus, in their displays of the uses of electricity for heating and cooking, occupy spaces in the center at the east end of the arena. On the left of these exhibits the Electric Testing Laboratories have their booth. Here may be seen exhibited meters of all kinds, oscillograph, potentiometers, frequency indicator, standard resistances, conductivity bridge, cable testing sets, photometers and many other interesting features to show the extent of the work which their laboratories are prepared to undertake. Between the hours of 2 and 6 p. m. voltmeters, ammeters and wattmeters will be checked up free of charge. Also lamps will be compared at these hours, gratis.

Just beyond are the exhibits of the New York Edison Company, or rather, the exhibits of the several manufacturing companies, whose apparatus (direct-current only) can be used on the Edison mains. Among the most attractive are portable electric-driven centrifugal pump for contractors, also for hotel and apartment-house use, electric-driven printing press, proof press, sweating machine, electric and electro-pneumatic tools, hoists, vacuum cleaners, dough mixer, surfacing machines, adding and sorting machine, beer pumps, air pumps and many of the other appliances shown in the exhibits of the Brooklyn Edison Company. Through the courtesy of the New York Edison Company the spaces of the Roger Williams Company, Sibley & Pitman, Consolidated Telegraph and Electrical Subways Company, and many others were supplied with electricity.

In the Consolidated Subways' exhibit were shown a typical manhole, with its high and low-tension cables, service wires and the development of the splices on each illustrated. Specimens of relics found in excavating in New York were shown in a case close by.

Directly next comes the exhibit of the General Electric Company. This, as shown in the accompanying picture, is laid out with a main booth roofed with an arched canopy, forming a galaxy of light, and two open wings on each end. The front wing is devoted to the motor, household and culinary applications and electric ironing. The visitor can demonstrate personally the advantages of the electric-driven sewing machine, potato peeler, the ice-cream freezer; and observe the clothes both washed and ironed. Of particular interest is the electric carpet renovator, in which a motor drives a cylindrical brush, and a centrifugal fan, which produces a suction at the brush and delivers the dust into a receptacle; absolutely no dust escapes into the room. There are also on exhibit in this wing motor-driven dough mixers, coffee grinders and meat choppers. To heighten the interest in this wing a moving picture machine has been placed there, illustrating graphically the recent race between the General Electric Company's electric locomotive and a New York Central flyer, running 70 miles per hour. There is also an electrically operated Regina music box.

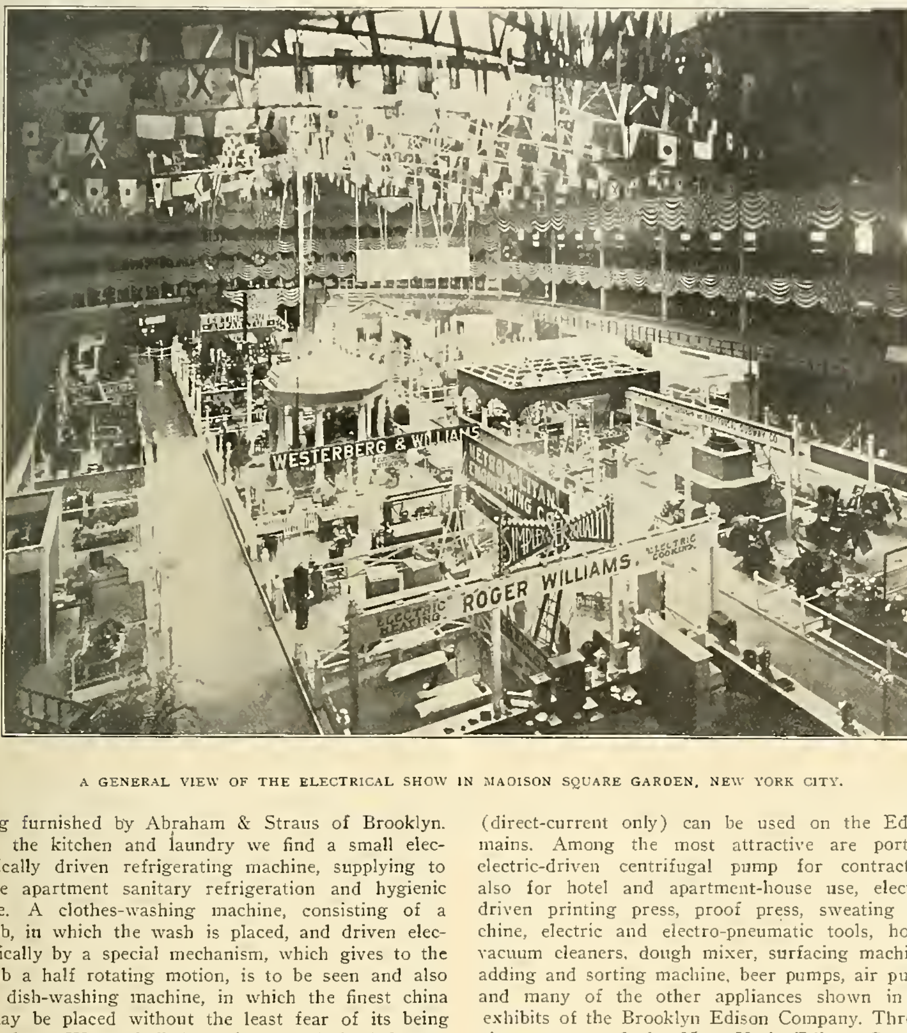
The main General Electric booth is devoted to a model dining room and a model kitchen. The former is furnished in "Mission." Over the table hangs an ornate shell dome in which is a 40-candlepower tantalum meridian lamp. The electric cigar lighter and the corn popper on the table are suggestive dining room conveniences, the electrically wired side table on which are an electric chafing dish and percolator, indicate the best way to provide for these modern necessities. The electric fan is not omitted. The model kitchen exhibits the electric kitchen cabinets, large and small size, in which busy demonstrators are preparing delicious biscuits, fudge, rarebits and other delicacies. A counter along the side is stocked with a complete assortment of electric heating and cooking appliances, many in operation, for examination by the curious and interested. Perhaps the article on this counter attracting the most attention and exciting the greatest comment is the electric luminous radiator. Already the inquiries regarding this device have resulted in many sales.

The end wing of this exhibit is devoted to industrial applications. Attracting considerable attention, partly on account of its noise, is an Ingersoll-Temple rock drill in operation. A three-horsepower motor drives an air compressor and pulsator, the energy being transmitted to the drill through the medium of compressed air. It is a machine which combines both the advantages of the pneumatic and purely electrical drills. A one-horsepower motor drives a cabinetmaker's circular miter saw. The greatest interest on the part of the general public is probably evinced in connection with the mercury arc rectifier automobile-charging set, which is in operation, with switchboard equipment. Of special mention, however, is a 30-kilowatt four-cylinder direct-connected gasoline generator set which the General Electric Company is just placing on the market. A new electrically driven floor sander in which a two-horsepower motor drives a 15-inch sanding drum is in use for demonstrating. A 20-kilowatt Curtis turbine steam generator set, used for train lighting, and a disassembled turbine, showing the advantages of construction, with a Bridgeport double 12-inch emery planer driven by a two-horsepower induction motor, and numerous small motors for various applications complete the exhibit in this wing.

On the left side of the main booth a color booth of four sections has been placed, each section being lighted by a standard illuminant, viz., enclosed arc, Welsbach gas, incandescent electric and Nernst electric. This color-comparison exhibit is an educational feature for the purpose of illustrating the effect of artificial illuminants on colors; for instance, blue appears green when viewed under some illuminants, such as gas and incandescent electric lamps.

The crowds were so great and the interest manifested in the General Electric Company's exhibit so intense that a large portion of the New York office force had to be pressed into service to answer inquiries, there being 12 or 15 men present. The exhibit is in immediate charge of Mr. W. J. Canning, who is in charge of electric cooking and heating sales in the New York territory. Miss Winifred Potts, in the household department, is assisted by five lady demonstrators. Among those from out of town were Mr. C. C. Chesney, manager Pittsfield works; Mr. F. H. Gale, in charge of advertising, exhibits and electric heating appliances; Mr. H. B. Wilson of the heating department, Pittsfield; Mr. E. L. Callahan, electric heating department, Chicago, and Mr. C. E. Bibble, small-motor department; Mr. J. O. Case, exhibit engineer, and Messrs. H. J. Mauger and H. Fulwider, electric heating department, Schenectady.

Another exhibit of great interest is that of the Westinghouse Companies, which occupies a space of about 2,000 square feet, and is perhaps the most varied of any at the Electrical Show. Approximately twenty applications of electric motors are shown, including ironing machines for the home and for laundries; pipe-threading machinery, showing the most compact arrangement with this sort of work that has yet been made possible, the outfit being operated by means of a motor, rheostat, switches and wiring all on one bed; a blower for ventilating mines, subways, etc.; vacuum cleaner, made by the Sanitary Devices Manufacturing Company, for the renovation of houses, hotels, etc.; exhaust fan made by the American Blower Company, for ventilating purposes; the Watson-Stillman pump, for the raising of water to small house tanks for summer residences, hotels, etc.; a rotary air compressor, for the operation of compressed air, tools, inflation of automobile tires, etc.; Yale & Towne hoist, for factory uses; dish-washing machinery, for the cleaning of dishes in the home and in hotels and restaurants; Singer sewing machine for domestic purposes; textile loom, which will be operated to show the manner in which fabrics are woven; dough mixer, showing the manner of mixing dough in the home and in the



A GENERAL VIEW OF THE ELECTRICAL SHOW IN MADISON SQUARE GARDEN, NEW YORK CITY.

bakeries; and last, but perhaps most interesting to the commercial man, is the phonograph in conjunction with the shaver. All of the apparatus is driven by Westinghouse motors, and in attendance with each exhibit is an expert who explains the operation of the machinery.

In the same space the Westinghouse Lamp Company, very much to the edification of visitors, gives continuous demonstrations of incandescent-lamp manufacturing, showing the different processes through which an electric incandescent lamp passes before it is ready for use as an instrument for illumination. The Westinghouse Electric and Manufacturing Company shows a full line of its arc lamps for all currents and voltages, as well as a complete line of current-measuring instruments. Fan motors for all circuits are shown, and transformers of various types and sizes are exhibited. The space is attractively lighted with Nernst lamps mounted on columns. This, as is well known, is the lamp that has come into such general use for storehouse, church and other lighting. It has many admirers, on account of its beautiful light and the tungsten light attracts especial attention. Tungsten being the most modern as well as the most efficient electric incandescent illuminant, is being closely observed by those interested in electric lighting. The National Electric Lamp Association has brought this lamp to the point where it can be operated horizontally as well as vertically and a number are on exhibition at the association's attractive booth to the right as one enters. This was the most noteworthy improvement to be seen along this line. The naturally brilliant quality of the light given by these lights attracted considerable attention.

Directly adjoining the booth of the National Lamp Association is that of the Driver-Harris Wire Company, which has on exhibition the various grades and kinds of wire produced by it. Across the center isle to the left the India Rubber and Gutta Percha Insulating Company has on display Habirshaw wires and cables of all kinds.

The electrical show has apparently come to stay in New York, and it will be looked forward to each year as a medium for the display of new developments, especially in the commercial world, and

A PROMINENT EXHIBIT AT THE NEW YORK ELECTRICAL SHOW.

economy in current consumption. Cooper Hewitt mercury-vapor lamps are also exhibited from the ceiling of the Madison Square Garden, demonstrating the value of this lamp for the lighting of large areas, such as shops, factories, train sheds, wharves, etc.

The Westinghouse Machine Company shows storage batteries for central-station work and also sparking batteries for automobiles. A 15-horsepower type "SA" motor of Westinghouse make is shown in the exhibit, operating under load on a 220-volt direct-current circuit, and attached to this machine is a speed-indicating device.

It may be interesting to note, in connection with this exhibit, that apparatus manufactured by five of the Westinghouse Companies is shown. The Westinghouse Companies embrace a circle of about 25 companies, altogether employing about 40,000 men. There are about 25 factories in different parts of the world, the largest, of course, being at East Pittsburg, Pa. These form the nucleus of all the works, and from these all the others have grown. At East Pittsburg are employed 20,000 to 25,000 men. The works cover an area of altogether about 100 acres. In New York city all these companies have offices at different places.

The Federal Sign Company and the Metropolitan Engineering Company both have on display many signs of very original pattern, which, being studded with incandescent lamps, gave great brilliancy to their respective spaces, while the Advertising Mirrorgraph Company's flashers blink at you on either side as you enter the arena.

The Marconi Wireless Telegraph Company has in operation at either end of the Garden a small station, and marconigrams can be sent from one to the other for the amusement of the public. The New York Telephone Company has a very imposing space to the left as one enters the arena, where are on exhibit all the various kinds of telephonic connection, which the company is prepared to furnish, from the simple subscribers' instruments to the complicated up-to-date switchboard.

The Beck flaming arc can be seen in the illumination of the exterior and interior of the Garden itself, as well as in the booths of the New York Edison Company, United Electric Light and Power Company and the Driver-Harris Wire Company.

Among the hundreds of cellulose, Gem, metalized, tantalum and tungsten lamps displayed by the National Electric Lamp Association, the new inventions and applications. Among the officers of the electrical show are Arthur Williams of the New York Edison Company, James R. Strong of the National Electrical Contractors' Association, Dudley Farrand of Newark, and W. W. Freeman of Brooklyn. George F. Parker is president, James C. Young secretary, and Walter Neumiller treasurer.

Among exhibitors not previously mentioned are the following-named:

Morlite Company—Tungsten lamps.

Mechanical Appliance Company—Watson multipolar motors and generators.

F. Wesel Manufacturing Company—Proof presses.

Chicago Pneumatic Tool Company—Electric and air tools and accessories.

Dayton Hydraulic Machine Company—Centrifugal pumps.

Crocker-Wheeler Company—Generators and motors.

Roth Bros. & Co.—Motors.

American Floor Surfacing Machine Company—Floor cleaners.

Robinson Machine Company—Victoria vegetable peeling machine.

Spencer Turbine Cleaner Company—Suction cleaners.

Hygienic Cleaning Company—Portable vacuum dust extractor.

Temple-Ingersoll Company—Electric air rock drill.

F. Alexander Electric Company—Arc lamps.

G. M. Gest—Electrical conduit wires.

Kenny Electric Manufacturing Company—Electric novelties.

Monoton Construction Company—Electric construction.

Safety Car Heating and Lighting Company—Electrical equipments.

Standard Roller Bearing Company—Ball bearings.

Telharmonic Music Company—Electric music.

Sunbeam Incandescent Lamp Company—Lamps.

Warren Electric and Specialty Company—Lamps.

American Wire Brush Company—Brush cleaners.

Robert Findlay Manufacturing Company—Electric fixtures.

Holophane Glass Company—Globes.

Brunswick Refrigerating Company—Refrigerating and ice-making.

Robbins & Meyer Company—Motors and applications.

Emerson Electric Manufacturing Company—Buffing motor.

Charles W. Leveridge—Showcase reflectors.

T. R. Almond Manufacturing Company—Flexo desk lamp.

The Street-railway Conventions.

Beginning on October 14th and concluding on October 18th, the American Street and Interurban Railway Association and its three subsidiary organizations of street-railway accountants, engineers and claim agents will meet in annual convention in Atlantic City. The parent or American Association will meet on the Steel Pier, the Accountants at the Chalfonte Hotel, the Engineering Association on the Steel Pier and the Claim Agents at the St. Charles Hotel. Headquarters of the American Association will be at the Marlborough-Blenheim.

Following are the full programmes of two of the associations:

American Street and Interurban Railway Association.

Wednesday, October 16th, 9:30 a. m. to 1 p. m.—Convention called to order. Address of welcome. President's address. Report of executive committee. Report of secretary and treasurer. Addresses by presidents of affiliated and allied associations. Announcements. New business. Reports of committees on (a) membership, (b) compensation for carrying mails, (c) subjects, (d) car wiring, (e) standardization of equipment. Papers—"The Technically Trained Man and the Electric-railway Profession," by Prof. H. H. Norris, Cornell University, Ithaca, N. Y.; "The National Fire Protection Association and Its Work in the Street and Interurban Railway Field," by Ralph Sweetland, Boston, Mass.; "The Influence of the Design of Railway Structures on Economy of Operation," by H. J. Campion and William McClelland, consulting engineers, New York, N. Y.

Thursday, 9:30 a. m. to 1 p. m.—Appointment of nominating committee. Reports of committees on (a) promotion of traffic, (b) rules, (c) heavy electric traction. Papers—"Light Freight Handling by Electric Lines," by P. P. Crafts, general manager, Iowa and Illinois Railway Company, Clinton, Iowa; "Freight Service on Electric Railroads," by H. H. Polk, president, Interurban Railway Company, Des Moines, Iowa; "A Department of Publicity," by J. Harvey White, advertising manager, Boston Elevated Railway Company, Boston, Mass.; "Advertising from the Street-railway Standpoint," by A. W. Warnock, general passenger agent, Twin City Rapid Transit Company, Minneapolis, Minn.; "The Problems of a Small Road," by H. S. Cooper, manager, Galveston Electric Company, Galveston, Tex.; "The Use of T Rail in Cities," by C. Gordon Reel, vice-president, Kingston Consolidated Railway Company, Kingston, N. Y.

Friday, 9:30 a. m. to 1 p. m.—Reports of committees on (a) insurance, (b) rules for the construction of modern car houses, (c) municipal ownership, (d) public relations. Papers—"Public Policies of the Past and Future," by C. Loomis Allen, vice-president, Utica and Mohawk Valley Railway Company, Utica, N. Y.; "Interurban Railway Fares," by Theodore Stebbins, J. G. White & Co., New York, N. Y.; "Municipal Ownership in Great Britain and the United States," by William J. Clark, New York city. Discussions—"Reduced-fare Agitation" and "Depreciation from the Financial and Managerial Standpoints." Report of nominating committee. Election of officers. Resolutions. Unfinished business. Adjournment.

American Street and Interurban Railway Engineering Association.

Monday, October 14th, 2 p. m. to 5 p. m.—Convention called to order. Address—John I. Beggs, president, American Street and Interurban Railway Association. Reading of the minutes of the last meeting. Address of the president. Annual report of the executive committee. Annual report of the secretary-treasurer. Appointment of convention committees. Reports of special committees. Report of committee on control apparatus. Report of committee on maintenance and inspection of electrical equipment.

Tuesday, 9:30 a. m. to 12:30 p. m.—Report of committee on way matters. Papers—"Care of Electric-railway Tracks," by George L. Wilson, engineer, Twin City Rapid Transit Company, Minneapolis, Minn.; "Rails and Joints as Affected by Traffic in New York City," by W. Boardman Reed, engineer, New York city. Report of way committee on "Rail-corrugation Investigation." Report of way committee on "Concrete Tie Investigation." Report of sub-committee on "Rail and Rail Matters."

Tuesday, 2 p. m. to 5 p. m.—Report of committee on standardization. Report of committee on Open vs. Closed Terminals for Car Storage. Report of committee on Operating and Storage Car-house Designs. Question Box.

Wednesday, 9:30 a. m. to 1 p. m.—Joint meeting of "American" Association and allied associations.

Wednesday, 2:30 p. m. to 5:30 p. m.—Paper—"Gas Engines," by Paul Winsor, chief engineer motive power and rolling stock, Boston Elevated Railway Company, Boston, Mass.; "Gas-engine Operation," by W. W. Cole, general manager, Elmira Water, Light and Railway Company, Elmira, N. Y.; "Steam Turbines," by St. John Chilton, engineer, Allis-Chalmers Company, Milwaukee, Wis.; "Operating Features of Curtis Turbines," by August H. Kreusi, engineer, General Electric Company, Schenectady, N. Y.; "Recent Developments in Steam-turbine Power-station Work," by J. R. Bibbins, engineer, Westinghouse Machine Company, East Pittsburg, Pa. General business. Election of officers.

The programmes of the Accountants' and Claim Agents' associations are equally well supplied with papers and discussions of interest to the membership. The accountants begin their convention on Tuesday morning and end on Thursday morning. The claim agents start in on Monday afternoon and conclude on Wednesday afternoon.

In the matter of railroad rates, the Trunk Line Association, New England Passenger Association, Eastern Canadian Passenger Association and the Southeastern Passenger Association have granted a rate of a fare and a third on the certificate plan for all points within their territories. The Central Passenger Association has granted a uniform rate of two cents a mile within its territory. The Western Passenger Association grants special one-way rates to its eastern terminals. The Southwestern Passenger Bureau grants reduced one-way rates to St. Louis. From Chicago the Pennsylvania Railroad announces that it will run a special train leaving the Union Station at noon on Sunday, October 13th, arriving in Atlantic City about noon the next day. C. L. Kimball of No. 2 Sherman

Street, Chicago, can give further information in relation to this train.

Atlantic City is abundantly supplied with hotels. Arrangements are made directly with the hotel management by visitors to the conventions.

All the delegates and guests of the American, Accountants', Engineering, and Claim Agents' associations will register and receive badges at the association booth, which will be located at the Board Walk entrance to the Steel Pier. This booth will be kept open from 9 o'clock a. m. to 6 o'clock p. m. during all days of the convention. It will be the general headquarters for all the associations, and will serve as an information bureau concerning association matters. The Manufacturers' Association will also have a booth at the same place, which will take care of similar matters relating to the exhibitors and the members of the Manufacturers' Association.

The American Street and Interurban Railway Manufacturers' Association is making great preparations for a fine exhibit, which will cover the entire Steel Pier. This exhibit will be larger and more comprehensive than ever before. More than 200 different companies have already been assigned exhibit space, and the total amount of floor space will be considerably greater than that used at the 1906 convention exhibit in Columbus.

Delegates to the American Association convention are requested to attend the Tuesday afternoon session of the Engineering convention, when the report of the Engineering Association's committee on standardization will be presented and discussed. The report of the American Association committee on standardization will be short and will be based upon the work of the Engineering Association committee.

It is expected that there will be a roll call at each session of the various conventions. Notices will be sent to the various companies immediately after the convention, informing them at what sessions their representatives were present.

President Beggs and the executive committee of the American association have decided that there will be no annual banquet this year. The entertainment committee of the Manufacturers' Association has practically completed its plans for the convention week. This committee will probably arrange for a theater party on Thursday evening to take the place of the annual banquet. Entertainment features will also be provided for the other evenings of the week.

Quebec Cantilever Bridge.

The collapse of the Quebec cantilever bridge over the St. Lawrence River between Sidney and St. Romauld, five miles above Quebec, resulting in the death of some 80 workmen on the afternoon of August 29th, draws attention to the really remarkable size of this structure and the imporant engineering undertaking involved. The original plans for the structure were prepared in 1851, but it was not until 1898 that the actual work of raising the funds for construction was begun. It took more than 40 years of agitation on the part of the business men of Quebec to get the bridge under way.

The point where the crossing over the river is made is 175 miles nearer the sea than the nearest present crossing, the Victoria bridge, Montreal, and the channel here is 2,000 feet wide and over 200 feet deep. These conditions made necessary the use of the cantilever type of bridge with the unusual span of 1,800 feet. The total length of the bridge is to be 2,220 feet.

There are so many novel features of construction and methods of conducting the work of building this bridge, that, even with the recent serious setback, much has been learned which would otherwise have remained untried. For the first time in the history of bridge erection, electricity has been used exclusively, and with gratifying results, for operating all the hoists and other machinery. There has been a very apparent absence of smoke, noise and the confusion usual to a large undertaking of this sort.

The electric current for operating all the motors is generated by the hydro-electric plant of the Canadian Electric Light Company at La Chaudiere Falls, three miles from the bridge, and among the units installed there is a 1,000-kilowatt Allis-Chalmers water-wheel type alternator. This current is transmitted at 2,400 volts to motor generator sets installed on the approach span to the bridge, where it is transformed to 550-volt direct current and distributed to all parts of the work.

Air for operating the pneumatic hammers, drills, reams, etc., is furnished by two motor-driven air compressors also placed on the approach span and connected to a three-inch main, running through the center of the bridge, from which branch lines were tapped.

The cost of the completed structure was estimated at $10,000,000, of which $5,000,000 had already been spent. The concrete work alone, which has been completed for nearly three years, and for which 40,000 barrels have been used, cost about $2,000,000.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe.

XXXVII. Electric Railways.

Car Accessories.

Resistances are always used in connection with controllers for regulating the speed of trolley cars, and, except on very small equipments, these resistances consist of cast iron grids assembled in a frame and connected so that all the grids are in series. The grids are thoroughly insulated from the frame in which they are supported, and are strung on rods with insulating washers between them, so there is a free circulation of air around each grid. The end frames, between which the grids are clamped, are made of either cast-iron or sheet-steel. The latter makes a very substantial frame, which is considerably lighter than cast-iron, and is not so liable to be broken by blows or by the jarring of the car.*

As more or less of the resistance is used on different steps of the controller, several terminals are used on the resistance, and these are generally arranged to be clamped between the grids at desired intervals. An important feature in connection with these resistances is to have all parts accessible for making the connections and to have them so assembled that a broken grid can be quickly and easily replaced.

For equipments of small capacity smaller resistances are sometimes used which are composed of several cells. These cells are built up of sheet-steel ribbon wound in coils with asbestos between each layer. These cells, like the grids, are connected in series and are provided with several terminals. The function of resistances on electric cars was fully explained in Chapter XXXV. under "Controllers."

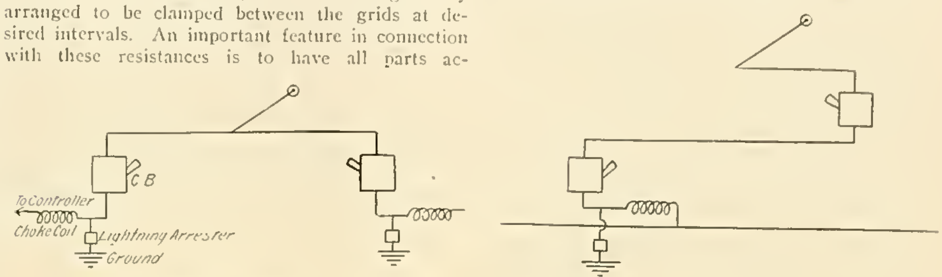
Canopy Switch.—A canopy switch is placed under the hood of the car directly over the motorman's head, and it consists of a single-pole switch, by means of which the current from the trolley may be entirely cut off from the apparatus on the car. When the car is equipped with controllers at each end, a canopy switch is placed under each hood, and the two switches are connected in series. These switches are generally used on equipments of small capacity, and it is necessary to use a fuse with them for the protection of the motors and controllers in case of an overload. On large equipments, automatic circuit-breakers generally replace the canopy switches.

Fuses.—The fuse is placed in the trolley circuit before it reaches the controller, and a number of types of both open and closed fuses are used for this purpose. Where a car is fitted with a motorman's cab the fuse box will be located in the cab; otherwise it is generally placed underneath one side of the car body at a point which is easily accessible for changing the fuses. The fuse consists of a short length of either copper wire or some composition metal which will melt and break the circuit when more than a safe amount of current for the motors passes through it. In one style of fuse-box it is only necessary to open the cover and drop in the fuse wire. Closing the cover clamps this wire in circuit.

Automatic Circuit-breakers.—An automatic circuit-breaker is generally used on equipments of large capacity, in which case the canopy switch and fuse are omitted. By means of an automatic circuit-breaker the current can be cut off from the car at any moment by tripping the breaker by hand, and a solenoid magnet which can be adjusted for a definite current is contained in the circuit-breaker, which automatically opens the circuit when the current exceeds the amount for which the magnet is adjusted. In one design of circuit-breaker the electromagnet is connected in series with a single-pole switch, and a single coil serves the double purpose of a winding for the operating magnet and a blowout coil.

In addition to the main switch contact, there are provided arcing tips. When the circuit-breaker is opened the main switch contact opens slightly in advance of the arcing tips, so that all of the arcing is concentrated on these tips, which are easily renewable, thus leaving the main contacts smooth and clean. When the circuit-breaker is closed, it is held in closed position by means of a latch, and it closes against a heavy spring, which forces it open instantly when the latch is released. The operating magnet releases this latch on overload, allowing the circuit-breaker to fly open. A tripping rod is also provided by means of which the latch may be tripped by hand.

The circuit-breaker not only protects the car wiring and apparatus in case of a short-circuit, but it also opens the circuit in case the motorman turns on the current so rapidly as to endanger the motors. Where circuit-breakers are used on each end of the car they may be connected either in series or in parallel, as shown in the accompanying diagrams. If they are connected in parallel, two lightning arresters and two choke coils are necessary. If they are connected in series, only one lightning arrester and one choke coil are required; but in this case the circuit-breaker on the rear of the car is liable to open, which would require a trip through the car in order to reset it.



Parallel Connection. Series Connection.

CAR CIRCUIT-BREAKERS.

Lightning Arresters.—One or two lightning arresters are always used on each car, as indicated in the accompanying sketches, and they are located in the trolley circuit before it reaches the controller. The function of the lightning arrester is to divert static discharges to the ground before they can pass through the apparatus on the car and puncture the insulations of the windings. The theory of lightning arresters, and the principles upon which a number of the types operate were fully described in Chapter XX. Ordinarily one lightning arrester for each car is sufficient, except when the automatic circuit-breakers are connected in parallel.

Trolleys.—The wheel trolley, which is familiar to everybody, is universally used for overhead direct-current systems of five to six hundred volts pressure. On third-rail systems the trolley is replaced by contact shoes, which are fastened to the sides of the truck and rest upon the surface of the third rail. In high-potential alternating-current roads the pantagraph form of trolley is generally employed.

The wheel trolley consists of four principal parts, namely, the base, trolley pole, trolley harp and trolley wheel. The bases are provided with a swivel, so that the trolley may be turned in either direction according to the direction of car travel, and the socket which holds the trolley pole is pivoted so as to swing in a vertical plane. Heavy adjustable tension springs tend to hold the trolley normally in a vertical position, and when the pole is pulled down to a sufficient angle to run under the trolley wire, the tension of these springs keeps the wheels in firm contact with the wire.

The trolley pole is formed of hollow steel tubing, slightly tapered, which gives the lightest construction for the required strength. The trolley harp is placed on the upper end of the trolley pole and contains journals in which the trolley wheel revolves, and usually has some form of contact springs for taking the current from the wheel. As the trolley wheel revolves at a very high speed, and frequent arcing between the wire and the wheel tends to destroy the wheel, provision is generally made for removing the old wheels and placing new ones in the trolley harp with but little trouble.

This high speed also requires specially careful lubrication, as oil or grease has not been found suitable for this service. Graphite bushings are

*Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

largely used, consisting of a brass shell with a spiral groove filled with graphite. Some of these wheels are made with roller bearings.

In some climates the use of sleet wheels is necessary for removing the coating of sleet and ice which occasionally forms on the trolley wire. This ice acts as a non-conductor and entirely cuts current off from the car when a smooth trolley wheel is used. To overcome this trouble special wheels are provided with sharp ribs in the groove, which bears against the wire, and these ribs cut the ice from the wire as the wheel passes under it.

Third-rail Shoes.—Third-rail shoes are used to collect current from the third rail, and they are of the sliding-contact type, unlike the trolley wheel, which has a rolling contact. Four shoes are generally provided on each car, and they are supported on the sides of the truck close to the journal boxes, for the reason that these points of the truck remain a fixed distance from the third rail when the car is passing around curves. The shoe consists of a cast-iron block which rests against the third rail and makes contact either by its own weight or in some cases by means of a spring. These shoes are thoroughly insulated from the truck, and provision is generally made for folding them back out of the way when not in use.

Wherever cars are liable to be turned end for end, third-rail shoes must be provided on both sides of the car. These shoes are generally supported by links, which permit the shoe to accommodate itself to any variation in the height of the third rail.

Car Heaters.—Most all car heating at the present time is done either by electric heaters, or by hot-water heaters. Electric heaters are generally used in city and suburban cars, while hot-water heaters are chiefly used in large interurban cars. The hot-water heater consists of a stove containing hot-water coils, and as this requires considerable space this method of heating is generally only employed on cars provided with a cab exclusively for motormen.

Hot-water heating is probably the cheapest as well as the most efficient kind of heating, but requires more attention than electric heaters, and is also dirtier than the latter, on account of the coal and ashes, which must be carried on the car. The dirt, however, when confined to the motorman's cab, is not objectionable to passengers. The pipes from the heater are led along the sides of the car and are extended out so as to form a coil under each of the cross-seats. The piping is so arranged that there is a gradual fall in the pipes from the place where they leave the heater to where they return to it.

An expansion tank is placed on top of the car in which there is a small opening to the atmosphere, in order to prevent the water reaching a dangerous pressure and to permit the escape of steam should any be formed. From the expansion tank the hot water flows down, circulating through the coils under the seats and returns again to the lowest part of the heater, thus maintaining a constant circulation.

Electric heaters consist of coils of iron wire which are heated by the passage through them of a current of electricity. The iron wire is wound on tubes of insulated material, and a number of these coils are assembled together and are mounted in a frame of non-combustible material. As there must be free circulation of air about the coils in order to warm the car, these heater units are surrounded with perforated metal to prevent mechanical injury of the coils and at the same time permit free circulation of air through them.

The connections of heater coils vary in different makes of heaters. In some cases they are arranged to be connected either in series or in parallel, so as to give different degrees of heat. In other cases coils of two different resistances are used, and each is connected in an independent circuit. This allows three different degrees of heat, as the high-resistance coils can be used alone, the low-resistance coils used alone, or both coils used together.

It is not advisable to run electric heaters at too high a temperature, as when the iron wires are heated very hot they oxidize rapidly and are very liable to become broken. It is better practice to use a large number of heaters which can be run at a moderate temperature, as the heaters are less liable to damage, and the same amount of heat is produced by the larger amount of radiating surface at a lower temperature as would be obtained from a smaller number of heaters run at a higher temperature.

[illegible] heaters offer an opportunity for a considerable waste of current unless managed with good judgment, the temperature of the car should be carefully watched, and the heaters turned off when not required. By turning them on and off at intervals considerable current can be saved, and there is no sudden drop in temperature when they are turned off, as the heaters maintain heat for a considerable time after the current is shut off. The amount of current consumed by the heaters depends, of course, upon the size of the car and the temperature of the outside air. Under average conditions the heaters for a moderate-sized car will consume from five to eight or nine amperes, and under severe conditions this amount may be considerably increased.

[*To be continued.*]

QUESTIONS AND ANSWERS.

Resonance Formula.

C. F. W., New York, still fails to understand the critical formula for resonance:

$$2\pi n L - \frac{1}{2\pi n C} = 0,$$

for he asks "why is it necessary to add to L, if C is reduced, to again strike a balance."

ANSWER.

This is a little problem in mathematics. To see through it, it is best to simplify it and substitute ordinary numbers for L and C. Let n have such a value that $2\pi n = 1$; then $L - \frac{1}{C} = 0$, or $L = \frac{1}{C}$. Now let $L = 2$ and $C = \frac{1}{2}$; evidently $2 = \frac{1}{\frac{1}{2}}$. Next let $L = 3$ and $C = \frac{1}{3}$, and surely $3 = \frac{1}{\frac{1}{3}}$. In other words, if L is increased, C must be correspondingly diminished in order to maintain the balance.

Alternating-current Problems.

G. H., St. Paul, Minn.: 1. I made a voltage test on a three-wire, 220-volt, 60-cycle alternating-current system recently when there was a large load between the neutral wire and one of the mains. The voltage on that side of the system was 90 and on the other side it was 100 volts, whereas between the outside mains there was a reading of 198 volts. Why was it not the sum of the two branch readings, or 190 volts?

2. How do you make a test to find the impedance voltage of a transformer?

3. What is a two-phase system?

ANSWERS.

1. The reading across the outside mains should have been equal or less than the sum of the two branch readings, if all readings were taken at the point where the three mains either enter or leave the switchboard. If there was a slight difference in phase between the two sides of the system the reading across outside mains would have been less than the sum of the branch readings. The discrepancy may have been caused entirely or partly by taking the high reading on the machine or transformer side of the switchboard and the low readings on the load side. Or, more likely, if separate voltmeters were used for the high and low readings, they may not check, due to errors in calibration or adjustment. These errors sometimes occur in the same instrument, it being not uncommon to find a voltmeter correct at one portion of the scale and incorrect at another, or that has different degrees of error in different parts of the scale.

2. The impedance voltage of a transformer is the voltage that must be applied to the primary coil to produce full-load current in both coils when the secondary is short-circuited. To determine it, cut out the transformer, short-circuit its secondary, then connect in series with the primary an ammeter and a variable rheostat of sufficient resistance to cut down the low-tension voltage to about two per cent. of the primary voltage and of sufficient carrying capacity to carry the full-load primary current. Adjust this resistance to a maximum and then connect this primary circuit across the low-tension mains. Gradually decrease the resistance till the full-load current is indicated on the ammeter, and then measure the potential difference over the primary with a voltmeter, this reading being the desired value.

3. A technical definition of a two-phase system is the following: A two-phase system is a network of conductors which has two distinct electrical circuits receiving current from the same alternating-current generators, or from several generators connected in parallel, the electromotive forces of the two circuits being practically 90 degrees out of phase. To understand the phase relation more clearly it must be remembered that an alternating current goes through four changes in every complete cycle or period: (a) An increase from zero to maximum in one direction; (b) a decrease back to zero; (c) an increase from zero to maximum in the reversed direction; (d) a decrease back again to zero. Each complete cycle being regarded as 360 degrees, each one of these quarter periods is 90 degrees. In the two circuits of a two-phase system, therefore, the electromotive force of one is always a quarter period, or 90 degrees, ahead of the other, and since the two do not rise and fall in unison or phase, they are said to be 90 degrees out of phase.

York Haven Plant to Double Its Capacity.

That sufficient electric current may be generated to more fully meet the demand for its product, the York Haven (Pa.) Water and Power Company, as originally proposed, is doubling the capacity of its plant. Within the next year 10 additional turbines will be erected in an addition to be built to the present power house, which will give the company a supply of 20,000 horsepower for the market. E. F. Baker, general manager of the company, says that all the electricity generated at the York Haven plant is being used and that during October and November the plant will have an output of more than 10,000 horsepower. At present the company is supplying current for lighting and power purposes in several counties in Southern Pennsylvania. Its product is being used for street lighting and 85 per cent. of the industrial operations in York, and the running of trolley cars in the county; street lighting of Harrisburg; street lighting and operation of manufactories in Middletown; street lighting of Carlisle and other Cumberland Valley towns and the operation of the lines of the Valley Traction company and street lighting in Steelton and 1,500 horsepower for the operation of the Pennsylvania steel plant in that borough.

A 12,000-Miles Wireless Message.

A news dispatch from Sydney, N. S., states that while the engineers were testing several new receiving cones on the tops of the towers of the Marconi station at Port Morien on the most easterly point of Cape Breton, on October 7th, the operator in the room below picked up a message that was sent from Manila in the Philippine Islands, nearly 12,000 miles away, or practically half way around the world. The message said to have been received was that the American cruiser Philadelphia had arrived there with all on board well.

At the time experiments were being made to perfect means for receiving messages from Ireland. Several were received, when suddenly the Philippine message was picked up. The Marconi experts say there is no doubt the message was sent by the Manila station and that their instruments must have been perfectly in tune with those at that remote point.

This forms a new and most wonderful record, if the reports are true. About a fortnight ago the station at Savannah, Ga., reported a communication it had received from a warship cruising in the Pacific Ocean about 4,000 miles distant.

Another Power Project on the Susquehanna.

The Conawingo Electric Company, with charter rights to dam the Susquehanna River at Conawingo, eight miles from Havre de Grace, Pa., is said to be getting ready to build a new power plant with 100,000 horsepower capacity to rival the McCall's Ferry power plant. The object is to transmit power to Baltimore, Philadelphia, Wilmington and perhaps to New York city. It is proposed to construct the power house on the Hartford County side of the river, the same as the York Haven Water and Power Company's plant. The dam, it is said, will be about the same height as the McCall's Ferry dam and will back the water as far as Peachbottom, a few miles below McCall's Ferry. If this is the case, the Susquehanna River from Chesapeake Bay to York Furnace will be navigable.

Fall Meeting of American Electrochemical Society.

The fall meeting of the American Electrochemical Society will be held at the Chemists' Club, 108 West Fifty-fifth Street, New York city, on October 17th, 18th and 19th. In addition to the programme of papers there will be a lecture by Dr. George F. Kunz on "The Diamond and Moissanite," a subscription dinner on Friday evening and excursions to Mr. Edison's laboratories and to the Long Island City power house of the Pennsylvania Railroad and other points of interest.

Factory Lighting.

By A. P. Biggs

From a standpoint of illumination, the lighting of factories may be divided into space and applied lighting. For general space and floor lighting there must be some large source of artificial light, and the sources now available are the electric and gas arcs, the Cooper Hewitt and Nernst lamps. The incandescent lamp in large sizes is still inefficient as compared with these others, and in ordinary sizes does not give the illumination necessary.

An arc requires minimum cost for installation; has the greatest efficiency per watt expenditure and lowest maintenance cost. The unsteadiness of an arc is not serious in space lighting, and while the shadows from a single arc are apt to be annoying, the arc on the whole is the best unit for such work as above noted.

The Nernst lamp is desirable in small space lighting, in low-ceiling machine shops and in foundries. In one instance a complete installation of Nernst lamps is giving excellent results. The lamps are spaced from 8 to 10 feet apart at a standard height of nine feet. The light is soft and pleasant, and current consumption low.

For particular application of artificial light, single incandescents are the sources used. Although the installation of a lamp at each machine in every kind of business is not sanctioned by all illuminating engineers, it has the sanction of custom, the recommendation of the wiring contractor, and enjoys the hearty endorsement of those responsible for getting the same amount of work out of the machine by artificial light as is expected by daylight.

In a shop having low ceilings and much window surface, illumination may be good from natural sources for the first six months or so, but after that, by continuous process, the windows, ceilings, walls, posts and everything blacken and cease to let in or to reflect any light. The lighting installation fares the same way, and the workman shades his eyes by covering the lamps with anything available, until there is almost no light available.

An example of shop practice with individual lights—uncommon because definite data accompanies it—was presented by Mr. George C. Keech, before Chicago section of Illuminating Engineering Society in May last. A bare lamp, 13 inches above face plate of drill press, and seven inches from center, gave 3.7 foot candles at center of face plates. The dirtiest lamp in the shop when substituted, gave 1.55 foot candles, while a new clean lamp in the socket gave 5.7 candles.

When the customer gives us the opportunity of making recommendations upon his equipment, we generally advise him to place at every machine a drop or bracket light with reflector, and that he use eight-candlepower lamps wherever possible. Often, to satisfy the customer that the efficiencies and economies pointed out are worth securing, we loan him a half a dozen styles of shades and reflectors, and he purchases when he has determined the kind most suitable. Further—and here the policy of the company may seem heretical—space lighting is often disposed of by advising and urging the use of gas arcs. All possible short-hour burning is turned over to the gas company, and the electric-light company is relieved from the "lighting-bill' complaint, which formerly afflicted us for several months each winter. As this policy results from our differential rates, its presentation may be comforting only to those who make high prices per kilowatt-hour for lights burned but few hours per year; unless the "Flat-rate" man wishes to mend his way.

The usual factory lighting can be considered by central-station men as none other than unprofitable business, which is to an extent a necessary evil. By reason of its character, the brute requires all of the attention and all of the equipment which more respectable branches of the industry necessitate, but refuses to make adequate return on the investment and work to supply its need.

The assumption is not to be made that the Detroit company is securing proper and adequate return for its service in this branch of lighting. The company has certain rates and is, as a public-service corporation, required to furnish and does furnish service for all customers. Further, it is needful that this unprofitable business have a fairly low rate in order that we get the profitable business that goes with it.

The rates at which this class of lighting is sold in Detroit are as follows:

First—Open Order—60 hours' use per month of the demand at 16 cents per unit, balance at 4 cents per unit. This agreement is not a contract, having no definite term.

Second—Demand Contract—30 hours' use per month at 16 cents per unit, balance at 4 cents per unit; minimum bill 30 hours' use per month of maximum demand at 16 cents; term, one year.

1. Paper read at the Toledo convention of the Ohio Electric Light Association on August 21st. The author is with the Edison Illuminating Company of Detroit, Mich.

The following discounts for prompt payment are allowed on both agreements:

On bills less than $50, 10 per cent

On bills $50 and less than $100, 15 per cent

On bills $100 or more, 20 per cent.

Under "Open Order" we furnish standard incandescent lamps and renewals and will trim and care for arcs and Nernsts owned by the customers. Under "Demand" we furnish all incandescents, arcs, Nernsts, renewal and maintenance.

The "Open Order" is the most common prescription for factory lighting. It cares for that class of customers whom we all term "Short Hour," who use our service as auxiliary to sunlight and daylight; who have a few places which, due to poor construction of building, blackened windows, or later construction by their neighbors, need light occasionally during the day, but whose principal service is from dusk to 5:30 p. m., and who either cannot or will not make, nor pay us for making, the investment necessary for good lighting.

The "Demand Contract" is suited to the lighting conditions of but a small portion of factories, inasmuch as it is designed for satisfaction of long-hour burners. The factory whose conditions are met by it is probably one in which there is a requirement for a large number of individual lights, and for small lights in isolated parts of the factory, for which there is necessity for service all through the day.

To illustrate that under our rates factory lighting is unprofitable to us, the following cases have been figured to show cost to consumer under "Open Order" and under "Demand Contract," and the amount the business should have brought in in order that it might just begin to be profitable, the later amount being arrived at as fixed charge per kilowatt-year plus operating costs per kilowatt-hour:

		Connected	Demand	Earnings	Income per Year	
					Demand	Minimum
	Kwh.	Kw.	Kw.	Open Order.	Contract.	Allowable.
1...	4330	29.0	12.0	$ 552.00	$ 632.00	$ 780.00
2...	8163	36.6	13.5	916.00	815.65	973.89
3...	1800	5.6	2.2	220.00	157.00	172.30
4...	6850	30.6	22.2	884.00	1,061.70	1,410.80
5...	10410	26.3	17.6	1,168.70	875.80	1,262.80
6...	3052	16.6	9.16	416.70	492.93	500.40
7...	1644	5.1	2.81	226.72	170.25	201.10

Nos. 1, 2, 3, 4, 5—On open order, 60 hours' use of the demand.
No............ 6—On demand contract.
No............ 7—On open order, 60 hours' use of connected load.

The first three calculations are for a customer, carriage manufacturer, in successive stages of his business. For two years he did all his lighting by clusters; at the end of that time, by reconstruction of building, the electric lighting was reduced from 13 kilowatt Demand to two kilowatts, and all general floor lighting was done by gas arcs. Only in this third year, after the changes had been made which took from us the pleasure of serving 650 lamps, did we make any profit on the business.

The fourth and fifth calculations are successive years in a cigar factory—a six-story building lighted throughout by incandescents. At the end of the first year given, the customer was persuaded to change 300 individual lights from 16 candlepower bare, to eight candlepower lamps with reflectors. Demand was reset and he was billed upon 60 hours' use by its readings—as he was an Open Order customer. He saved considerable, and we only lost 10 per cent. on the lighting business, against 60 per cent. the year before. His power business in the last year amounted to 30,800 kilowatt-hours, with a demand of 11.6 kilowatts.

The sixth is a manufacturer of shirtwaists, skirts, etc.; has all electric equipment, using electric arcs for general floor lighting. His lighting business, which was on demand contract, lost us but eight dollars. During this year we had the profit from sale of 20,000 kilowatt-hours for power, with demand of 8.5 kilowatts.

The seventh, which is a bathtub factory, has space of 20,000 square feet—has woodworking, sheet-metal and brass-foundry departments. For space lighting gas arcs are used, and the business gave us some respectable return.

As a public-service corporation having established rates we must sell at these rates whether the customer causes us to lose on service, or brings us revenue from it. We tell customers that by our experience his lighting will be cheapest for him, say, on demand, but inform him that there are so many conditions of surroundings, location of lights, faults of building design, amount of natural lighting, etc., that he must fix his conditions and try it out for himself. Usually we install such services on Open Order. If we find later that the Demand Contract rate will be to the customer's advantage, we offer it to him.

Our rates are based on customer's demand even when the Open Order is taken. If demand is same as connected load, and the customer signs the Open Order, we will bill him at 60 hours' use of the connected load at 16 cents.

If his installation is greater than his demand, we install demand indicators and bill on showing of indicators.

If he has many empty sockets in his installation, we install demand indicators, and probably bill on connected load until demand shows that customer has fitted empty sockets with foreign lamps and would have us continue to bill him without increasing his rate.

By the same method of figuring as used above, a business begins to be profitable to us when the customer has paid for 480 hours' use of demand per year at 16 cents, say 40 hours per month. As an approximation to get at classification of business as profitable or unprofitable, the consumption of current per year of factories as found in several customers' ledger accounts has been divided by 12 times demand, giving hours' use of demand per month. All of these factories are operating on a regular 10 hour day.

Number of Cases.		Average Hours' Use of Demand per mo.	
5	Bakeries, wholesale	107	
8	Brass Works	57	
2	Breweries	85	
2	Brush	12	
4	Candy	51	
3	Chemical	10	
7	Cigar	29	
9	Clothing	37	(5 cases average 11.9)
3	Engravers	70	
3	Harness	35	(2 cases average 11.9)
1	Knitting	9	
14	Machine Shops	31	(7 cases average 13.4)
3	Paper Box	13	
4	Printing	20	
8	Sheet and Metal	18	
3	Shoes	33	(2 cases average 13.7)
2	Toys	31	
1	Upholstering	4	
1	Wire Works	12	
6	Woodworking	24	(4 cases average 11.10)

From their nature, several kinds of business are invariably profitable. The wholesale bakers use some lighting for 24 hours per day. Breweries have a good bit of small power about their establishments which is shut down about 4 p. m. and the lighting load up to that time continues quite uniform throughout, making their lighting demand negligible.

Machine shops and brass works need electric light for individual machines only, and give a good lighting load summer and winter. The clothing manufacturer, whose record makes the best showing of his class—to our way of thinking—in the above list, has on each machine a movable arm carrying lamp of low candlepower with parabolic reflector, permitting operator to bring source of light close to work without unpleasant effect on eyes; all his space lighting is by gas arcs.

We persuaded one customer operating a brass foundry to put in gas arcs for all lighting, and further satisfied him that, with little hardship, his air compressor could be shut down in the afternoon at such times as would prevent any increase of total load due to shop lighting. As a matter of general policy, in addition to giving other advice, we recommend to the manufacturer that a fraction of the amount spent this last year for lighting, be turned over to a window cleaner and a man with a hand pump and a tank of whitewash; expecting that both of us will then be better satisfied with his factory lighting.

Our conclusions then are: That an electric-light company cannot afford to take on all factory lighting offered to it; that it is obliged to take a certain amount which is inherently unprofitable: that it should minimize this amount by (first) advising the customer how to reduce his demand by utilizing light to best advantage—that is to say, by good illuminating engineering; (second) advocating the transfer to daylight hours of any power load that can be dispensed with during the evening hours, and (third) by passing over to the gas company such factory space lighting as can be profitably furnished by gas arcs, retaining for electricity the long-hour localized lighting.

It is worth while to note that the new metal filament incandescents may modify these conclusions. They will not change the rates of demand to sales, but they may make gas so comparatively expensive as to put it out of competition either partially or altogether.

Vermont Electrical Association.

The sixth annual convention of the Vermont Electrical Association was held on September 18th and 19th at Paige's Hall, St. Albans, Vt. The meetings were well attended and the papers read evoked much interest. Among these were the following: "Heating," by James I. Ayer of Boston, Mass.; "Notes of a Layman on Electricity and Its Allied Forces," by E. L. Bates of Bennington, Vt.; "Rates and Systems of Charging," by J. S. Codman of Boston, Mass.; "Modern Illumination," by V. R. Lansingh of New York city.

The following-named gentlemen were elected as the officers for the coming year: President, E. E. Larrabee, Bennington, Vt.; first vice-president, Frank H. Parker, Burlington; second vice-president, J. E. Davidson, Montpelier; secretary and treasurer, C. C. Wells, Middlebury.

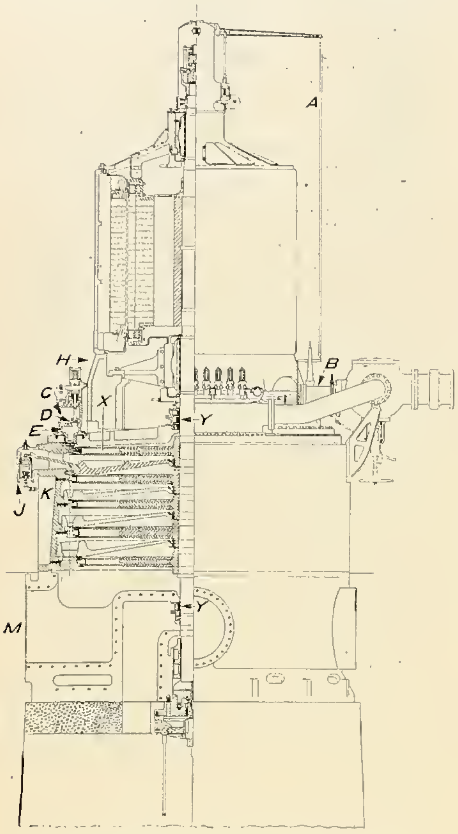
An enthusiastic meeting and banquet of the Vermont section of the Sons of Jove was held in connection with the convention, at which 22 new members were initiated. An inspection trip was made to the power plant of the Vermont Power and Manufacturing Company at Fairfax Falls.

Curtis Steam Turbine-generator.

Although now widely used and well known in this country, a brief general description of a large Curtis steam turbine-generator, taken from a handsome bulletin issued by the General Electric Company, will be of interest. The half cross section of a 9,000-kilowatt unit shown herewith illustrates the simplicity, rigidity and beautiful mechanical proportions of this type of unit.

The turbine-generator set may be considered conveniently in four parts: First, the governor; second, the generator; third, the turbine proper; and fourth, the exhaust base.

The governor is of the centrifugal type and transmits its motion through the connecting rod (A) to the hydraulic cylinder (B), which controls the



HALF CROSS SECTION OF A 9,000-KILOWATT CURTIS TURBINE-GENERATOR.

valves. The steam chest (C) is connected to the main steam pipe, and steam is admitted by the raising of the main valves (D), through the passage (E) into the first stage nozzles.

Steam passes through the first row of revolving buckets, then through a set of intermediate buckets (X), then through the second row of moving buckets on the first stage wheel and in the same manner through the nozzles and buckets of five stages in succession. It will be noticed that the buckets and nozzles increase rapidly in size in succeeding stages as the pressure falls and the volume of steam increases. The parts are so proportioned that the steam gives up approximately one-fifth of its energy in each of the five stages.

The stator, or generator frame, completely encloses the generator, thus insuring noiseless action and at the same time providing for a vigorous and positive ventilation. The generator is mounted on the base (H), which is bolted to the turbine casing.

The turbine shown is of the five-stage type and exhausts into the base and through the opening (M) into the condenser. The method of mounting the revolving wheels on the shaft and their relative position in each stage are indicated; also the method of supporting the diaphragm or cast-iron separating pieces which form the divisions between the different stages. The step-bearing is outside the base, but belted it, as shown.

The intermediate bearing is supported by a spider at the bottom of the generator, the upper bearing by the shield which covers the generator.

The automatic stage valve (J) connects the first stage directly to a set of auxiliary second-stage nozzles. Thus the overload capacity is increased, not by admitting high-pressure steam into an intermediate stage with corresponding reduction in efficiency, but by widening the steam belt. The space (K) is filled up with lagging and covered with sheet-steel casing, thus giving the turbine a finished and compact appearance.

Since the pressure on each side of the rotating wheels is the same, it will be seen that no special provision is required to neutralize steam thrust. The fact that there is no necessity for a complicated arrangement of balance rings, which occasion heavy and variable leakage losses, constitutes one of the most important advantages of this type.

Air and steam leakage are prevented by the carbon packing rings shown at (Y), and these rings are practically frictionless, since there is no pressure of carbon on the shaft and since the action of carbon on steel produces a highly polished surface without tendency to cutting or friction.

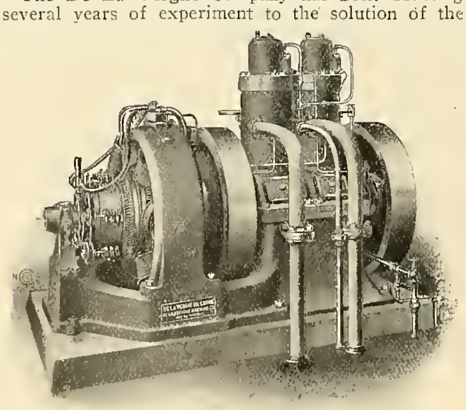
The chief advantage asserted for the Curtis steam turbine is high efficiency at all loads. Other important advantages are simplicity, moderate initial cost, economy of space, low cost of maintenance, economy in foundations, absence of oil in condensed water, minimum labor and skill required in attendance, etc.

Generators used with these turbines are of the revolving-field type, and the rotor is so designed that it acts as a powerful impeller, which forces a large volume of air definitely into the parts of the generator structure requiring ventilation. A copious supply of clean, dry air at as low a temperature as possible is required. This air is taken into the generator generally through a single opening, and is discharged after it has circulated through the magnetic cores and windings. The outside casing of the stator is a closed casting which serves to deaden sounds which may be occasioned by movements of air in the machine, and at the same time does not prevent proper flow of air to all parts which it should reach. The air-impelling force of the rotor is so definite that the air supply can be drawn through a pipe from some outside source, which is generally desirable in order to secure cool air. The method of ventilation employed with these generators has a practical advantage in that it is practically noiseless.

A New Vertical Kerosene Oil Engine.

Kerosene oil engines are not known as well as gas and gasoline engines, although they have been on the market for over 15 years. A type which has been frequently referred to is the "Hornsby-Akroyd," a heavy slow-speed machine, operating on the four-stroke cycle, single-acting, horizontal, built by the De La Vergne Machine Company, New York, in sizes up to 250 horsepower. While this engine is with great success applied to all kinds of stationary and even portable work, there is a demand for a lighter, faster and vertical engine for use for marine purposes and for driving direct-connected high-speed electric generators, fans, centrifugal pumps, etc.

The De La Vergne Company has been devoting several years of experiment to the solution of the



15-HORSEPOWER KEROSENE OIL ENGINE DIRECTLY CONNECTED TO A 10-KILOWATT GENERATOR.

problem, and now, that a number of engines have been operating satisfactorily for many months, at various kinds of work, it has been decided to manufacture the engine as now perfected. This engine is especially designed for the use of ordinary kerosene or fuel oil, obtainable anywhere, and not for gas or gasoline, thus eliminating danger of accidents.

Granted that the oil engine consumes the same weight of fuel per brake horsepower per hour as the gasoline engine, namely, about nine-tenths of a pound, the company says that one gallon of oil will develop $6.7 \div 0.9 = 7.44$ B. H. P. for one hour, while one gallon of gasoline will develop $5.8 \div 0.9 = 6.44$ B. H. P. for one hour. The relative market prices are at present 10 cents and 17.5 cents, respectively; consequently one horsepower-hour costs, with oil, $10 \div 7.44 = 1.34$ cents, and with gasoline, $17.5 \div 6.44 = 2.72$ cents—or fully twice as much. With fuel oil, the cost is lower still.

The accompanying illustration shows a twin-cylinder De La Vergne engine which operates on the two-stroke cycle, and is single-acting; hence the crank-shaft receives in each revolution two impulses, causing the engine to run much steadier than a four-cycle engine. The chief characteristic is the absence of an electric igniter. This, together with the usual batteries or other sparking devices, and the mixing valve, eliminates much trouble, because it requires skill to keep these things in proper working order. Similar to the "Hornsby-Akroyd," the cylinder head is shaped as a bulb and kept hot enough by the successive explosions to ignite the combustible mixture. This bulb or vaporizer is made of gun iron, heated up at the start by a kerosene blow lamp.

Preignitions, which cause a great deal of annoyance and loss of power, cannot occur in this engine, for on the up-stroke there is nothing but air in the cylinder which has entered under slight pressure from the enclosed crank case through the port. Just as the piston is reversing its motion, and not before, oil is sprayed into the vaporizer by the nozzle. The heat of the walls of the vaporizer and the hot air resulting from the high compression, at once vaporize the oil and burn it rapidly, thus giving the descending piston an impulse. Just before the end of the down-stroke, the exhaust port is uncovered by the piston to let the burnt gases escape to the atmosphere. No exhaust valve is required.

It is, of course, necessary that the oil be forced into the vaporizer suddenly, at the right time and in quantity to suit the load on the engine. This is accomplished by a small plunger pump which is under the control of an ingenious and simple throttling governor fastened to and revolving with the flywheel. A centrifugal crank-pin oil ring is turned out from the solid of each crank, and with a straight oil hole so disposed that it is always kept clear by the action of centrifugal force. All oil cups have been eliminated, oil being supplied to the cylinders and all bearings, except, of course, the wrist pin, from one forced feed central oiler actuated from the crank-shaft. After the oil reservoir is filled for the day, oiling requires no more attention.

The lower half of the crank case of a twin-cylinder engine is water-cooled. A small rotary pump driven by spur gear on the shaft circulates the water first through this crank case and around to the three bearings; then through the two cylinders and heads around the spray nozzle. This cooling prevents heating of the air aspirated into the crank case and keeps down the temperature of the lubricating oil and that of the bearings. The two outer shaft bearings and the lower half of the center bearing are carefully lined with special bearing metal. The upper half of the center bearing is of phosphor bronze; it unites the two cylinders and makes the joint air-tight.

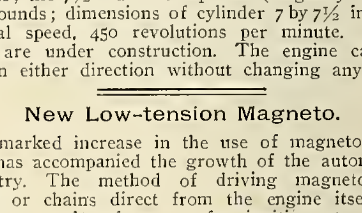
The 15-horsepower engine weighs complete 1,180 pounds; the 7½-brake-horsepower (single cylinder), 750 pounds; dimensions of cylinder 7 by 7½ inches; normal speed, 450 revolutions per minute. Other sizes are under construction. The engine can be run in either direction without changing any part.

New Low-tension Magneto.

A marked increase in the use of magneto ignition has accompanied the growth of the automobile industry. The method of driving magnetos by gears or chains direct from the engine itself insures a supply of energy for ignition at correct and regular intervals. The magneto is simple and eliminates complicated wiring with the attendant dangers of short-circuits, and avoids the use of vibrating spark coils and batteries.

The General Electric Company has recently developed a magneto which is said to embody the most desirable features of construction as determined from its past experiences in other lines of work. This magneto is of the low-tension type and differs mechanically in many respects from other machines on the market at the present time. The general construction is most substantial and without superfluous trimmings. The general appearance of this magneto is shown in the accompanying illustration.

A number of especially desirable features are noticeable in the construction of the armature. One end of the armature winding is brought out through the hollow shafting by means of a steel conductor. The insulation bushing between the shaft and this conductor is of bone, and is there-



NEW LOW-TENSION MAGNETO.

fore little affected by moisture or light. The current is carried from the steel conductor by means of a phosphor-bronze spiral spring to the lever nut which forms the outside terminal, thus avoiding any loose contacts. A hard-rubber cover screwed to the bearing carries the contact with all its parts. This cover is provided with a knurled exterior. The grounded side of the armature winding is firmly fastened to the core, and a carbon brush insures good contact between armature winding and frame or ground.

The magnets are of the double type, sprung on the frame and secured by one screw on each side, thus minimizing the detrimental effect of drilling the magnets.

The design of the armature allows generous insulation and also permits two other important advantages. With this magneto an open-circuit voltage of over 100 volts is easily obtained, while a short-circuit current of approximately 0.4 ampere is available. In order to secure this high short-circuit current the resistance of the armature winding is as low as possible, while the number of turns is sufficiently high to give an adequate open-circuit voltage.

The Ward Leonard Motor-starting Rheostats.

In the April, 1907, "List of Electrical Fittings that have been Examined and Approved by the Underwriters' National Electric Association," page 30, certain types of motor-starting rheostats made by the Ward Leonard Electric Company of Bronxville, N. Y., are specifically enumerated as in compliance with the National Electrical Code after testing. As the subject of motor-controlling rheostats is just now exciting much attention among electrical men, it will be worth while to consider

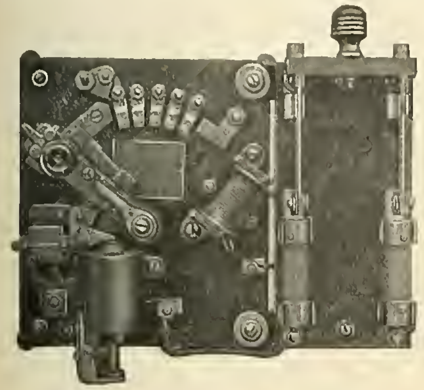


FIG. 1. MOTOR-STARTING RHEOSTAT.

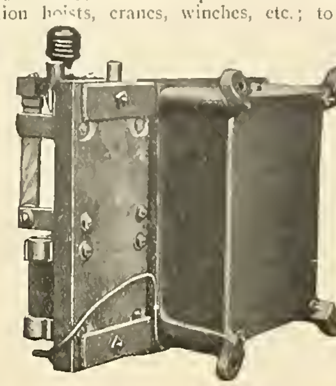

FIG. 2. BACK VIEW OF MOTOR-STARTING RHEOSTAT.

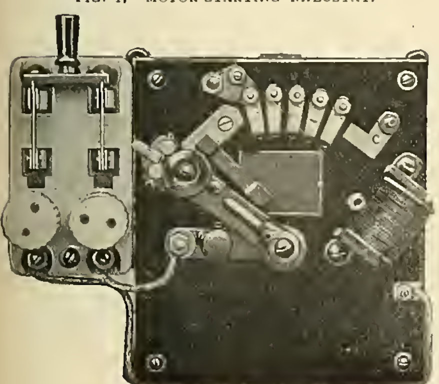

FIG. 3. NO-VOLTAGE RELEASE STARTER.—THREE-HORSEPOWER, 220 VOLTS.

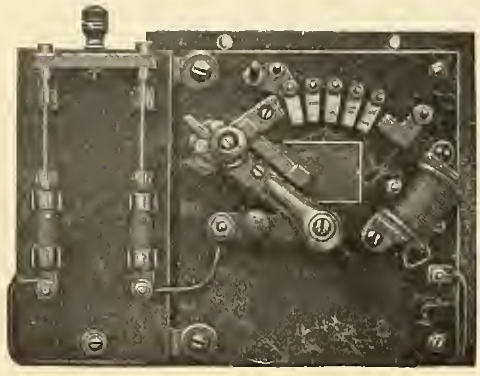

FIG. 4. NO-VOLTAGE RELEASE STARTER WITH BACK MOUNTING OF SLATE.

the advantages the manufacturer asserts as characteristic of these devices.

For one thing, it is declared that no other motor starter on the market gives the same protection afforded by this one. For protection against overload due to starting too rapidly these starters have a circuit-breaker as a part of the starter, and this circuit-breaker can be set at any predetermined amperes from one-half load to 50, 100 or 200 per cent. overloads, or higher. For protection against closing the circuit-breaker upon short-circuit or overload, and holding the breaker closed till damage occurs, the circuit-breaker is functionally related with the no-voltage arm in such a manner that it is impossible to close the overload switch except when the no-voltage arm is in a protective position. Overload protection during the period of starting the motor as well as at all other times is positively assured.

The rheostat is "universal," first, because it can be used to start any known type of direct-current motor, whether shunt-wound, series-wound, separately excited, or any other known type, allowing speed control by field regulation. Second, because it is equipped with switch and fuses, making it a complete outfit ready for mounting. Third, because it has a capacity for one-minute starting duty. It is the intention of the manufacturer to place this apparatus upon the market at such a low price that it will be found more profitable to install than a separate switch, fuses and rheostat wiring, etc. In sizes below those requiring 25-ampere fuses a porcelain base combined switch and fuses (approved) is used. In larger sizes approved plain finished switches and approved fuses are used.

Fig. 1 shows this motor starter. Fig. 2 shows the back of the rheostat, showing the method of attaching the switch and fuses. Fig. 3 shows a plain no-voltage release starter of three-horsepower, 220-volt size. Fig. 4 shows a no-voltage release starter equipped with back mounting of slate.

Electrical Equipment of New Battleships.

The General Electric Company has received orders for the electrical equipment of the two new battleships, No. 28 and No. 29. The former is to be built by the Newport News Ship Building Company, and the latter is in course of construction in the Fore River Ship Building Yards at Boston, Mass. These are the two largest war vessels ever built in this country, and a notable feature of No. 29 is that it is the first battleship to be propelled by turbine engines. These are of the Curtis type and have a capacity of approximately 25,000 horsepower. The one set of turbines can be used for both high speed and cruising. In addition to this advantage and the attendant economy in space and weight, the absence of reciprocating parts and consequent vibration and strains is expected to make this battleship the speediest in the navy.

Four 300-kilowatt Curtis turbo-generating sets will be installed on each ship to supply the lighting circuits and furnish power for about 100 motors, varying in size from two to 75 horsepower. These motors will be used to operate the turrets, ammunition hoists, cranes, winches, etc.; to run the forced draft and the hull ventilation fans, and to supply power to the laundry and workshops. The vessels will be equipped with four 36-inch and four 60-inch searchlights.

Steam-turbine Demonstration by United States Navy.

Turbine ships have been in use by the British naval authorities for some time, beginning with the diminutive turbine launch "Turbinia," which appeared first at Queen Victoria's Diamond Jubilee naval review at Spithead in 1897, uninvited, and proceeded to attract the attention of the British Admiralty to the novel type of propelling machinery installed in it by deliberately trespassing in and out between the lines of warships, thereby challenging the patrols, which were unable to come near, much less overtake the swift little craft. So convincing was the argument of the Parsons turbines that at the end of March, 1907, there were 14 turbine-driven warships completed for the British navy, aggregating 107,000 horsepower, and 49 building aggregating nearly four times that amount.

Now it is reported that the United States Naval Department will enter upon an interesting demonstration of the comparative merits of the steam turbine by the placing in commission of three similar scout ships, the Salem and Birmingham, being built by the Fore River Ship Building Company of Quincy, Mass., and the Chester by the Bath (Me.) Iron Works.

These boats are the same model, having similar boiler outfits and alike in every respect except that the Salem and the Chester will be equipped with two types of turbines, those of the Chester being Parsons type, similar to that built by Allis-Chalmers Company, Milwaukee, and the Birmingham with reciprocating engines.

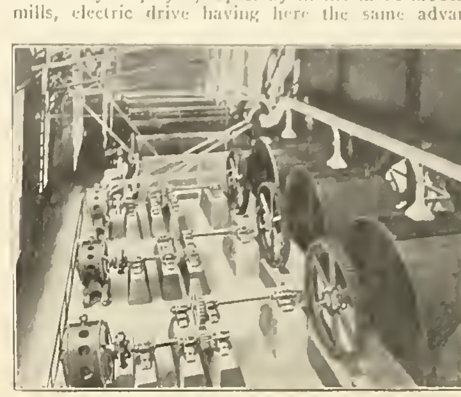
The horsepower of each vessel being 16,000, the Chester will have four shafts with a high and low pressure Parsons turbine upon each of two of these and a cruising turbine upon each of the other two.

The comparative performance of these trial vessels will naturally be watched with interest.

Electric Motors for Cement Mills.

By R. B. Williamson.

For driving the various machines used throughout a cement mill, electric motors are now almost universally employed, especially in the more modern mills, electric drive having here the same advan-



INDUCTION MOTORS DRIVING BALL MILLS.

tages of flexibility and economy that have been demonstrated in so many other lines of work. The elimination of belting and countershafting is specially desirable in a cement mill, where the gritty dust makes the maintenance of both belts and bearings expensive.

In some mills, particularly those located in the West, power is purchased from transmission companies, but usually each mill is provided with a steam plant of its own. In either case the alternating-current system is almost invariably used in modern installations, and it may be either 60 or 25 cycles, two or three-phase. Although direct current has been used in a few cases, the present practice is to use alternating-current motors almost exclusively for this class of work. The polyphase induction motor has many advantages, not the least of which is the absence of commutator and brushes. The cost of maintenance is less than for direct-current machines, and in the dusty atmosphere of a cement mill, the simple "squirrel-cage" rotor of an induction motor is much less liable to give trouble than the wound armature of a direct-current machine.

In these mills the motors are used for operating rock crushers, ball mills, tube mills, rotary kilns, hoists, conveyors, pumps, etc.; in fact, for all the machines used throughout a modern cement plant. In most instances the motors are run at or near full load continuously, and the service as a whole is especially severe. In nearly all cases they are of the squirrel-cage type, with short-circuited secondary—a type that necessarily operates at constant speed. For variable-speed work the induction motors are provided with a wound rotor connected through collector rings and brushes to an external resistance. By this means the speed can be varied at the expense of lower efficiency. However, collector rings and brushes are undesirable features when exposed to cement dust, and these motors are used as little as possible; they are installed occasionally for operating rotary kilns, where a variation in speed is sometimes desirable, and also for electric hoists; but for practically all other classes of work constant-speed squirrel-cage motors are preferred.

Probably the most severe service is that demanded of motors for running ball and tube mills. These mills are used for grinding the raw material before calcining, and also the clinker from the rotary kilns. For driving the ordinary sized ball mill a 50-horsepower motor is required, while for a 5 by 22-foot tube mill a 75-horsepower motor is usually installed; a 5½ by 22-foot tube mill requires about 95 horsepower, and a 6 by 22-foot, 115 horsepower; the 5 by 22-foot mill is the size generally used.

Ball and tube mills, especially the latter, are difficult to start. The material clings to the sides of the mill, particularly in the tube mill, where pebbles are used to effect the grinding, and at starting the whole mass has to be swung up until the first half revolution has been made. This demands heavy starting torque, usually amounting to 1½ to 2 times full-load torque. It is desirable, therefore, to use for these mills a motor having starting torque higher than for ordinary service. If this is not done, the motor will take an excessive current at starting, or, if the voltage drops to any great extent, the motor may even fail to start the mill at all. Motors for this service must be of liberal size to give the requisite starting torque, and also operate continuously at full load in a dusty atmosphere without undue rise in temperature. It must be remembered that in cement mills the fine dust gets into the ventilating passages in the motor, and they may in time become clogged up, thus materially increasing the temperature rise.

The starting apparatus used with these motors must also be of liberal design in order to carry heavy starting currents. Sometimes the mills are started by throwing the current off and on, giving them two or three swings until they finally turn over. This is especially hard on the stator, and should not be necessary if the motor has ample starting torque. All starters have oil-immersed switches for changing the connections from "starting" to "running," and transformers are provided so that a reduced voltage can be applied to the motor at starting, thus reducing the current taken from the line. For this severe starting service, where the motors are frequently operated by an unskilled class of help, the starters can be fitted with a device that prevents the handle from being left on a starting position; if left on a starting position it at once returns to the off position, thereby preventing a burnout of the starter.

Motors for operating these mills are usually belted and run at moderate or slow speed. On 60 cycles, 50-horsepower motors running at approximately 850 revolutions per minute full load have been used for ball mills, but a slower speed motor is more desirable, and 670-revolutions-per-minute machines are now recommended. On 25 cycles, four-pole motors running at approximately 700 revolutions per minute full load are used.

For 5 by 22-foot tube mills a 75-horsepower motor running at 670 full load on 60 cycles is suitable, while on 25 cycles speeds of 700 revolutions per minute or 470 revolutions per minute are available, the latter being preferred. Motors are belted directly to the main driving shaft on the mill, from which the latter is driven through spur gearings.

As regards voltage and frequency, the majority of cement mills are operated on 440 or 550 volts and frequencies of 60 or 25 cycles. Although there are instances where 2,200-volt motors have been used, the lower voltages are preferable on account of the greater security of the insulation on the motors and greater safety in working around them. There does not appear to be any settled practice as regards frequency, either 60 or 25 cycles giving satisfactory results; in many cases the frequency is fixed by that of the transmission system from which power is obtained, and most plants supplied from such systems are operated at 50 or 60 cycles.

As regards mechanical features, it is important that the bearing sleeves be arranged so that they can readily be removed and relined. All bearings are made as dustproof as possible by means of felt dust guards, and journals are of liberal dimensions.

The accompanying picture of induction motors driving ball mills is from a photograph taken in one of the numerous cement mills in which the complete equipment was built and installed by the Allis-Chalmers Company of Milwaukee.

Electrical Equipment of New County Building, Chicago.

Now nearly completed, the large new County Building at Randolph, Clark and Washington streets, Chicago, is one of the imposing structures of the city. It contains 40 court rooms and is 374 feet long, 157 feet wide and 205 feet high. The machinery room, as noted in an article in the Wire Market News, is centrally located in the basement, and from this point conduits and wires radiate into every remote corner for the operation of 15,000 lights and 1,000 horsepower in motors. The power plant includes 16 ventilating and miscellaneous motors in attic; five ventilating fans, 15 elevators, two high-duty fire pumps, two house pumps, one drinking-water pump and one pneumatic-tube motor in basement; one stoker, three ash-handling machinery, two ejector sets and two emergency pump motors in sub-basement. All necessary arrangements have been made for a generating plant, but for the present, current for this load will be taken from the Edison three-wire direct-current mains, which are now connected to a three-panel service board under the Clark Street sidewalk. Four separate sets of mains connect to this board from different generating stations of the power company, so that the supply can be shifted from one to another as emergency requires.

The main operating switchboard, erected and connected by the Arthur Frantzen Company, is a handsome 10-panel affair, built on white Italian marble slabs two inches thick and mounted on a substantial iron frame 25 feet long and seven feet high. There are four light-feeder, four power-feeder, one light-service and one power-service totalizing panels, which represents a remarkably flexible control of power from a single point in the engine room. The mains for lighting are carried in conduit through two vertical raceways, one on the north and the other on the south side of the elevator lobby. From the two centers on each floor submains are run to cabinets in their respective wings for control of wing lights. Fifty-two cabinets totaling 1,500 circuits are distributed throughout the building. The panels are built of white Italian marble with polished bus-bars, plug fuses and receptacles and represent a high class of workmanship.

Wiring Conditions in Kansas City.

The National Board of Fire Underwriters has made a full and interesting report on electrical conditions at Kansas City, Mo. By city ordinance, a city electrician, under the supervision of the superintendent of buildings, is given control over inside and outside electrical wiring. The city electrician is appointed by the mayor, subject to confirmation by the upper house of the Common Council, for the term of two years. He is required to be expert in the theory and practice of installing electrical wires and apparatus and to have had at least five years' practical experience. Mr. C. M. Caldwell, the city electrician, was appointed to his present position in February, 1900. He was inspector in the department for two years previous and is well qualified for his position. He is assisted by two inspectors and a clerk. He or his assistants examine all new inside work, making inspections during installation and on completion. Old work is inspected when in connection with new work and on special request; a systematic reinspection of a part of the business district is made each year during the slack time in the winter months. Outside work receives only a general supervision.

Notices, stating that the equipment is approved, are placed in prominent positions on each installation inspected and found to comply with the ordinances. These serve to notify lathers and others that the wiring may be concealed. Wiring concealed before inspection is condemned, and a red notice posted, but recourse to this is seldom necessary. A notice warning carpenters, plumbers, etc., from interfering with wires or placing anything within two inches of them, is also in use. Good records are kept of inspections and approvals. A small fee is charged for inspections.

A city ordinance, passed in January, 1903, requires that before any electrical wiring or apparatus is installed, altered or added to, an application must be made to and a permit obtained from the city electrician. It is the duty of the city electrician to inspect and examine thoroughly all electrical apparatus and devices, either upon the public streets and highways of the city, or within buildings, and to condemn all that, in his opinion, may be dangerous or improperly installed. Appeal may be made to a board, composed of the chief of the fire department, the superintendent of buildings and the city engineer; the decision of this board is final. It is unlawful to use electric current for light, heat or power before a certificate of electrical inspection has been granted by the city electrician, and service connections may not be made until a service permit has been obtained. The National Electrical Code, with some additions and slight changes, has been adopted as the standard.

Every person, firm or corporation owning or controlling electrical wires for the transmission of light, heat or power is required, at time of fire, to disconnect such wires as may be designated by the mayor, any officer of the fire department, or the city electrician or his deputies.

The city electrician is required to keep a full record of all permits, condemnations and inspections. Electrical contractors must secure a license, have an established place of business and satisfy the city electrician that they are competent to do electrical wiring; contractors are under a $5,000 bond to observe the city ordinances.

An ordinance passed in July, 1903, requires all overhead wires in the district bounded by the north line of Second, west line of Jefferson, south line of Eighteenth and east line of Forest to be placed underground within one year from the date of its passage. This ordinance also requires all overhead wires extending along or across the boulevards of the city to be placed underground.

In June, 1907, 25 new and 50 old representative inside installations were inspected by a National Board engineer to ascertain the quality of the new work being installed and the general condition of the old wiring. In the new work inspected a total of 95 defects was found, an average of 3.8 per equipment, showing a good installation. There were 20 different violations of the National Code, due to poor workmanship and the inspection department not insisting on a strict adherence to the Code in several particulars. Among the more prominent defects were: Fuses too large for the circuit; flexible cord too long; unapproved flexible cord for portables; wires not protected from mechanical injury; unapproved work at meter; rheostat or starting box not properly mounted, and no drip loop at service entrance.

In the old work inspected 395 defects of 92 different kinds were found, an average of 7.9 per equipment, indicating, according to the insurance interests, the need of a systematic reinspection of all old wiring. Besides those enumerated under new work, the following violations of the Code were noted in ten or more risks: Circuits overloaded; link-fuse cut-outs not standard; unapproved link fuses; unapproved flexible cord for pendants; joints not soldered and taped; wires in contact with or not properly separated from gas pipes or other metallic or conducting bodies; wires not properly supported; switches broken or in poor condition. Many other defects occur, but each only a few times. There are no series arc lights or other high-tension circuits in buildings.

As regards outside work, light and power wires are underground in a small section of the business district; telephone wires are largely underground, with pole distribution, and the wires of one telegraph company are partly underground; otherwise, all wires are overhead. There is no district which is entirely free from overhead wires, the underground ordinance not having been enforced. Overhead telephone and telegraph wires are on different poles from light and power wires. Overhead trolley wires are on practically all of the principal streets, and, with few exceptions, all of the car lines in the city pass through the congested-value district. Overhead light and power wires are double and triple-braided weatherproof, in fair to good condition, on poles 100 to 120 feet apart. Transformers are on poles or brick building walls. All overhead light and power circuits are protected by lightning arresters at the power house and at frequent intervals on the line. Overhead low-tension circuits are well protected with fuses and lightning arresters.

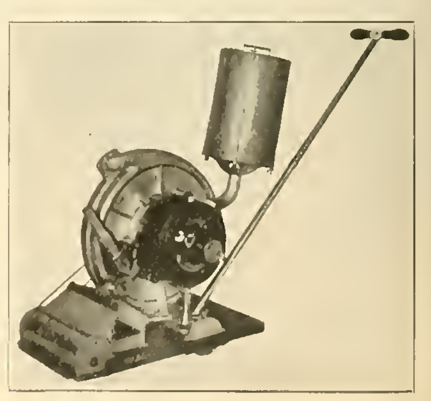
The Metropolitan Street Railway Company and the Kansas City Electric Light Company, which are practically one company, operate the street-railway service and furnish most of the electric light and power. The Edison three-wire direct-current system, 110-220 volts, is used exclusively in the congested-value district and adjacent territory. Three-phase, 2,300-volt alternating current, transformed to 104 volts at pole transformers, is used in outlying districts. A 500-volt direct-current power circuit is in use to a small extent, and a few motors are on the grounded street-railway circuit, it is said. Street-railway current is 575 volts direct current, with overhead trolley and ground return. Series street arc-light circuits are mainly under 5,000 volts alternating current; one circuit is 6,500 volts. Three-phase 6,600-volt alternating current is generated at two power houses and transmitted, mainly underground, to four substations, from which one or more of the above described currents are distributed. Several small plants supply current to individual buildings, generally 110 volts direct current. The following-named companies maintain low-tension or signalling systems: Kansas City Home Telephone Company, Missouri and Kansas Telephone Company, Western Union Telegraph Company, Postal Telegraph and Cable Company, Missouri District Telegraph Company and the municipal police signalling system.

The city electrical laws are good; the electrical electrolytic action and reports no trouble from this source other than an occasional breaking of a lead house service in the vicinity of the street-railway power stations. The telephone companies make periodical tests of their cables and report little trouble. Rails are well bonded with stranded copper compression bonds.

The city electrical laws are good, the electrical department is well organized, has good control over new inside wiring, and this class of work is being installed practically in accordance with the National Electrical Code. The notice-posting system adopted by the city electrician is productive of many good results.

The Electric Renovator.

One of the most interesting exhibits to be seen at the New York Electrical Show was that of the electric-driven renovator, illustrated by the accompanying picture. The construction of this machine is of the simplest, and, being absolutely enclosed, except the end of the motor bearing, there is small opportunity for injury. The renovator is equipped with three attachments, one to clean floors, carpets, cushions, mattresses and the like; the second for all small crevices, corners and confined places from floor to ceiling, and the third for walls, pictures, ornaments, decorations, fixtures, etc. The manufacturers of this simple device (which consists of



THE ELECTRIC RENOVATOR.

an electrically driven suction fan and rotating brush, with a convenient receptacle for receiving the dust and dirt removed, all mounted upon a wheeled base, as shown) assert that the expense of removing and replacing delicate decorations will more than offset the cost of the "renovator," which can be operated by the most inexperienced help. The device is made by the Electric Renovating and Manufacturing Company of Pittsburg, Pa.

Production of Tungsten and Titanium in the United States.

The bulletin of the United States Geological Survey shows that there was mined in this country in 1906 tungsten ore valued at about $349,000 and aggregating 928 tons, which was a gain of 29 per cent. in value and of 15½ per cent. in quantity over the previous year. The rise in value of this metal stimulated the production considerably and will probably continue to do so. The principal constituent in the ores is tungsten trioxide and the chief ores are wolframite and scheelite. The greatest producing locality during 1906 was Boulder County, Colo., but tungsten mining was also carried on in California, Arizona, Montana, New Mexico and Washington. New deposits of scheelite are just being developed at Osceola, Nev., and at Murray, Idaho. No production of tungsten has yet been reported from the deposits in Alaska, Connecticut and Oregon. The large demand for tungsten for the new incandescent-lamp filaments will doubtless develop many of those deposits. Tungsten salts also find considerable employment in the textile industries.

According to Dr. F. W. Clarke, chemist of the United States Geological Survey, titanium should not be classed with the rare metals, since it is much more plentiful than lead, zinc, copper and other metals classed as "common." A great many schists and gneisses carry titanium and it is found in appreciable quantities in clays—not only surface clays but also those that have been dredged from the sea bottom. Many iron ores contain this metal. Added to cast-iron it greatly increases the strength of that metal. It is believed that titanium is used by various manufacturers to increase the tensile strength and elastic limit of steel, although these processes are kept secret. A number of firms are now trying to use titanium in incandescent-lamp filaments, but the difficulties in reducing it to a pure metallic state have hindered this utilization. Titanium compounds are extensively used in arc-lamp electrodes.

Waterpowers Neglected in Saxony.

Waterpower is not used to any great extent in Saxony, being entirely limited to small saw and corn mills in outlying mountainous districts. The laws relating to the development and use of waterpower give the right of concession to the ministry of public works. Before any concession is granted the applicant must file plans of the system proposed, buildings, etc., and power required. These plans are laid before the local technical commission, which reports to the ministry. No large projects have been accepted during the last decade.

The government has no waterpower station in operation at present. Formerly a few turbines were in use for milling purposes on the Upper Elbe, but have been discontinued. All waterpower plants at present in operation are in private hands, controlled by the government. As far as can be ascertained there are only a few plants established, all of which develop but sufficient power for the needs of the mills which own them; no power is rented or sold.

In the absence of any figures as to waterpower it is impossible to make any comparison with steam power, but the former is absolutely negligible.

Telegraph Companies Deny Joint Action.

Attorney-general Jackson of New York appeared on October 2d before Supreme Court Justice Ford and asked for an order to show cause why he should not be permitted to begin an action against the Western Union and Postal telegraph companies. In his petition he declares that the companies have violated the laws of the state which prohibit monopolies and the restraint of trade. He seeks to annul the charters of the two corporations. He declares that the two companies entered into an agreement by which a uniform rate should be charged for messages, and that under this agreement the tariff for messages was materially increased by both companies, the said increase being in many instances 20 per cent. over and above the rate of charge in force prior to the establishment of the new tariff of charges.

Representatives for both companies assert that there is absolutely no foundation for the charges of the attorney-general and contend that the two companies are absolute rivals.

Traffic on the Chicago and Oak Park Elevated Railroad for September showed a daily average of 43,059 passengers, being an increase of 146 a day compared with the corresponding month last year.

Electrical Conventions in New York.

On the evening of October 1st a joint meeting of the Street Railway Association of the State of New York and of the Empire State Gas and Electric Association was held in Madison Square Garden in connection with the New York Electrical Show. This meeting considered questions of public policy.

The first speaker was the Hon. Frank W. Stevens, chairman of the Public Service Commission of the second district of the state of New York, whose subject was "The Work of the Public Service Commission, Second District, and Its Policies with Relation to the Corporations Under Its Supervision." Mr. Stevens outlined in general the work of this newly appointed commission and declared it probably would devote most of its time to three lines of activity: First, investigation of accidents; second, study of the finances of public utility corporations, and third, consideration of public complaints about traffic arrangements for both passengers and freight.

Mr. Henry J. Pierce, president of the International Railway Company, Buffalo, N. Y., next spoke on "The Electric Railway Situation of Today." He said that public-service corporations that were properly conducted would welcome investigation by the new commission, of which Mr. Stevens was head, as they had confidence in the fair-mindedness of the commissioners. He urged the latter to relieve these corporations from the burden of excessive taxation.

The next address was by Dr. Alex. C. Humphreys, president of Stevens Institute of Technology, on the "Control of Gas Companies by State Commissions." After showing that both good and evil had resulted from the present agitation for control of public-utility corporations, he pointed out the importance of uniform systems of accounts and records in enabling state commissions to reach correct and just decisions.

The last speaker was Mr. Everett W. Burdett, chairman of the committee on public policy of the National Electric Light Association. He spoke on "Public Control from the Corporate Standpoint." Referring to the attitude of public-service corporations in the United States toward public regulation and control, he said that it had undergone a great change in recent years, and he had no doubt that before long most corporate interests would realize that an unfriendly attitude is a short-sighted policy, and that good service is the best assurance against hostile legislation and burdensome regulations.

The Empire State Gas and Electric Association held an independent meeting on October 2d in the auditorium of the New York Edison Company, 44 West Twenty-seventh Street. Reports of officers and committees were read. Papers were read as follows:

"The Meter-testing Situation and Report of Meter Committee," by R. M. Searle; "Buying Light," by E. L. Elliott; "Gas Standards," by A. E. Forstall; "Franchise Taxation," by L. C. Palmer; "Municipal Ownership in New York State," by G. Marston; "The Agitation for Underground Distribution in Place of Overhead," by W. W. Cole.

The following-named officers were elected: President, S. R. Bradley; vice-president, P. T. Glidden; treasurer, T. O. Horton; executive committee, Arthur Williams, W. T. Morris and R. M. Searle.

Western Electric Company to Sell Telephones to All Comers.

After thirty years of continuous manufacture of telephones and telephonic apparatus, manufacturing exclusively for the Bell telephone companies, the Western Electric Company of Chicago has made an important change in its sales methods and will hereafter sell telephones and supplies to all who may care to buy. This plan has been under consideration for some time, but it was only with the completion of a large addition to the Chicago plant that the company found its facilities sufficient to branch out into a general business. The company is now prepared to make quotations on telephones, apparatus and equipment of every nature and description

President Theodore N. Vail of the American Telephone and Telegraph Company, speaking of the new plan, said that a great improvement was looked for in the relations between the public and the associated Bell companies. He declared that at the present time many inefficient telephone instruments are in use, and it is desired to see these replaced by standard instruments.

Amish People Have Changed Their Minds.

The Indiana correspondent of the Western Electrician notes that the Nappanee Telephone Company is making plans for extensive improvements and extensions into the country, where a large community of Amish Church people live who have heretofore refused to have telephones in their houses, it being deemed irreligious to do so. These people are frugal and have recently changed their minds and are now demanding a large number of telephone connections. The Nappanee company, it is reported, will soon go into the market for the necessary material for the construction of these new lines.

Method of Increasing the Inductance of Telephone Cables.

A patent was recently granted to Mr. Walter C. Yeatman of Chicago, and assigned by him to the American Telephone and Telegraph Company, which relates to the deadening effect of capacity in telephone cables on the alternating currents transmitting speech. The inventor professes to have a very much simpler method of supplying the requisite inductance necessary for overcoming the capacity of the cable than the insertion at definite intervals of loading coils, as advocated by Dr. Pupin.

The object of the inventor was to obviate the expensive features of the Pupin plan and to secure as effective or better results by distributing the inductance uniformly along the conductors in a simple and inexpensive manner. The preferred method advanced by Mr. Yeatman is to use copper wires that have a thin, even coating of pure iron electrolytically deposited thereon. The result is said to be that the reactance of the circuit is so increased by the magnetic sheath that the effects of capacity are neutralized, or practically neutralized, and the efficiency of the transmission is greatly increased. The conductor can thus be made a simple one in the form of a continuous copper core surrounded by a continuous sheath of electrolytic iron, and this can be insulated in the usual manner, so that the wire can be handled and used just as any other simple conductor now in use.

As a matter of still further improvement the inventor arranges to send a direct current through the cable or conductor at the same time that the voice current is passed through it, and this direct current increases the magnetic flux in the material composing the sheath, and thereby increases the permeability of the same and still further increases the effective reactance. The direct current may be transmitted over the circuit at the same time as the voice currents without interfering with their transmission, it is said, by a number of well-known means. The simplest of these is a repeating coil or transformer at either end of the circuit, in the center of which is the source of constant electromotive force sending the direct current over the line, and the other windings of which are connected to the source and receiver of the voice currents. This source of direct current may be a storage battery and can be used also for signaling or supervising connection. A battery at each end or at only one end may be used. Where two batteries are employed it is not thought advisable in telephonic transmission to connect one side of both of these batteries to earth, as a difference of earth potential between the stations would then cause an unequal amount of current to flow through the two conductors, thereby causing their self-induction to be unequal and the line unbalanced. In practice, the inventor says, it would be found that these batteries should be of from 20 to 200 volts electromotive force, the latter value being taken as the highest value which would be found expedient to use as a working pressure in a paper-insulated cable.

The inventor prefers to use for the magnetic sheath a metal of high permeability and low electrical conductivity, such as electrolytic iron. The conductor—which, to enable the best results to be obtained from the magnetic sheath, should not be of too great diameter—may be constructed in this form in any suitable manner which will give the large magnetic permeability and small electrical conductivity required. However, the best way to secure the iron coating or sheathing is by electrodeposition, thus obtaining a metal of the best magnetic qualities. With electrolytic iron the permeability is extremely high and the hysteresis losses low, both of which tend to increase the efficiency of transmission. The high permeability of the iron increases the amount of self-induction for a given amount of iron and so lowers the current attenuation. Or, for any required amount of self-induction in the conductor a thinner coating of electrolytic iron suffices, with a corresponding decrease in the longitudinal electrical conductivity of the sheath, and a like decrease, therefore, in the "skin effect" and eddy current losses, which are among the factors that determine the attenuation of the current waves.

A cable made up with composite conductors as described, insulated with paper and twisted in pairs and surrounded with a lead sheath, while possessing the characteristics of neutralizing capacity, and thereby permitting the transmission of electrical wave energy is a simple continuous cable, easy to manufacture, to lay and to maintain, and avoids the inconvenience and expense of the complicated structures heretofore provided for this purpose.

The inventor says that careful calculations show that for a periodicity of 1,000 per second, which corresponds approximately to that of the transmission of speech, a cable composed of iron-plated copper conductors, such as here proposed, through which a magnetizing current is passed, will transmit a given amount of electrical energy 3½ times as far for the same efficiency, as the corresponding plain copper wire cable, and without the distortion of wave lengths of the higher frequencies, which occurs in telephonic transmission over ordinary cables. This absence of distortion in the conductor of Mr. Yeatman's invention is due to the fact that the value of the attenuation constant is practically the same for the various telephonic frequencies, so that all frequencies are attenuated alike, and the current waves have substantially the same relation to each other at both ends of the conductor. It results from this that the voice currents are transmitted clearly and distinctly without the muffling effect that accompanies speech transmission over ordinary conductors, and in consequence speech is intelligible even when the conductor is very long and attenuation very great.

Indiana Telephone Items.

John H. Wilkinson, who purchased the North Judson telephone exchange, proposes to put it in first-class condition and extend several lines.

The Farmers' Telephone Company of Lamb will erect and equip a new telephone system.

The Brazil Farmers' Telephone Company of Brazil will install a new switchboard and construct several new lines.

The New Home Telephone Company of Linton, which also controls the telephone companies at Jasonville, Bloomfield, Worthington, Lyons and Switz City, will spend nearly $40,000 in improvements and extensions.

The matter of the telephone and telegraph as applied to the operation of steam and electric railways is to be inquired into by the Indiana railroad commission.

The Rushville Co-operative Telephone Company of Rushville, although co-operative in name, has none of the mutual features peculiar to a co-operative system. The company has moved into its own new and elegant building and has almost completed the installation of a modern automatic telephone system, with all the wires radiating from the new building underground. The entire cost of everything complete will be about $50,000.

The Home Telephone Company of Wabash, one of the pioneer Independent companies of the state, is preparing to move into its new building, now almost completed. The building is said to be one of the most modern for a telephone exchange in the country. A new common-battery system of 1,280 lines and 3,000 ultimate capacity is being installed. S.

GENERAL TELEPHONE NEWS

The Northwestern Telephone Exchange Company announces the cancelation of the half rates for toll service during the night hours. The reduced rates made the night service congested, and the change is on that account.

The officials of the New England Telephone and Telegraph Company were notified a few days ago in Boston that the corporation had been indicted by the grand jury. The indictment is the result of the investigation made by District Attorney John B. Moran relative to the charge that politicians had obtained from the company employment for their constituents in violation of the law.

At its regular meeting this week the Chicago City Council adopted a resolution directing the committee on state legislation to draft a bill to confer upon the city the power to fix rates for street railway, subway, telephone and telegraph service with a view to its passage by the Legislature. This action was taken to make sure the city would have the power to enforce the rate-regulating clause of the present pending Chicago Telephone Company franchise, should it be passed by the council.

Information concerning the present condition and plans of the Illinois Telephone and Telegraph Company (Illinois Tunnel Company) is to be secured by a committee of the Chicago City Council according to a resolution adopted this week. The resolution states that the company has without authority transferred its franchise to another company; has failed to install a telephone system according to the terms of the franchise, and is devoting the tunnels to freight transportation service exclusively. An ordinance which was referred to the proper committee asked for the repeal of the franchise of the company.

CORRESPONDENCE.

Continental Europe.

Paris, September 25.—A new line of electric railroad in the Alpine region which presents considerable interest is the Locarno-Bignasco road, and it runs throughout the whole length of the Maggia Valley. It is soon to be started and will open up a picturesque region which has been but little frequented heretofore on account of lack of means of communication. In fact, the Maggia Valley, which is one of the finest of the southern region of Switzerland, was almost cut off from the rest of the country, as it is difficult of access and can only be reached by gorges or long passages over the mountains. For this reason it has been neglected by tourists, but the new electric road will bring it within easy reach of the railroad lines of Switzerland or Italy. The present line has been promoted chiefly by Mr. Soldati, prominent in Swiss politics, and not long since Parliament voted in favor of building three narrow-gauge roads, one in the Blenio Valley, a second from Lugano to Tesserete, and the present line of the Maggia Valley. Part of the funds were supplied by the government, but the greater portion, $540,000, is supplied by a stock company formed for the purpose. Work was commenced on these lines in 1905, and it met with some difficulties on the first section from Locarno to Ponte-Brolla, as this had to be built along the side of the mountain. The line crosses the Maggia River upon a high bridge. At the latter locality is built the hydro-electric station. From here the road mounts in an easy grade by Maggia, Someo and Cevio, and reaches the terminal point, which is about 18 miles from the start.

The Pyrenees Electric Company, which is now in formation in the southern region of France, will undertake to develop a number of waterfalls in the central region of the Pyrenees. Current will be taken by a network of lines through the southwestern region and will supply many towns and villages. The new company is to be formed in several stages, and the capital of $1,300,000 will be employed in carrying out the first portion of the work. When this is entirely completed, there will be as much as 90,000 horsepower furnished by the different hydraulic plants. It is stated that the new company is assured of a large consumption of current, as it lies at a point midway between two extensive regions, to wit, the region of Toulouse in France, and the Spanish district of Barcelona, and these two districts have not as yet been supplied with current to any extent. The future of the new company seems promising.

At Moschi, in East German Africa, has been opened a new telegraph station, and it will be used for international service. The locality of Moschi is situated about 160 miles to the northwest of Mombo, which lies at the foot of the Kilimandjaro Mountains.

In France a new company has been formed for the purpose of carrying on operations in the northern region at Valognes and Montebourg, relating to the supply of current and the erection of the necessary electric plants. The headquarters of the company are located at Paris.

The Japanese government recently decided to hold an international exposition in that country, which is fixed for the year 1912, and preparations have already been begun to this effect. It will be held at Tokio, and will be preceded by a series of expositions in different cities of the empire. This year the municipality of Tokio is organizing an exposition which is to be held in the Veno Gardens.

A. de C.

Great Britain.

London, September 28.—The Municipal Tramways Association, which numbers among its membership practically all the municipal tramway authorities of the country, is now holding its annual conference at Manchester, Mr. McElroy, the general manager of the Manchester System, being president. In the presidential address, Mr. McElroy contrasted America and Great Britain. He stated that in tramway matters America has taught Great Britain many lessons, for which we had certainly reaped the benefit of her pioneer work in electrical traction. During his recent visit to the United States he had come to the conclusion that we now had little or nothing further to learn from America on matters connected with construction, equipment and co-operation generally, but we still had a very important lesson to learn from there in the way the population was spread by the energetic manner in which tramways were extended in districts absolutely unbuilt upon. In America they did not wait until a district grew before they provided transit facilities. In America, for the most part, these facilities were provided by private companies working for their own selfish ends, but it was a lesson which the municipalities of this country should bear in mind. Of the technical papers read at the meeting, one of the most interesting was by the manager of the Chesterfield tramways, in which he expressed the opinion that a considerable extension of wheelbase for tram cars would come into general use later, and he instanced 10 feet.

In connection with tramway matters, mention may be made of a new type of tramcar which has been devised by a Liverpool man. So far only a model has been constructed, but the principle adopted has something to recommend it. By an arrangement of folding and hinged doors, passengers are enabled to enter the car at the conductor's end and always leave it at the driver's end. The model is being inspected by many tramway managers but so far no detailed particulars of it have been given away.

About a month ago I reported that the Home Office had published a new set of regulations (in draft) dealing with the use of electricity in factories and workshops. Being published in the summer comparatively little notice was taken of them for a week or so. Now that people are back from their holidays, however, there appear to be considerable discussion and criticism, and, apart from individual companies, the various chambers of commerce throughout the country have entered into the matter with vigor. At Bradford there has been a public discussion, and I believe the London Chamber of Commerce has also taken the matter up. The very excellent example set by the Board of Trade in connection with other similar rules, viz., to call a conference of interested persons was not followed by the Home Office, and this is one of the points of attack.

The annual meeting of Messrs. Dick, Kerr & Co. was held last week. Although the net profit for the year amounted to over $400,000, this was about $30,000 less than last year. This was attributed to the high price of copper and the continuation of the very keen competition which has existed for such a long time. The point of the chairman's speech was that although the Board of Trade returns, as a general thing, indicated that the country was exceedingly prosperous, yet a careful study of the true position, so far as the electrical industry was concerned, would prove that the margin of profit now was less than when the Board of Trade returns, some years ago, showed a less prosperous condition of things for the country as a whole. To that extent the Board of Trade returns did not indicate the true position

We have not had to wait long for evidence that the continued rise in the price of coal has had a detrimental influence upon the accounts of electricity works. Thus at West Ham, hitherto regarded as one of our most successful electrical undertakings, at any rate in the extra metropolitan district, there has been a somewhat serious loss owing in the main to this cause, the coal bill being $12,500 more than it would have been on the old price of coal. Similarly at Kingston-on-Thames the extra coal bill has been sufficient to prevent a small profit being made. It is becoming the common practice now, however, for central-station managers to stipulate, in the case of long contracts, that there shall be a specified increase in the price corresponding with the increase in the price of coal. Of course, this cannot be put into effect in the case of ordinary lighting consumers, but more than one manager has been thankful for the existence of this clause in his large power contracts.

Little has been heard of the Victoria Falls power scheme for some little time now, but within the past few days a notice has been sent around to the press stating that the capacity of the Germiston station together with that at Brakpan (purchased respectively from the General Electric Power Company and the Rand Central Electric Works) are now loaded to their full capacity, and that the former is being extended pending the erection of the 24,000-horsepower station, the machinery for which is said to be in an advanced state. Sir Charles Metcalfe, Mr. R. D. Mershon of New York and Mr. Arthur Wright, the consulting engineers to the scheme, are all in South Africa at the present time, with some of the directors. G.

Dominion of Canada.

Ottawa, October 5.—The City Council of Kingston, Ont., will ask the Ontario Hydro-electric Power Commission to quote prices for 2,000 horsepower of electric energy, to be supplied at the city power station, ready for distribution.

It is now understood that the Electrical Power Company of Niagara Falls is anxous to come in and supply the Hydro-electric Power Commission of the Ontario government with electrical energy at Niagara Falls. Representatives of the company have seen the local prime minister and members of the commission in regard to the matter. The company, which before would not quote rates satisfactory to the government, now desires to come in on the same terms as the Ontario Power Company, which made an agreement with the government of Ontario to supply power at the Falls at $10.40 for an amount of electrical energy up to 25,000 horsepower, and at $10 above that amount.

The Marconi Wireless Telegraph Company of Canada has issued a notice to the effect that rates on messages exchanged between vessels and shore stations, in the Gulf and River St. Lawrence, will be reduced from $2 for ten words to $1, and in some cases to 50 cents for ten words. This step has become desirable on account of the increasing amount of business being done with ships. For each additional word over, ten words the charge will be six cents a word.

An immense work is being prosecuted by the Montreal Light, Heat and Power Company and the Provincial Light, Heat and Power Company at the Coteau du Lac Rapids, where a million and a half dollars is being expended on a hydro-electric plant. The two companies intend that the plant shall be complete in every detail. The object is to secure power for Montreal. The work is situated about 30 miles from Montreal, and it is expected that it will be completed so that power can be brought to Montreal this autumn. The dam has a 50-foot head and the plant will develop about 15,000 horsepower. W.

Winnipeg, October 3.—At a meeting of the City Council, Calgary, Alberta, it was decided to at once call for tenders for the construction of the electric street railway to be built by the city. Mayor Cameron or City Engineer Thorold may be addressed.

A special meeting of the shareholders of the Canadian General Electric Company has been called for October 28th to amend the by-law recently passed to issue $2,000,000 preference stock having priority of claim over the common stock in the matter of dividends. English interests, which were to take the bulk of the new stock, demanded that it be made plain that this stock has priority over all assets of the company as well as priority in the matter of dividends. The meeting, which will be held in Montreal, is called to amend the by-law to that effect.

Mr. Stinsel, representing the Minneapolis Street and Town Lighting Company, Minneapolis, Minn., has applied to the Town Council, Carnduff, Saskatchewan, for a franchise to light the town and supply power.

The Board of Trade, Olds, Alberta, is considering the securing of an expert on the matter of developing waterpower on the Little Red Deer River, 13 miles west of town. Address S. Craig, Olds, Alberta.

Tenders for the construction of Winnipeg's power plant at Point du Bois were opened on October 2d. In all there are over 100 different bids for the 27 different parts of the work. The number of tenders received is an indication that there is a brisk competition for the various parts of the work, and, in the opinion of the power committee, the work will only cost about $2,750,000, against the estimate of $3,250,000. Alderman Pulford or Cecil B. Smith, civic power expert, Winnipeg, Man., may be addressed in relation to this work.

The Ratepayers of Kelowna, B. C., voted favorably on a by-law to provide $40,000 for waterworks and electric light. J. F. Burn, Kelowna, B. C., may be addressed.

The directors of the Central Electric Light Company, Portage la Prairie, Man., are considering the spending of $35,000 on extensions to their plant for the purpose of making provision for the supply of power during the day. They also propose to double the number of arc lights on the streets, but will require an extended contract from the council before undertaking this. R.

New York.

New York City, October 5.—On Sunday, October 6th, four New Haven trains are scheduled to arrive at Grand Central Station from Stamford, Conn., and this will mark the beginning of the last stage of this great enterprise in electric railroading. Within two or three months it is expected that every one of the New York, New Haven and Hartford passenger trains will drop its steam locomotive at Stamford and will be propelled by electric power alone for the remainder of the journey. Since July 24th five electric trains have made the round trip from New Rochelle to the Grand Central Station daily, and since August 5th ten have completed the trip from Port Chester to New York and return daily. Stamford is 34 miles from New York. The Westinghouse Company has supplied the railroad with all of its locomotives and equipment. The New Haven road uses both the third rail and overhead catenary suspension systems. From near Woodlawn to the Grand Central the New Haven uses the New York Central's third rail, supplied with direct current of about 650 volts. The overhead wires, however, carry a potential of 11,000 volts and all the necessary transforming and converting apparatus is self-contained in each locomotive.

The Brooklyn Rapid Transit is preparing to put into operation 150 "pay-as-you-enter" cars. On these cars the passenger must hand the conductor his or her fare before entering the body of the car. Under the present system the company says that the fares missed by the conductors amount annually to fully a five per cent. dividend on the company's stock. It is further argued that by this plan the conductor will not have to leave the rear platform and in consequence many accidents will be avoided.

The annual report of the Brooklyn Rapid Transit Company for the year ended June 30, 1907, has been made public and presents some very interesting figures. During the year 511,839,437 passengers were carried, an increase of 13.1 per cent. over the previous year. The average gross earnings per passenger decreased from 3.89 cents for the previous year to 3.60 cents, and the averare net earnings per passenger from 1.70 to 1.48. The average number of cars operated daily for the 12 months is 2,093, as against 1,922 for the year 1906, an increase of only nine per cent. The cost per car mile is given as 17 cents, which is one cent more than that given for horsecars 30 years ago. As to increase in equipment—143 convertible surface passenger cars and 100 enclosed surface passenger cars, also two 7,500-kilowatt turbo-generators have been put in operation, and orders have been placed for an early delivery on 100 elevated motor passenger cars and five 10,000-kilowatt turbo-units with all necessary equipment, two of which will be put in service the ensuing year. The extension of the power houses to receive this equipment will be completed early in 1908.

Prof. B. B. Beltwood of Yale University announces that he has discovered a new element of the radium family. He says: "Strong evidence has been obtained of the existence in the uranium minerals of a new radio-active element which emits both alpha and beta radiations, but which produces no emanations and therefore resembles in its chemical properties thorium. It is without doubt a disintegration product of uranium and is in all probability the immediate parent of radium. The name "ionium" is proposed for this new substance, a name derived from the word "ion," and is especially appropriate because of the ionization action which it possesses in common with the other elements which emit alpha rays."

The fifty-second college year of the Polytechnic Institute of Brooklyn opened on Monday, September 30th, with an entrance class of 85 day students and over 200 evening and extension students. The Polytechnic is again offering instruction to engineers engaged in the practical field, the studies to be pursued evenings and on Saturday afternoons. It has greatly enlarged its corps of instructors, and the courses to be given by C. O. Mailloux and Charles P. Steinmetz and others will be of the greatest interest. The Institute has also enlarged its steam and gas-engine laboratory and has added new machinery, and has also equipped a new laboratory for the testing of materials. Prof. William D. Ennis, who has been in the practical field for about 10 years, being a graduate of Stevens, class 1897, will take charge of the department of mechanical engineering. E. H. S.

Northwestern States.

Minneapolis, October 5.—The Northwestern Interurban Electric Railway Company has been organized at Moorhead, Minn., with T. T. Bubb as president and T. R. Brown, secretary. The company proposes to build a trolley line from Fargo, N. Dak., to Detroit, Minn.

The Winnebago Traction Company of Oshkosh, Wis., which recently went into the hands of a receiver, will be reorganized, and $100,000 will be expended on the Oshkosh plant and $300,000 on an interurban line to Berlin, Wis.

A contract for financing the Omaha and Nebraska Railway Company has been negotiated by the H. J. Folts Company of Minneapolis. The line will be an electric road and will extend from Omaha to Hastings, Neb.

The Dakota Electric Company has been organized at Grand Forks, N. Dak., by C. F. McLean and associates.

The Wagner (S. Dak.) and Lake Shore Traction Company is purchasing material for its proposed electric line.

The Fremont Gas and Electric Light Company of Fremont, Neb., is negotiating with the city council for the sale of the system there to the city. R.

Michigan.

Grand Rapids, October 5.—The Shiawassee Light and Power Company of Corunna has purchased another 250-kilowatt Warren generator which will be able to generate 300 horsepower. The company's capacity will soon be doubled by the raising of the company's dam to a 15-foot head. The company will now light three more towns, Durand, Vernon and Byron. It is already lighting Perry, Bancroft and Morrice.

An appraisement of the Kingsley power plant at Manchester is being made with a view to purchase by the city and the establishment of a municipal electrical-lighting system Mr. Kingsley wants $22,000 for the property, which was established fifteen years ago.

The village of Northport is installing a $5,000 municipal lighting plant.

The Eagle Tanning Company at Grand Haven is preparing to install electrical equipment. William H. Mead of Holland has the contract. The plant will have a 300-horsepower engine and a 200-kilowatt generator. Induction motors of 15 to 50-horsepower will be installed.

Work of construction by the Electric Land and Development Company of Traverse City on the Tyler dam site near Walton has begun. There are four available dam sites on the river, two with a 40 foot head, one with a 37 foot head and one with a 35 foot head.

The Canal Street Business Men's Association of this city has on foot a project for making the street a "great red way." Flaming arc lights are to be erected every 50 feet on the street for a distance of four blocks.

The directors of the Traverse City Board of Trade are pushing the project for an electric road from that city to the north and for city street railway lines, a franchise for which has been let to the Carter Company.

Rigid restrictions have been placed on the Michigan United Railways by the city of Kalamazoo. Cars must be heated so as to maintain a temperature of 75 degrees and not less than 60 degrees. Two thermometers must be placed in each car. Cars for the use of transporting material must be operated between 12 o'clock midnight and 5 o'clock in the morning. All cars, including interurbans, must be stopped at any corner that passengers desire to get on or off. There are many other minor restrictions. L. W. B.

Indiana.

Indianapolis, October 5.—The Evansville, Petersburg and Vincennes Railroad Company, incorporated last week, has already secured 11 miles of the right-of-way of the proposed trolley line from Evansville to Petersburg. It is the purpose to build the road sufficiently strong to do a good freight business. This road will give Evansville five traction lines.

Regular service was begun during the past week on the Richland branch of the Evansville and Eastern, nine miles, and the Seymour extension of the Indianapolis and Southern, 20 miles.

A. A. Anderson, superintendent of the Indianapolis, Columbus and Southern and the Indianapolis and Louisville electric railways, announces that the fare from Indianapolis to Louisville will be $1.90, and the round-trip fare $3.45. All fares for intermediate points have also been arranged, and a schedule of the mileage and tariff rates has been filed with the State Railroad Commission.

The Indiana Harbor and East Chicago Electric Company has filed articles of incorporation, proposing to construct a plant to supply East Chicago and a number of other cities and towns in Lake County, with light, heat and power. The promoters are Harry H. Phillips, Rollie M. Cole, H. S. Oakley, C. B. Woods and C. W. Sherman. The same persons have also incorporated the East Chicago and Indiana Harbor Water Company to establish a plant to supply East Chicago and nearby towns and cities with water.

Taking advantage of a recent court decision, officials of the Winona Interurban Railway Company will start action to force the Lake Shore Railroad Company to accept the mileage used on the electric line between Warsaw and Goshen and on all the Murdock lines in Indiana and Ohio. For several months past there has been an understanding between the officials of the Bg Four Railroad and the officials of the Winona interurban company whereby conductors on the two roads have orders to accept either form of mileage. Should the point raised by the electric road officials carry in their favor, patrons can purchase 1,000-mile books from the electric road for $15, and in the event this mileage can be used on the railroads the patrons will get a rate of 1½ cents a mile. The contract on the cover of the mileage books just issued by the Winona Interurban Railway Company and the Murdock lines contains a clause which makes it possible for one, two or more persons to ride on mileage from the book. If the Winona company wins its point, purchasers of these mileage books can go to Chicago over the Grand Trunk, Lake Shore, Wabash, Baltimore and Ohio, Pennsylvania, Nickel Plate or Erie railroads on these mileage slips. S. S.

Pacific Slope.

San Francisco, October 2.—Samuel L. Naphtaly, manager of the City Electric Company, which was expecting to start up its new electric-light and power system in San Francisco about October 15th, has failed to come to an agreement with the International Brotherhood of Electrical Workers and a strike is imminent. The union is in conflict only with those companies owned by the Fleishhacker and Mack interests. These are the American River Electric Company, the Truckee River General Electric Company, the Reno Traction Company, the Nevada Light, Water and Power Company and the City Electric Company. The proposed strike would cut off the electric power which operates the pumps and hoists in the Comstock mines at Virginia City, Nev.

Officials of the Metropolitan Light and Power Company state that they are about to close a deal with the Stanislaus Electric Power Company by which the former will be able to sell electricity in this city for light and power purposes. Leopold Wallach of New York, representing the eastern people in the Metropolitan company, is expected here this week to confer with President Michaels and assist him in closing the deal with the Stanislaus Electric.

James Mullen of the California-Nevada Electric Power Company is out with a corps of surveyors running a pole line from Bridgeport, Cal., toward Bodie and Aurora.

The American River Electric Company has just made a highly satisfactory test of its new steam turbine generator at Stockton, Cal., an auxiliary to the waterpower plant at Placerville. A duplicate steam plant will be erected beside the present one.

The contemplated improvements to be made in the municipal electric plant at Pasadena, Cal., will cost, according to one estimate, $195,000, while another estimate places the cost at $245,000. Because of the difference Prof. C. L. Cory of Berkeley, Cal., has been appointed to make a closer examination of the project.

Bids are requested for the construction of 42 miles of telephone line from Red Bluff, Cal., to the property of the California and Massachusetts Copper Mines Company.

The Northern Light and Power Company is now getting material for its Cow Creek power house, near Redding, Cal., and the building will soon be under way.

The contract for a $1,700 power house to be built on the grounds of the insane asylum at Las Vegas, N. M., has been awarded to M. M. Sundt.

The Ocean Shore Railroad Company, which will operate electric trains between San Francisco and Santa Cruz, Cal., is conducting an active campaign in the latter city for the sale of its bonds, as upon this sale depend the completion and operation of the road in the near future. The company may yet run through trains early next year.

The Central Electric Company has been incorporated in San Francisco by L. R., H. W. and J. L. Boynton, with a capital stock of $25,000.

The Napa Valley Electric Company has been incorporated at Napa, Cal., to conduct a general electric and gas-lighting, heat and power business. The capital stock is $200,000. Work will be begun at once. The organization of this company is regarded as the first step for a branch of the Snow Mountain Line in Napa County. A.

PERSONAL.

Elmer H. Littlefield, superintendent of the ninth division of the Boston Elevated Railway, died on September 30th at his home in Allston, Mass.

Percy H. Thomas and N. J. Neall announce the formation of the firm of Thomas & Neall, electrical engineers, with offices in New York and Boston.

J. G. White, the contracting engineer of New York, is the subject of an interesting article in the October Review of Reviews by David F. St. Clair entitled "A Yankee Engineer on Five Continents."

George W. McClure has resigned his position as superintendent of the Norwich and Westerly (Conn.) electric railway to become superintendent of construction and equipment of the Illinois Traction system. His headquarters will be at Danville.

Mr. Frank Stout, for the last nine years a salesman for I. P. Frink, now occupies a similar position with the Bryant Electric Company of Bridgeport, Conn., and will represent it in the territory controlled by the branch of the sales organization which in general can be described as the territory east of Buffalo and Pittsburg.

Mr. Harry De Steese of New York has been appointed Eastern representative of the International Timber Preserving Company of Chicago, which manufactures the timber preserver, "Neosote." Mr. De Steese has been connected with electrical and allied interests for nearly a score of years and has made himself an enviable reputation as an aggressive business man.

G. D. Hettrick, chief engineer of the Iowa and Illinois Railway Company of Clinton, Iowa, has gone to Texas to accept a position with the El Paso Electric Railway Company as chief engineer. He has been with the Iowa and Illinois road for the last three years, and will be succeeded by J. B. Skiff, who has also been connected with the company for some time.

H. H. Vreeland has resigned from the position of manager for the receivers of the Metropolitan Street Railway Company and the New York City Railway Company. Mr. Vreeland is admittedly the best posted man on street-railway matters in New York. His resignation follows the inquiry before the New York public-service commission into the affairs of the Metropolitan company. Mr. Vreeland will be succeeded by Oren Root, vice-president and general manager of the New York City Railway Company.

ELECTRIC LIGHTING.

W. A. Mason and others are organizing a company in Texhoma, Okla., to build an electric-light plant.

Representatives of the Chicago and Milwaukee Electric Railroad Company assert that if permission is granted the company to enter Racine, Wis., it will be in a position to make a bid for the street lighting at a figure considerably below that now paid by the city.

C. C. Smith has been granted a franchise for an electric-lighting system in Exeter, Neb.

E. E. Bigham of Minneapolis, Minn., has been granted an electric-light franchise in Northome, Minn.

Oscar Kihlberg and others have been granted a franchise for an electric-light and power plant in Sulphur Springs, Ark.

An electric light and power plant has just been installed on the Robbins Ranch, 30 miles from Aberdeen, S. D., by Minneapolis representatives of the Fairbanks-Morse Company. The plant is operated by water from an artesian well. It furnishes 30 lights for the house, barn and other buildings, and there is plenty of power for feed cutting, etc. F. H. Barnard, manager of the ranch, is delighted with the plant. The Aberdeen Engineering Company installed the machinery.

ELECTRIC RAILWAYS.

Yegen Bros. have been granted a franchise for an electric railway in Billings, Mont.

The Oklahoma Electric Terminal Company has been incorporated to furnish terminal facilities in Oklahoma City. The capital is $2,500,000.

Electric cars were operated for the first time in Eugene, Ore., on September 26th. The trial run was made from the depot to the University of Oregon, and was in charge of Mr. A. Welch, general manager of the Eugene and Eastern Railway Company, which built the system.

The complete traffic returns of the elevated roads of Chicago for September show an increase of 1,881,733 passengers. These figures for September compare as follows for 1907 and 1906, respectively: Metropolitan, 4,229,372, 3,809,244; South Side, 3,547,677, 2,692,472; Northwestern, 2,923,413, 2,825,254; Chicago and Oak Park, 1,350,520, 1,342,279; totals, 12,050,982, 10,169,249.

The report prepared for the Illinois Railroad and Warehouse Commission by the Metropolitan Elevated ailway Company of Chicago to cover its operations in the 12 months ended June 30th shows gross earnings of $2,800,000, net earnings of $1,438,400 and a balance of $430,700 for the stock. This is at the rate of 4.9 per cent. on the preferred stock outstanding.

The Oklahoma Central Interurban Railway, Telegraph, Telephone, Light and Power Company was incorporated at Guthrie, Okla., with a capital of $5,000,000 for the main purpose of building a system of electric lines between McAlester and Cheyenne amounting to about 500 miles. Among the incorporators are: C. D. Freeman, Denver, Col.; Leon Brown, St. Louis, Mo., and F. M. Stone, Weatherford, Okla.

The Philadelphia Rapid Transit Company reported for the last fiscal year the largest gross earnings in its history. The net earnings, however, have vanished and a deficit of $364,048 was shown. The president of the company attributes this poor showing to the unusually heavy claims for damages that amounted to $1,217,986. In the last 10 years the percentage of gross earnings required for settlement of damage claims rose from 2.5 to 7 per cent.

POWER TRANSMISSION.

The Pennsylvania State Water Supply Commission has put into effect a law giving it authority over all obstructions in streams, and hereafter permits must be received before erection of any power dams, wing walls, embankments, bridge piers and wharves. The commission has a force of engineers to inspect plans and sites for proposed work and every locality on which it is intended to build this fall must first be approved. Several proposed enterprises have been held up pending grant of authority by this board and in three instances hearings will be held on protests.

Kennebec River and its important tributaries furnish some of the best waterpowers of the country, besides affording many excellent sites for further development, and the welfare of the whole state of Maine is involved in the wise extension of the use of this river and its branches for waterpower, for log driving and lumbering, and for municipal and other purposes. To meet the constant demand for information in regard to the hydraulics of this great drainage basin, the United States Geological Survey has just issued, as Water Supply Paper No. 198, a report embodying all available data in regard to the flow of the streams and the possibilities of regulating that flow by means of storage, opportunities for which are exceptionally good.

PUBLICATIONS.

The Weston Electrical Instrument Company of Newark, N. J., issues a leaflet illustrating many of its portable and switchboard instruments, both for direct current and for alternating current. F. B. Badt & Co., 1503-1505 Monadnock Building, Chicago, are western sales agents for the Weston company.

The Western Electric Company's arc-lamp department at Hawthorne, Ill., has published and is ready to distribute a pamphlet describing the various types of direct and alternating-current arc lamps made by the company.

The Wire Market News is the name of the house organ of the Western Wire Sales Company of 324 Dearborn Street, Chicago. The latest number contains interesting articles on copper and other subjects.

The General Electric Review for September contains a number of interesting and well illustrated articles, including "Fundamental Principles of Centrifugal Fans," by Maxwell W. Day; "Gyroscopic Forces," by W. E. Miller; "Potential Control of Alternating-current Systems," by Ernst J. Berg, and "Recent Advances in Illuminating Engineering," by W. D'A. Ryan.

Under the direction of the Swiss railway authorities there has been compiled a comprehensive directory of Swiss steam, electric, funicular and street railways. This work, besides giving the salient features of each line now in operation, with headquarters address, includes all projects now under construction and also the 111 projects for which concessions have been granted, with addresses in each case. It is in the French language.

The new Standardization Rules of the American Institute of Electrical Engineers have been separately published, bound in paper or cloth, and are to be had by addressing the Institute at 33 West Thirty-ninth Street, New York city. These rules were adopted in June, 1907, and it is to be noted that they supersede the rules of the Institute adopted in 1902. Copious extracts from the new rules were made in the Western Electrician of July 13, 20 and 27, 1907.

Mr. Sidney Aylmer-Small has written a book entitled "Electric Railroading as Applied to Steam Railways." The book is intended for the motorman, engineer and electrician, and should be found convenient as a handbook for reference. In it the author leads the reader through the elementary stages of electricity, bringing him to a comprehension of its application to railway operation. The book has 450 pages and 500 illustrations, with a full leather binding. It will be ready November 1st, Frederick J. Drake & Co., 350-52 Wabash Avenue, Chicago, being the publishers.

The Blake Signal and Manufacturing Company of 246 Summer Street, Boston, Mass., has just published an instructive booklet entitled "Requirements for Efficient Telephone Train Dispatching." To get the best and most reliable results in telephonic dispatching it is pointed out as being necessary to install an efficient signaling system, such as the Blake signals, as this enables the dispatcher to call a train crew at any desired point to communicate his orders to them and also gives him a means for visually reminding them of these orders. The booklet also gives valuable rules for making the dispatching safe and yet rapid, so as to permit a maximum volume of traffic to be expeditiously handled.

The October number of For California, a monthly publication published by the California Promotion Committee of San Francisco, is devoted entirely to the electrical resources and developments of the state. A page editorial calls attention to California's two resources, fundamental to manufacturing—raw material and power—both of which are within the borders of the state in abundance. The longest transmission of electrical energy in the state (and probably in the world) is given in the editorial as 350 miles. Several good articles are devoted to the development of power from mountain streams, electric traction and the use of electricity on the farm. A list of 106 hydroelectric power stations is given ranging in capacity from 75 horsepower to 26,000 horsepower.

SOCIETIES AND SCHOOLS.

The tenth annual meeting of the Kansas Gas, Water, Electric Light and Street Railway Association was scheduled to be held on October 9th and 10th at the Commercial Club rooms, Topeka, Kan.

Arthur A. Noyes, acting president of the Massachusetts Institute of Technology, made his first appearance as president before the students of that institution on October 3d. Professor Noyes has given up his office as head of the physico-chemistry research laboratory and is devoting all his time to his duties at the Institute.

MISCELLANEOUS.

The City Council at Akron, Ohio, has adopted a resolution requiring the wires on Main and Howard streets, between Jackson and Federal streets, to be placed underground. The electric-railway company will be allowed to keep its trolley, feed and span wires where they are, but all others, including telephone and telegraph wires, must be buried. This is the main retail district of the town.

Guests of the Monongahela House, Pittsburg, Pa., were badly frightened a few days ago by a series of explosions near the hotel which sounded to them like the rattle of musketry. Investigation revealed that a street car in Smithfield Street had hit a wagon loaded with boxes of electric incandescent bulbs. The exploding lamps made the noise.

At a meeting held recently in Marion, Ohio, the Marion Electric Association, composed of the Marion Electric Supply Company and the Marion Railway, Light and Power Company, was organized. The association, which is to promote the electrical business in Marion, is planning for an exhibit to be held some time in November. The officers are: President, D. J. Sheldon; secretary, Frank Glosser; treasurer, W. G. Lucas.

A large tract of coal land in the province of Alberta has been purchased by the Great West Coal Company of Port Arthur, Ont., as a result of recent investigations, and claims have been filed for 12,000 acres of what is said to be the best coal land in the Northwest. In connection with the development of the coal lands, the company has acquired the charter of the Great Western Railway, which extends from Calgary through the coal fields to the international boundary.

Responding to an American inquiry relative to the demand for pumps in the Dunfermline (Scotland) district, Consul J. N. McCunn says that steam pumps are now becoming obsolete, and in most of the collieries electrically driven pumps are being adopted. This class of pumps found in most favor is what is termed the "three-throw," and centrifugal or turbine pumps. The electric three-throw pump is a type which has an extensive application and is operated by the intervention of gearing.

Writing from Cartagena, Consul I. A. Manning states that the platinum industry in Colombia (South America) seems to be attracting considerable attention from abroad. Recently a French company, headed by Albert L. de Lantreppe of London has made some heavy purchases of mining properties in the platina district. It is soon to send competent engineers to make a complete study of the region from which platina is taken at present, and especially of their properties. Other capitalists and companies have also recently secured large holdings, which they expect to develop more scientifically than has been usual in working the mines.

"Worthwine a Good Lineman" is the heading of a recent news item in a daily paper. But further perusal shows that this statement has nothing to do with electrical construction work; it merely indicates that the college football season is at hand.

TRADE NEWS.

Frank W. Morse of Boston has removed from 116 Bedford Street to 514-516 Atlantic Avenue.

The address of the Birmingham office of the Crocker-Wheeler Company has been changed from 2119 Third Avenue to Woodward Building, Birmingham, Ala.

The Massachusetts Chemical Company of Walpole, Mass., will exhibit at the American street and interurban railway convention at Atlantic City, N. J., October 14th to 18th. Messrs. A. T. Baldwin, L. O. Duclos and A. E. Duclos will represent the company with a full line of samples, descriptive literature and souvenirs.

An American consul in South America reports that a city of about 200,000 inhabitants is about to issue a call for bids, open for four months, for contracts to supply drainage and electric power. He says that contracts will probably be tied together and that interested houses should send an expert representative at once. Address the Bureau of Manufactures, Washington, D. C., referring to No. 1463.

The many old friends throughout the West and Northwest of Mr. J. E. Ham will be interested to know that through the home office of the Waterbury Company of New York he has recently received the appointment as representative of that company in the West for the introduction of the company's high-grade insulated wires and cables. It will be recollected that Mr. Ham for a long time represented the Hazard Manufacturing Company in the West. The headquarters of the Waterbury Company's new western manager will be at that institution's branch office, 108 La Salle Street (Stock Exchange Building), Chicago.

BUSINESS.

The American consulate, Amoy, China, would like to receive catalogues, commercial publications, etc., from all American business houses desiring to enter that field.

Secretary J. D. Kenyon of the Sheldon School, 209 State Street, Chicago, sends out a letter in which he calls attention to the facilities of that institution for teaching the science of business and of successful salesmanship.

F. B. Badt & Co., Monadnock Building, Chicago, call attention to the merits of the Excello flaming arc lamp. This lamp, taking 6 and 10 amperes and at 55 volts across the arc, gives 1,300 and 2,500 mean hemispherical candlepower and will burn from 10 to 17 hours. It is used for both direct-current and alternating-current circuits and for either indoor or outdoor lighting.

The Central Electric Company of Chicago reports very large sales on Stanley G-I arc lamps, for which it is agent. Referring to the new type "K" lamp, the company says that it is the simplest arc lamp on the market and asserts that no matter what the conditions, current or circuit, it can furnish a type "K" lamp which will give good light and do it economically. The company is sending out to the trade special bulletins on this lamp and requests inquiries for descriptions and prices.

The New York Central and Hudson River Railroad Company has made extensive and varied use of the Dossert solderless connector in the electrification of the road. It has used up to date over one thousand straight two-way connectors of all sizes up to 1,000,000 circular mils and of cable taps it has used an even larger number, of sizes from 350,000 circular mils up to 1,350,000 circular mils. These cable taps were used principally in tapping off from the third rail in series of three to connect by way of the structure to the overhead cables. Dossert & Co. also made for the New York Central an emergency jumper clamp connector. In case of a break in the third-rail current the connector is attached to the third rail on either side of the break, thus preventing a tie up of the service until the regular flow of current is re-established. Dossert & Co. are addressed at 242 and 244 West Forty-first Street, New York city. They will have an exhibit at the street-railway convention at Atlantic City next week.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) October 1, 1907.

867,256. Subaqueous Light System. Léon Dion, Wilkesbarre, Pa., assignor to the Dion Submarine Light Company, Wilkesbarre, Pa. Application filed November 6, 1906. Renewed July 10, 1907.

As a means for illuminating a marine course, electric cables are laid along the course at the bottom of the body of water and a series of permanently submerged electric lamps buoyantly supported above the cables. The lights under the incoming course are of a different color from those under the outgoing course.

867,257. Fuse-box Support. James S. Doyle, New York, N. Y. Application filed January 24, 1907.

A truck frame beam has brackets supporting a spring strip at its ends. A bar supported upon this spring carries a fuse box so as to permit it to have fairly free movements.

867,312. Electric Wire Connector. John A. Shutz, Richmond, Ind., assignor of one-third to Madison L. Kirkman and one-third to William H. Woolley, Richmond, Ind. Application filed December 3, 1906.

This device connects the cables together in tandem. Each cable is soldered into a terminal lug provided with an interlocking wedge and a longitudinally coiled spring extending out from the wedge portion. These springs are adapted to contact with a shoulder on the opposing lug so as to separate the cables. A band slides over the united lugs and holds the interlocking wedge together against the action of the springs.

867,319. Electrode. John W. Stubbs, Middlewich, England, assignor to the General Electrolytic Parent Company, Limited, of Great Britain. Application filed April 9, 1907.

This electrode consists of a mass at end of a conductor composed of a mixture of powdered carbon, resin and tetrachloride of carbon.

867,320. Electrolytic Process and Product. Clinton P. Townsend, Washington, D. C., assignor to Elmer A. Sperry, Brooklyn, N. Y. Application filed April 24, 1905.

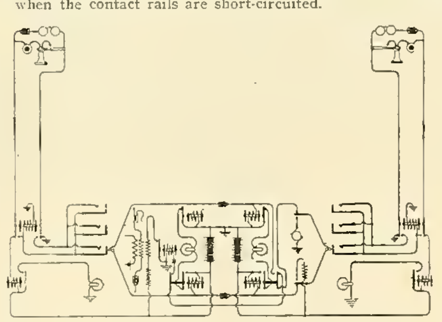
This is a method for producing lead oxide and consists in passing a current from an anode of lead through an acetate solution, producing lead acetate and a plumbite, which are subsequently combined to form lead oxide.

867,329. Block-signal Apparatus. Frank C. Williams, Philadelphia, Pa. Application filed July 17, 1905.

Each signal point is provided with an electromagnet whose circuit is closed by a passing train, thus setting the signal to danger in the block ahead and releasing the one at the entrance of the block just traversed. Another electromagnet has its circuit closed only when a train passes a danger signal, and this magnet immediately operates a motor on the locomotive or car which brings the train to a full stop.

867,331. Automatic Safety Controlling Means for Trains. David S. Affleck, Chicago, Ill. Application filed August 16, 1906.

The track is subdivided into electrically insulated blocks, which are also provided with signal and safety contact rails. When a block is occupied the contact rails of the adjacent blocks are short-circuited. The locomotives are equipped with signaling devices, actuated by contact with the signal rails, and with a local circuit normally energized which shuts off the power and puts on the brakes when the contact rails are short-circuited.



NO. 867,349.—TESTING SYSTEM FOR TELEPHONE LINES.

867,335. Cementitious Pole for Supporting Overhead Wires and the Like. William M. Bailey, Richmond, Ind., assignor to the American Concrete Pole Company, Richmond, Ind. Application filed December 17, 1906.

A reinforced cement pole consists of an elongated cement body enclosing a number of longitudinal rods remote from each other and disposed about the longitudinal axis of the body, and a wire disposed in a continuous spiral about and closely encircling the rods substantially from end to end of the body.

867,349. Testing System for Telephone Lines. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, Chicago, Ill. Application filed July 27, 1903.

A high-resistance test relay is adapted to be connected with any one of a set of cord circuits by inserting the answering plug in the jack of the calling line, and to be disconnected by inserting the calling plug in the jack of the called line. (See cut.)

867,354. Automatic Weighing Machine. Clinton A. Douglass and Fred L. Jones, Denver, Colo. Application filed April 15, 1907.

A scale has situated above it a hopper with a discharge outlet provided with a cut-off. A chute below the outlet has a gate at its lower end, which is operated simultaneously with the cut-off. An electrically operated latch arm holds these open until the circuit is closed by the tipping of the scale beam and then the latch is released and a spring closes the gate and cut-off.

867,355. Safety Device for Heaters. Ira Filson, Springfield, Ohio. Application filed May 28, 1906.

An electromagnet has its circuit closed by a thermostat when the temperature of the heater reaches a desired maximum. The stop clock in the gas supply has an extended arm adapted to be struck by a weighted lever pivoted near by. The armature of the magnet prevents the fall of this lever until the circuit is closed, whereupon the gas is shut off.

867,358. Ice and Sleet-cutting Contact Shoes. Rutherford Fullerton, Columbus, Ohio. Application filed March 13, 1907.

This device has ice-cutting members which lie across the rail at an angle thereto and which engage with the rail at its edges. Springs draw these members into engagement with the edges of the rail.

867,364. Automatic Railroad Signal. William H. Harris, Stark, Mont. Application filed January 9, 1907.

The signal is operated by the passage of trains through the medium of two circuits containing electromagnets. These magnets actuate pawls that engage ratchet wheels which move the signal disks.

867,391. Storage-battery Plate or Grid. Joseph Marx, Buffalo, N. Y. Application filed January 30, 1907.

The grid is made with a series of shelves and vertical ribs. Upon the shelves are placed units of active material in such a way as to leave space between the units and vertical ribs to allow for expansion.

867,406. Rail Bond. Lewis T. Pates, Upper Alton, Ill. Application filed December 26, 1906.

Rail ends have pairs of oppositely inclined apertures and a rail bond has pairs of prongs forced into the apertures and bent in opposite directions thereby.

867,415. Rail Bond. Frank W. Richey, Chicago, Ill., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 5, 1902.

The conductor has loops at its ends fitting over terminal heads that are flanged to receive them. A plate is welded over the loop and to the projecting end and flange of each terminal.

867,416. Electrical Conductor. Frank W. Richey, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 10, 1904.

A terminal of an electrical conductor has an expanding device comprising a pin having end portions connected by an intermediate reduced portion and a split bushing surrounding the reduced portion.

867,436. Lead Pigment and Similar Compounds. Elmer A. Sperry, Brooklyn, N. Y. Application filed August 30, 1906.

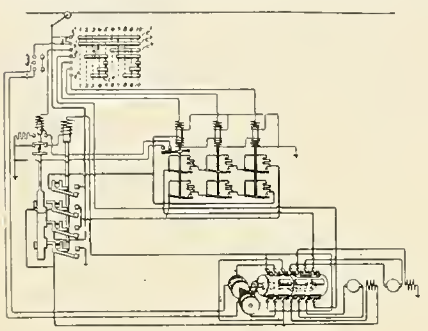
This is a process for preparing lead pigments and consists in using lead as anode in an electrolysis that produces metallic lead at the cathode, which is then used as anode in another electrolyte depositing a lead compound. This compound is finally subjected to a reagent at a high temperature so as to form the product desired.

867,440. Three-wire Molding Receptacle. James S. Stewart, New York, N. Y., assignor to Annie Stewart, New York, N. Y. Application filed June 29, 1906.

An insulating base has a sleeve and central stud terminal suitable for receiving a lamp or attachment plug. Two terminal clips pass through the base on one side so as to connect to two of the three circuit wires in the molding and still allow the receptacle to be symmetrically placed over the molding.

867,448. Signaling System for Railways. Louis H. Thullen, Edgewood, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed June 23, 1906.

This system is adapted for electric railways which use the rails as one side of an alternating current for propelling the cars. The track is divided into block signaling sections, each of which contains a relay and a source of alternating current of different frequency from that of the power current. The relay has two coils, one having inductance in series with it and the other capacity so as to produce a movement of the relay armature in one direction by current of one frequency and in the reverse direction by current of a different frequency.



NO. 867,476.—MOTOR CONTROL.

867,452. Electrolytic Bleaching of Cotton. August A. Vogelsang, Dresden, Germany, assignor to the British Hosiery and Electrolytic Bleaching Company, Limited, London, England. Original application filed September 21, 1901. Divided and this application filed July 28, 1902.

This process consists in placing the whole of the material in a vat at one time, treating it with caustic solution, collecting from an electrolyzer bleaching liquor in a separate vessel in sufficient quantity to cover the whole bulk of the material and in sufficient strength to bleach it without further electrolytic treatment, admitting the collected liquor into the vat after the withdrawal of the caustic liquor and allowing the bleaching liquor to act *in situ* on the material continuously until this liquor is exhausted.

867,456. Electrode for Arc Lamps and Method of Making the Same. William S. Weedon, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed December 10, 1903.

This method consists in forming a mixture containing substantially seven parts of titanium oxide and one part of carbon, forming electrodes out of the mixture, and, prior to the completion of the electrodes, converting the mixture into titanium sub-oxide.

867,475. Motor-starting Rheostat. Eugene R. Carichoff, East Orange, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed May 25, 1905.

The rheostat is made up of superposed spiral grids connected in series. Each unit is provided with a short-circuiting switch, which is normally open but can be closed by means of an electromagnet whose armature actuates the switches successively.

867,476. System of Control. Eugene R. Carichoff, East Orange, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 19, 1906.

A speed controller for a motor or motors has a series of individual switches arranged to cut resistance out of the motor circuit step by step. Actuating coils for the switches are operated successively as the counter electromotive force of the motor rises. (See cut.)

867,481. Prepayment Meter. Frank P. Cox, Lynn, Mass., assignor to the General Electric Company, Schenectady, N. Y. Application filed July 14, 1897.

A motor meter is provided with a switch connecting in the load. This is closed by the insertion of a coin and held closed by a latch which is electromagnetically released when a predetermined amount of electrical energy has been consumed.

867,482. Locking Mechanism for Controller Handles. Archibald S. Cubitt, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 2, 1906.

The controller handle carries a dog engaging stops on the top of the controller box that are so shaped as to permit free movement of the handle in one direction and only intermittent movement in the other. A button release in the handle can release the dog only when the handle has fully reached certain definite positions.

867,483. Self-adjusting Brake for Hoists. Philip J. Darlington, Glenridge, N. J., assignor to the Sprague Electric Company. Application filed May 11, 1904.

A motor-driven hoist has two adjustably pivoted braking arms, one having a link pivoted to it, the other having a bell crank lever pivoted to it and to the link. A connection from the lever is arranged to draw the pivots of the braking arms closer together when these have an increased [illegible] range of pivotal movement due to wear.

867,484. Spur-geared Hoist. Philip J. Darlington, Glenridge, N. J., assignor to the Sprague Electric Company. Application filed May 11, 1904.

A motor-operated hoist has a spring-applied brake arranged to normally prevent a lowering movement of the hoist and to exert a reduced restraint upon the hoisting movement. Means are provided on the controller for causing the brake to be released when the controller is moved to lowering position.

867,486. Electric Locomotive. Samuel T. Dodd, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed February 18, 1907.

An electric locomotive with driving wheels and idlers has an equalizing link suspended between a driving wheel and idler and supporting a portion of the weight of the locomotive frame. Pneumatically actuated means are provided for shifting the effective load-point on this link, these means being operated by the motor-controlling switches.

867,494. Fire-alarm Telegraph System. Manious Garl, Akron, Ohio. Application filed October 20, 1905.

This system has an alternating-current generator as source of current, a normally closed line circuit, a normally open ground circuit and local alarm circuit. A relay in the line circuit normally keeps open the local circuit which is closed by breaking the line circuit. The ground and line circuits are opened and closed alternately.

867,496. Fuse. Henry Geisenhöner, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed June 29, 1903.

This fuse is a combination of a body containing two chambers, of a fuse in one of them, a spring in the other connected with the fuse, and a lock for preventing the operation of the spring when only a temporary over-load occurs.

867,509. Electric Switch. Edwin Johnson, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed August 24, 1905.

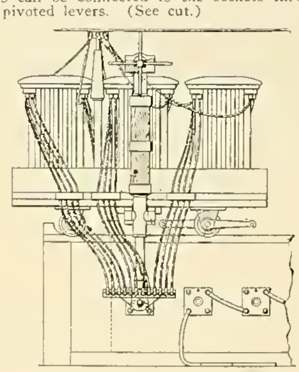
This switch has two sets of contacts, a contact disk, a spring-actuated stem connected therewith, a toggle pivoted to the stem, a plunger and a rocker actuated by the plunger and operating to set and trip the toggle.

867,517. Method of Preliminary Treatment for Accumulator Plates. Henry Leitner, Maybury, Woking, England. Application filed August 25, 1904.

The process consists in immersing the plate in a weak electrolyte comprising not more than 3½ per cent. of sulphuric acid, to which is added not more than 3½ parts per 1,000 of hydrochloric acid, subjecting the plate as an anode to an electric current of high density and maintaining the electrolyte at a temperature of not more than 85 deg. F., artificial cooling thereof being resorted to.

867,519. Electric Furnace. John T. Marshall, Metuchen, N. J., assignor to the General Electric Company, Schenectady, N. Y. Application filed January 26, 1907.

This furnace has a box-like structure with carbon tubes extending across the box that are held in metallic sockets in the walls thereof. A carriage, movable over the top surface of the furnace, carries transformers whose secondaries can be connected to the sockets through a system of pivoted levers. (See cut.)



NO. 867,519.—ELECTRIC FURNACE.

867,522. Means for Automatically Controlling the Speed of Railway Trains. Daniel J. McCarthy, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed April 25, 1907.

The brake-controlling valve on the train has placed near it a magnet responsive to currents of a certain high frequency. Along the track are placed means for exciting the coils of the magnet with frequencies proportional to the speed. When this reaches a predetermined value the brakes are applied.

867,528. Point Shifter for Tramways and the Like. George D. A. Parr, Leeds, England. Application filed August 18, 1905.

The point in a track switch is operated by an electric motor through the medium of weights alternately raised and lowered by the motor. A latch normally restraining movement of the weights is electrically operated from the car.

867,542. Attachment for Electrical Furnaces. Samuel M. Weaver and William Ambler, Cleveland, Ohio. Application filed September 29, 1905.

The casing carries thermo-couples and a pan mounted for supporting the work in a fixed relationship to the couples.

867,543. Filling for Thermal Cut-outs. Frederick H. Weston, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed April 22, 1905.

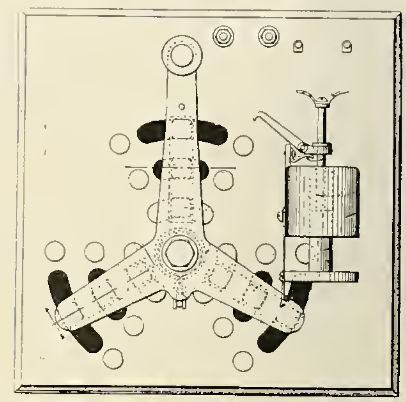
An absorptive filling for enclosed fuses consists of dry granules of slaked lime and calcium sulphate.

867,544. Electric Arc Lamp. Edward F. Winfield, Los Angeles, Cal. Application filed March 14, 1905.

An electric arc lamp has two vertical supports, insulated brackets secured thereto, a solenoid between the front edges of the upper brackets, and a carbon holder in the forward edge of the lower bracket. Means are connected with the solenoid for holding and feeding a carbon. A cross bracket is mounted on the supports intermediate their ends, and a reflector on the bracket with its forward end extending beyond the front edges of the brackets.

867,547. Starting Device for Alternating-current Motors. William C. Yates, Schenectady, N. Y., assignor to the General Electric Company, Schenectady, N. Y. Application filed October 18, 1905.

This is a starter for single-phase induction motors employing a phase-splitting device for starting. It has a no-voltage release for holding it in running position and spring for returning it to "off" positon. A stop prevents moving the handle direct from "off" to running positions without first pausing at starting point. (See cut.)



NO. 867,547.—INDUCTION-MOTOR STARTER.

867,555. Chandelier. Frederick A. Burton, Wahpeton, N. D., assignor of one-third to Christina E. Kouba and one-third to Peter H. Stenerson, Wahpeton, N. D. Application filed June 21, 1906.

This chandelier is made in two parts, the lower one being capable of vertical adjustment and being held by frictional rollers to the upper part. A coiled spring carries the electric wires.

867,561. Measuring Instrument. Albert G. Davis and Caryl D. Haskins, Schenectady, N. Y., assignors to the General Electric Company, Schenectady, N. Y. Application filed March 15, 1904.

A motor-meter has a flexible connection betwen its rotor and its shaft for supporting the weight of the shaft and parts carried by it. A ring-bearing prevents lateral displacement of the shaft.

867,563. Automatic Block-signaling System. Daniel J. McCarthy, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Application filed August 16, 1907.

An alternating-current block-signaling system has home and distant-signal blades, a reversing relay through which the blades are controlled by the track circuits, a line circuit, an alternating-current slot magnet, and a slow-motion circuit-controlling device for controlling the circuit of this magnet.

REISSUE.

12,700. Electric-traction Apparatus. Alfred Zehden, Frankfort-on-the-Main, Germany, assignor to J. M. Woodward, Cleveland, Ohio. Application filed August 21, 1907. Original No. 782,312, dated February 14, 1905.

A rail-like armature and an electromagnet are mounted on a carriage, the armature being located relatively to the magnet, so that by the co-operation of these parts the carriage is not only moved forward but its weight is counterbalanced in whole or in part.

PATENTS THAT HAVE EXPIRED.

Following is a list of electrical patents (issued by the United States Patent Office) that expired October 7, 1907:

437,682. Electric Safe Lock. G. L. Damon, Boston, Mass.
437,704. Regulator for Electric Generators and Motors. R. Lundell, New York, N. Y.
437,720. Conduit Electric Railway. E. M. Reed, Wichita, Kan.
437,754. Electric Meter. J. Einstein and S. Kornprobst, Munich, Germany.
437,763. Electric Meter. A. Reckenzahn, Clapham, England.
437,767. Arc Lamp. R. H. Brach, St. Paul, Minn.
437,771. Electric Steam Generator and Water Heater. H. R. Butterfield, Waterville, Me.
437,789. Electric Ceiling Block. A. E. Nichols, Leeds, England.
437,832. Electric Motor. J. Emmner, Jr., Washington, D. C.
437,835. Electric Motor. G. Little and G. J. Little, Passaic, N. J.
437,848. Secondary Battery. H. Lampert, Jr., Chicago, Ill.
437,859. Electrical Transmitter and Indicator. D. Kelley and M. C. Parkhurst, Somerville, Mass.
437,868. Galvanometer. A. M. Ritchie, Brookline, Mass.
437,901. Electric Arc Lamp. C. W. Hazeltine, St. Louis, Mo.
437,926. Galvanometer. T. Harris, Detroit, Mich.
437,930. Receiving Instrument for Telegraphy. W. M. Miner, Plainfield, N. J.
437,946. Brush Holder for Electric Motors. E. A. Sweet, Milford, Mass.
437,953. Conduit and Electric Conducting Rail Therefor. J. H. Wehrle, Newark, N. J.
437,986. Telephone System. A. Graham, London, England.
438,036. Pole for Electric Wires, etc. E. Verstraete, St. Louis, Mo.
438,037. Rheostat. J. C. Vetter, New York, N. Y.

WESTERN ELECTRICIAN

EVERY SATURDAY

Vol. XLI. CHICAGO, OCTOBER 19, 1907. No. 16

Moderate-sized Searchlights for the Mercantile Marine.

By Dr. Alfred Gradenwitz.

Searchlights, as well known, are projectors giving intensive illumination, to allow any objects to be searched and watched from a distance. To this effect the light of an electric arc lamp is concentrated by a parabolic mirror, which reflects it in the shape of a beam of very small angle. Both the mirror and lamp are located in a casing, which is free to move in all directions.

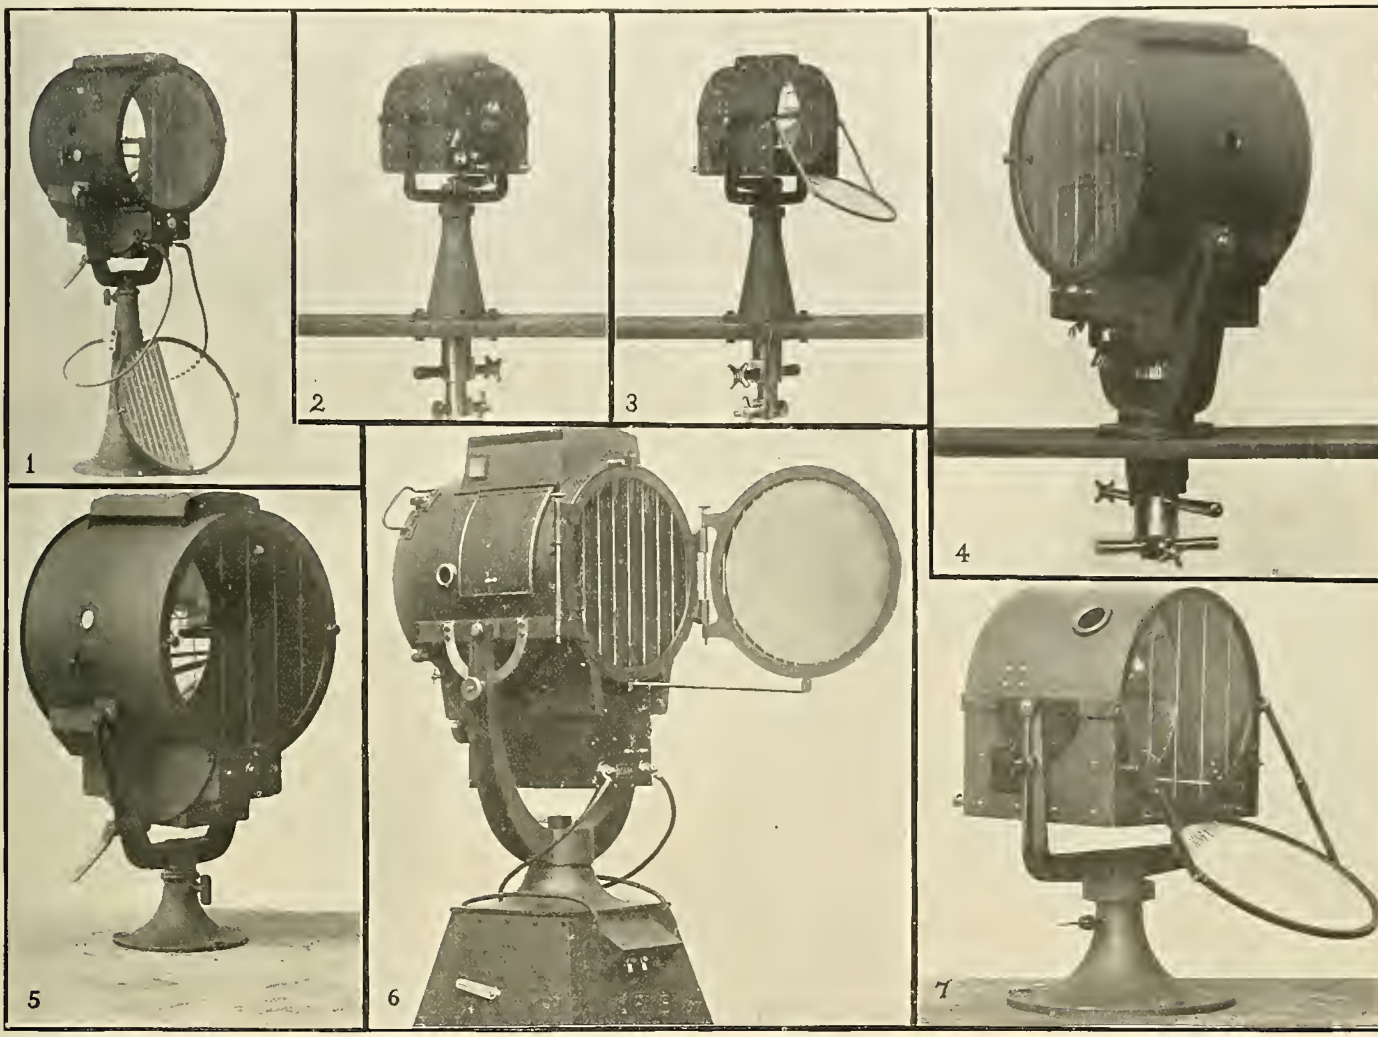


Fig. 1. Projector on Column with Metal Parabolic Mirror 350 Millimeters in Diameter.
Fig. 2. Projector Adapted to be Secured to Pilot-house Railing. Glass Mirror 210 Millimeters in Diameter.
Fig. 3. Pilot-house Projector with Ripple-glass Screen.
Fig. 4. Pilot-house Projector with Metal Parabolic Mirror of 450 Millimeters.
Fig. 5. Projector of 450 Millimeters Diameter on Low Stand.
Fig. 6. Suez Canal Type of Projector with Parabolic Glass Mirror of 450 Millimeters and Dispersing Screen.
Fig. 7. Low-stand Projector with Non-polished Parabolic Glass Mirror.

MODERN SEARCHLIGHTS OF MODERATE SIZE FOR MERCHANTMEN AND YACHTS.

Only continuous current can be used for the operation of searchlights. In alternating-current lamps there are formed at the ends of the two carbons opposite each other two equivalent sources of light, each of which radiates about half of the total energy converted into light to opposed directions. Now, as reflectors can be used only for one side, utilizing the light of one carbon, only half of the available energy can be resorted to for producing the desired effect. Moreover, the light from the other carbon would interfere with observation by dazzling the eye through the brightly illuminated objects surrounding the projector and by interposing between the observer and object a veil consisting of numberless small particles suspended in the atmosphere.

In continuous-current lamps, on the other hand, practically the whole of the light is generated in the crater of the positive carbon, from which the light rays are mainly projected to one side in a conical beam. Owing to this one-sided radiation the lamp is especially adapted for use in connection with a concave mirror, concentrating and projecting any light supplied to it in the shape of a projector beam.

The searchlights described herewith are mainly intended for use on board merchant ships and dredges, or on motor boats and steam yachts. A special searchlight on board merchant ships serves to light the edge and banks of canals on traversing the latter, while projecting no light immediately in front of the ship, so as not to dazzle any approaching vessels. These searchlights, the prototype of which is used on the Suez Canal, have been termed Suez Canal projectors.

The luminous intensity of a searchlight depends in the first place on the size of the mirror and next on the current intensity feeding the arc lamp. Projectors for merchantmen and dredges are usually designed for currents of from 6 to 50 amperes, while the smaller type of motor-boat searchlight is designed only for six amperes. The potential difference between the carbons of the arc obviously depends on the current intensity, and in the case of six amperes is about 43 volts, while increasing with increasing current intensities, though at a far slower rate than the latter, till a figure of about 47 volts is reached at 50 amperes.

The mirrors in the case of merchant-ship searchlights (Figs. 1, 4 and 5) are parabolic metal mirrors, of a diameter varying between 250 and 450 millimeters. The smallest searchlights for motor boats are provided with non-polished parabolic glass mirrors 210 millimeters in diameter. Figs. 2, 3 and 7 show searchlights designed for motor boats and steam yachts. The Suez Canal searchlight (Fig. 6) has a polished parabolic glass mirror 400 to 450 millimeters in diameter. Such mirrors combine the best obtainable optical qualities with a satisfactory and practically constant efficiency.

Each searchlight can be fitted with a device for allowing the beam to spread and to increase the lighted field. This is termed a disperser, and is a system of vertical plane-convex cylinder lenses fitted whenever desired before the front aperture of the searchlight.

The searchlights represented in Figs. 1, 2, 3, 4, 5 and 7 can be provided with rippled glass dispersers for an angle of about 12 degreees, while the Suez Canal projector (Fig. 6) is fitted with polished glass dispersers for angles of 6, 12, 15, 20, 30 or 45 degreees. It may also be fitted with polished dispersers for an angle of 15 degrees with a dark central field of five degrees, which design is especially adapted to the original purpose of this searchlight, namely, to light the banks of canals on the passage of the vessel. Merchant-ship projectors (Figs. 1, 4 and 5) may equally well be equipped with this special type of disperser for the passage of canals.

Each searchlight comprises a ventilated sheet-iron housing with a round locking glass, divided into strips, dark inspection glass for inspecting the arc and a shunt arc lamp with horizontal carbons, which is controlled either automatically or by hand. A device for adjusting the crater of the positive carbon to the optical axis is usually provided.

The housing rests in a trunnion, and can be rotated through 360 degrees round the vertical axis and about 45 degrees (in the case of the searchlights of Figs. 2, 3 and 7 through 25 degrees) by hand in a vertical direction, being readily fixed in any position. The projectors are provided with three different types of support, viz., flat cast-iron bases (Figs. 5 and 7), high cast-iron columns (Fig. 1) and cast-iron column or base for fitting on the pilot-house railing (Figs. 2, 3 and 4). In the last-named case the drive for the vertical and horizontal rotation is controlled from the interior of the pilot house.

The searchlight of the Suez Canal type (Fig. 6) is usually installed on sheet-metal pedestals, the size of which is adapted to the conditions of the case, and in this design can be also fitted on the pilot house.

A Novel Self-contained Electric Hoist.

A new and rather interesting electric hoist has been invented recently by James L. Pilling of Chicago, who has secured a United States patent on the device. The inventor aimed to design a power hoist of the block and tackle order that

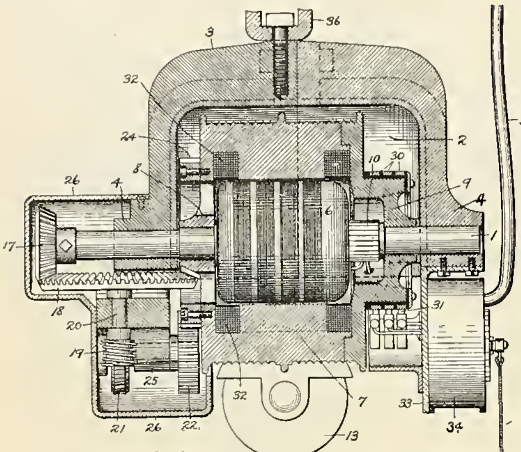

Fig. 1. Vertical Longitudinal Section.

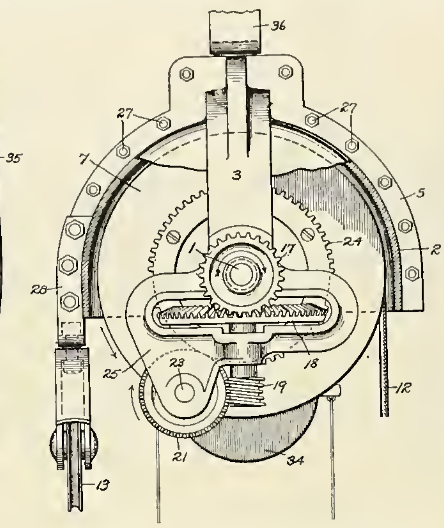

Fig. 2. Rear Elevation with Gear Casing Removed.

A NOVEL SELF-CONTAINED ELECTRIC HOIST.

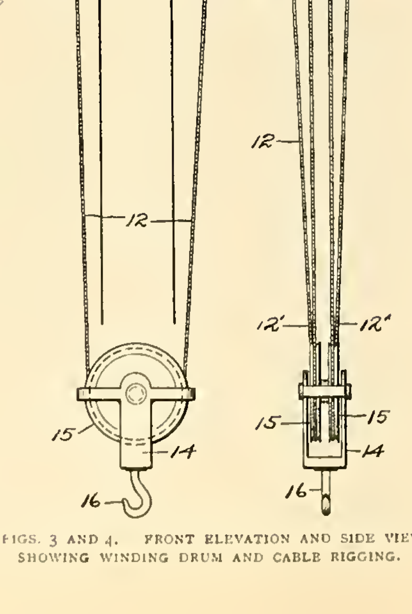
would be compact, simple and inexpensive in construction and yet capable of raising heavier loads in proportion to its own weight than power hoists heretofore constructed. The invention embodies a number of novel features.

The preferred form of this hoist is shown by the accompanying illustrations, of which Fig. 1 is a vertical longitudinal section and Fig. 2 is a rear elevation wherein the gear case is entirely, and the main casing partly, removed. Fig. 3 is an elevation of the front end of the hoist, while Fig. 4 is a side view, omitting the casing so as to show the winding drum. Figs. 3 and 4 show the full cable rigging for the hoist.

The framing of the hoist consists of an inverted U-shaped yoke (3) and a bell-shaped main casing or frame (2), which are preferably made integral with each other, but are divided transversely into two parts bolted together at the flanges (5) to permit of ready access to the interior mechanism. The yoke (3) terminates in the two bearings (4) for the main shaft (1).

The armature (6) of the motor is keyed on this shaft, which also supports the field (7) in such a way that it can revolve about the shaft, the two hubs (8) and (9) being provided for this purpose. Both armature and field revolve when the motor current is applied, since they are geared together by a system of gearing giving them opposite directions of rotation. The periphery or yoke of the field (7) is made cylindrical to form the drum upon which the lifting cables are wound and its outer surface is spirally grooved for this purpose. In order to preserve the balance of the hoist when loaded, both ends of the cable (12) are attached to the drum (at opposite ends thereof), thus forming one or more loops or bights for carrying a sheave-block. As shown, two loops or bights (12') are formed by carrying the cable up and around a sheave (13), suspended from the frame (2) of the hoist. A sheave block (14) suspended from the loops (12') carries two sheaves (15) and a lifting hook (16). The top sheave-block (13) is swiveled on a wrought metal clip (28), which is bolted to the flanges (5) at one side of the bell-frame. This arrangement of the hoisting cable is adapted to balance the frame of the hoist when loads are being lifted. The tendency of the load is to cant the hoist upwardly at the side to which the sheave (13) is attached. The downward pull of the cable upon this sheave counterbalances the tendency referred to, and the hoist frame will hang substantially the same when loaded as when unloaded.

The armature and the field are geared together in order to provide for holding suspended loads, and also in order to utilize the rapid rotation of the inner part or armature of the motor. This gearing is preferably a locking gear that will permit the rotation of the motor in either direction, but will not permit rotation of the cable drum by the suspended load even though the motor be switched off. The gearing as shown comprises a bevel pinion (17) on the shaft (1), a bevel gear wheel (18) and a worm (19) on a shaft (20), a worm wheel (21) and a spur pinion (22) on a shaft (23), and a gear (24), driven by the pinion (22) and secured to the field (7). The bearings for shafts (20) and (23) are provided with a casting (25) which may be either integral with, or secured to, the frame (2). The worm gear (19—21) forms a noiseless and absolutely reliable lock against backward rotation of the drum by a suspended load, and holds the load at any height while the motor is stopped. This gearing is so arranged as to cause the armature and field of the motor to turn in opposite directions, whereby the full power of the motor is obtained. When lifting a load the parts rotate in the direction of the arrows shown in Fig. 2. The object of driving from pinion (17) to a larger wheel (18) is to avoid excessive heating of the worm gearing by reducing the speed thereof. The gearing is enclosed by a casing (26), the lower portion of which forms a chamber for oil to lubricate the gears 19, 21, 22 and 24.



FIGS. 3 AND 4. FRONT ELEVATION AND SIDE VIEW, SHOWING WINDING DRUM AND CABLE RIGGING.

As the field is rotative, it is provided with collector rings (30) and brushes (31), through which the current is taken into the field windings (32). One field hub (9) carries the armature brush holders (not shown), and two of the rings (30) are in connection with them. The brushes (31) are held by a bracket (33) supporting also the motor controller (34). The leads from these brushes (31) pass into the controller, and a cable (35) leads from the controller to the supply conductors.

The operation is as follows: The hoist is suspended by its hook (36) and the object to be lifted is attached to the sheave-block hook (16). When the motor is started its two parts turn in opposite directions, the armature at a comparatively high speed; the speed of the outer part being controlled by that of the inner part through the medium of the gearing. The outer part, that is, the drum, draws up the two ends of the cable (12), which draws up the sheave-block (14). The cable winds from the ends toward the center of the drum. Suppose now that the motor should be intentionally or accidentally stopped. The weight of the load tends to turn the worm wheel (21), but that member cannot turn while the worm is at rest; thus the load is held suspended without the use of brakes, ratchets or other troublesome devices. The load is lowered by running the motor in reverse direction. The worm gearing prevents racing of the motor at such times and enables the operator to lower away as slowly as desired.

The winding drum need not be of the same diameter from end to end. A portion thereof may be of smaller diameter to receive a cable for hoisting very heavy loads.

Grounded Neutral in High-tension Systems.

At the meeting of the American Institute of Electrical Engineers in New York on October 11th the recently elected president, Mr. H. G. Stott, presided, and gave a brief inaugural address, reported elsewhere in this issue. The subject of the evening was "The Grounded Neutral in High-tension Systems," and papers were presented by Paul M. Lincoln, engineer of power division of the Westinghouse Electric and Manufacturing Company, Pittsburg; F. G. Clark, superintendent of power station of the Pennsylvania Tunnel and Terminal Railroad Company, Long Island City, and George I. Rhodes, assistant engineer of the Interborough Rapid Transit Company of New York city. The papers and discussions covered advantages and disadvantages of the grounded connection under various conditions, more particularly the possibility of cutting out faulty feeders without interrupting the service. The function of series resistance in the ground connection also received attention.

Before opening the meeting for the discussion President Stott announced the presence of two distinguished German visitors, Messrs. Wallen and Schrottke of the Siemens-Schuckert Company in Berlin and also of the Verband Deutscher Elektrotechniker.

Written contributions to the discussion were received from F. G. Baum of San Francisco and O. S. Lyford, Jr., of New York, and were read.

The oral discussion was opened by P. Junkersfeld of the Commonwealth Edison Company, Chicago, and continued by Philip Torchio, New York Edison Company; N. J. Neall, Boston; J. B. Taylor, General Electric Company, Schenectady; C. Schwartz, New York Central Railroad Company, New York; C. W. Stone, General Electric Company, Schenectady, and Charles F. Scott, Westinghouse Electric and Manufacturing Company, Pittsburg. Messrs. Lincoln and Rhodes, authors of two of the papers, then spoke, and the discussion was closed by Dr. C. P. Steinmetz of Schenectady. Although no conclusion was reached, a great deal of valuable material was brought out, some of which is presented in this issue of the Western Electrician and some of which will appear in a future issue or future issues, if space permits.

Narcosis by Blue Rays of Light.

A dentist at Geneva, Dr. Radard, after having for several years made experiments with the narcotic effect of blue light, has submitted his results to the Swiss Society of Odontology. According to Consul William Bardel at Bamberg, Dr. Radard asserts that a complete narcosis can be obtained if the rays of a blue electric light are brought to bear on the human eye while all other rays of light, particularly of daylight, are kept off of it. The narcosis thus obtained is so complete that, during the same, little dental operations, such as pulling or filling teeth, etc., can be executed without causing the patient the least amount of pain. While the effect of the blue rays is a very strong one, that of violet-blue and green rays is less intensive, and yellow or red rays show no effect at all.

Inland Empire Electric-railway System.

As readers of the Western Electrician are aware, from previous articles, one of the most important systems of electric railways in this country is that of the Spokane and Inland Empire Railroad Company, with headquarters in Spokane, Wash. Planned, built and operated by men prominent in the successful upbuilding of that portion of Washington, Oregon, Idaho and Montana, known as the "Inland Empire," the affairs of this large electric-railway system are directed by Mr. Jay P. Graves, president; F. Lewis Clark, first vice-president; A. L. White, second vice-president; W. G. Davidson, secretary, and H. B. Ferris, treasurer.

The "Inland Empire" reaches from the Rockies on the east to the Cascades on the west, and from the Selkirks of British Columbia to the Blue Mountains of Oregon. This territory of 150,000 square miles, with the growing city of Spokane, now nearing 100,000 in population, as the metropolis, has great wealth in its mines, forests and agricultural districts. To aid in the development of these resources there are excellent natural waterpowers in the rivers of the Northwest to furnish power for manufacturing and for operating electric railways.

MARKETING WHEAT VIA THE SPOKANE AND INLAND ELECTRIC RAILWAY.

Foremost in the ranks of this development is the Spokane and Inland Empire Railroad, known as the Inland Empire System, whose lines assist as well as share in the general prosperity of the Spokane country. This company has acquired the Spokane and Inland Railway, a railroad of "steam practice" (that is, equivalent to the best steam railroads), but electrically operated, extending south from Spokane 76 miles to Colfax, Wash., and 92 miles southeast to Moscow, Idaho; the Cœur d'Alene and Spokane Railway, an electric road reaching eastward from Spokane to Liberty Lake, Wash., and Cœur d'Alene and Hayden Lake, Idaho, a distance of 40 miles; the Spokane Traction Company, an electric street railway, having 31.5 miles of lines in the city of Spokane; the Spokane Terminal Company, having passenger and freight terminals and rights-of-way in Spokane, and the Spokane Power Development Company, including two power sites on the Spokane River, one developed to generate 20,000 electrical horsepower, and a valuable franchise for the distribution of light and power in Spokane.

With the Spokane and Inland division now operating to Colfax and Palous, the several lines of the Inland Empire System aggregate over 200 miles. With extensions now contemplated and under way the total miles in the system will aggregate 225 by June 1, 1908. Material additions to the equipment of the Cœur d'Alene and Spokane and the Spokane local divisions have been found necessary this last year. Traffic agreements have been entered into with two of the principal transcontinental steam railroads, thus giving the system access to markets east and west.

For the 113 miles of railroad in the Spokane and Inland division, power is furnished from a frequency-changing station in Spokane. Current is transmitted from this station to the sub-stations along the lines to Colfax and Palous, a distance of 76 miles. A 275-cell storage-battery equipment for this division shows a saving in operation of approximately 50 per cent. in power bills.

The passenger equipment on the Spokane and Inland division consists of Brill 58-foot coaches finished in mahogany and with seating capacity of 64 each. The road is built of 70-pound steel, fir ties, and well ballasted for carrying the heavy freight and passenger trains of this division.

Twenty-five miles south of Spokane is the Mt. Hope passenger and sub-station. This, like the other passenger and freight depots of the division, is of modern construction, brick with concrete foundation, economical in maintenance and fire risk. In the sub-stations, which are located every 10 or 15 miles, the high-tension current is received and reduced from 45,000 to 6,600 volts and applied to the wire for operating trains.

An example of the rapid growth of Spokane's rural communities, since the inception of the Spokane and Inland division, is afforded by the village of Valleyford, located 10 miles south. Here a prosperous and beautiful suburb has sprung up in one year. At Spring Valley Junction, 40 miles from Spokane, the Colfax and Palous branches of the Spokane and Inland division meet. Headquarters of the division superintendent, chief dispatcher, etc., are located at this point.

The Spokane and Inland is being extended from Palous 16 miles to Moscow, Idaho. In Palous the road passes through the center of town on an elevation, avoiding all grade crossings. Joint freight yards are used at this point with the W., I. and M. Railway, which runs 65 miles east to Potlatch, Idaho, tapping the Potlatch lumber district.

Oakdale is 53 miles from Spokane on the Spokane and Inland division. It has a population of 1,500. Passenger and freight service was opened to the town on April 15, 1907. Garfield is 65 miles south of Spokane and is one of the foremost shipping points in the Palous country. Passenger and freight traffic was inaugurated to Garfield on June 1st.

The first train out of Colfax was operated on July 31st. The Spokane and Inland freight and passenger terminals and yards are located in the heart of Colfax. The site for the new depot occupies the block directly opposite the county courthouse. Car barns and machine shops of the division are located at Olive and Cincinnati streets. Four miles north of Colfax it was found cheaper to drive a tunnel 622 feet through a 200-foot hill rather than to follow a one-mile detour of the Palous River. A view of this tunnel is given in one of the accompanying pictures.

It is said that 10,000,000 bushels of wheat and 40,000 tons of oats and barley were produced this year in the territory directly tributary to the Spokane and Inland division. A chain of 30 grain warehouses is being operated along this division. Warehouses are 50 by 150 feet and have a capacity of 40,000 sacks of grain, or 50 carloads. One of the accompanying pictures shows a string of farm teams waiting in line to unload their grain in one of the warehouses of the electric road. A traffic agreement has been entered into between the Inland Empire System and the Great Northern Railway, giving markets in eastern states and on the Pacific Coast.

COLFAX TUNNEL ON THE INLAND EMPIRE SYSTEM.

Farmers along the lines of the Spokane and Inland division have shown their anxiety to utilize the new electric railway by delivering their grain before the warehouses were completed. This division has been double-tracked between Greenacres and Spokane Bridge. It is said to have one of the most substantially built roadbeds in the United States.

The Cœur d'Alene division, as stated, extends eastward to Liberty Lake, Cœur d'Alene and Hayden Lake, a distance of 40 miles. It serves the Spokane Valley, Spokane's beautiful lake region, and affords the most direct route to the famous Cœur d'Alene mining country. Passenger traffic on this division has made an average increase annually of 30 per cent. This season's increase over that of 1906 was 40 per cent., and the increase in freight traffic 75 to 80 per cent. United States railway mail service was inaugurated on the division August 12, 1907.

"SHOSHONE FLYER" LEAVING SPOKANE.

In the city of Cœur d'Alene the company has well-equipped electric docks, shown in one of the pictures, where the trains connect with the Red Collar Line for Harrison, Wardner and points on the St. Joe and St. Maries rivers. It is 68 miles from Cœur d'Alene to Head of Navigation on St. Joe River. The company has a handsome terminal building in Cœur d'Alene. This is the chief city in Northern Idaho, and it has increased in population from 1,000 to 8,000 since the opening of the electric line in December, 1903.

Parlor-car service on the Cœur d'Alene division was inaugurated on June 29, 1907, and has proven a remarkable success. The eight-mile branch from Cœur d'Alene to Hayden Lake was opened August 15, 1906, and has made greater earnings per car-mile than any other division of the system. Hayden Lake is one of Spokane's popular summer resorts, lying 40 miles east of the city. Passenger and freight service was opened to Liberty Lake, Spokane's most popular bathing resort, on June 15th. This lake lies among the hills 16 miles east of Spokane. It is on a two-mile branch running south from the main line at Liberty Junction.

"ELECTRIC DOCK" IN COEUR D'ALENE, IDAHO.

In the city of Spokane is the Electric Terminal Building, which is one of the best equipped in the United States. It is centrally located in the block next the new postoffice. Forty-two passenger trains leave and arrive at the terminal building daily. One of the pictures shows the Shoshone Flyer leaving Spokane. St. Louis type of cars are used on 31.5 miles of city lines now in operation.

The company has a very complete system for connecting the Inland Empire System with all the steam lines entering Spokane. The terminal yards are 300 by 2,000 feet, centrally located, with three of the large steam-road yards to the north and the Northern Pacific yards to the south, terminal tracks connecting all. The freight terminal building used by all the divisions is located at Ferry and Market streets and is 40 by 300 feet in size.

The Inland Empire System owns two valuable power sites on Spokane River. The power plant at Nine Mile Bridge will generate 20,000 horsepower and will be completed in December. It is expected that 5,000 horsepower will be required for use on the railway system, leaving the balance for market purposes. A franchise is owned by the company for distribution of current for light and power in Spokane.

The Aurora, Elgin and Chicago electric railway and the Metropolitan Elevated Railway of Chicago have put in service two new funeral cars, which will be run to the Oak Ridge, Mount Carmel, Waldheim, Concordia, Forest Home and Elm Lawn cemeteries.

Electrical Engineers of the Iron and Steel Industry Organize.

The first annual meeting of the Association of Iron and Steel Electrical Engineers was held in the rooms of the Engineers' Society of Western Pennsylvania in Pittsburg on October 11th and 12th. The association, which is the outgrowth of a meeting of electrical engineers in Pittsburg last spring, has for its object the application of electrical machinery and appliances to the iron and steel industry. Thirty-three men prominently connected with electrical generating plants and equipment departments of a number of large companies throughout the country constitute the charter membership.

The first session of the annual meeting was devoted largely to the election of officers with the following result: President, James Farrington, superintendent of electrical department of La Belle Iron Works, Steubenville, Ohio; first vice-president, J. C. Reed, electrical engineer of the Pennsylvania Steel Company, Steelton, Pa.; second vice-president, G. W. Sturgess, electrical superintendent of the Lackawanna Steel Company, Buffalo, N. Y.; secretary, G. H. Winslow, electrical engineer of the National Tube Company, Pittsburg; treasurer, E. W. Yearsley, electrical engineer of the Midvale Steel Company, Philadelphia.

Following the adoption of a constitution and by-laws at the morning session papers were read by E. W. Yearsley, George W. Richardson and D. B. Rushmore. In the afternoon the following-named gentlemen spoke: A. C. Eastwood, D. S. Kendall, Gano S. Dunn, R. P. Wright, C. T. Henderson, B. A Behrend, R P. Jackson and Paul M. Lincoln. Those present were taken to the works of the Westinghouse Company at East Pittsburg, where luncheon was served at noon.

An elaborate dinner was served at the Duquesne Club in the evening. At the remaining sessions addresses were given and papers read by M. Van Blarcom, C. E. Skinner and L. E. Bogen. The initial meeting was very successful, and it is planned to hold a number of meetings each year to take up electrical questions.

The following companies are represented among the charter members: Colorado Fuel and Iron Company, American Steel and Wire Company, Carnegie Steel Company, La Belle Iron Works, Phoenix Iron Works, Republic Iron and Steel Company, Youngstown Sheet and Tube Company, Illinois Steel Company, National Tube Company, Alan Wood Iron and Steel Company, Lorain Steel Company, Jones & Laughlin Steel Company, Seneca Iron and Steel Company, Pennsylvania Steel Company, American Bridge Company, Inland Steel Company, Lackawanna Steel Company, Bethlehem Steel Company, Lukens Iron and Steel Company, Maryland Steel Company and the Midvale Steel Company.

The Possibility of Regular Transatlantic Wireless Service.

Regular wireless transatlantic telegraph service is at hand, according to officials of the Marconi company, as reported in the daily newspapers on both sides of the water. At the present writing, however, the service does not appear to be available for public use, and the skeptics, like the gentleman from Missouri, still insist that they must be shown. The subject naturally attracts much attention in England, where stocks of submarine-telegraph companies are largely owned. Under date of October 4th the London correspondent of the Western Electrician has this to say about it:

"For the second time within a few years the Marconi Wireless Telegraph Company, by persistent newspaper notices that a transatlantic wireless-telegraph service is about to be inaugurated, has been responsible for a very considerable drop in the value of the shares of the cable companies. Curiously enough, this fall is accompanied by very emphatic denials that Mr. Marconi can accomplish all he claims to be able to do. As a matter of fact the new service was to have been started in the middle of September; we are now told that it will be in a few weeks' time.

"Apart from those quarters which are very distinctly pro-Marconi there is, in the first place, considerable skepticism as to the commercial achievement of transatlantic wireless telegraphy, and secondly, even assuming it is accomplished, the effect upon the traffic is likely to be infinitesimal. In all the notices and articles which the Marconi company manage to get into the papers, one never hears a word of the speed at which it claims to be able to work.

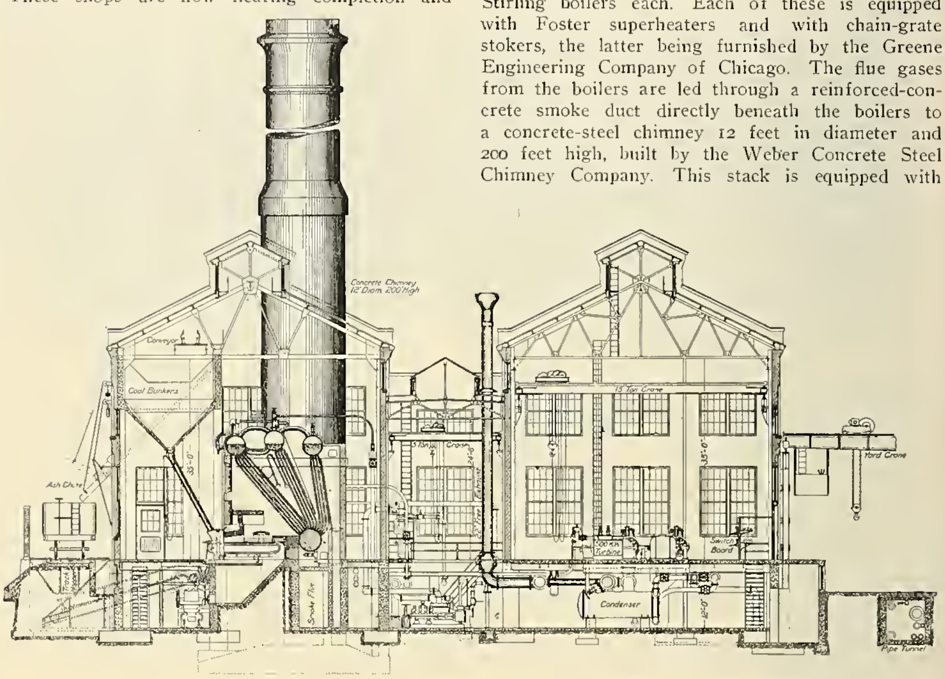
"Attention has been called to the very serious drop from 29 to 16 in the value of Anglo-American deferred shares. But a special interest attaches to this company, for in its last report a large sum was taken from revenue to meet depreciation in the company's invested cable renewal fund, and in the City this fact is recognized as being responsible for a great part of the decline.

"Already business men are being reminded of the possibility of delay through the wireless messages having to be retransmitted from Ireland by Postoffice wires, and the advantage of the present direct cable communication between our Stock Exchange and Wall Street is being pointed out and made much of. Comparatively few people seriously believe that any damage will be done to the existing cable traffic."

Power House for the "Big Four" Railroad Shops.

It has come to be practically standard practice in large industrial plants to generate all the power in one place and to transmit it electrically to the various shops and buildings. There is no uniformity, however, in the systems of electrical distribution used, as their selection is chiefly governed by the requirements of, and conditions about, the plant. An interesting example of a plant where special conditions were met is in the design of the power house for the new repair shops of the Cleveland, Cincinnati, Chicago and St. Louis Railway, located at Beech Grove, near Indianapolis, Ind. This railway is commonly referred to as the "Big Four" system.

These shops are now nearing completion and will be the largest of their kind in the country. There are 20 buildings, the power house being near the center of the group. Adjoining the shops a large freight yard and two roundhouses are being built. Each of the latter will have stalls for 25 locomotives.



CROSS-SECTION OF POWER HOUSE FOR "BIG FOUR" RAILROAD SHOPS NEAR INDIANAPOLIS.

The power house will furnish for the entire plant not only electric light and power, but also compressed air, service water, exhaust steam for heating, live steam for the steam hammers in the forge shop, and high-pressure water for hydraulic riveters and other tools.

The layout of the power house is clearly shown in the accompanying plan and sectional elevation, and the construction illustrated by the view taken about six weeks ago. The building, which is 114 feet by 128 feet, is of brick and steel construction to harmonize with the architecture of the other shop buildings. The foundations are of concrete, the column piers being reinforced. Sub-structure masonry is of shale brick of a dark color lined with sand lime brick. The turbine room is finished with a red pressed-brick wainscoting about six feet high. The roof is of slate laid on wood sheathing. By the liberal use of large windows in the side walls, and of monitors and skylights in the roof, an extremely well-lighted building is obtained. At present the building is closed on its east end by a wooden bulkhead to allow for future extension, which is contemplated at an early date. The power station will be ultimately twice its present size.

The available water supply was a vital factor considered in determining the character of the power-house equipment. The design finally adopted is an interesting illustration of how an apparently hopeless situation from the viewpoint of efficiency can sometimes be forced to give highly economical results by a careful study of requirements and by harmonizing these into a satisfactory working plan.

It was found that all water would have to be drawn from deep artesian wells and that a large supply of water was required for the locomotive roundhouses, which water would have to be chemically treated in a water-softening process to make it suitable for boiler feed. It was therefore decided to make the main generating units in the power house condensing by passing all the cold water direct from the wells through surface condensers, where its temperature would be raised from about 55° to about 90° F., then to the water-softening tanks, where the treating process is more effective with warm water, and finally to the roundhouses and boiler-feed pumps. By this plan abundant condensing water is secured without the need of a cooling tower. The condensing feature made the use of steam turbines advisable, and this resulted in the choice of three-phase alternating-current generators. The use of treated water permitted the selection of high-capacity water-tube boilers.

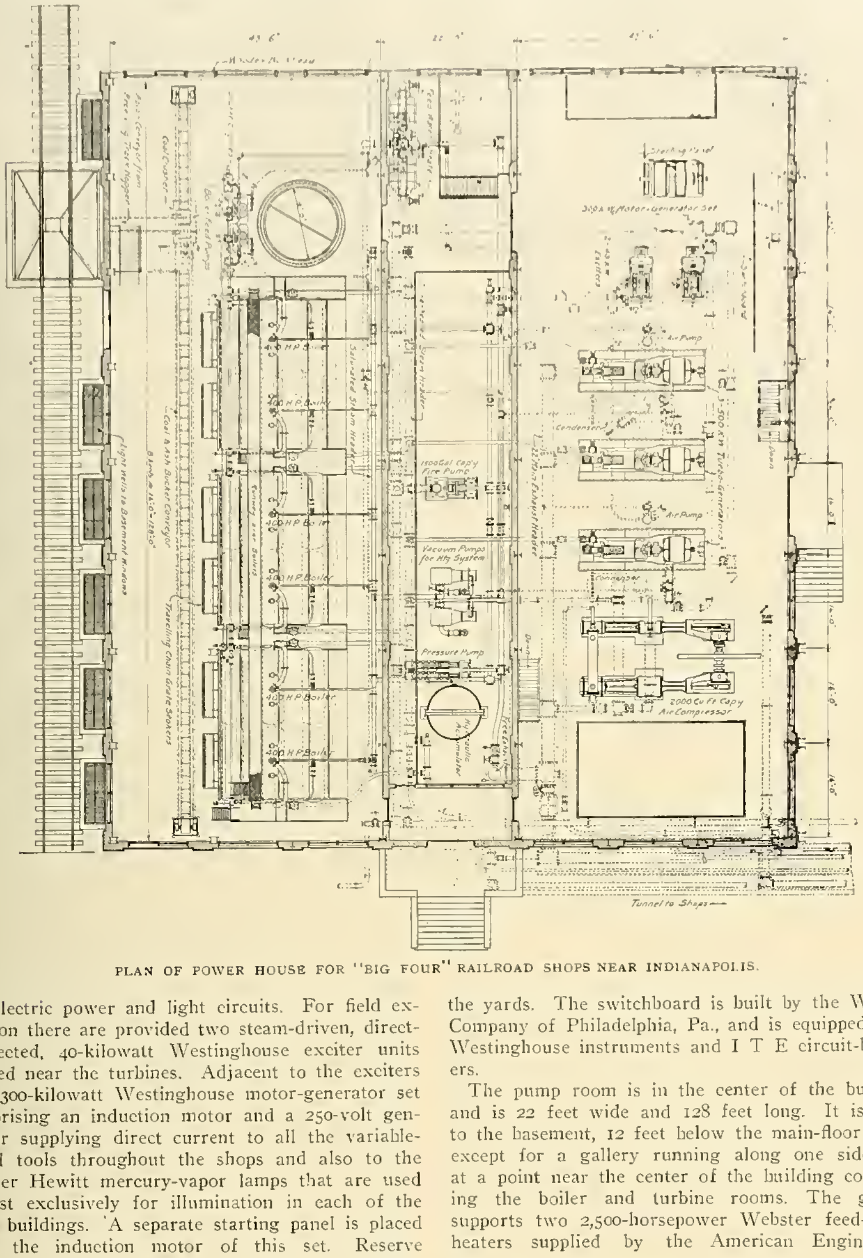
The boiler room is 46 feet wide by 128 feet long and contains three batteries of two 413-horsepower Stirling boilers each. Each of these is equipped with Foster superheaters and with chain-grate stokers, the latter being furnished by the Greene Engineering Company of Chicago. The flue gases from the boilers are led through a reinforced-concrete smoke duct directly beneath the boilers to a concrete-steel chimney 12 feet in diameter and 200 feet high, built by the Weber Concrete Steel Chimney Company. This stack is equipped with lightning conductors installed by Carl Bajohr, St. Louis, Mo.

Coal is first received in a track hopper adjacent to the building, from which it is carried to a coal crusher in the basement by means of a small apron conveyor. After passing through the crusher the coal falls directly onto an endless-bucket conveyor, which carries it to the end of the basement and then up and over the coal bunkers, into which the coal is automatically dumped. These bunkers are located over the boilers and are built of reinforced concrete. From the bunkers the coal is fed to the stoker hoppers by means of steel spouts. Ashes are fed, by means of spouts, from the doors in the ash bins of the boilers into the same conveyor used for coal. The ashes are lifted up and dumped into overhead ash pockets, located directly in front of the stack, from which they may be loaded through spouts into empty cars on the track adjoining the building. All the coal and ash-handling machinery was furnished by the Link Belt Company, Chicago.

The boiler-feed pumps are placed in front of the stack on the boiler-room floor to make them readily accessible to the boiler-room attendants without going any distance from their posts of duty in front of the boilers. The pumps are of the duplex upright Admiralty type, supplied by the Dean Bros. Steam Pump Works of Indianapolis. The stoker engines are located near the feed pumps and are belted to the stoker-operating shaft, which is hung from the floor beams in the basement. In the boiler room there are installed numerous structural steel runways, making all piping and apparatus perfectly accessible for repairs.

The turbine room is of the same dimensions as the boiler room and is separated from it by the pump room. At the west end of the turbine room is located the air compressor, furnished by the Laidlaw-Dunn-Gordon Company of Cincinnati, Ohio. The compressor is of the cross-compound two-stage type and has a capacity of 2,000 cubic feet per minute. Alongside of this compressor is a reserve space for the installation of a similar unit whenever the needs of the plant require it.

Next to the compressor are located the three main generating units, each consisting of a Westinghouse-Parsons steam turbine, direct connected to a 500-kilowatt, 60-cycle, three phase, 480-volt Westinghouse generator. These machines are to run at 3,000 revolutions per minute and will supply all the electric power and light circuits. For field excitation there are provided two steam-driven, direct-connected, 40-kilowatt Westinghouse exciter units located near the turbines. Adjacent to the exciters is a 300-kilowatt Westinghouse motor-generator set comprising an induction motor and a 250-volt generator supplying direct current to all the variable-speed tools throughout the shops and also to the Cooper Hewitt mercury-vapor lamps that are used almost exclusively for illumination in each of the shop buildings. A separate starting panel is placed near the induction motor of this set. Reserve space is provided nearby for the future installation of another motor-generator set and one more exciter.



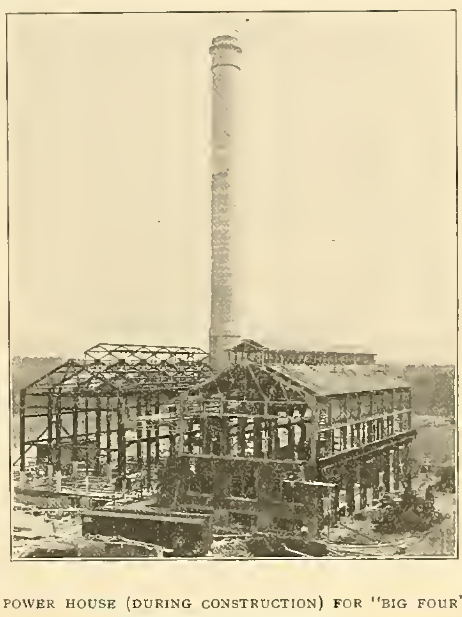
PLAN OF POWER HOUSE FOR "BIG FOUR" RAILROAD SHOPS NEAR INDIANAPOLIS.

The turbines and compressor are arranged to be run condensing almost all the time, but the exhaust can also be turned into the heating system for the buildings, if the exhaust from the steam hammers in the forge shop, which will be normally used for heating, should prove insufficient on exceptionally cold days. Two wet-vacuum system condensing outfits are being furnished by the Wheeler Condensing and Engineering Company. Each consists of an Admiralty type surface condenser and a steam-driven air pump. These condensers are so arranged that each takes care of two units. The exhaust steam from all the auxiliary engines and pumps is carried to the boiler feed-water heaters by a separate system of piping.

From each of the various generators lead-covered rubber-insulated cables are carried to the switchboard in tile ducts laid in the concrete floor. All these ducts lead to a slate-covered trench 14 inches wide by 8 inches deep, running back of the entire length of the switchboard. All the cables pass through this trench and turn up through switches in the slate cover to the circuit-breakers. All feeders go out at right angles to the switchboard in clay ducts in the floor to the north basement wall, where they drop six feet in split-tile ducts laid in chases in the wall, to the underground distributing system which runs out at right angles from the north wall to the numerous shop buildings. These underground conduits are separate from the pipe tunnels. No overhead transmission is used.

The switchboard consists of 15 panels, each two feet wide, which includes, besides the generator and exciter panels, alternating current and direct current feeder panels, three blank panels for future generators and exciter, and a panel for the series alternating current arc-lamp system for lighting all the yards. The switchboard is built by the Walker Company of Philadelphia, Pa., and is equipped with Westinghouse instruments and I T E circuit-breakers.

The pump room is in the center of the building and is 22 feet wide and 128 feet long. It is open to the basement, 12 feet below the main-floor level, except for a gallery running along one side and at a point near the center of the building connecting the boiler and turbine rooms. The gallery supports two 2,500-horsepower Webster feed-water heaters supplied by the American Engineering Specialty Company of Chicago. These heaters are equipped with purifying, filtering and oil separating accessories and are automatically operated.



POWER HOUSE (DURING CONSTRUCTION) FOR "BIG FOUR" SHOPS NEAR INDIANAPOLIS.

On the floor of the pump room is located nearly all the pumping apparatus that supplies the shop buildings. There is a 1,500-gallon Underwriters' fire pump, furnished by the George F. Blake Manufacturing Company of New York. Next to it are located two Marsh vacuum pumps for the heating system, which discharge the heating returns from the entire system into the feed-water heaters. There is also installed in this room a hydraulic pump and accumulator, designed to furnish water at a pressure of 1,500 pounds per square inch to the hydraulic riveters in the boiler shop. These pumps are all steam driven.

At the end of the pump room is the entrance to the pipe tunnel, which carries all compressed air, live-steam, exhaust-steam-heating and low and high-pressure water piping to the different buildings for shop and roundhouse service. The pumps drawing the supply water from the three artesian wells are five motor-driven deep-well pumps made by the George F. Blake Manufacturing Company. Each of these pumps has a capacity of 250,000 gallons per 24 hours. They are located in little rooms off from the pipe tunnel and deliver the water to the condensers in the turbine room, as already described.

The steam piping of the power house consists of two separate and distinct systems, superheated steam being supplied to the turbines and compressor only, and saturated steam being furnished to all auxiliaries. There is, however, a cross-connection between the two steam headers for use in case of emergency. In all steam leads from the boilers are placed automatic stop and check valves, and in all steam leads to units, except those to pumps, are placed receiver type steam separators. Wherever possible the use of long-radius pipe bends will be employed to give flexibility and to provide for expansion without the use of expansion joints. Wrought-steel flanges have been used throughout on the high-pressure steam piping.

Traveling cranes are provided for the turbine and pump rooms. The former is a 15-ton crane furnished by the Niles-Bement-Pond Company of Philadelphia, and the latter a five-ton crane supplied by the Niles Tool Works of Hamilton, Ohio.

The complete plans of this power station, including the building, as well as of the shops as a whole, were designed by The Arnold Company of Chicago, subject to the approval of the motive-power department of the Cleveland, Cincinnati, Chicago and St. Louis Railway Company, represented by Mr. William Garstang, superintendent of motive power, and of Mr. B. D. Lockwood, mechanical engineer.

A Curious Proposal in England.

"I have frequently called attention to the extremely unsatisfactory conditions, both industrial and financial, which exist in the electrical industry here," writes the London correspondent of the Western Electrician under date of October 4th, "and it is not surprising to hear that some effort is being made to put the industry upon a better footing. I hear that with the object of finding a remedy for the present state of things it is suggested that a union of electrical interests should be formed. I believe that the editors of the electrical journals have been approached to take the initiative and to act as an organizing committee until sufficient support has been obtained to enable a representative council to be constituted. This part of the programme of the organizers of the movement, however, has not met with complete success. The idea is that everyone interested in electrical undertakings, whether as shareholder, employer or employe, should join, the annual subscription to be 50 cents. This is as much as is known at the moment, beyond the fact that the union will start without political bias and with neutrality in relation to municipal ownership and other like matters. The modus operandi has yet to be explained."

Annual Report of Western Union.

In the annual report of the Western Union Telegraph Company, just issued, the total revenues show a fair increase, but expenses increased to a greater extent than the increase in income, with the net result that revenue income was $746,372 less than the previous year. The report states that contracts covering 19,213 miles of railroad were closed during the year, compared with 8,311 miles in the previous year. There was issued during the year $7,200,000 of the $25,000,000 four per cent. convertible redeemable bonds due November 1, 1936. The total revenue for the year ended June 30, 1907, was $32,856,406 and the total expenses $26,532,196.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

507 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 150 Nassau Street, New York.

Telephone, 5220 Beekman.

Trade Supplied by Western News Co.

SUBSCRIPTION, in advance, postage prepaid $3.00 for a full year of 52 numbers in the United States, Alaska, Porto Rico, Cuba, Mexico, Hawaii and the Philippines; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; Canada, $4.00 a year; other foreign countries in the Postal Union, $5.00 a year; single copies 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own*. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

REMITTANCES.—All checks, drafts and other remittances should be made payable to the order of the publishers, the **Electrician Publishing Company**, and addressed to the offices of publication, Suite 507, Marquette Building (204 Dearborn Street), Chicago, Illinois, U. S. A.

CONTENTS OF THIS NUMBER.

DEPARTMENTS.

AN IMPORTANT contribution to the literature on illumination is the paper recently read before the Chicago Section of the Illuminating Engineering Society by Mr. F. J. Pearson on "The Lighting of a Large Retail Store," summarized in this issue. Since the subject of illumination came so prominently to the front a few years ago, considerable discussion has been indulged in on the subjects of residence and factory lighting, but comparatively little consideration has been given to more efficient methods of store illumination.

This is an important field for investigation, and it is gratifying that the management of the great establishment with which Mr. Pearson is connected undertook such exhaustive tests before adopting a new lighting scheme. This fact makes the conclusions reached of much more value than would be the case if an arbitrary choice had been made, although it is to be remembered, of course, that the individual conditions of merchandising governed in the selection. This retail store, which is perhaps the largest in the world, has done a great service to electrical men in making these tests. Mr. Pearson's paper should prove interesting reading for both store managers and central-station men as well as all interested in more efficient and effective store lighting.

SELENIUM CELLS are now engaging more attention than for some time past, owing to the increasing possibilities of varied application in the industrial arts, instead of being confined chiefly to laboratory experiments. It is therefore interesting to note the statement of R. Marc in a German chemical journal that gray crystalline selenium exists in two distinct polymorphous forms, which may be distinguished as A and B. A is a non-conductor, B a good conductor of electricity. The transition from the A form at 140° to the B form on heating to 200° has now been observed microscopically. It has also been found that there is a difference in the solubilities of the two modifications. B is probably rather less soluble in carbon bisulphide than A. The equilibrium mixture at the ordinary temperature is sensitive to light, which displaces the equilibrium from A to B, just as does rise of temperature. The action of the light is, however, a photo-chemical and not a calorific effect.

Mr. Marc makes the following recommendations for those interested in the construction of sensitive selenium cells: (1) An addition of 0.1 to 0.5 per cent. of silver or other efficient catalytic agent; (2) the complete transformation (preferably in an oxygen-free atmosphere) at 200° (this can be best traced by the use of a galvanometer); (3) the establishment of a complete equilibrium at the ordinary temperature; (4) the employment of as thin a film of selenium as possible; (5) the arrangement of the electrodes should be such that the rays of light fall upon the places of greatest current density; (6) access of moisture is to be prevented.

SHALL the neutral of alternating-current high-tension systems be grounded, and if so shall it be through a resistance or direct? This is an important question, and it was discussed at the New York meeting of the Institute last week. Much valuable material was brought out on which the Western Electrician draws to some extent in this issue. As was to be expected, no definite conclusion was reached. After listening to the discussion, Dr. C. P. Steinmetz confessed that he knew less about the advisability of grounding the neutral than before, because every statement on one side had been paralleled by another of directly opposite effect. However, he thought the system should not be grounded where grounding is not necessary, as opposed to the idea of grounding everything unless there is a special reason to the contrary. It may make a difference whether the system is an overhead transmission system or an underground cable system in city streets. Resistance in the grounding is used where it is judged unsafe to ground without.

In concluding his discussion of the subject, Dr. Steinmetz gave his hearers some advice of a quite unusual nature. We quote it:

"I desire to draw your attention to the general principle of all human nature where the trend of the times is very strong in one direction, as, for instance, in favor of using induction motors instead of synchronous motors, or vice versa, or grounded neutrals instead of running ungrounded neutrals. Under such conditions, wherever you meet a case in which it is doubtful if you should do one thing or another, it is usually safe to decide on that which is against the favored practice, for the reason that nobody can remain entirely unbiased in his judgment if the general trend of sentiment is in a certain direction. Therefore, where he thinks the advantage about equal he unintentionally, in most cases, favors that side which is the fad of the time. Consequently, it would be fairly safe to decide in favor of the other side."

Other things being equal, then, decide against the trend of the times in questions of engineering judgment. This recommendation is rather risky, for it uniformly prefers the opinion of the minority to that of the majority. The minority may be right, and it is well to be on one's guard against mere popular clamor; nevertheless, it would appear to be an unwise plan to decide always against the trend of events when the scales appear to be pretty evenly balanced. This "trend of events" has brought us where we are, and the fact that a majority favors a certain course should have due weight.

Perhaps the preponderance of opinion, in this particular case, favors grounded neutrals; perhaps not. But in either case the engineer will do well to study his own particular problem in the light of all information he can get, and then decide for himself without any fear of faddism on the one hand or of lack of progressiveness on the other.

INDUCED ELECTROMOTIVE FORCE in an alternator shaft is the subject of an interesting article by F. Punga and W. Hess recently published in our German contemporary Elektrotechnik und Maschinenbau and summarized by Science Abstracts of London. It is pointed out that in the case of certain high-speed alternators the bearings have been found to wear away very rapidly, and a difference of potential of a few volts has been found to exist between the shaft and the bearings. At first sight it might be supposed that the film of oil surrounding the shaft would form a sufficient insulating barrier, but practically such has not been found to be the case, and where the trouble alluded to has been experienced it has become necessary to insulate completely the bearing pedestals from the bedplate. The trouble arises from the presence of an electromotive force induced in the alternator shaft.

In order to account for this electromotive force the author considers a turbine-driven alternator having a four-pole revolving field and a stationary armature divided into two parts by a horizontal plane. The joints between the upper and lower halves of the armature, even if made with the utmost care, are magnetically imperfect and offer an appreciable reluctance. Hence the field flux will vary between certain limits for different positions of the armature. Since part of this flux passes through the shaft it follows that during the rotation of the field a certain fraction of the field flux will periodically move across the shaft sideways (i. e., along radial planes) in opposite directions, thereby inducing an alternating electromotive force along the shaft whose period is equal to that of the main current. The effect can only occur in 4m-pole machines, where m is an integer. It would obviously not occur in a two-pole alternator.

The author's theory is confirmed by some results obtained with a four-pole machine, in which the reluctance of the joints was progressively increased by widening the gaps between the two halves of the armature. The electromotive force measured across the ends of the shaft was found to increase with increase of the reluctance of the joints, and its value agreed fairly well with the calculated value.

There is a possibility of turning this effect to useful account in the construction of alternators required to furnish very large currents at a pressure of only about 20 volts or so (as in certain electrochemical operations), and the authors develop the theory of this peculiar type of alternator, in which there would be no special armature winding, the shaft of the machine taking the place of such a winding. The current would be collected by a sufficiently large number of brushes applied to the end portions of the shaft. It is the fact that the design of such low-voltage machines on ordinary lines presents formidable difficulties.

FOR the many kind words and congratulations which it has received on the occasion of the recent appearance of its Twentieth Anniversary Number, the Western Electrician returns appreciative thanks. We are pleased that our effort to make the issue worthy of the occasion and of the industry has been recognized by our co-workers in the electrical field.

The Street-railway Conventions.

[Special dispatch to the Western Electrician.]

Atlantic City, October 15.—The street railway convention special which left Chicago on Sunday noon by the Pennsylvania lines made an uneventful but very delightful trip to Atlantic City, arriving there in about 22 hours. The delegates in all numbered 76 individuals, and the Pennsylvania Railway, as represented by City Passenger Agent Frank S. Bamford, was indefatigable in its efforts to make this convention trip a pleasant one.

The St. Louis special train, in charge of Arthur S. Partridge, arrived at Atlantic City on Sunday also. Among the well-known street-railway people on board were President John I. Beggs of the American Association and Richard McCulloch. This train also brought representative street-railway men not only from St. Louis and Illinois points but from as far west as Oklahoma, Texas and Indian Territory. The passengers numbered 60 in all.

Perhaps the first thought that struck many of those attending the street-railway convention of 1907 at Atlantic City related to the fitness of the place for such a large gathering of representative Americans. For years the street-railway convention has, so to speak, been wandering from place to place, and after its many vicissitudes in its yearly work of obtaining a suitable meeting place, it would seem as though the ideal is found in Atlantic City's qualifications.

Convention exhibits are admitted nowadays to be almost equal in importance to discussions of policy, management and technical matters. At Atlantic City the Steel Pier presents admirable advantages for large exposition purposes. This steel structure extends from the Board Walk out at sea for more than a quarter of a mile, and with its four enclosed halls, large arcade and broad promenades, now all fitted with permanent booths, presents strikingly suitable facilities to the street-railway manufacturers and supply men.

Comparatively speaking, the exhibits at Atlantic City, in so far as the number is concerned, are only slightly in advance of the Columbus convention of last year. The exhibits at Columbus numbered 195, while the booths on the steel pier at Atlantic City under a hurried count show a figure of 210.

This convention was made remarkable by the fact that as early as Sunday night practically all the 210 booths were ready for visitors. This celerity and promptness is to be highly commended, especially when one remembers how unwieldy and very heavy as a rule are the supplies and machinery presented for the inspection of street-railway men.

For such exhibits as those appertaining to rolling stock, track welding and the like, a comparatively large area of ground is available just across the Board Walk from the Steel Pier. In this open-air exhibit space a switch is installed to connect the exhibition tracks with the existing tracks in the street, so that the rolling-stock exhibit can be operated on its own wheels. This 500 feet or so of track also affords facilities for demonstrations of welding.

While last year at Columbus red, white and blue were the standard convention colors, this year at Atlantic City green predominates as the basic color use for decorating. The floors are covered with green matting and the green burlap backgrounds in the booths are a most satisfactory adjunct in the general color scheme.

The Engineering Association.

The opening session of the American Street and Interurban Railway Engineering Association was called to order yesterday (Monday) afternoon by President H. H. Adams of Baltimore at 2:40, introducing John I. Beggs, president of the American or parent association. Mr. Beggs, as usual, made a business-like and well-pointed address. He prefaced his remarks by emphasizing the advantage that had obtained in the division of the association into parts, so that the engineering association could devote itself more particularly to its special work, leaving the American association to its more general work.

Mr. Beggs called attention to the incalculable benefit of this convention work to all the street railways in the country, whether they hold membership in the association or not. He deplored that all the street-railway companies throughout the country could not be brought to a realization of the great advantage to themselves in taking membership in these associations. If there ever was a time when it was imperative that the representatives of these properties should stand shoulder to shoulder, now is that time. Mr. Beggs stated that the work of the committee on standards had appealed to him very strongly, dwelling somewhat at length upon his own efforts in obtaining the advantages from standardization.

President Adams, at the conclusion of Mr. Beggs' remarks, made a short address thanking the speaker. C. L. S. Tingley of Philadelphia, president of the Accountants' association, was then called upon. Past president Olds of Milwaukee then made a speech of reminiscence, following which President Adams delivered his annual address.

Mr. Adams said that the advantage of committee work in connection with their association had been impressed upon the executive committee even more forcibly during the last year than ever before. He too emphasized the importance of the work of the standardization committee. This had become so large that it is now necessary to subdivide and appoint sub-committees to handle various parts of the equipment. He pointed as an example the practice of steam roads in this respect, and that it was the practice of the latter to have standing committees.

Reverting to the report as submitted by the standardization committee, Mr. Adams characterized it as the most important one that has been presented in the history of the association. This report shows that steps have been taken toward uniform practice in gearing for motors. The committee had met a cordial response from motor designers. Further steps in the question of uniform design in certain of the motor parts is only a question of time. Consequently he felt that it was exceedingly desirable that a good foundation be made through the taking of definite action at this meeting on this report.

Mr. Adams illustrated the importance of the adoption of the recommendations by stating that the brake shoes and heads that are recommended will reduce to a minimum the number of patterns required and accomplish several other economies.

Referring to the report of the committee on "Maintenance and Inspection of Electrical Equipments," the speaker stated that the report showed the necessity of still further investigation and recommended the appointment of several standing committees.

Returning to the question of standardization, which is unquestionably near to his heart, President Adams referred in a most complimentary manner to the co-operation of the manufacturers in this work. He stated that manufacturers were always welcome at conferences on standardization.

Claim Agents.

The claim agents' convention was opened yesterday afternoon. Mr. H. C. Bradley of Chicago, the acting president, made an address replete with interest to the claim agent of any public-service corporation, whether street railway or electric light. He said that in his own city not only is the number of claims per annum increasing very rapidly, but there is a very constantly increasing difficulty in successfully resisting fraudulent claims in the courts. Long agitation against franchises, etc., added to the ordinary prejudices which exist against corporations, the work of hostile newspapers, etc., are year by year making the claim agent's work harder and harder and of much more importance.

The speaker directed attention to the report of a well-known transportation company, recently published, which, he stated, shows that the enormous increase of money expended on personal-injury claims running progressively through several years had at last caused a deficit in the finances of that company. This report, according to the speaker, shows that the personal-injury expense had increased during the last few years from about 2½ per cent. of the receipts to about seven per cent. of the gross receipts. Mr. Bradley referred also to the personal-injury tramp that goes from city to city, and he suggested co-operation in the matter of intercommunication between the members of the association in order to head off such fraudulent work.

General Outlook.

It is estimated that there are as many as 2,000 traction officials in Atlantic City. It is said that one of the important matters to be taken up is the creation of a special course of university training for the traction experts of the future, and that Prof. H. H. Norris of Cornell University is or will be here to outline a plan through which this result may be accomplished.

Another subject that will receive much attention relates to more comprehensive adoption of the turbine engine for electric traction service. In the engineering session of yesterday afternoon the belief was expressed that in the comparatively near future trolley trains of [illegible] will supersede single cars in all large [illegible].

After dinner last evening a series of [illegible] recitations was given by Miss Kitty Cheatham in the solarium of the Marlboro-Blenheim. Afterwards the ladies and delegates indulged in informal dancing. For this afternoon a roller-chair parade is scheduled, and as the weather is all sunshine this delightful function will doubtless be carried out.

This evening will be held the annual reception in honor of the president and other officials and their ladies. This also in the solarium of the Marlboro-Blenheim.

Tuesday's Sessions.

The Accountants' convention was called to order this morning according to schedule and opened with an address by President John I. Beggs of the American association. This was followed by the annual address of the president, Mr. Tingley. The reports of the executive committee and of the secretary and treasurer were presented. This was followed by several interesting papers, and in the afternoon there was a lunch and a social in the Chevy Chase room at the Marlboro-Blenheim Hotel.

At the meeting of the Engineering association there was a paper on "Care of Electric-railway Tracks," by George L. Wilson of Minneapolis. This was followed by various reports of committees. This concluded the morning session. The afternoon session was occupied in part with reports of committees on standard traction and on open versus closed terminals for car storage.

In the Claim Agents' association papers were read by R. R. Schoenen, H. K. Bennett, Harry H. Vories and E. C. Carpenter. F. L. P.

Kansas Gas, Water and Electric Association.

The tenth annual meeting of the Kansas Gas, Water and Electric Association, held in the Commercial Club rooms, Topeka, Kan., on October 9th and 10th, was the best meeting ever held by the association. From an educational viewpoint the proceedings were of great value to central-station men. Eleven new central-station managers were elected to membership, and the general discussion of the various topics was of great interest and value to all present. The association seems to have taken on new life and the addition of valuable new members will be of much benefit to the association.

President E. S. Springer of Leavenworth was in the chair. In his annual address he reviewed the improvements and changes made during the last year and spoke of the work done by the association.

The first paper was by E. L. Callahan of the Chicago office of the General Electric Company, on "Commercial Importance of Heating Devices to the Central Station." Mr. Callahan gave a practical paper on the introduction of heating devices and how they could be used to make money for the plant.

W. E. Sweezey, superintendent of the Junction City Electric Railway, Light and Ice Company, gave an offhand talk, which was very practical, on the management of a small plant, and spoke especially of how the management should treat the public and its customers.

One of the best papers presented was by J. S. Skinner, superintendent of the Lawrence Electric Light Company, on "Increased Sales to Present Consumers."

"The Underground Water Supply for Municipalities of Kansas" was a tabulated statement of the recent investigation made under a recent act of the Legislature, and showed what good work had already been done.

Prof. B. F. Eyer of the State Agricultural College gave "Economies of High-efficiency Lamps," and supplemented a paper on the same subject by F. W. Willcox of the General Electric Company. This subject interested every member present greatly.

"The Benefits of the Association" were to have been set forth by F. W. Mackey of St. Joseph, Mo., but he was detained. The paper will be published in the proceedings.

"Electric Law" was treated by John C. Nicholson, president of the Electric Light Company of Newton. The subject was discussed, first, as to the relation of the company to the public; second, the relation of the company to third persons, and third, the relation of the company to its employes, with special emphasis on the law of damages.

"Natural Gas vs. Electricity" was the subject of John T. Huntington, superintendent of the Topeka Edison Company. Mr. Huntington showed how electric companies could and should succeed where there is natural-gas competition. This was especially valuable to many members of the association who have natural gas to meet.

"Municipal versus Private Ownership of Public Utilities" was the subject of a well-digested paper by Jesse Shaw, superintendent of the city waterworks of Topeka, and who was formerly superintendent of the same plant under private ownership.

The discussions were animated and very interesting, and in nearly every case confined strictly to practical suggestions on points brought out by the paper read.

The following-named officers were elected for the ensuing year:

President—C. L. Brown, Abilene.

First Vice-president—A. L. Newman, Arkansas City.

Second Vice-president—W. A. Scouthern, Hutchinson.

Third Vice-president—W. R. Murrow, Independence.

Secretary and Treasurer—James D. Nicholson, Newton.

Executive Committee—W. S. Grosvenor of Kingman, J. N. Wells of Pittsburg and Willis Watson of Dodge City.

The Topeka Edison Company, the Topeka Railway Company and the local entertainment committee made things pleasant for the visitors. The local committee consisted of A. M. Patten, L. G. Trealeaven, John T. Huntington and Jesse Shaw.

The Lighting of a Large Retail Store.

On the evening of October 10th was held the first meeting of this season of the Chicago Section of the Illuminating Engineering Society, and it proved to be the best attended meeting in the history of the Chicago branch. After the customary dinner at a downtown restaurant the meeting adjourned to the auditorium of the Commonwealth Edison Company, kindly placed at the disposal of the society. Shortly after 8 p. m. Chairman Keech rapped for order and introduced Mr. Frederick J. Pearson, electrical engineer for Marshall Field & Co. of Chicago, who read an interesting paper on "The Lighting of a Large Retail Store," from which the following facts are taken:

About two years ago Marshall Field & Co. began to investigate the newer systems of illumination with a view of adopting more efficient illumination for their large retail store. Extensive rebuilding operations were in progress and it was desirable to adopt a more satisfactory lighting system than that then in use, which consisted of enclosed arc and old-style carbon-filament lamps. At that time the connected lighting load amounted to the equivalent of 32,000 16-candlepower incandescent lamps. At the present time this has been increased to the equivalent of 57,000 such lamps.

Manufacturers of the various illuminants recently brought forward were invited to submit samples of their lamps for competitive tests, and the tests instituted were carried on during a period of 18 months. Laboratory results were discarded and the experiments were carried out with lamps actually installed in the store under regular merchandizing conditions.

The fundamental requirements that all the lamps submitted should possess were laid down as the following: Efficiency, low-energy consumption per candlepower; color, nearest to that of the spectrum; low maintenance cost; high intrinsic light source to decrease the number of units required and to permit placing the lamps nearer the ceiling; units to be obtainable in different sizes; flexibility, an illuminant suitable for the large variety of merchandise handled, there being 350 different sections in the store, representing nearly as many classes of merchandise; accessibility for repairs; adaptability to present wires; low first cost of lamps; low first cost of fixtures; absence of bare light sources.

The lamps tested were: Gem metallized filament, tantalum, Nernst, diffusing arc, tungsten and carbon filament. The last lamp was put in only for comparison; the tungsten was so fragile that its filament was soon broken, and the diffusing arc, while giving excellent efficiency results, met with little favor from the store management. Thus the three active competitors were the Gem, tantalum and Nernst lamps.

The principal tests were 10 in number. The tests were conducted as nearly as possible under similar conditions. Representatives of the different interests were present on all occasions. The photometric instruments used were a Weber photometer from the laboratories of Armour Institute of Technology and a luminometer from the Chicago Edison Company's laboratory. Each of these as well as the electrical instruments used had been carefully calibrated and were in the hands of expert operators. All photometric observations were taken at a distance of 32 inches above the floor, this corresponding to the standard height of counters. All observations were repeated a great many times and average results recorded. As much, if not more, importance was placed on visual tests of the quality and color value of the lights as upon the actual candle-foot illumination and efficiency data. This was to give the 350 section managers an opportunity to express their opinions on the value of the different illuminants for their particular needs.

All the lamps met some of the fundamental requirements previously mentioned, and the three principal competing lamps met nearly all in varying degrees. The lamps giving the higher intrinsic brilliancy gave the best results. The average results given by these three lamps are summarized as follows:

Lamp.	Size.	Watts per Sq. Ft. at Counter Plane.	Candle Ft. at Counter Height.
Gem	137 watt	1.42	3.96
Tantalum	85 watt	1.12	3.15
Nernst	3 glower	1.09	3.42

The life tests gave the following average results:

Lamp.	Rated Candle-power.	Watts per Mean Horizontal Candlepower. Initial.	After 200 Hours.	Useful Hours' Life.	Ultimate Hours' Life.
Carbon	16	3.1	3.25	480	600
Gem	125	2.55	2.75	375	550
Tantalum	40	2.10	2.68	325	490
Tungsten	50	1.29	1.56	...	...
Nernst	50	2.51	2.65	471	560

The first four lamps were run at 114 volts, the last at 228. The tungsten lamp gave out during the test. After 700 hours the tantalum was black.

As a result of all these tests it was decided by the store management that the Nernst lamp gave the best results, for it had shown a good efficiency, was guaranteed to require the lowest maintenance cost and above all had the best color of the several illuminants.

It was therefore decided to adopt the Nernst multiple-glower lamp for the entire store lighting. A direct-current lamp was preferred, as the store gets all its current from the Edison direct-current mains, and the installation cost and operating losses of rotary converters were sought to be avoided. The manufacturers of the Nernst lamp had just perfected a lamp that they were willing to guarantee on direct-current, and this was the first large installation of this type of lamp.

The illuminating intensities decided on at the counter level in general were the following:

First floor, 4.5 to 5 candle-feet.

Upper merchandizing floors, 2.5 to 3 candle-feet.

Merchandise basement, 3.5 to 4 candle-feet.

Sub-basement, packing and storage rooms, 2.25 to 2.5 candle-feet.

The requirements in the different sections varied, some wanting more and others less illumination than the average. For instance, in the millinery salesrooms an intensity of 1.5 candle-feet was regarded as sufficient. In some of the workrooms, where operators worked on sewing machines, individual drop lamps had to be retained. In others with ceiling lights an intensity of five candle-feet was deemed necessary.

In general Marshall Field & Co. wanted more light for the same money rather than the same light for less money, and therefore had adopted higher intensities than those customary for this service. Except in a few sections they had replaced practically all the old incandescents and arc lamps by installing something like 5,200 new Nernst lamp fixtures in about 40 days. They had the courage to adopt a practically new type lamp on a large scale and were entirely pleased with the results.

In the beginning of the discussion of the paper Mr. Pearson was asked a number of questions. In answer to some of these he said that in a dry-goods store the illumination should be of such a character that colors appear in their true shade, which was the particular feature that gave the Nernst lamp the preference. Moreover, it was the lamp that had met the approval of nearly all the section managers and was the best suited therefore to meet their different requirements, and thus do away with the multiplicity of systems that had been in vogue. A uniformity of system was desirable even as to the workrooms.

J. R. Cravath said the test results showed that the height of the lamps above the floor cuts little figure if proper reflectors are used to throw the light downward where it is most desired. Differences of less than 25 per cent. in efficiency could be remedied by the selection of proper glassware. The old-style fixtures threw the light largely to the walls and ceilings. By turning these wasteful rays into useful directions the lamps could be raised to a higher level so as to get a more uniform distribution on the working plane.

G. H. Stickney of Lynn, Mass., thought that this store was not typical of most large department stores; the size of the bays was uncommon. Arc lamps have been mostly used for store lighting, even in stores of the highest grade, with very good results. The color of the light should be as near as possible to daylight, as matching of goods is difficult if any part of the spectrum rays is absent. The diffusing arc lamp gives all that can be desired in that respect, and he would have liked to have seen it given more consideration.

Mr. Pearson replied that merchandizing conditions are different from what an engineer can govern. He was highly pleased with the efficiency of the arc lamp, but that was not the main thing to be considered. He said that no 10 out of the 350 section managers of the store wanted to use the arc lamp, and if this meant anything it showed that experienced merchants did not think the arc lamp suited to bringing out delicate tints.

Max Harris of Pittsburg said that the general use of arc lamps was because high-candlepower incandescents and more efficient illuminants had not been perfected until a few years ago, so that store managers had not much choice to select from.

R. F. Schuchardt of the Commonwealth Edison Company said it should be noted that the plan of illumination was selected by merchandise men and not by illuminating engineers. He would advocate the use of lamps corresponding to the kind of illumination used where the goods purchased are to be utilized; for instance, incandescents for the sections where evening clothes are sold. Personally he thought the incandescent light was more pleasing and restful to the eye than that of the Nernst lamp.

Mr. Harris asked whether ceiling lights could not have been used exclusively even in rooms where sewing machines were used. He knew of some firms that had done so with good results and great economy of current.

Mr. Pearson answered that they had experimented with the use of ceiling lights for even the sewing rooms, as they had desired to use them throughout the buildings if possible. They found, however, that the operators claimed shadows were cast by the arms of the machines, and they protested so much that the individual drop lights had to be restored.

George C. Keech said that it was largely a matter of education, and cited the mercury-vapor lamp as an illuminant that one had to get accustomed to before the prejudice against it could be overcome.

Mr. Naylor of Marshall Field & Co. facetiously remarked that no doubt a great many tailors would work contentedly at home sitting near a kerosene lamp, but when working for Marshall Field & Co. they would demand about six arc lamps apiece.

E. W. Lloyd of the Commonwealth Edison Company said that when working on white goods, ceiling lights were amply sufficient, but for dark browns or blacks individual lights were necessary.

Mr. Pearson was asked why the rapid improvements in the tungsten lamp had not caused them to pause before selecting a less efficient lamp. In answer the representative of Marshall Field & Co. said they had looked hopefully on the tungsten lamp, but came to the conclusion that the present installation would pay for itself before an entirely satisfactory tungsten lamp was put on the market.

Lightning Arresters and Protection Discussed at Purdue.

The Purdue University branch of the American Institute of Electrical Engineers held a meeting in the Electrical Building at the university on October 8th, the discussion centering on recent Institute papers on the protection of electrical construction from lightning. Professor Plumb, speaking of the number and placing of arresters, brought out some interesting facts. No arresters are in use at Purdue, and as a result the three-kilowatt transformer in the science building was put out of commission during a recent storm, due, probably, to surging on the line which created enough pressure to jump a ¾-inch air-gap.

The various kinds of lightning arresters were described by Professor Esterline, who said that expounding a theory of lightning was a bold move. The higher voltages and longer lines of today have changed conditions, existing in the earlier days, when little trouble was encountered. The meeting was favored with an address by Professor Benjamin, the new dean of the engineering school, who expressed an interest in the Institute.

Chicago Street-railway Situation.

A draft of a new plan for the reorganization of the financial system of the Chicago Union Traction Company has been prepared by representatives of the various interests who met in New York. The plan will be submitted to representatives of the bondholders and later will be submitted to the bondholders for approval. As the bondholders learn of the need of their individual action through default on their interest, they are expected to communicate with their trustees, and then, it is said, they will be urged individually to accept the plan of reorganization.

The Board of Supervising Engineers says that 45 miles of new track has been laid in the city under the direction of the board. New rails are being laid in all parts of town, but the South Side is receiving slightly more attention because the City Railway Company has accepted its ordinance. Meanwhile work also is progressing on the North and West Sides, with the traction board under virtual supervision.

Telegraphers' Executive Board Suspends Union President.

The general executive board of the Commercial Telegraphers' Union has summarily suspended Samuel J. Small, president of the union, for advising a surrender in the strike. This action was taken at a meeting in Chicago on October 14th. The executive board intends to conduct the strike with renewed vigor and will handle the situation until a successor to Mr. Small shall be elected at a meeting to be held in Milwaukee on October 23d. It is said that local unions throughout the country generally favor the action of the board.

In the face of this demonstration the telegraph companies say they received more applications for work on the day following the suspension than on any day since the strike began.

ELEMENTS OF ELECTRICAL ENGINEERING.

By Geo. R. Metcalfe

XXXVIII.—Electric Railways.

Electric Car Lighting.

The lighting circuit of a trolley car is generally taken off from the trolley circuit before it reaches the main fuse or circuit-breaker. This is done so that if the fuse blows or the circuit-breaker opens the lights in the car will not be extinguished. The lighting circuit, however, is protected by its own fuse box, and each circuit of lamps has its separate switch. As the standard trolley voltage is from 500 to 550 volts, and ordinary incandescent lamps are made for about 100-volt circuits, it is necessary to wire five of these lamps in series across the 500-volt circuit, and in large, well-lighted cars four or five or more of these circuits are used.

It is obvious that if one lamp in a circuit is broken or burned out, the circuit will be opened and the other four lamps extinguished until the defective lamp is replaced.

It is not advisable to use lamps of very high efficiency for car lighting, as the constant jarring of the car tends to destroy the filaments rather rapidly. As has been explained in a previous chapter, the higher the efficiency of the lamp the more brilliantly it burns, because of the small diameter of the filament. By using a lamp of lower efficiency which has a correspondingly thicker filament a more reasonable length of life is obtained. Filaments for street-car lamps should preferably be made with several convolutions, or should be anchored to the bulb by means of a short piece of wire looped around the filament at one end and attached to some part of the glass bulb at the other end. The object of these devices is to secure a short stiff filament which will not be broken by the jarring of the car, or will not be sufficiently flexible to come in contact with the glass bulb.

In addition to the lamps for interior car lighting, platform lights, sign lights and headlights are generally necessary. These lights are generally wired so that the platform light on the front end and the sign lights and headlight on the rear end will be extinguished on turning a switch, and the corresponding lights on the rear and front end will be lighted. No general rule, however, can be laid down for car-lighting circuits, as the number of lamps and their location vary greatly with the style of the car, the number and size of the illuminated signs and the kind of headlights used. The only general rule to be followed is so to arrange the circuits that five lamps will always be connected in series.

In many cases arc headlights are used, especially on interurban cars, and to a more limited extent these are also used for interior car lighting. If a four-ampere enclosed arc is used alone for a headlight it will require about 70 volts, and the difference between this and the 500 volts of the trolley circuit must be lost in a resistance which is placed under the car and connected in series with the headlight. It is apparent, therefore, that very much more energy is absorbed by the reistance than is utilized by the headlight, and this arrangement is therefore very inefficient from an electrical viewpoint.

A more economical arrangement, which, however, makes considerable complication in wiring is to arrange a number of the incandescent lamps in the interior of the car in series with the arc headlight. In this way the energy wasted in heating the resistance is utilized for interior lighting. Where the interior of the car is lighted with enclosed arc lamps a number of these can be wired in series with the headlight, thus avoiding the use of a resistance.

Arc headlights are almost always attached to the car dash by means of brackets, which are grounded to form one terminal of the lamp, and the other terminal consists of a plug which fits into a socket on the car dash. The switch is placed between the trolley circuit and the lamp resistance, so that when the headlight is turned off the resistance is dead. The switches on all the light circuits should be placed between the trolley and the first lamp, so that if a ground occurs on any part of the lamp circuit the current may be cut off from the entire circuit.

Car Wiring.

Only the most substantial methods of car wiring should be permitted on trolley cars, as owing to the jolting of cars, the splashing of mud and water and the rough usage to which cars are subjected, unusual opportunities are offered for grounds, short-circuits, breakage, etc.

The exposed wires underneath the car running from the controllers to the motors are bunched into cables and frequently covered with a canvas hose, which is made waterproof by several coats of insulating paint. On some cars special boxing is built under the car to accommodate the wiring, and the very best practice, although rather expensive, is to provide iron conduits heavily enameled both inside and out.

As the car body which carries the wiring rests on springs there is often considerable movement between the body and the trucks, which must be allowed for in connecting the motors to the cable. This is done by making several coils in the connecting wires, which permit the motion of the car without bringing any strain on the connections.

If soldered joints are required the wire should be securely cleated beyond the joint so as to prevent any motion of the jointed part. The vibration of the car tends to crystallize the solder and eventually open the joint, so it is important to keep all soldered connections as free from vibration as possible.

Where conduits are used the conduit is not depended upon for insulation, but its chief function is to offer mechanical protection for the wires. These conduits should be grounded so that in case any wire becomes grounded upon the conduit it will be short-circuited and thus blow out the fuse or open the circuit-breaker, thus preventing any further damage.

Trucks.

All electric cars are mounted on trucks, which are either single or double, according to the length of the car. The short cars used in city service are generally mounted on single trucks, while the long cars are mounted on double or swivel trucks. Trucks consist of iron structures which carry the journal boxes, wheels and axles, the motors, the brakes and the brake rigging, and they are built so as to constitute complete units, independent of the car body.

In single trucks the car body is simply laid upon the upper frame of the truck, so that whatever strains or distortion occur within the frame of the truck are not transmitted to the car body. The truck frame holds the journal boxes and consequently the wheels and axles at a fixed distance apart, although the journal boxes have a slight vertical movement, due to being supported on springs which prevent the vibration of the wheels being transmitted to the car.

The wheel-base is the distance between the centers of the journal boxes, and this distance is limited to about seven feet on single-truck cars, and is considerably less on double-truck cars. This limit in the length of the wheel base is necessary on account of the curves around which the cars have to pass. It is evident that if the road bed was always a straight line, any length of wheel base would be permissible; but as trolley cars pass around curves of quite short radius and the axles are held rigidly parallel, the wheels cannot accommodate themselves to the curvature of the track and would not be able to travel around a curve at all if the wheel-base were too long.

The greatest difference between trucks of different manufacture consists in the arrangement of the springs which are interposed between the car body and the truck frame. Both spiral and elliptical springs are used for this purpose, and various combinations of both kinds are used, as either kind alone permits too great an oscillation of the car bodies.

Double-truck cars have small swivel trucks located near each end of the car, and the car body is mounted upon them in an entirely different way than that used with single trucks. Swivel trucks are connected to the car only by means of a kingbolt in the center of the truck, around which the truck is free to turn, thus permitting it to accommodate itself to any curvature of the track. These trucks are very similar in general construction to the standard type of truck used on steam-railroad cars, but are usually arranged so as to permit the car body to be hung much closer to the ground than are the steam-railroad cars. There are two crossbeams under the car known as the car body bolsters, and an iron beam across the center of each swivel truck and the truck frame. Each car body bolster rests upon a truck bolster, the kingbolt passing through the middle of each. Side bearings are also provided between the car body and the ends of the bolster to prevent the body from tipping over when the car is unbalanced. Springs are placed between the bolster and what is called a spring plank, and the latter is suspended from the truck frame by means of links which permit a certain amount of side motion. Other sets of springs are located between the truck frame and the journal boxes, so that all shocks to the wheels are transmitted to spiral springs first, and then through elliptical springs before reaching the car body.

Most of the trucks in use have four wheels of equal diameter, but there is one type of truck known as the maximum traction truck which has two large wheels on one axle and two considerably smaller wheels on the other. The large wheels carry about three-quarters of the weight of the car and the small wheels the balance of the weight. In this type of truck the motors are mounted on the axles carrying the large wheels.

Car Wheels.

Most of the car wheels in service are made of cast-iron, although within recent years solid steel wheels and wheels with steel tires and cast-iron or wrought-iron centers have been introduced to some extent. That part of the wheel which rests upon the track is called the tread, and the part which extends below the track and which prevents the wheel from leaving the track is called the flange. In all cast-iron wheels the tread and flange are chilled in order to make them extremely hard. The tread of car wheels is made slightly cone-shaped, which assists the wheels in passing around curves.

The chief difficulty in the maintenance of car wheels is to keep the tread and flange in proper shape. The wear on the flanges soon reduces their section, and if allowed to wear beyond a certain limit the flanges are liable to break off, permitting the wheels to leave the rail. It is therefore necessary after the car has made a certain mileage to remove the wheels and turn the flanges and treads down to proper shape again.

Steel wheels are initially much more expensive than cast-iron wheels, but they maintain their shape very much longer, so they are able to make a far greater mileage than cast-iron wheels. If the expense of removing and turning down each of these kinds of wheels is taken into account the cost of steel wheels during their entire life is probably not much in excess of cast-iron wheels, owing to the reduced cost of maintenance of the former.

When steel-tired wheels are used the tires can be removed and new ones substituted. These tires are shrunk on to the centers and may be removed by placing them in a specially constructed furnace, in which they are heated up until they expand sufficiently to drop off.

Where grooved rails are used in city streets the wheel flanges are made smaller than the standard flanges for steam-road service, as the rail grooves are not large enough to accommodate the standard-sized flanges. There is a tendency, however, to increase the size of the flanges on electric car wheels on account of the number of high-speed interurban cars which operate on city streets. The standard-sized flanges are very much safer in high-speed service.

Car wheels are fastened rigidly to the axle. The seat on the axle is turned a few thousandths of an inch larger than the bore in the hub of the wheel, and the wheel is then forced onto its seat by means of a hydraulic press.

[To be continued.]

Note.—This series of articles, intended to survey, briefly, the whole field of applied electricity for light, power and heat, was begun in the Western Electrician of February 2, 1907.

To Prevent Telescoping.

General Manager Frank Hedley of the Interborough Railway Company of New York city has invented a simple device for preventing telescoping of cars in wrecks. Generally cars are telescoped by the end of one car rising above the platform of the next car, in which position the raised car can go easily through the woodwork above the platform. Mr. Hedley's device is an attachment adapted to be secured to the end of the car platform which has three prongs on its outer surface. When two cars come together these prongs interlock and prevent either car from rising above the platform of the other. A number of cars on the Interborough system are equipped with the device.

The Peterson Heat, Light and Power Company of Des Moines, Iowa, is applying for a franchise in Aberdeen, S. D.

SOME CONGRATULATIONS.

H. McL. Harding, New York: "I desire to congratulate you upon your twentieth anniversary."

William J. Hammer, New York: "I congratulate you upon your Twentieth Anniversary Number."

Hugo Reisinger, New York city: "I have looked over your Twentieth Anniversary Number, and I wish to say that I consider it a very interesting and handsome number."

Elihu Thomson, General Electric Company, West Lynn, Mass.: "You are to be congratulated on getting together such an amount of interesting historical material for the Twentieth Anniversary Number, which I have just read."

E. E. Keller, vice-president Westinghouse Machine Company, East Pittsburg, Pa.: "You certainly have reason to feel proud of your Twentieth Anniversary Number, and I congratulate you on the success that has met your efforts."

Ralph W. Pope, secretary American Institute of Electrical Engineers, New York: "Kindly accept my congratulations for the continued success of the Western Electrician, which I have watched with much interest since its first issue in 1887."

Charles A. Brown, patent attorney, Chicago: "I wish to congratulate you on the completion of the second decade of your paper. I have been very much interested in the commemoration number, and compliment you on the high character of the issue."

C. E. Flynn, president Conneaut and Erie Traction Company, Erie, Pa.: "I remember the first issues of the Western Electrician and congratulate you on the successful life of the paper. 'Many happy returns of the day.' May we all be here twenty years hence!"

B. F. Stewart, Chicago: "The Twentieth Anniversary Number of the Western Electrician is a 'crackerjack' and covers so much of interest that I shall preserve it for the pleasure of rereading from time to time and for reference. May you live long and prosper!"

Charles E. Gregory, president Guarantee Electric Company, Chicago: "I read your Twentieth Anniversary Number of the Western Electrician, and wish to compliment you on the interesting character of the whole publication. I shall preserve my copy for its historical value."

George A. McKinlock, president Central Electric Company, Chicago: "I read the Twentieth Anniversary Number of the Western Electrician with considerable interest and profit. The story of the time was told fully and completely in that number. I congratulate you on having put out such a successful number."

C. A. Tupper, Allis-Chalmers Company, Milwaukee: "We examined with much satisfaction the Twentieth Anniversary Number of the Western Electrician, and desire to congratulate you upon its appearance. The articles bear evidence of careful selection and are replete with information of interest to the trade."

W. S. Bissell, The F. Bissell Company, Toledo: "We congratulate you not only on your twentieth anniversary, but on your issue commemorating the event as well. This number appealed to us as being particularly interesting, although we feel that this is a characteristic that may be applied to all issues of your publication."

John P. Barrett, Chicago: "I have read your anniversary issue from cover to cover and am free to say it is the most complete electrical production I ever saw. It is impossible for me to mention individually the many splendid papers therein. They were all good. As for the photograph gallery, it is the best that was ever bunched."

Charles D. Shain, New York: "Permit me to congratulate you and your staff on your Twentieth Anniversary Number. It is indeed a pleasure to me to see again the faces of the boys of twenty years ago. God bless them all! I wonder how many of us will be left twenty years from now! I trust the Western Electrician, in any event, will go on forever."

Chicago Evening Post: "The Twentieth Anniversary Number of the Western Electrician, just from the presses, contains matter of great interest to the field. There are 98 pages and 140 illustrations, about half of the latter being portraits of men who have been identified with the electrical development of the West. There are also a number of articles reviewing the various features of electrical activity."

Prof. H. S. Carhart, University of Michigan, Ann Arbor, Mich.: "The Twentieth Anniversary Number of the Western Electrician contains a variety of most interesting history and reminiscence. It presents a fascinating epitome of the astonishingly rapid advances in the applications of electricity for the last quarter of a century. In this connection I am reminded of the fact that the first incandescent lamps that ever came to Chicago, so far as I know, were sent to me in Evanston by Mr. Edison in May, 1881. They were not mounted, and I connected them in circuit by means of the loose terminal copper wires, and lighted them with a Grove battery imported from London. There are doubtless persons still living in Evanston who will remember these pioneer lamps. You deserve congratulations for your success in assembling papers from such an array of contributors in your excellent anniversary number."

Alex Dow, vice-president Detroit Edison Company, Detroit: "Your Twentieth Anniversary Number was exceedingly interesting to me, as it must have been to all of us who knew our Chicago 'before the Fair.' Some of the reading matter, and particularly some of the illustrations, brought back warm memories—so warm that I forgive you for making me realize that I am getting old."

Chicago Record-Herald: "The Twentieth Anniversary Number of the Western Electrician has just been issued. Mr. Samuel Insull contributes 'Some Recollections of Central-station Development,' Bion J. Arnold 'The Rise of the Electric Railway' and B. E. Sunny 'The Electrical Upbuilding of the West.' The issue contains 140 illustrations, including portraits of many men who have been identified with the electrical development of the West."

P. C. Burns, president American Electric Telephone Company, Chicago: "I have read the Twentieth Anniversary Number of the Western Electrician with much interest and pleasure. The historical feature of it was particularly interesting to me. Time certainly flies. It does not seem possible that twenty years have passed since Mr. Kreidler first started the Western Electrician. I remember with pleasure the first visit he made me at St. Louis some time previous to your publication's birth."

Elmer W. Gillmer, secretary and treasurer Peerless Electric Company, Warren, Ohio: "I have read with a great deal of interest the articles presented by the various men who have been and are prominent in the electrical industry, and I have no doubt that these articles will prove very interesting to all of your readers. What strikes me forcibly, in addition to the above, is the number and character of the advertisements contained in your paper, and I must congratulate you on the very evident success of this number."

A. O. Kuehmsted, vice-president Gregory Electric Company, Chicago: "So far I have had only time to glance at your anniversary number, but I have decided to take it home and read it at my leisure. It is the most interesting number of any trade journal I have seen in years, and personally I am very much interested in the historical articles dealing with the men who have been prominent in electrical affairs in this vicinity, and I feel that everyone in the electrical business will feel the same interest that I do. I shall keep it in my library for future reference."

B. E. Sunny, vice-president General Electric Company, Chicago: "I congratulate the Western Electrician and yourself on the twentieth anniversary of the publication, and I also congratulate you on the Twentieth Anniversary Number, which, aside from being full of interest to the people who have known the Western Electrician and yourself for so long, is a masterpiece of the publisher's art. The Western Electrician has filled a very important position in the development of the art all of these years, and has been exceedingly helpful. I sincerely hope that its prosperity, as well as your own, will be continuous."

F. S. Terry, first vice-president National Electric Lamp Company, Cleveland: "A letter from your office calls my attention to the fact that the Western Electrician will this year have its twentieth birthday. Time does certainly pass along rapidly, and it is hard to realize that twenty years have passed since the day you came into my office on Randolph Street, and showed me the dummy of the Western Electrician. You certainly have given reasons for congratulations, and can take credit to yourself for your uninterrupted success. I trust that you will be able to look back upon your next twenty years with equal satisfaction."

George A. Damon, managing engineer The Arnold Company, Chicago: "Your very interesting and valuable Twentieth Anniversary Number brought considerable pleasure into our office. Individually for myself and collectively for The Arnold Company, we wish to congratulate you upon this fine issue. We feel sure that everyone connected with the electrical art will thank you for the very valuable articles contained in the issue. We can testify that your work is an added inspiration for further efforts in the constantly growing electrical field. May we all have something worthy of record in your Thirtieth Anniversary Number."

Chicago Daily News: "The Twentieth Anniversary Number of the Western Electrician is an enlarged number, containing 98 pages and 140 illustrations, about half of the latter being portraits of men who have been identified with the electrical development of the West. It contains also a number of valuable articles reviewing the various features of electrical activity. Among the notable contributions are: 'Some Recollections of Central-station Development,' by Samuel Insull, president Commonwealth Edison Company, Chicago; 'The Rise of the Electric Railway,' by Bion J. Arnold, chairman Board of Supervising Engineers, Chicago Traction; 'Electric Power Transmission,' by Charles F. Scott, consulting engineer, Westinghouse Electric and Manufacturing Company; 'Dynamo-electric Machinery and Its Evolution During the Last Twenty Years,' by B. A. Behrend, chief engineer and chief designer, Bullock Works, Allis-Chalmers Company, and others equally authoritative."

George Cutter, South Bend, Ind.: "I wish to express my great appreciation of your Twentieth Anniversary Number. It was quite a surprise to me, as I did not anticipate you were going to give such charming little histories of development of different branches during the last twenty years. It is through such concise historical sketches that we appreciate forcefully the wonderful progress made in our loved profession in a short time. It makes one feel proud of the achievements of the past and hopeful for the future. I must repeat that I consider your Twentieth Anniversary Number, as you got it out, a valuable publication, and I extend to you my heartiest compliments."

B. A. Behrend, chief engineer Bullock Electric Manufacturing Company, Cincinnati: "I have been greatly interested in this anniversary issue, and I sincerely congratulate you upon the excellent work done by your editors in making the number a worthy commemoration of the twenty years of the existence of your paper. Those of us who have been instrumental, during the last ten years, in the building up of the electrical industry of the Middle West appreciate the existence of a journal of your standing with a power for good which is considerable. If the management and editorial direction of your paper stand for the expression of independent views; if you support, without bias, the interests of the public at large against individual interests; if you make yourself the mouthpiece of those who have something to say, although their opinions may not meet with favor and applause from certain influential persons, your paper will fulfill a great mission in the development of this western country. We are only just beginning to realize the enormous potential wealth and possibilities of the states commonly termed the Middle West. The eastern states which are bordering upon our territory are the great industrial states of the Union; the western states which are bordering on our territory are the great agricultural states of the Union. The Middle West is a gigantic clearing-house, through which the products of industry and agriculture are passing. The future of the manufacturing industry, and of the electrical industry in particular, in which we are interested in this section of the country, is bound to be tremendous. You and ourselves, and all those who have chosen this part of the country for their field of work, have great problems to solve and great responsibilities. There is grandeur in the vista of the future of the Middle West, and your paper will, I earnestly hope, be a power for good in this development. I congratulate you upon the excellent issue in which you commemorate the coming of age of your paper."

Portland and Salt Lake City May Be Connected by Electric Railway.

The Los Angeles Herald of recent date, printing what is said to be information emanating from the office of E. P. Clark, the prominent electric-railway man of Los Angeles, says that Portland, Ore., and Salt Lake City are soon to be connected by a modern electric-railway system to be built by Los Angeles men and operated by electric power generated by the snows of Mount Hood.

"Mr. Clark and his associates," says the Herald, "have control of the waterpower of Mount Hood, have an immense electric plant under way and have about 25 miles of the new system graded. The latent power of Mount Hood will eventually be to the Pacific Northwest what the power of Mount Whitney (first made feasible by John Hayes Hammond) is to Central California and the San Joaquin Valley, and what the Sierras will be to the Los Angeles-Owens River aqueduct."

"Originally the Mount Hood enterprise was stated to be merely a plan for getting tourists to the peak —a sort of Mount Lowe inclined-railway arrangement. This has secretly developed into a plan by which Central Oregon and later Northwestern Nevada and Northern Utah will be put in close touch, and that by electrically operated trains, the biggest electric scheme in America today."

"Completion of the through line by the shortest most practicable line is now the main object of the locating engineers who are secretly working for the Mount Hood Railway and Power Company. With a stealth of movement seldom surpassed by right-of-way men, these agents of Los Angeles have completed their lines over the eastern slopes of the Cascades, thence southeasterly into Nevada as far south as Winnemucca, and then almost due east to the metropolis of Utah. Because of the activity of Harriman engineering parties in that country the Clark men easily masked their purposes. It is stated that the heaviest work in the ascent of Mount Hood will be done this winter by the construction forces."

The Grounded Neutral, With and Without Series Resistance, in High-tension Systems.[1]

By Paul M. Lincoln.

The object of this paper is to raise for discussion the question of grounding the neutral, a question that continually confronts the engineer operating an alternating-current generating, transmitting or distributing system. The writer wishes to consider this question from the viewpoint of the operating engineer, since it is naturally he who is most interested.

The questions that would arise in the mind of the operating engineer would probably be these:

1. Why should the neutral be grounded? What advantage would be gained, if any? And what disadvantages would be encountered?

2. If a ground is used, shall it be at one point of the system, or several?

3. Shall a resistance be used between the neutral and the ground? and, if grounded at several points, shall a resistance be used in each place?

4. If a resistance is used, how much? and what shall be its current-carrying capacity?

5. What character of resistance is best?

Let us begin at the beginning of this list of questions and itemize, so far as possible, the advantages and disadvantages of a grounded neutral. The first part of this discussion will deal with the general question of ground versus no ground. Later in this discussion the modifications introduced into this general discussion by use of resistances, multiple grounds, etc., will be briefly treated.

Advantages.—(A) Electromotive force between conductor and ground remains fixed and constant.

(B) Prevents abnormal static induction on neighboring circuits.

(C) Provides opportunity for using the ground as a working conductor.

(D) Makes possible the detection (and immediate removal, if desired) of any grounded portion of the system.

(E) Insures equality in the condenser current drawn from each phase.

Disadvantages.—(F) One ground disables a part or the whole of the system.

(G) A proper ground is difficult to obtain.

Discussing more in detail these points of advantage and disadvantage, we find:

(A) In practically every transmission system the greatest danger of breakdown of insulation exists between line and ground, rather than between lines; it is therefore highly important that the voltage from line to ground be permitted to assume no abnormal or excessive value. The higher the line voltage the greater becomes the importance of this point, since the factor of safety of insulation naturally decreases with increasing line voltage. With the neutral fixed at ground potential, it is impossible to obtain, between any conductor and the ground, more than a certain definite proportion of the maximum line voltage. In a three-phase system—including as it does practically all transmitting and distributing systems—the voltage between the neutral and ground is about 58 per cent. of that between conductors. If, therefore, the neutral be connected permanently and solidly to ground, the maximum potential that can develop between the line and ground is about 58 per cent. of the voltage between the conductors. With an ungrounded system a ground on one conductor will cause full line potential to develop between the two remaining conductors and ground.

On further analysis it is doubtful if all the advantage apparent at first sight is really obtained, for it can safely be asserted that in the large majority of cases it is not the action of the steady line voltage that causes breakdowns in the insulation of transmitting or distributing system; the voltage strain necessary to cause breaks in insulation is usually very much higher than the normal voltage applied, even in the case where a system is operating with one conductor grounded. The condition giving rise to trouble is to have superimposed upon the normal line voltage a so-called "surge" of such value that when added to the normal strain their resultant causes sufficient strain on the insulation to break it down. Lightning is the usual cause of surges, although they may be caused by many other things; for instance, by switching, or a partial ground, or a broken conductor, or a heavy short-circuit. Insulation being once broken down, the normal voltage is usually sufficient to maintain an abnormal flow of current through the break. With the neutral grounded, a momentary break in insulation at one point on one conductor gives rise to opportunity for a destructive arc at that point. With the neutral ungrounded, before a destructive arc can take place there must be simultaneous breaks on the insulation of two separate conductors. The use of a resistance between the ground and neutral modifies these conditions, as will be discussed in a later paragraph.

A very material advantage incident to this fixing definitely the maximum potential of conductors above ground is that it allows a much closer adjustment of lightning arresters than would otherwise obtain; that is, the arresters can be adjusted so that a comparatively small rise above normal potential to ground will discharge across them. In an ungrounded transmission system it is not safe to adjust for a discharge potential materially [illegible] than line voltage; otherwise, in the event of one conductor becoming grounded, the constant [illegible] charge which necessarily occurs over the lightning arresters between the two good conductors and ground will destroy the arresters within a short time.

(B) An advantage incident to keeping the neutral of a transmission system at ground potential is to prevent abnormally large static induction by a transmission line on neighboring circuits. Those who have endeavored to operate a telephone line in proximity to a transmission line will realize the importance of this point. It is evident, without further explanation, that so long as the neutral of a transmission line is at ground potential its static influence on neighboring circuits is practically negligible. If, however, one of the conductors of the line is grounded, the static induction of the remaining two is usually sufficient to prevent the satisfactory use of telephone circuits strung on the same right-of-way. Grounding the neutral will prevent such a condition.

As to electromagnetic induction, it is evident that the grounded neutral can have no influence unless the ground is carrying current. In that event, electromagnetic induction on neighboring circuits is increased. This increase is due to the fact that the return circuit through the ground, instead of being in close proximity to the outgoing circuits, thereby neutralizing most of its action, is at a comparatively great distance, making the inducing loop of large area and comparatively great power.

(C) In a three-phase transmission system with the neutral grounded both at the generating station and a sub-station, it is perfectly possible to continue the transmission of power with one of the conductors out of commission. In this case, if the phases remain balanced, the ground will carry a current 1.73 times that in each of the two remaining conductors. Furthermore, it is perfectly possible to continue to transmit single-phase power with only one of the three conductors remaining. In fact, some transmission plants make a practice of running but a single wire to some customers using single-phase current, and but two of their three conductors to other of their customers using polyphase currents, relying in each case on the ground to act as a return conductor for the normal operating current. Still other plants make use of the ground as a working conductor only in emergency.

It must be counted as a distinct advantage in favor of the system with a grounded neutral that it makes available at any time the use of the ground as a working conductor. This does not mean that the ungrounded system cannot make the ground available, but in the latter case special switching arrangements must be provided, while in the former its action as a working conductor is practically automatic.

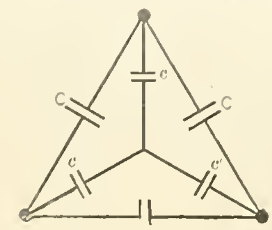
The practicability of using the ground as a working conductor is also dependent upon the ground resistance. This is an element that varies largely with geological formations, soil, season, moisture, parallel return circuits, and construction of ground plate; it is therefore difficult to make any general statement covering this matter. However, there seems to have been no difficulty in using the ground as a conductor for moderate amounts of power at pressures of 20,000 volts and above.

(D) and (F) With a grounded neutral, a ground on any conductor will cause a short-circuit. This fact may be regarded as an advantage or a disadvantage, depending upon circumstances, and also upon the point of view of the operator. If it is possible by use of the grounded neutral automatically to cut out the damaged conductor, and continue service to the affected part of the system over other lines, the grounded neutral may undoubtedly be regarded as an advantage. If, however, the grounding of the neutral means an interruption of service which could be avoided with an ungrounded neutral, the grounding may be justly regarded as a disadvantage. Protection of service is of great importance to the operator, and he is willing to run very considerable risks in order to give continuous service. That certain portions of his system are temporarily overloaded, or that part of his line conductors are temporarily undergoing an abnormal insulation strain to ground, is of no particular moment so long as service is being rendered and the abnormal condition does not give rise to further trouble. When considering questions of protection of service, the use of resistance in the ground connection is at once involved; the discussion of this phase will be treated in subsequent paragraphs.

(E) All alternating-current transmission lines take from the generators a condenser current whose volume depends upon the size, length and disposition of the transmitting conductors and upon the voltage and frequency supplied to them. These currents may be considered as flowing over two paths, as follows:

[illegible] Through the [illegible] formed [illegible] the conductors [illegible] as shown at (c), and [illegible] Through the condensers formed [illegible] ing the conductors [illegible] plate and the ground [illegible]

[illegible] currents through the [illegible] independent [illegible] grounding [illegible] The currents through the condensers (c), however, depend upon the potential of the neutral with respect to ground. With the neutral at ground potential, the condenser currents through (c') are taken equally from each of the three conductors. Assuming an extreme case, one of the three conductors grounded, all the currents through (c') are taken from two of the conductors, and, further, the total kilovolt-amperes represented by these currents is double what it would be with the neutral at ground potential. A moment's investigation will show this latter point. With the grounded neutral the total kilovolt-amperes, taken through capacities



CONDENSER CURRENT ON TRANSMISSION LINES.

(c'), may be assumed as proportional to $3\ c'\ E_1^2$, where E_1 is the potential between any conductor and the neutral. Grounding one conductor has the effect of short-circuiting one of these condensers and throwing a potential of $E = \sqrt{3}\ E_1$ upon the other two. In the latter case the total kilovolt-amperes taken by condensers (c') is $2\ c'\ E^2 = 6\ c'\ E_1^2$.

When the charging current is large compared with the generator capacity, it is probable that such an increase in its volume, as well as taking it largely from two of the three conductors, would cause a serious unbalance in voltage between phases. This seems to be a good, though not controlling, reason for maintaining the neutral at ground potential.

(G) A satisfactory ground is very difficult to obtain. The antiquated idea that the ground is of zero resistance, because it is of practically infinite cross-section, has long since been recognized as an error. In case of grounding to a buried plate, most of the resistance of the ground occurs in the immediate neighborhood of the ground plate, and the ground resistance depends upon the character and condition of the soil in the immediate neighborhood. This is to be expected on account of the fact that it is only in the immediate neighborhood of the ground plate that the cross-section of the ground, considered as a conductor, is sufficiently restricted to give rise to any appreciable resistance. The conditions other than the character of the soil that make for a low-resistance ground are moisture and the exposure of a large surface of ground-plate; the larger the exposed surface the lower the resistance. It is this reason that makes water-supply systems good grounds.

Even where good engineering practice dictates a resistance in the neutral, the unavoidable resistance in the ground connection is not so valuable as it might be, because of its extreme variability. The difference of the seasons, as well as the drying-out action of any ground current that may flow, will cause large variations in ground resistance. However, on high-potential systems the presence of even the maximum amount of resistance that is contingent upon good construction is rarely sufficient to cause trouble.

Modifications Due to Use of Resistance and Multiple Grounds.

If an operating engineer has come to the conclusion that his neutral should be grounded, the next question is, naturally, that concerning the number of places to ground—whether it shall be at his power plant or plants only, or at other points where neutrals can be obtained. The answer to this question usually depends upon the object sought in grounding. If it is the use of the ground as a working conductor, there must naturally be grounds both at the generating and receiving points. On the other hand if the object is to prevent an abnormal voltage rise on any conductor, due to the grounding of another, then the grounding of the neutral at one point is sufficient and in most cases preferable.

In some methods of connection the problem is still further complicated by the entire absence of an available neutral. In any three-phase system a delta connection of transformer or generator windings gives no opportunity of obtaining a neutral. A delta connection requires the use of a separate auto-transformer connected across proper points of the delta, from the winding of which a tap may be brought out for the neutral connection. A three-phase star-connected generating system has of

1. A paper presented at the meeting of the American Institute of Electrical Engineers in New York, October 11, 1907. The author is engineer of power division of the Westinghouse Electric and Manufacturing Company.

course the neutral at the star connection. If, however, a bank of transformers has both the primary and secondary connected in star, the star connection is not necessarily at the neutral point. In this case the neutral is practically free to move around anywhere within the three-phase triangle; in case of a dead short-circuit on any transformer, the voltage on that particular one disappears and the two remaining transformers assume the whole potential of the line, being then virtually connected in V. If, therefore, the star connection of a star-to-star group of transformers be connected to ground it does not follow that the neutral is grounded; if one side is connected in delta and the other in star, then the star connection can be treated as a fixed point at the center of the three-phase triangle. In a star-to-star group proper conditions can be assured only by connecting the star point on either side to a fixed neutral—such, for instance, as the connection of the star of the transformers to the star point of the generating system. The star point of the generating system being fixed at neutral, this also fixes the transformers.

The question as to how many points of a system shall be grounded is naturally influenced by the above considerations. The final answer, however, must be dictated by considerations which depend upon the reason leading to making any ground connection.

Probably the most important question in connection with this whole matter of grounding the neutral is that as to the use of resistance between the neutral and ground and the amount of resistance that is best. In considering this question the following analysis is pertinent: In any polyphase system, so long as each conductor has the same capacity and ground, the same insulation from ground and a balanced load, the neutral will remain at ground potential, whether it is connected to ground or not. In other words, so long as conditions on the transmitting or distributing system remain normal there is no occasion for grounding the neutral, as nothing will be accomplished thereby. The object sought in grounding the neutral is to take care, not of normal conditions, but abnormal ones. It is the first thought of the operating engineer to maintain his service, and he therefore installs automatic circuit-breakers and other devices to protect his system in case of an abnormal condition arising. The abnormal conditions that may arise are: First, short-circuits; second, open circuits, and third, grounds.

1. Short-circuits.—By short-circuit is meant accidental connection in any manner between conductors of opposite polarity. It is evident that under this condition the behavior of automatic devices is in no way influenced by grounding the neutral, so that the consideration of this contingency is not pertinent to this paper.

2. Open Circuits.—In a three-phase line, with the neutral grounded at both generating and receiving stations, the ground will, under normal conditions, carry no current, even though the ground be of zero resistance. If, however, one of the conductors should break, the ground immediately begins to carry current. If induction or synchronous motors are being used at the receiving end, the three-phase relation will be approximately maintained, the degree of approximation depending upon the ground resistance and upon the relative motor load to non-motor load. If the neutral is grounded at one point only, an open circuit in one conductor will have an effect no different from that which would take place if the neutral were not grounded, except that the distribution of charging current between conductors will be somewhat disturbed and more or less of this current would pass through the ground connection.

3. Grounds.—A ground is the most frequent abnormal condition that is encountered, and also is the one most affected by grounding the neutral. With the neutral connected direct to ground, another ground on any conductor means a short-circuit; the action of automatic circuit-breakers will then take place accordingly. The amount of current that will flow through such a short-circuit can be limited by inserting resistance, and practically the only object of resistance is to cause such a limitation of current.

The flow of excessive currents, such as would take place were there no resistance, is detrimental for several reasons. It throws an unnecessarily great strain upon the circuit-breakers which are called upon to interrupt the current. The large current flow which takes place may cause a phase distortion and drop of voltage which may, in turn, be sufficient to cause synchronous apparatus on the line to drop out of step. Almost invariably an arc takes place at the point of grounding of conductors, and an excessive current will cause excessive destruction at this point. A dead short-circuit on any system causes a heavy shock, due to the tremendous currents, and a consequent tendency to distort the windings of any synchronous apparatus connected to the system.

All of these objections can be overcome to a greater or less degree by resistance in the neutral. Increased neutral resistance, however, while it limits the current flow through a grounded conductor and overcomes the above objections, can do so only by allowing an increase in the potential of the two good conductors above ground while the current flows. If the object in grounding is to prevent such an abnormal rise, the inserting of resistance tends to defeat that purpose. The choice of the proper resistance becomes a question of compromise between the disadvantages of going to either extreme. There seem to be good reasons for adopting a ground resistance which will lie between the following limits; on the one hand, large enough to prevent a severe shock to the system; or the voltage on the affected phase dropping to a point where the synchronous apparatus will drop out of step. This consideration will dictate a resistance that will not allow more than, say, three times full-load current at the most to flow through the armatures of the generators supplying the circuits. On the other hand, the resistance must be small enough to permit sufficient current to flow to trip the heaviest circuit-breaker on the system.

In all alternating-current circuits there is present a condition equivalent to a neutral grounded through a certain amount of resistance, in that static capacity exists between any conductor and ground. The longer the line and the higher the voltage and frequency, the lower the resistance in the equivalent circuit having a resistance in grounding connection. The effect of a grounded neutral, either with or without resistance, is, in case a conductor becomes grounded, to pass a current of greater or less volume through the affected conductor and into the ground. The effect of the static capacity of conductors to ground is exactly the same, the difference being that no current passes into the ground at the generating station, and that the phase relation of the current through the capacity to the electromotive force producing it is not the same in both cases. The static capacity of an overhead conductor to ground is, with ordinary line construction, from 30 to 50 per cent. greater than that between conductors. Assuming a fault that makes the affected conductor of the same potential as the ground, the affected conductor will take roughly 50 per cent. more charging current than the unaffected ones. It may be noted also that the total kilovolt-amperes of charging current in all conductors will be increased about 33 per cent. Where the normal charging current amounts to a considerable percentage of the total generating capacity, as it will in long, high-voltage, high-frequency lines, it will be seen that the condenser effect has the same action as a moderately low grounded resistance.

If a ground resistance be used the question of its current-carrying capacity is an important one. Since current is drawn through the ground resistance only during emergencies, its capacity should be chosen to meet the maximum that any emergency can throw upon it. Usually the time during which current will flow is limited to the time required to trip a circuit-breaker, probably not more than a few seconds at most. The quantity of current that will flow as a maximum is also fixed as that which is required to trip out the heaviest set circuit-breaker. The question of current-carrying capacity is therefore one which depends upon the character and setting of the safety devices used.

As to the character of resistance, permanency is the most essential. Considerable latitude is allowable in the amount of resistance, but that latitude does allow variations of many hundred per cent., such as past experience has shown is apt to take place with graphite mixtures of similar structures. A metallic resistance is satisfactory, but has the objection of being expensive and bulky when the voltages involved are high. This problem has not yet been satisfactorily solved, but it seems probable that where high resistances are demanded—200 ohms or more—some form of non-metallic resistance will be found of sufficiently permanent character to be satisfactory.

In the preceding matter the writer has endeavored to present some of the considerations to be taken into account when this question of grounding the neutral arises. There are so many variables connected with this matter that it is impossible to draw any conclusion that will be general in its nature. The proper action to be taken depends upon the specific conditions surrounding each individual case.

Electrical Operation of Sarnia Tunnel.

Machinery in the electric power house of the Grand Trunk Railway in Port Huron, Mich., was started up for the first time a few days ago. This power house, a part of the electrical equipment in the electrification of the Port Huron Tunnel, is 100 by 100 feet, two stories high, and of concrete, brick and steel construction. Two turbine-generator units of 2,500 horsepower each are installed. The boilers, coal handling apparatus and auxiliaries are of the most modern type.

Current from this power house will be used for operating trains through the tunnel between Port Huron and Sarnia, a total of nine miles of track, including side tracks. Besides, it will furnish light and power for pump houses, round houses and yards in Port Huron and Sarnia, and the shops, customs offices, sheds, etc. Arrangements have been made for 500 electric lights in the tunnel proper, and in the yards there will be 27 arc lights, and many incandescents in the buildings.

The electrification of the tunnel and the installation of the power house, distributing system and locomotives has been in progress the last year under the direction of the Westinghouse company. At present there are three large electric locomotives. All electric wires from the power house are led through a shaft into the tunnel. Bion J. Arnold was the consulting electrical engineer of the Grand Trunk Railway.

Industrial Education.

The first monthly meeting this season of the American Society of Mechanical Engineers was held in the main auditorium of the Engineers' Building, New York city, on the evening of October 8th. A little over 100 members were in attendance and the subject of the evening, "Industrial Education," was well presented. A short business meeting preceded the presentation of papers. A motion was made and carried that the Mechanical Engineers' Library Association and the American Society of Mechanical Engineers be consolidated into the one society, to retain the name of the latter.

The first paper of the evening, "College and Apprentice Training," giving the relation of the student engineering courses in the industries to the college technical courses, was by Prof. John P. Jackson of the State College of Pennsylvania. Its purport was set forth in the Western Electrician of last week.

Prof. Dugald C. Jackson of the Massachusetts Institute of Technology then spoke of the conditions in the college, how the men were already worked to over their limit and could not give thought to other lines than study, but that this is a serious fault and is being realized and rectified partially by some of the colleges. Professor Jackson then spoke upon post-graduate work. It was desirable to extend the four years' course into five or six. Very few of the engineering schools, however, possess facilities successfully to carry on this extension work with ample space and laboratory facilities. The Davis bill now pending in Congress allows money for each of the manual training and agricultural colleges in the several states. The money to be spent, however, is determined by an expert educational commission in each state. This question is of considerable moment, and influence should be brought to bear upon the respective representatives from the several states to modify this act.

Announcement was then made that Dr. Henry S. Pritchett, president of the Carnegie Foundation and also president of the Society for the Promotion of Industrial Education, was unable to be present, as had been announced.

The next paper was by Prof. C. F. Parks of Lowell Institute, who spoke upon the desirability of the education of the foreman, under whose care came so many young men, and also of the courses which had been established for their training. The courses require the attendance of the young man two hours on three or four evenings each week and an equivalent amount of study at home. The course extends over two years and includes the more elementary studies—mathematics, drawing, etc., and lectures illustrated with problems and tests on the work in hand. A large proportion of the men are draftsmen and mechanics, whose average age is about 27 years. Professor Parks concluded by stating that it was this kind of material that we needed in our industries and that it was desirous to educate them along these lines.

Mr. A. A. Hamerschlag next spoke upon the individual and the necessity of not forgetting the student in all of this development. He spoke very discouragingly of the apprentice courses as given in several large manufacturing companies, and stated that these courses were run to the financial betterment of the company, and that the returns to the student were far from satisfactory and did not represent the returns which the student gave to the companies. The apprentice gets into a certain restricted set, makes the foreman resentful, and upon the completion of the course is very narrow in his experience with any apparatus but that manufactured by the particular company under which he has labored.

A number of other speakers gave their views upon these courses, and the matter was left with many distinct views standing, representing the several interests at stake. Secretary Calvin W. Rice then requested that the matter be presented in a more definite form so that an expression of the society might be made.

Mr. F. W. Taylor of Philadelphia then spoke upon the condition of the student as he left college and compared his mind to a sponge. While at college he is taught to absorb all the knowledge that he can and as he leaves he still has this idea with him, that he must keep right on absorbing all the information that is possible. What he really needs is to be put at some real, hard, long, monotonous work, something that is dull and disagreeable but which will bring him into touch with what men of the business world have to contend with. It is this sort of training which is of value to the young graduating engineer. S.

The Grounded Neutral.[1]

By F. G. Clark.

During the consideration of the design of one high-tension installation the question of grounding the neutral was investigated and resulted in a decision to ground the neutral points of the generators through a limiting resistance. It was my privilege to contribute to that design and to recommend that this resistance be omitted. The reasons for grounding, the reasons for and against the resistance, and facts relatively to operation covering a period of over two years may therefore be of interest in connection with this discussion.

The installation comprises a power station centrally located for the ultimate conditions prescribed, but unfavorable to the preliminary electrification of a steam railroad requiring seven sub-stations, and underground and overhead transmission of three-phase current at 11,000 volts and 25 cycles. Fig. 1 will give an idea of the present and ultimate conditions. The future circuits from the power station will be underground cables. There are now five 250,000-circular-mil three-phase circuits leading from the station underground to No. 1 cable house. From there the feeders are aerial to sub-station No. 3. This will be seen to be the distributing point for the present installation. Two aerial circuits lead to sub-station No. 5. At cable house No. 2 the circuits are submarine, and again at cable house No. 3 submarine cables are used from the north end of the draw to the sub-station.

The feeders leading east and west from sub-station No. 3 are underground. Three circuits lead to sub-station No. 2, and from there two circuits lead to sub-station No. 1. Three circuits lead to sub-station No. 4 and are overhead from cable house No. 4. From No. 4 sub-station one circuit leads direct to sub-station No. 6 and another to portable station No. 1, and from there to No. 6. At portable station No. 1 a three-phase No. 2 conductor branch leads to sub-station No. 7. One circuit leads from sub-station No. 4 to portable station No. 2, and from there a single-phase No. 1 conductor circuit leads to transformer station No. 1. A typical location of this system and length of feeders is shown in Fig. 2.

The protective features are low-equivalent lightning arresters, inverse time-element relays on circuit-breakers, a peculiar method of operating exciters, and the grounded neutral. A voltage regulator has lately been installed and has a bearing on the situation.

The lightning arresters are used in connection with choke coils at the ends of all overhead feeders. They tend to protect the underground feeders, the station apparatus, and to a certain extent the aerial transmission lines from the effects of lightning and from static strains due to switching, grounds or short-circuits. The arresters are set to discharge at 8,500 volts. The pressure between the ground and two conductors of the 11,000-volt three-phase system, with one conductor grounded, is 11,000 volts when the neutral is not grounded; it is 6,380 volts when the neutral is dead grounded; it is between 6,380 volts and 11,000 volts with resistance in the neutral conductor. The locations of the lightning arresters are shown in Fig. 2.

The inverse time-element relays afford protection against overloads and are used in connection with the oil circuit-breakers on all feeders. The speed in opening the circuit-breaker varies with the increase of current in the circuit controlled.

The relays at the power-station ends of the feeders are set to allow a maximum of current to flow for a period of five seconds before they actuate the control circuits to open the circuit-breakers. This is just above the amount of current allowed as a maximum per feeder. The relays at the nearest sub-station are set to open the circuit-breakers on feeders to more remote sub-stations in four seconds for the same current. The relays in the sub-station next in progression are set for three seconds with the same current, and so on. The relays are connected with series transformers, one on each leg of the circuit controlled, to open the circuit in the event of one leg grounding.

The excitation of the generators depends upon induction motor generators, with no steam exciter or battery reinforcement, although both are available for starting up in case of an interruption. The induction motors are supplied from the main generators through transformers and have about 25 per cent. slip. The output of the exciters depends upon the power factor, which decreases with the voltage. The excitation automatically ceases whenever the bus-bar voltage goes below 5,000.

A voltage regulator tends automatically to increase or decrease the generator excitation as its voltage lowers or rises. The effect of this is to increase the intensity of the accidental overload and therefore hasten the automatic interruption. This is a radical change from the usual practice of holding up the exciter voltage under all conditions. It means a few more power-station interruptions, but less damage when short-circuits occur and less time lost in sub-stations.

The foregoing explanation of the protective features of this installation may appear to be irrelevant to a discussion of the grounded neutral, though it has a bearing which should not be overlooked. The neutral point of each generator is led to a bus-bar through a fourth pole of the generator circuit-breaker. The neutral bus-bar is connected to one end of a cast-grid resistance suitably insulated. The other end of the resistance is connected to a ground plate located in earth, kept moist with salt water. There is 6.7 ohms resistance, or sufficient to allow 1,000 amperes in the neutral circuit in the event of a ground. A current of 1,000 amperes will raise the temperature of the resistance approximately 1,000° F. in one minute. An ammeter on the switchboard indicates the amount of current in the neutral connection. A pilot lamp lights whenever 50 amperes or more flows through the resistance. This lamp remains lighted until an auxiliary circuit is opened and has been instrumental in determining the number of short-circuits that were also grounds.

The grounded neutral affords protection against rises in potential and high-frequency oscillations, due to grounds. An accidental ground will establish a power circuit supposedly sufficient in all cases automatically to open the circuit-breaker. Were the neutral not grounded, the accidental ground would allow the charging current to be discharged through it, tending to burn the insulation and cause a short-circuit in the case of an underground cable or burn off the conductor in the case of an aerial line. The electrostatic change would also tend to cause oscillations in the case of underground cables and possible breakdowns at various points of the system. This has occurred during the operation of several high-tension systems.

Grounding the neutral has the disadvantage of increasing the number of short-circuits and consequently the interruptions of service. These short-circuits are dangerous to power-station apparatus, as they may cause breakdowns involving greater expense and loss of service than the possible resonance troubles. There are conditions peculiar to each installation which have a bearing on this question, and these conditions determine the necessity of a resistance in the neutral circuit, the amount of resistance to be used, whether more than one generator should be grounded.

In systems where synchronous converters have low synchronizing power the voltage drop due to grounds will cause the converters to drop out, and a limiting resistance must be placed in the grounded neutral. In other systems the generator coils are insufficiently braced, and resistance in the neutral is a preventive for generator breakdowns. In stations where the generators are driven by slow-speed reciprocating engines the neutral points cannot be connected to a common bus-bar on account of cross-currents. A resistance would be required for each generator [illegible] neutral grounded.

A consideration of these [illegible] to [illegible] resistance of 6.7 ohms [illegible] that of the installation described. It was anticipated that the resistance would allow sufficient current to flow through the ground to clear the system of that ground, and that grounds on two legs or short-circuits would be cleared by the inverse time-element relays, or, if very close to the power station, by an interruption of service due to the "killing" of excitation. The events of operation indicate that the neutral ground is essential and that the other protective features perform their function suitably.

Conditions obtain, however, which [illegible] the proper operation of the protective feature. One instance will serve to illustrate this point. A wire-rigged sloop which had been anchored near the cable house No. 2 draw (Fig. 1) drifted out of the channel until a stay-line connected with one leg of the transmission circuit, causing a ground. The ground held for about three minutes, when the boat shifted and another part of the rigging connected with a second leg, causing a short circuit which opened the circuit-breaker. The current in the ground circuit was approximately 400 amperes, which was not sufficient to open any of the circuit-breakers between the ground and the power station. It was enough, however, to burn off an anchor chain and several of the wire stays on the boat and to raise the temperature of the neutral resistance to that of a bright-red heat.

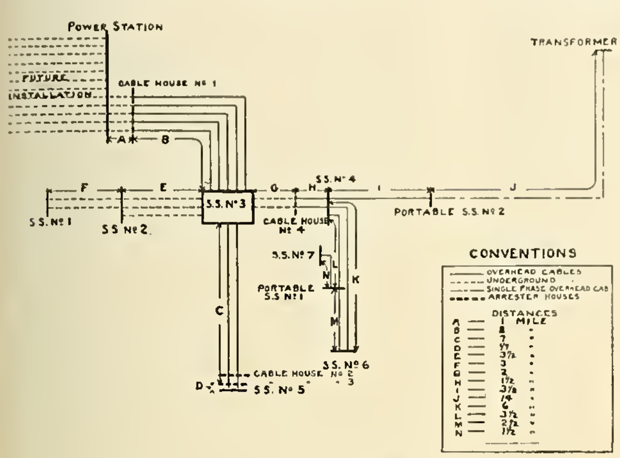


FIG. 1. POWER HOUSE CONNECTIONS.

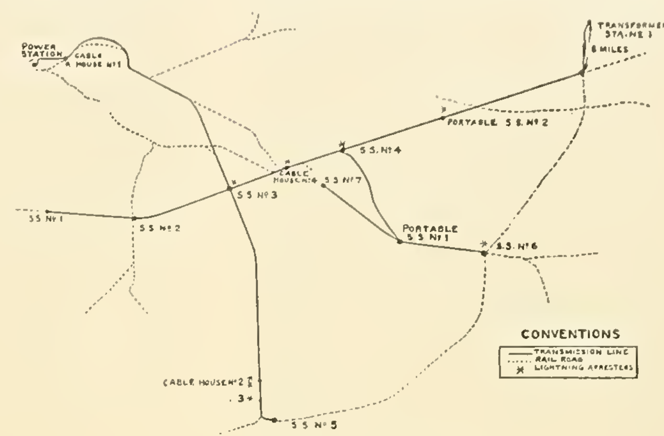

FIG. 2. FEEDERS FROM POWER HOUSE.

When the ground occurred the neutral point rose from 0 to about 2,700 volts, and the two ungrounded legs were approximately 9,000 volts to ground. The electrostatic condition very nearly approached that which would obtain in an ungrounded system. The lightning arresters being set at 8,500 volts, began to discharge, and oscillations were a possibility.

The inductive drop and the resistance of the ground added to the set resistance of 6.7 ohms were sufficient to limit the current to 400 amperes. With the 6.7-ohm resistance out, the current would have been above 650 amperes, or sufficient to have opened the nearest controlling circuit-breaker in less than one second. The inductive drop was about 1,000 volts and the resistance through the ground sufficient to divert the current to the numerous telephone lines as paths of least resistance. The fact that telephone troubles are not coincident with grounds of short duration would seem to indicate that induction is not an important factor in this particular case. There have been no indications of trouble in telephone or telegraph lines, due to induced potential.

Some action must be taken to prevent this ground current from causing trouble. The grounded neutral is a preventer of electrostatic troubles and therefore should be retained. The resistance is a positive detriment to receiving the full benefit of this effect. It should, therefore, be omitted whenever the local conditions will permit. In the case described, this can be done without perceptibly increasing the hazard to apparatus. This would enable the relays to clear any of the grounds that have occurred within five seconds.

A transmission line may be so long that its total drop and the resistance of the ground will produce a condition analogous to that described. Such a case would require special treatment, as, for example, providing a low-resistance neutral conductor leading to a point safely within the area normally protected by the neutral ground at the station and equipping the feeders to points beyond, so that they may be open by a relay. The relay could be actuated by a small current flowing in this extension of the neutral and in phase with current flowing in one leg of the feeder. Such a condition does not obtain on the system described, and we can therefore be reasonably assured that in removing the neutral resistance we will have removed the cause of trouble incident to the grounded neutral.

During two years' operation there have been over 70 short-circuits. About 25 of these have caused sub-station interruptions and six have been close

[1] A paper presented at the meeting of the American Institute of Electrical Engineers in New York, October 11, 1907. The author is superintendent of power station of the Pennsylvania Tunnel and Terminal Railroad Company at Long Island City, New York.

enough to cause power-station interruptions. About one-half of these short-circuits showed a ground connection. There have been 10 grounds, of which the neutral ground cleared eight. One held for four minutes and one for three minutes, both developing into two-wire short-circuits.

It is quite probable that in a system operating with underground cables only there would be no outside disturbances in connection with sustained grounds. The lead sheaths which are generally bonded together in manholes would provide the path of least resistance for the ground circuit. The ultimate installation will require underground cables, and except for the greater power effects and greater charging current will alter the present situation but little.

The American Institute of Electrical Engineers.[1]

By Henry G. Stott.

The American Institute of Electrical Engineers has over 5,100 members, of whom approximately 90 per cent. are residents of this country and 10 per cent. residents of foreign countries. Of the 4,600 domestic members, approximately 22 per cent. reside within one hour's travel of our national headquarters, and 70 per cent. within a distance which can be covered in twelve hours or less.

Our proceedings and transactions, available to all, undoubtedly are the most valuable asset of membership, but next to that may we not say that the social side ranks next in value? It is obviously impossible for us all to meet one another, as our domestic membership alone is distributed over a territory of 2,970,000 square miles. To meet this difficulty, however, the sections and university branches have been organized, so that now besides the national headquarters in New York, we have 20 sections and 17 university branches located at all great centers of membership. At these sections and branches not only are the papers presented at the New York meetings discussed, but original papers are also presented and discussed.

It will thus be seen that we are gradually evolving an organization somewhat similar to that of our state and federal governments, and as the process of evolution goes on, the constitution may have again to be readjusted to meet the new conditions.

Article I. of our Constitution speaks of the "advancement of the theory and practice of electrical engineering and of the allied arts and sciences."

When we look back over our Transactions for the last ten years, we cannot help being struck by the admirable way in which we find there recorded almost everything of note which has contributed to "the advancement of the theory and practice of electrical engineering," but so rapid has been the evolution of the theory and practice of electrical engineering, that the "allied arts and sciences" have been to a large extent squeezed out.

With every new application of electricity comes the demand for men who are not only specialists in that particular art, but who at the same time are electrical engineers, as, for example, in the applications of electricity to electrochemical processes, railways, illumination, transmission of power, mining, utilization of electricity in the numberless manufacturing processes, all of them calling for highly specialized knowledge in the allied arts.

It would therefore seem as if the time is now ripe for carrying out all the objects mentioned in our Constitution, and the papers committee is now endeavoring to broaden the scope of the Institute work without allowing their efforts to scatter too much. In order to assist in this work, some of the committee work has been reorganized. For example, the old high-tension transmission committee, which has done such excellent work, now becomes a sub-committee of the papers committee, and a new sub-committee on railways has been formed. Additional sub-committees will be appointed as necessity seems to require.

In accordance with the unanimous vote at the last annual convention, the board of directors has authorized the appointment of a committee on education to co-operate with other education committees in recommending a syllabus of studies for electrical engineers at our universities.

In furtherance of this work, a special meeting devoted to educational subjects will be held toward the end of this year, when those in charge of educational work will be free to devote some time to this most important subject.

In connection with educational work, we have available to our members not only our own library, but also those of the American Society of Mechanical Engineers and the American Institute of Mining Engineers, aggregating approximately 30,000 volumes, and forming the most valuable collection of technical works in the world. This joint library, however, is only open from 9 a. m. to 5 p. m.; but a movement is now on foot to change the present organization so as to make the library available up to 10 p. m.

When distinguished foreign engineers visit this country we have had no person or persons who could officially welcome them in the name of the American Institute of Electrical Engineers, so that this duty or pleasure has fallen heavily upon a small number of members, who have on numerous occasions acted as an unofficial reception committee. It would therefore seem as if it would lend to the dignity of these receptions, while giving authority to our members who are willing to incur the necessary expenditure of time and money, if a strong representative reception committee were appointed in each large city, so that our guests could be passed on from one city to another and thereby be saved a great deal of trouble, by finding immediately where they could see the particular apparatus or get the information they desired.

In conclusion, it now seems probable that our annual banquet will be held in January when we hope to have several distinguished guests address us, and I trust that the members of the Institute will remember that not only in our technical work, but in our social work, your officers whom you have elected need your constant support and encouragement.

1 Inaugural address (somewhat condensed) of the new president of the American Institute of Electrical Engineers, delivered the meeting in New York on October 11, 1907

Test of 7,500-kilowatt Westinghouse-Parsons Steam Turbine.

The following data comprise the principal results obtained during the eight-hour economy test on September 1, 1907, upon a turbine installed earlier in the year at Waterside Station No. 2 of the New York Edison Company. This test was conducted entirely by the New York Edison Company, under the direction of Mr. J. P. Sparrow, chief engineer. The various arrangements therefor were carried out in accordance with the mutual agreement between builder and operator entered into previous to the test, and the results, as herein given, were obtained by independent computation.

The turbine unit tested is of standard Westinghouse construction throughout. It has a maximum rated capacity of 11,250 kilowatts and was built to operate on 175 pounds steam pressure, 26 inches vacuum and 100 degrees superheat. Under these conditions, the turbine unit was guaranteed to have a minimum steam consumption of 15.9 pounds per kilowatt hour at the generator terminals with a normal speed of 750 revolutions per minute. Incidentally, the electrical efficiency of the generator was guaranteed to be 97.8 per cent., exclusive of friction and windage, at a load corresponding to that sustained during the test. The results of the tests, detailed below, show an economy about 7.5 per cent. better than the guarantee.

Methods of Conducting the Test.

Load.—During the test period, No. 2 Waterside Station sustained practically all of the 25-cycle load on the system, of which the unit under test carried practically 70 per cent., the remainder by the other turbine units in the station. This load was maintained as constant as possible by remote control of the turbine governor by the switchboard operator. Between the first and the last hours of the test, the maximum variation in load was held within 4 per cent. above and below mean. During the last hour, however, the load decreased somewhat. Previous to the test this turbine unit had been running on a load of 7,000 kilowatts, which was increased to its test load 10 minutes before the start.

Calibration.—Three-phase electrical load was measured by the two-wattmeter method, using two Weston indicating wattmeters of the standard laboratory type. These instruments were calibrated at the New York Electrical Testing Laboratories immediately before and after the test. Power factor was maintained substantially at unity, and all electrical readings were taken at one-minute intervals.

Steam Consumption.—As a surface condenser was used in connection with this turbine unit, the water rate was determined by weighing the condensed steam delivered from the condenser hot well. This condensation was weighed in a tank mounted upon platform scales, with a reservoir above large enough to hold the condensation accumulating between each weighing. These weighings of 12,000 to 13,000 pounds each were made at intervals of five minutes.

Gland Leakage.—By the loop method of connecting the gland water supply, the necessity for correcting condensation by an amount equivalent to the weight of the gland water used is avoided. It will be noted that a continuous gland water circuit is used entirely outside of the weighing apparatus, and that all overflow from the standpipe returns to the hot-well delivery.

Condenser Leakage.—As the circulating water is quite salt, any condenser leakage may immediately be detected by the salinity of the condensed steam, which should be pure distilled water. On this account, condenser was determined entirely by chemical analysis, employing the silver-nitrate test with a suitable color indicator. This method proved extremely sensitive, and possessed a decided advantage over the ordinary method of weighing the leakage accumulating during a definite period when the condenser is idle and under full vacuum. As samples of circulating water and condensed steam could be taken at the same time, this method made it possible to discover any change in the rate of condenser leakage taking place during the test, while the method of weighing, above described, provides only an average result during the period.

Hot-well Correction.—In this condensing plant the delivery of the hot-well pump is automatically controlled by a float valve in the interior of the hot well. This maintains the water level therein at a practically constant point, and hence no correction had to be made for difference in level of water in the hot well before and after the test.

Steam Supply.—Steam pressures and temperatures were determined close to the turbine throttle. As usual, the degree of superheat was obtained by subtracting from the actual steam temperature the temperature of saturated steam at the corresponding pressure carried at the time. All gauges and thermometers were calibrated previous to the test at the U. S. Testing Bureau. Both pressure and superheat were somewhat below the guarantee.

Vacuum.—Vacuum was measured directly at the turbine exhaust by means of a mercury column with a barometer alongside for reducing to standard barometer—30 inches. This also obviated the necessity for temperature correction between the two mercury columns. During the test the vacuum was not maintained quite up to normal.

Results of Tests.

The following data represent the results of the tests, calculated for the conditions as actually run; i. e., for instrumental errors only:

Duration of test	9:30 a. m. to 5:30 p. m.
Average steam pressure at throttle, lbs., per sq. in. gauge	177.5
Average superheat at throttle, degrees F.	95.74
Average vacuum (referred to 30 in. barom.) in. mercury	27.31
Average load on generator, kw	9,830.48
Average steam consumption, as tested, lbs., per kw. hour	15.15

Test Corrections.—Owing to the departure, during the test, from specific operating conditions upon which guarantees were based, it was necessary to correct the observed results by the following amounts:

Pressure (2.5 pounds high) correction, 0.25 per cent.; vacuum (0.69 inch low) correction, 1.84 per cent.; superheat (4.26 degrees low) correction, 0.29 per cent.

These corrections were mutually agreed upon previous to the test as representative of this type of turbine. When applied to the observed steam consumption given above, the following results, representing contract conditions, are obtained:

Av. corrected water rate during 8-hr. test	14.85 lbs. per kw. hr.
Guaranteed water rate	15.9 lbs. per kw. hr.

Log.—It is interesting, as a check upon the average figures above presented, to observe the results segregated into hourly periods. The load was considerably lower during the first and last hour than during the main part of the test. Neglecting, therefore, these two hours and considering only the six-hour period from 10:30 a. m. to 4:30 p. m., the results are as follows:

Average corrected water rate, six hours	14.8 lbs. per kw. hr.
Equivalent water rate	10.65 lbs. per bhp. hr.
Equivalent water rate	9.8 lbs. per ihp. hr.

The two latter quantities are determined by applying conversion factors for generator efficiency and for internal losses.

In connection with these tests, a noteworthy agreement exists between the results noted and those previously obtained from tests of machines similar in design installed in the Manhattan Station of the Interborough Rapid Transit Company, New York, and the Long Island City Station of the Pennsylvania Railroad. At the same loads and with equivalent operating conditions, the performance of the machines is almost identical. These economic results, while not exceeding in actual steam consumption the best records of European practice, yet are extremely good in view of the moderate operating conditions under which the test was conducted.

Rapid Building Operations.

There has recently been completed at Newark, N. J., a lamp factory for the General Electric Company. On the 24th of one month ground was first broken by the contracting firm doing the work, and on the 23d of the following month the building was finished and the manufacturers' machinery was being installed—a period of 29 calendar days—with no night or Sunday work, and a half holiday on Saturday for the skilled labor.

The cost of the factory was approximately $50,000, with a bonus and forfeit clause, and in one week of five and a half days the pay-roll amounted to $6,000. About this time 400,000 bricks were laid in 11 working days, or an average of some 36,000 bricks a day. It is interesting to note that 280 men were employed in building this factory.

Salmond Bros. of Newark, N. J., were the contractors for this work, and Messrs. Wilson, Harris and Richards of Philadelphia were the architects for the General Electric Company.

It is pointed out that the new metallic-filament lamps are particularly well adapted for the well-known portable self-contained electric lights, or so-called "electric torches."

The Direct-current System of Power Transmission.

A critical consideration of the high tension direct-current system of power transmission appeared recently in the Zeitschrift für Elektrotechnik und Maschinenbau of Potsdam, Germany. It is stated to be due to a well-known English engineer, who does not wish his identity to be disclosed. The author discusses the paper read recently by Mr. Highfield (briefly referred to in the Western Electrician of March 30, 1907, page 277) before the British Institution of Electrical Engineers, and objects to the relation obtained for the effects of insulation for direct and alternating current. He also contends that Mr. Highfield's figures for the erection and working costs are on the wrong basis, and makes out a much better case for the three-phase system. The following abstract of the paper in the German publication is taken from the Electrician of London:

It is a general characteristic in all tests on insulating materials that the disruptive voltage increases at a less rate than the thickness of the material. If a sheet of insulating substance breaks down at a certain voltage, the voltage required to break down a sheet double the thickness is much less than double that in the former case. This law is also applicable to liquids and gases. In all cases the proper relation between voltage and thickness is hard to determine, as it depends on the form, nature and size of the electrodes as well as on the temperature and general properties of the material. According to Baur, who made tests on a large number of materials, the relation may be expressed by the equation: $D = Kt^{2/3}$, where D is the effective voltage, t the thickness in millimeters, and K a constant which must be determined for each material. The specification of the Engineering Standards Committee for three-core cables with a working voltage of 11,000 between the cores requires an insulation thickness of nine millimeters between copper and lead. The three-core cable used by the County of Durham Company, whose working voltage is 20,000, has insulation 13 millimeters thick. The factory of safety for a power transmission cable is hard to determine, owing to the considerable influence which the length of time the current is flowing and other practical factors have on the result. It may be supposed, however, that under certain conditions the breaking-down voltage in these cables is about three times the working voltage. K then becomes in the first case 7,600 and in the second 10,800, or a mean value of 9,200.

It may, therefore, be admitted that with the present-day methods of manufacture, and using ordinary materials, the value of K for a finished cable is about 10,000. These relations, however, appear in a new light when it is stated that a sheet of insulating material of given thickness requires a voltage 2½ times as great to break it down when direct current is used instead of alternating. For the proper discussion of this question it may be supposed that a continuous voltage has half the disruptive strength of alternating. A cable was shown before the Institution of Electrical Engineers which was in use on a 50,000-volt direct-current system. This cable had an insulation thickness of 14 millimeters between conductor and lead sheath. The cable could, therefore, only be used for 25,000 volts alternating. The factor of safety would be 3, and K would be equal to 13,000. From further data given on this subject by the author it is shown that no such general law for insulation thickness at different voltages and with a certain factor can be given. The equation is of the order $D = Kt^n$, K being a constant depending on the insulating material. The exponent n is always less than 1 and decreases rapidly with increasing diameter of conductor. No such law can be established for cables insulated with different materials.

In the sketch of the typical bulk-supply area given by Mr. Highfield the direct-current system working at 100,000 volts requires 84 miles of cable 0.1 square inch in cross-section. The system can be earthed at the middle point, so that there is only a pressure of 50,000 volts betwen conductor and earth. Trenching running to 84 miles is also required. The three-phase system working at 20,000 volts between conductors requires 52 miles of three-core cable, each core having a cross-section of 0.75 square inch, and 66 miles 0.5 square inch in cross-section. Earthing the neutral point requires the insulation between conductor and lead sheath to withstand 11,500 volts. Trenching amounts to 85 miles in this case.

Mr. Highfield put the total cost of the direct-current cable at £580 per mile, which is 1.57 times greater than that for the material alone. This factor will be greater for the three-phase cable, and may be taken as 1.8. Mr. Highfield puts the cost of the two three-phase cables required at £1,050 and £900 per mile. In reality they only cost £784 and £608 per mile. The costs for trenching were given as £900 per mile for direct current and £1,000 per mile for three-phase. These two items were shown in the discussion to be too high; they are sufficiently covered by £700 per mile, even taking into account the special conditions prevailing in the neighborhood of London, where the requirements of the property owners have to be considered. The total cost for mains in this scheme would be £107,000 for direct current and £141,000 for alternating, a difference of 32 per cent. According to Mr. Highfield, the amounts would be £124,320 and £199,000, a difference of more than 60 per cent.

The employment of direct current is, accordingly, only to be recommended from a commercial point of view when the network expense are small compared with the three-phase system. The greater part of these economics are, however, imaginary, and in nowise cover the higher costs of the direct-current generating station.

The following points in the paper are open to criticism: The units chosen for the three-phase system should be larger and those for the direct-current system smaller. The largest units at present working on the direct-current system are only 600 kilowatts (Moutiers-Lyons), and, except for these, the largest is 400 kilowatts. The buildings costs will, therefore, become smaller in the case of the three-phase and larger for the direct-current system. This also applies to the cost of the machinery proper and to the switch gear. The costs for boilers, auxiliary machinery and coaling arrangements given by Mr. Highfield for the direct-current system are too low, as the greater number of smaller units increases the steam consumption. The lower efficiency of the direct current system requires that a greater number of units must be generated for the consumer to receive a specified amount than if a constant-voltage system were employed.

Owing to the peculiar conditions of the direct-current system, the distribution losses are always the same. Therefore the efficiency of transmission is low at light loads and high at full load. As far as upkeep costs are concerned, direct current is at a disadvantage for the following reasons: The distribution losses are the same at all loads, and therefore the percentage loss increases as the load decreases. On a constant-voltage system the reverse is the case. The percentage loss on the direct-current system may be very small, being placed by Mr. Highfield at three per cent. at full load.

The author concludes by stating that no great future can be predicted for the direct-current system.

Arc and Incandescent Lighting Compared.

By W. D'A. Ryan.

The only logical comparison of candlepowers for various illuminants, particularly for interior lighting, is the mean spherical, whether it be that of incandescent, arc, mercury or other lamp. Suitable reflectors may be used to change the distribution of the light on any of the lamps to meet the conditions, with the possible exception of one which has such a strong vertical distribution that it is difficult to change its direction without serious loss. The common practice of figuring illumination on the initial candlepower basis should be discouraged. Some poor examples of illuminating engineering are monuments to this practice, and the arc is frequently discredited by a false conception of this important point.

Briefly, in figuring illumination, about 10 per cent. should be added to the initial illumination of the arcs, and about 20 per cent. to the incandescents to cover depreciation, globe deposit, etc., thereby representing service conditions.

Over a period of 1,000 hours, under all conditions of operation, we can say that the multiple enclosed arc lamps, whether alternating or direct current, will run between two and three watts per mean spherical candlepower. This covers a wide range of currents, and also the variations due to carbons, feeding, globe deposit, etc. Compare this, for example, with the standard incandescent lamp of 3.1 and 3.5 watts per horizontal candlepower, with clear bulbs. The former has a mean spherical efficiency of 3.76 watts, initial, and the latter 4.24, initial. After the lamps have burned to the limit of their so-called useful life, namely, to the point where the candlepower is 80 per cent. of the initial, the efficiency of the former is 4.5, and of the latter 5.1 watts per mean spherical candlepower. If these lamps were frosted to conform with the prevailing demand, the figures would stand nearer 5 for the former, and 5.5 for the latter. Furthermore, it is not customary immediately to remove lamps when they reach 80 per cent. of their initial candlepower, so it is safe to say that the standard incandescent lamps, of the initial efficiencies mentioned, will average, over a period of 800 to 1,000 hours, anywhere from four to six watts per mean spherical candlepower, with a renewal cost of from one-half to six-tenths of a cent per kilowatt-hour, as compared with 0.2 to 0.3 cent per kilowatt-hour for the maintenance of the arc lamp. This gives for the arc lamp practically double the light under service conditions, over the period of time mentioned. Notwithstanding the difference in efficiency, there are many cases where arcs are used when incandescents would give better results, and vice versa. It is not altogether a question of efficiency and cost, but a question of adaptability to surroundings.

Now, while the Gem lamp with clear bulb shows [illegible] an improvement [illegible] to 20 per cent [illegible] lamp [illegible] somewhat [illegible]

The tantalum lamp [illegible] limitations, the cost is relatively high [illegible] under the circumstances, the improvement in efficiency is not sufficiently great to warrant its replacing Gem lamps to any considerable extent, especially where the cost of current is low.

The tungsten lamp promises to rival the arc in initial efficiency. We have no evidence as to whether or not it will be its equal or superior under running conditions, that is, the service condition, with the time factor introduced. Furthermore, we know that where a white light is necessary, the tungsten cannot compete with the carbon arc, notwithstanding the somewhat general impression to the contrary, based possibly upon casual observation of exposed lamps, and not on actual color-selection test. On the other hand, the light is rather cold for domestic purposes. It promises, nevertheless, to revolutionize commercial lighting, but there is no reason why we should surrender the advantages of the arc lamp for all classes of lighting until we actually have a fair substitute.

I might state that it is the purpose of the illuminating engineering department of the General Electric Company to disseminate accurate and useful information in connection with the subject, and to be absolutely impartial in specifying apparatus, whether incandescent, enclosed arc, magnetite, tungsten, or other illuminants; it is only on this basis that illuminating engineering can properly progress.—From the General Electric Review.

Western Society of Engineers Discusses Telephone Rates.

The first regular meeting of the Electrical Section of the Western Society of Engineers for the 1907-08 session was held in the society's rooms in Chicago on the evening of October 11th. The meeting was devoted to the reading of a paper on the subject of "Telephone Rates for Large Exchanges," by Mr. W. H. Crumb of Chicago. There was not a large attendance, but the paper was attentively listened to by those present, and was briefly discussed by K. B. Miller, consulting electrical engineer; W. F. Burgess of the Chicago Telephone Company; C. A. S. Howlett, chairman of the Electrical Section, who presided; Prof. C. E. Freeman and others.

Mr. Crumb made no pretense of a suggestion as to what particular telephone rates should be, as such a determination is only possible after careful consideration of the many questions which must be given attention in order properly to establish equitable rates for large telephone exchanges. Much of the information and the charts and curves given in the paper were included in the report made by the special commission which recently reported on the telephone situation in Chicago to the City Council.

It is the duty, the speaker said, of any corporation giving telephone service in a large city, thoroughly to develop the territory and give good service at reasonable rates. This duty involves a problem in many respects more complex than that of any other public-utility corporation, partially because of the personal element, partially because of the varied classes of service necessary and partially because of the intangible character of the electric medium with which the telephone business is carried on, the delicacy of the apparatus used and the wide difference in the manner and extent of the use of the apparatus by the various subscribers.

The great problem which confronts all telephone companies, Mr. Crumb said, is that of supplying a good quality of telephone service to the small user at a price which he can afford to pay and still leave a fair margin of profit for the company. The price must be so graded that the large user shall not pay less than his fair share of the expense of maintaining the service and that the small user shall get service at a price within his means, the figures for both classes to leave reasonable remuneration. After going thoroughly into the engineering and business requirements necessary to successful and efficient operation of a telephone system in a large city the speaker outlined the two systems of charging—the flat-rate method and the measured-service method, the latter being favored by the speaker as the solution of the rate question in large exchanges.

In the interest of good service, economy of production and uniform justice in charging for the different classes of service, Mr. Crumb said that the measured-service plan is much to be preferred to the flat-rate plan. Maintenance expenses are very largely directly due to traffic, and all maintenance expenses must be considered as being directly or indirectly due to traffic and therefore distributed in proportion to the traffic. The same was said to be true of general expenses and fixed charges.

Depreciation and insurance on portions of the plant which are not economically underwritten by insurance companies are items of expense in producing telephone service which are often neglected or underestimated in the consideration of rates. Much of the depreciation on a telephone plant is directly caused by traffic. This is especially true of the depreciation of equipment; also depreciation due to the advancement of the art, as traffic often demands that present equipment and methods be replaced by more modern ones before those in use are worn out. The depreciation on parts of the plant which cannot be directly traceable as a result of traffic are indirectly due to it, as the object of the plant is to provide for traffic, and therefore depreciation charges should be classified in proportion to the traffic.

In order, therefore, to determine the proper rate to charge, Mr. Crumb said, the cost must first be ascertained for each class of service offered, and to do this means a careful investigation and determination of many questions. It means particularly that telephone companies must pay more attention to the results of their peg counts, and that they must be made in such a way that they will furnish the information necessary for the accurate fixing of rates. This complex problem offers many interesting opportunities to the telephone engineer, and Mr. Crumb hoped that the great telephone companies of the large cities would soon set about a means of determining the exact cost of the different classes of telephone service, so that it may be furnished without discrimination in charges to any class. "Not until our great telephone companies can truthfully say from their own knowledge that they are doing this can they claim to be discharging the duty which they assumed upon entering the telephone business."

In the brief discussion of the paper measured service was generally favored. One speaker believed that in working out a system of rates it would eventually be found advantageous to bring in a consideration of time unit and wire unit, but others thought that this would mean a complex system of individual rates; a classification of individuals charged on a measured-service basis would be complicated enough without involving the units of time and distance for each message.

Indiana Telephone Items.

The Richmond Home Telephone Company has moved into its new building and put its new automatic system in operation on the 15th inst. The Central Union Telephone Company, which has maintained a small exchange in Richmond, may turn over to the Richmond Home company all of its business and retire from the field.

The City Council of Martinsville will take steps toward inducing the Martinsville Telephone Company to make improvements necessary for an improved service. The company is owned by the New Long-distance Telephone Company, and the managers say they are quite willing to put in a new system in consideration of the city granting an extension of franchise for 25 years after the termination of the present franchise, 12 years hence. The company also asks to be permitted to increase the rates.

The filing of a suit in the Superior Court of Indianapolis by the New Long-distance Telephone Company against the Citizens' Telephone Company of Kokomo and the Central Union Telephone Company of Indianapolis, seeking an injunction and recovery of damages, is said to be the beginning of a big legal battle between the two big companies operating in the state. The New Long-distance Telephone Company, complaining of the two defending companies, alleges that it has an exclusive contract with the Citizens' Telephone Company of Kokomo to handle all of its long-distance business during the life of that company's franchise in Kokomo. It further alleges that in July, 1906, the company began affiliating with the Central Union Telephone Company and giving a portion of its business to that company in violation of the exclusive contract. S.

Telephone News from the Northwest.

The State Telephone Board of South Dakota has ordered a connection between the long-distance lines of the Independent Telephone Company of Yankton, S. D., and the Elk Point Telephone Company of Elk Point.

The State Railroad Commission of Wisconsin has ordered free telephones furnished to railroads to be discontinued, on the ground that such procedure is a discrimination in favor of the railroads and against the people who pay for their telephone service.

The Enderlin Telephone Company, Enderlin, N. D., has been incorporated with $50,000 capital stock.

Officers and managers of local branches of the Northwestern Telephone Exchange Company met at Fargo, N. D., to consider matters pertaining to the business. There was an attendance of 20. A banquet marked the closing of the meeting.

The Wisconsin Telephone Company has merged the Eau Claire and the La Crosse districts into the larger Eau Claire district with P. J. Skolsky as district manager with headquarters at Eau Claire as formerly. The new district comprises 23 counties and portions of two others, and has 17,000 instruments in 144 cities and villages.

L. A. Little has sold the Missouri Valley (Iowa) telephone exchange to W. A. Smith. R.

Independent Telephone Growth in Texas.

Austin, Tex., October 10.—The Independent telephone movement is having a steady growth in Texas. In addition to the long-distance and local telephone lines already in operation, applications for franchises for the establishment of systems are now pending in a number of towns and cities of the state. Franchises have been recently granted at Amarillo, McKinney and Granbury.

A syndicate has made application to the city commissioners of Dallas for a franchise for an Independent telephone system for that city. The applicants announce that they are prepared to expend from $1,500,000 to $2,000,000. The applicants are Captain A. J. Brown, John A. Barnard and C. F. Freeman of Dallas, and E. L. Swaine and F. J. Norris of Los Angeles. Mr. Swaine was formerly general manager of the Home Telephone and Telegraph Company of Los Angeles, Cal. Mr. Norris was formerly general auditor of the Los Angeles Independent Company. These two men are now in Dallas.

In their petition to the city commissioners for a franchise in Dallas the applicants call attention to the phenomenal development in the telephone field since the Independents gained a footing. They say that Independent systems are now in operation in many towns and cities of Texas, among them being Fort Worth, Waco, San Antonio, Abilene, Ennis, Waxahachie, Hillsboro, Weatherford, Sherman, Paris, Denison, Gainesville, Cleburne, Denton and Palo Pinto, and the building of an Independent telephone system in Dallas will aid in the development of the city to a greater degree than any other public utility at the present time. H.

International Independent Telephone Convention.

The annual convention of the International Independent Telephone Association will be held at the Coliseum, Chicago, on January 21, 22 and 23, 1908. This date is during the period of the third annual Electrical Show, and in connection with the exhibit of other electrical lines the Independent telephone manufacturers have arranged to make a large combined exhibit of telephones and telephone apparatus and will occupy the entire annex, containing over 10,000 square feet of floor area. This, it is said, will be the largest and most complete exhibit of telephones and telephone devices ever held at any one time.

GENERAL TELEPHONE NEWS

The Home Telephone and Telegraph Company of Lemmon, S. D., has been incorporated.

The Dakota Central Telephone Company seeks an extension of its franchise in Huron, S. D., and contemplates installing an automatic system.

The Michigan State Telephone Company reports a total of 130,884 subscribers as of July 31st, an increase of 499 subscribers for the month of July.

Frank Hafliger of Pekin, Ill., has been appointed manager of the Delavan office of the Pekin Telephone Company, succeeding W. K. McQuown, who is transferred to the office at Havana.

Among the telephone companies recently incorporated are the Stakes Plains Telephone Company of Lubbok, Tex., the Manitou Telephone Company of Manitou, Okla., and the Miller Telephone Company of Miller, Neb.

The Chicago Telephone Company reports a net gain of 1,923 in September in the number of its telephones in service, 1,325 being installed in the city. At the end of the month the company had in service 196,022 telephones, of which 140,770 were in the city.

The Salt Lake Telephone Company is exerting itself to get a permit to erect poles in Carson, Nev., and the Nevada Consolidated Company, organized by men of Carson, is also working for a telephone franchise there. The Sunset company has heretofore been the only one in the field.

Telephone users in Milwaukee representing various lines of business have forwarded a complaint, with 42 signatures, to the State Railroad Commission, asking for remedies for alleged "poor, insufficient, inadequate and unreliable telephone service" furnished by the Wisconsin Telephone Company.

When Charles Sumner, president of the Home Telephone Company, reaches Spokane from the East early in November it is given out that a contract will be entered into with the Interstate Telephone Company for local and long-distance connections, thus furnishing lively competition for the Pacific Telephone and Telegraph Company. The Interstate lines now reach a large number of points in the Spokane country, an area of 150,000 square miles in Eastern Washington, Northern Idaho, Northeastern Oregon, Southeastern British Columbia and Western Montana, and as soon as the lines now under construction and projected are completed the company will cover the bulk of the Pacific field in the Inland Empire.

CORRESPONDENCE.

Continental Europe.

Paris, September 28.—The new Lötschberg electric railway and tunnel, which is now in construction in Switzerland, will rival the Simplon line in interest, and will no doubt carry a heavy freight and passenger traffic. As upon other main lines, there will be run trains of different classes which will be distinguished by their destination, weight and speed. Among these will be trains designed for passengers only and for loads which do not exceed 300 tons. There will be a class of local passenger trains and also freight trains. As to the express and freight trains, they will use electric locomotives, according to the present project, but it is possible that motor cars may be used for some of the passenger trains. The system of electric traction which is to be used on the Lötschberg road is not as yet decided upon, and the choice now lies between the direct-current, three-phase or single-phase systems. On the Simplon road three-phase current at 3,000 volts is employed, but it is to be remarked that the choice was made simply because there were locomotives at hand which had been built on the type of the Valtelline locomotives, and it was desired to use these, otherwise the line could not be set working within a reasonable time. Neither technical nor economic reasons therefore led to the use of the present locomotives, so that for the Lötschberg road the question can be looked into much more carefully before coming to a definite decision. At the same time the Swiss government commission is collecting data on the same subject with a view to applying electric traction on the main lines throughout the country, and it will be an advantage to wait for the result of their researches.

As to the expense of operating the line, the comparative data indicate that the cost, compared with steam locomotives, which, besides, cannot be used here upon the 27 per cent. grade, will be somewhat lower, allowing for a heavy traffic, in spite of the higher first cost. According to estimates, the annual traffic on the new line will no doubt be at least 277,000 passengers and 500,000 tons of freight, counting one direction.

Among the new electric systems which are now being installed on the Continent I may note the new plant and line construction under way at Ougree, Belgium, where the municipality decided not long ago to operate such a plant by contract with a private company. The latter is known as the Liège Electric Company, and is to furnish the needed current at 6,300 volts. This current is delivered at a certain point in the town, and the municipality will undertake the rest of the work, including the transformation and the city lines for public and private lighting and motor current.

The postmaster-general at Adelaide, Australia, is to receive bids up to the end of the year for a central telephone outfit and 3,000 subscribers' instruments.

Preparations are being made at Lyons for an exposition and concourse of electric motors, to be held next year. The object is to bring out the best types of motor for use in small shops and for domestic purposes, and the Agricultural and Scientific Society is taking it in charge. An exposition of this kind was held in 1906 and was quite a success. Agriculture is to be one of the leading points to be considered this time. Lyons is the center of a region in France which is covered with networks of lines from hydraulic plants, so that motor current can be had at a low rate, and this gives a great field for the use of small motors.

A. DE C.

Great Britain.

London, October 4.—The Victoria Falls power scheme is always interesting, and that is the excuse for mentioning some remarks which have been made by Mr. Ralph D. Mershon, one of the consulting engineers, on his arrival in this country from South Africa. Mr. Mershon has not the slightest doubt that such a transmission scheme can be made profitable, an opinion based to some extent upon experiments with high voltages in 1897 and again three years ago. He further stated that everything that has occurred in connection with transmission at high voltage since his first report to the Victoria Falls Power Company has confirmed his first opinions as to the practicability and economy of the project. It cannot help being remarked, all the same, that the company continues to extend its steam stations. The enormous possibilities of the Victoria Falls, however, are such that from a personal inspection Mr. Mershon is satisfied that 300,000 horsepower is available, and if means were taken to conserve the water some little distance back from the falls there would be a further large addition to the power.

An interesting case of co-operation on the part of shopkeepers to improve the lighting of their thoroughfare and at the same time to make this of commercial value comes from Newcastle. A number of the shopkeepers in a prominent street joined hands and ordered 40 flame-arc lamps primarily to light the thoroughfare, but also incidentally to attract business. This action has been taken quite independently of the street-lighting authority, in fact the order has been given to a local power company.

Two further reports of British manufacturing companies are interesting in the present condition of affairs. The British Thomson-Houston Company shows a trading profit for the year ended March 31, 1907, of $75,000, but the whole of it, with the exception of a small sum carried forward, has had to be applied to various depreciations. Willans & Robinson, on the other hand, continue to draw themselves out of the financial troubles which threatened to extinguish them a few years ago, when the popularity of the steam turbine first had a detrimental effect upon the use of reciprocating engines. Having been driven to the necessity of reducing their capital, the company is able for the half year ended June 30, 1907, to pay a dividend of six per cent. upon its preference shares and 10 per cent. upon the ordinary shares. The net profit amounted to $80,000.

At the end of last week the subscribers, numbering about 20,000, on one of the largest London telephone exchanges were transferred to a new exchange building and plant within 15 minutes. To effect this without appreciable interference with the subscribers it need hardly be said that months of preparation had been required.

Inasmuch as a general railway strike would affect electric as well as steam railways, the position as between the railway directors and the men's union is of interest. The point under discussion is that the Amalgamated Society of Railway Servants demands to be recognized as the medium for laying the men's grievances before the directors, and the latter reject any such idea. Since the present acute position arose none of the directors has expressed any views but Sir George Gibb, the successor to Mr. Yerkes, upon the board of the Underground Electric Railways Company of London, has definitely declined to receive any deputation from the society at present. G.

Dominion of Canada.

Winnipeg, Man., October 12.—The ratepayers of Kenora, Ont., passed the by-law authorizing the expenditure of $75,000 for the completion of the waterworks and power plants. C. S. Draper can give information.

Cecil B. Smith, who has charge of the construction of the $3,000,000 power plant to be built by the city of Winnipeg, states the tenders received are satisfactory and are now being tabulated. Under the agreement, the successful bidders will be required to have the work completed within 27 months. The dam will be built so as to give 60,000 horsepower, but for the present machinery will only be put in for a 25,000-horsepower development. It is understood that the Anglo-Canadian Engineering Company of London, England, has bid on the work in bulk and offers to take Winnipeg debentures at 90 in payment for the work if its bid is accepted.

The gross receipts for the Toronto electric street railway for the financial year ended August 31, 1907, were $3,349,819.94, being an increase of $372,280.85 over the gross receipts for the previous year. The percentage paid to the city for the fiscal year ended with August 31st last was $409,964, as against $336,630.86 for the previous year. The gross increase in the receipts amounted to 11 per cent. and the city's percentage was increased 21 per cent.

Several weeks ago the Town Council of Revelstoke, B. C., advertised tenders for an auxiliary power plant of 300 horsepower. A large number of tenders were received from all over Canada, as well as some half dozen from American firms. The contract has been awarded to the Canadian General Electric Company, the price being $25,764. The new generator will be 60-cycle, 150-kilowatt, making 600 revolutions per minute. Superintendent Holden will have charge of the work of installation on behalf of the town.

The Bell Telephone Company has put in a large switchboard at the Canadian Pacific Railroad depot at Winnipeg. In future all the offices and yards of the company will receive telephonic communication from this switchboard. R.

New England.

Boston, Mass., October 12.—The receivers of the National Wire Corporation of New Haven, Conn., state that they expect to be able to realize $1,000,000 from the sale of the property and from the cash on hand. The liabilities of the company amount to $3,000,000.

The Connecticut Street Railway, which is practically a holding corporation for the New York, New Haven and Hartford Railroad, now operates 640 miles of street railways in Connecticut. Four hundred and eleven miles are owned outright, while 229 miles are leased. It serves 15 cities and 35 towns in Connecticut and five towns in New York state.

The express business is soon to be increased on both the Connecticut and Rhode Island street railways. Together with the express business, a development of freight business is contemplated. The companies will work in connection with the steam system of the New Haven Railway Company.

The Chicopee Manufacturing Company of Chicopee, Mass., is installing new spinning frames and a new generator of 800 horsepower. These new machines are to be driven by electricity. Twenty have been installed and 30 more are being prepared for use. Each machine has an individual electric motor. These machines will increase the output of the mill about 50,000 pounds a week. B.

New York.

New York city, October 12.—An important decision was handed down by the Supreme Court last week by which it is held that the Interborough Rapid Transit Company and the New York City Railway Company must pay the city of New York for the electric current used by the latter company in running the surface cars operated in connection with the subway. The court also restrained the Interborough Company from delivering power to the City Railway Company and the latter company from using, disposing or selling the current so obtained. An interlocutory judgment was also issued on condition that an immediate appeal be taken by the two railway companies from the decision. This action was brought last November by the Board of Rapid Transit Commissioners, which asserted that the Interborough company, which operates the subway, was violating the provisions of its contract with the city in supplying electricity to a subsidiary corporation which operates surface cars running from the Bronx to the upper part of Manhattan.

Next week the Public Service Commission will begin its investigation of the electric-lighting and power companies, paying particular attention at the first meetings to the methods of the New York Edison Company in dealing with its customers. It is expected that the investigation will last several weeks. Since its inception the commission has been in receipt of complaints from consumers of electricity, who assert that it is impossible for them to get fair treatment from the supply companies. Some of the questions that will be brought up will be the right of the supply company to turn off the service whenever a controversy arises and not restore the same till all questions in dispute have been settled; the right of the supply company to require the consumer to sign up a contract for one year or other specified period before service is given them, and other questions which the consumers desire to have settled to their satisfaction.

Lieutenant-commander Davis, the wireless expert of the United States Navy, has just returned from Norfolk, where he has been inspecting the wireless telephone installations, and he appears to have been favorably impressed. At present the Connecticut and the Virginia are the only ships equipped with wireless telephonic transmitting apparatus. It is also reported that the wireless-telegraph operator on one of the Old Dominion lines picked up the wireless telephonic waves when off shore about 20 miles. The cruiser Tennessee also was able to keep in touch with the instruments of the Navy Yard at a distance of 12 miles. The report that the regular wireless communication with the New York Navy Yard had been established through the completion of the Wallabout Bay station is rather premature, but Commander Davis expects to have it ready within a short time. The De Forest system is the one employed in all of this work.

Work of concreting the interior of the second or south tube of the Belmont Tunnel under the East River at Forty-second Street is about completed, and it is expected to run a car through this tube within the next few days. An experimental car is now running in the completed north tube, and has been for some time, and it is expected to switch this experimental car over to the south tracks when completed.

The Jersey City terminal station at Exchange Place, Jersey City, of the McAdoo Tunnel, is practically completed in the rough, and the tunnel through to Cortlandt Street has been driven about 85 per cent. of the distance between the two terminals. The date for completion is fixed at September 1, 1908. Exchange Place station has been cut out of solid rock to a depth of 85 feet below the surface of the street. Thousands of pounds of dynamite have been used in this blasting, but not one life has been lost. The station will be 150 feet in width and 1,000 feet long, counting the approaches. There will be four and in some cases five parallel tracks, two for express and two for local trains. E. H. S.

Ohio.

Toledo, October 12.—Conditions generally are rapidly resuming a more prosperous outlook here and it now seems probable that the latter part of the season will make up in some sense for the depression that has been prevalent here this summer.

The laying of rails on the Bucyrus-Marion electric railway has begun, the work being started at the Forks just north of Marion. Grading is progressing satisfactorily, although the company needs about 20 more teams.

A new electric sign has been installed at the People's Credit Clothing Store at Dayton. It is out of the ordinary and is the first to contain McDougall's latent patent feature of reflecting the light, making a saving in current.

A contract has been entered into with the Grave Electrical Company of Dayton for the extending of electric lights on all streets of Fort McKinley subdivision. This is the only suburb lighted with electric lights from its own plant.

Herbert C. Warren, new general manager of the Toledo and Indiana Railway Company, has strictly forbidden the use of liquor by employes while on or off duty.

The Marion Electric Supply Company installed two attractive signs in that city last week—one for William M. Jackson, in the Huber block, and one at its own establishment on Main Street.

The city of Mansfield is constructing a number of electric arches for street-lighting purposes. It is hoped to have the work completed by the time for holding the Feast of Ceres in the near future.

Dayton is fast becoming noted for its beautiful electric signs. The latest and one of the most beautiful is now being erected on the Krug Building on South Main Street. Nearly 1,000 red, white and blue electric lamps are so arranged and operated by a specially built electric machine that the waving of a United States flag is represented.

According to the first report from the office of the State Railway Commission, there are in Ohio 2,646 miles of interurban railway. Their capital stock is $114,216,225, and funded debt $82,926,000. The total cost of construction and equipment was $171,463,925, and their gross earnings for the year were $12,256,659, with net earnings of $4,885,334.

A complete new system of fire alarms is being installed at Canton, Ohio, by the Gamewell Fire Alarm and Police Telegraph Company.

A meeting of the Sixth District of the Ohio Independent Telephone Association will be held at Toledo on December 3d. Officers will be elected and delegates chosen to the conference of the international association, which will be held in Chicago in January. H. L. S.

Illinois.

Peoria, October 12.—The McMeen Electric Company of this city has been incorporated with a capital of $10,000 to manufacture electrical supplies. The incorporators are Roland C. Becker, J. E. McMeen and R. P. Squires.

The Antioch Electric Company of Antioch has been granted incorporation papers, to manufacture and sell electricity. The capital is $15,000 and incorporators, Hiram H. Kellogg, Jay R. Cribb and John K. Cribb.

The Ajax Battery Company of Chicago has been incorporated with a capital of $25,000 to manufacture and sell batteries. The incorporators are W. B. Davis, C. E. Gaylord and W. T. Jones.

A report comes from Dubuque that the Illinois Traction Company is planning to build a road from Galena to that city. The proposed line is to be an extension of the line from Freeport.

The village of Peoria Heights is now without street-railway service as a result of the failure of the Peoria Railway Company and the village to agree on a franchise. A compromise ordinance will undoubtedly be agreed upon before the time limit to remove the tracks expires.

The Brinkerhoff ordinance has been laid over for a week by the Springfield City Council, as the committee wished to make some changes as to the rates to be charged. V. N.

Northwestern States.

Minneapolis, October 12.—Work has been completed on the Fort Dodge, Des Moines and Southern Interurban line from Des Moines to Fort Dodge, Iowa.

The Boone-Webster City (Iowa) Interurban Company will file articles of incorporation shortly, capital $600,000. J. S. Crooks of Boone is secretary.

The Waterloo, Pella and Southwestern Railway Company is being organized with the intention of building an electric railway from Waterloo to Chariton.

Plans are on foot at Aberdeen, S. D., to construct trolley lines into the country surrounding that city.

The new street-railway system at Sioux Falls, S. D., has been placed in operation.

Grading is practically finished on the new "Arrow Line," which is to be built from the twin cities to the head of the lakes by the Twin City and Lake Superior Electric Railway Company.

W. A. Marin has been granted a street-railway franchise at Crookston, Minn.

W. M. Barnes of Des Moines, Iowa, is investigating conditions at Aberdeen, S. D., and may apply for a lighting franchise. R.

Pacific Slope.

San Francisco, October 9.—The strike of linemen and outside electrical workers which threatened for a time to tie up the operations of all the hydroelectric plants of the Fleischhacker system in the state of California as well as to prevent the starting up of the new City Electric Company of San Francisco, has been settled by the signing of an agreement which gives the employes $4.50 a day of nine hours.

There is no foundation for the reports recently published in local papers to the effect that Colonel Holbrook had received an offer from the Southern Pacific Railroad Company for natural gas from tracts of oil land eight miles north of Oakland, Cal., for the purpose of generating steam in a large electric power plant.

One million dollars' worth of instruments and equipment for the Home Telephone Company's system in San Francisco were purchased by President A. B. Cass of this company, who recently returned from the East. The goods will require some time to prepare, but will be rushed forward as soon as possible. Mr. Cass says that all instruments are automatic, and that San Francisco will have the best modern service in the country, notable improvements having been made in the equipment since the early systems were installed.

The extension work of the Pacific States Telephone and Telegraph Company between Fresno, Cal., and points on the west side of the San Joaquin Valley, suspended a year ago when the Sunset Telephone Company was absorbed by the Bell Telephone Company, will now be continued. The extension work is to make a long-distance connection between Fresno and several points not now in direct touch with that city. The cause for suspension is given as the introduction of new methods and complete reorganization of the system. New estimates are nearly completed, and other extensions are planned in the direction of Stockton and Lodi.

It is now announced that the California Gas and Electric Company's big power plant on Deer Creek, near Nevada City, will not be finished until next spring, though it was expected that it would be in running order early in December. The cause of delay is lack of steel pipe, as only 900 of the 6,400 feet required has been delivered.

Work on the large power plant being built on the Klamath River, near Klamath Falls, Ore., as a part of the Southern Pacific's proposed electric system over the mountains between California and Oregon, will be continued all winter. Great difficulty has been experienced in securing labor, but the work will be carried on as fast as possible under existing circumstances.

Plans are being made for an electric power plant for the Telluride Power Company in the Bear River country, Utah, which, when fully developed, will have a capacity of 40,000 horsepower.

L. D. Macy of Chico, Cal., is planning to build and operate an electric-light system in that town, to be run by waterpower.

Following the report of Supervisor Sachs and Light Inspector Byrne of San Francisco, the lighting committee has ordered the installation of about 60 arc lamps for the Mission, Ashbury Heights and Sunset districts.

The San Francisco supervisors have passed an ordinance appropriating $15,000 for a central fire-alarm station.

At a meeting of the directors of the Ocean Shore Railway Company, held October 4th, an assessment was levied of $5 per share, payable November 21st.

A break has been reported in the Alaska cable. It is apparently at a point about 200 miles south of Valdez. The United States cable ship Burnside has been dispatched to locate the break and make necessary repairs. A.

PERSONAL.

Harrison W. Smith, formerly assistant professor in electrical engineering at the Massachusetts Institute of Technology, has been made an associate professor. George B. Thomas has been appointed an assistant in electrical engineering.

Thomas P. Robb has resigned as president of the Northwestern Interurban Railway Company, which will build a trolley line from Fargo, N. D., to Detroit, Minn. Mr. Robb will act as constructing engineer. Jas. J. Lambrecht succeeds him as president.

C. D. Phillips, who has been trainmaster of the Peoria Terminal Railway of Peoria, Ill., has resigned and accepted a position with a new electric railway in Oregon, which is under the management of Guy Talbot, formerly manager in Peoria of the Terminal road.

Carl J. Printz, who for over 17 years was connected with the Allis-Chalmer Company and its predecessors, and for the last year and a half has been superintendent with the Milwaukee Electric Railway and Light Company of Milwaukee, Wis., has taken a position as chief engineer with the John Inglis Company, engine builders, in Toronto, Ont.

M. A. Beal, manager of the Rockford (Ill.) Edison Company, resigned that position on October 1st, after a connection with the company and its predecessors lasting 20 years. It is said that Mr. Beal will spend most of his time in the East, where he has property interests. He made a decided success as manager of the central-station business in Rockford.

Mr. Bion J. Arnold of Chicago is reported to have been selected by the Public Service Commission of New York as consulting engineer on certain transportation problems. Besides reporting to the commission on the equipment, service and power houses of the Metropolitan system, Mr. Arnold in this position would give his views on the subway problem, it is said.

R. F. Landis has been made general contract agent for the Northwestern Telephone Exchange Company of Minneapolis. He has been state contract agent for the Wisconsin Telephone Company at Milwaukee for the last eight years.

ELECTRIC LIGHTING.

E. N. Sanctuary and others contemplate the establishment of an electric-light plant in Alvin, Tex.

George R. Cooke and W. B. Johnson, business men of Palestine, Tex., are asking for an electric-light franchise.

Caledonia, Minn., has voted bonds to the amount of $6,000 for the purpose of establishing an electric-light plant.

The Anderson-Lacy Electric Headlight Company of Houston, Tex., has been incorporated with a capital stock of $10,000.

The Hennessey (Okla.) Electric Light, Power and Ice Company has increased its capital stock from $15,000 to $30,000.

The Standard Ice and Light Company of Magnolia, Ark., has been organized with a capital of $25,000 by R. L. Moore and others.

The Ely Traction Company has secured a 10-year lighting contract in Liverpool, Ohio, at a rate of $66 for arc lights and $28 per year for 50-candlepower incandescent lights.

Through the efforts of City Electrician Hughes and associates of Joliet, Ill., arrangements are being made for a big electrical show to be held in Werner Hall, Joliet, the first week in December.

Sealed bids will be received by the comptroller of the city of Bay City, Mich., until October 30, 1907, for supplying the city of Bay City with steam and electrical machinery to re-establish the city's electric plant according to the specifications on file in the office of the superintendent of electric light. C. J. Barnett is comptroller.

Stockholders of the Hartselle (Ala.) Electric Light and Power Company have elected officers and directors, with J. J. Cudd as president. A purchasing committee was also elected by the company and a suitable plant will be purchased at once and installed. The stock of the new company was readily taken up by business men.

The Citizens' Electric Company of Eureka Springs, Ark., has been reorganized, and the company now owns all the public utilities of the city. George Sengel of Fort Smith is president of the new organization. About $600,000 will be spent in extensions and improvements of the properties, which include electric railways, lighting, ice plant, opera house, amusement parks, etc.

The new power house of the New Orleans Railway and Light Company, at the head of Market Street, said to be the best equipped in the entire South, containing machinery valued at $2,500,000, was inspected a few days ago by city officials. On the first floor of the plant are the engines and generators, one-half of the space being devoted to the generation of current for the street-railway lines and the other half supplies commercial and city lighting.

A dispatch from Mexico City says that two strong groups of American, Canadian and British capitalists have effected a combination for the construction and operation of electric-lighting, traction and power systems in Mexico which will represent an initial investment of fully $15,000,000. Among the captalists interested in the project are William Lanman Bull of the banking house of Edward Sweet & Co., New York; Frederic S. Pearson, formerly chief consulting engineer for the Metropolitan Street Railway, and Sir William C. Van Horne of Montreal.

At Batavia, Ill., the City Council has just corrected a technical defect in the electrical inspection ordinance and its enforcement will be undertaken at once. The city operates the lighting station and has planned a complete rebuilding of its overhead lines and service wires. The superintendent of the station will make an examination of every electrical installation in the city to determine the condition thereof, and those which are found to be defective will be required to be overhauled or cut off. The underwriters' electrical bureau inspector has offered to assist in properly starting this inspection.

ELECTRIC RAILWAYS.

Plans for the consolidation of the four elevated railways in Chicago are being revived, and from the character of the renewed negotiations it is considered more than likely that something tangible will result. Conferences between representatives of the different companies have been held and long discussions indulged in. A factor that may force a union of conflicting interests is the Union Loop problem which is getting more aggravated every year. An immediate result of consolidation would doubtless be through routing of trains across the city, which would increase the loop capacity to nearly double that of the present arrangement.

In line with the recent message of Mayor Busse of Chicago, in which he recommends the electrification of the steam roads in the city, a tentative draft of a statute to prohibit railroads from using steam locomotives on suburban trains within the limits of cities of more than 200,000 population has been prepared by the corporation counsel's office, to be sent to the State Legislature.

Work of connecting the Evanston line of the Chicago, Milwaukee and St. Paul Railroad with the Wilson Avenue (Chicago) branch of the Northwestern Elevated Railway has been started. The first trolley pole was set at Ainslie Street. Stations will be established at Argyle, Edgewater, North Edgewater, Hayes Avenue, Rogers Park, Birchwood, Howard Avenue, Calvary, Dempster Street, Main Street, Noyes Street and Central Street.

In order to put the Mont Cenis Tunnel in a condition to maintain more effective competition with the other tunnels it has been decided to equip it for electric traction. After communications with the Italian government, the president of the council of the Mont Cenis Tunnel has announced that the line will be electrified between Bussoleno and Mendane and that a second track will be laid between Turin and Mont Cenis.

A report from Mount Holly, N. J., says that the Pennsylvania Railroad proposes electrifying more of its lines in South Jersey. According to the information, the roads from Camden to Mount Holly and Camden to Burlington are the routes selected for electrifying, and the work will be started after the completion of the electric road in Camden. The routes selected are thickly populated, and in many of the towns through which the third-rail would pass the principal business thoroughfares are along the railroads.

A Tacoma (Wash.) dispatch says that there is a strong probability that the Tacoma Eastern Railway Company will within a year or such a matter be operating its trains by electricity. The Nisqually Power Company, an auxiliary organization of the road, and John Bagley, general manager of the Tacoma Eastern, began condemnation proceedings recently against the syndicate owning the waterpower at the falls of the Nisqually, and Judge Reid has ordered that a jury be drawn to appraise the valuation of the water rights.

Within a year, it is said, electric cars can be run between St. Louis and Chicago by way of Springfield, Bloomington and Joliet, but this will not be on one system. The Pontiac Construction Company will commence the building of two lines or extensions of the present line between Pontiac and Dwight. The extensions will be made from Pontiac to Bloomington and from Dwight to Joliet. Fisher Bros. will finance the proposition. The line between Joliet and Bloomington will be operated as an independent line but will give direct communication with Chicago at Joliet, through the Chicago-Joliet line, now running.

The City Council of Chicago is considering an ordinance granting the Northwestern Elevated Railroad the right to build a stub-end terminal spur along North Water Street from Wells to Clark streets to be used during the rush hours to relieve the congestion on the Union Loop. Mr. B. J. Arnold, the city's traction expert, recommended the plan and sought to have the efficacy of a noiseless construction tested on this branch, so that, if practicable, it could be applied to the whole loop structure. There seems to be no opposition to the building of this short spur. It will probably serve also as the terminal of Chicago and Milwaukee electric trains when the extension to Evanston of the elevated road is completed.

A Milwaukee (Wis.) paper says that the Milwaukee Northern Railway Company will commence operations about November 1st, on Sixth Street from Wells north to the city limits. According to its franchise provisions, tickets will be sold eight for a quarter. The line has been practically completed to Port Washington. The interurban cars will be run once an hour at the outset and will be used for local traffic as well as the city cars, passengers being permitted to ride on them for as long or short a distance as they please for five cents within the city limits. The local cars will be run on a headway sufficient to accommodate the demands. The schedule and rates of fare and all other details of operation have been filed with the Railroad Rate Commission at Madison preparatory to opening the line.

PUBLICATIONS.

The Curtis steam turbine is said to be well adapted for driving horizontal-shaft electric generators. In bulletin No. 4534, recently issued by the General Electric Company, horizontal-shaft type steam-turbine sets up to 300-kilowatt capacity, both direct current and alternating current, are described. These units can be arranged to operate either non-condensing or condensing, those built for condensing service being suitable for non-condensing work in case of necessity.

The C. A. Manufacturing Company of Austin, Texas, has just published its new catalogue on wood preservation. The "C. A. wood preserver" (carbolineum America) is manufactured for this company exclusively in Manheim, Germany. It is a heavy dark brown oil stain, which impregnates all kinds of wood to a remarkable degree upon application without forming a coating or closing the pores. Its extra high specific gravity forces it into the capillary tubes of the wood. The catalogue will be sent to any address upon request.

Why should Westinghouse motors be used? These are the answers to this question, given by the industrial and power sales department: "Because both mechanically and electrically they are the best that engineering skill, combined with experience in motor building, can produce. Because only the highest grades of material are allowed to enter into their construction. Because our corps of experts is at your service to advise with you regarding your particular requirements." Motor-application booklet "A" will be sent on request.

"Vitrified Fire-clay Conduit" is the title of an attractive catalogue from the Clay Product Company describing the manufacture and styles of clay conduit marketed by the company. The booklet contains instructive tables, giving weights, measurements and freight per duct-foot, which should be useful to engineers and purchasing agents. Several new styles of conduit are described, which are designed to save labor and material in trench construction. The triangle three-way is a new design which has met with considerable success and demand from the largest users of conduit. The booklet may be had by addressing the company at its Chicago office, 48 East Van Buren Street.

The Central Electric Company of Chicago is mailing out to the trade a price list dated October, 1907, which applies to the company's 1906 and 1907 general catalogue No. 24. This price list has been revised to date and contains the very latest market figures in force at this time on all electrical appliances shown in the company's catalogue. The company requests that all holders of its catalogue who have not received a copy should write for one. In the back of the price list considerable space is devoted to the W. U. steel bracket, which is intended to replace the ordinary oak wood brackets. Attention is also called to the Central Electric Company's fixture department. A cut of a very attractive reading lamp is shown, and the company says that this department is carrying a large assortment of the most up-to-date lamps and lighting fixtures and will be glad to submit designs and quotations upon request.

SOCIETIES AND SCHOOLS.

A preliminary count of the enrollment at the University of Illinois, in the departments located in Urbana, shows an increase of at least 10 per cent. in the attendance at that institution. Numerically the largest increase, 180, is in the engineering college.

The American Society of Mechanical Engineers will hold its next regular monthly meeting on Tuesday evening, November 12th, in the building of the Engineering Societies, 29 West Thirty-ninth Street, New York city. The principal address will be made by Mr. Charles R. Pratt and will treat of features of construction and operation of the gearless traction electric elevator, which is being installed in the Singer and Metropolitan Life, New York's two highest buildings. The paper will be discussed by engineers and architects from New York, Philadelphia and Chicago. It is expected that the subject will be very exhaustively treated from the view of the architect and the engineer. The members of all professions are cordially invited to attend.

The University of Illinois branch of the American Institute of Electrical Engineers held a meeting in Urbana, Ill., on October 16th. Prof. Morgan Brooks abstracted the paper of Paul M. Lincoln on "The Grounded Neutral, with and without Series Resistance, in High-tension Systems."

The Minnesota section of the American Institute of Electrical Engineers held its first meeting of the season October 4th in Minneapolis. H. J. Gille presided and papers were read by E. P. Burch, Fred Brown, Prof. Geo. D. Shepardson and I. C. Vincent. The next meeting will be held in St. Paul early in November.

At the regular meeting of the Cornell University branch of the American Institute of Electrical Engineers in New York on October 11th, Prof. V. Karapetoff gave an informal address on troubles in transmission lines. The next meeting will be on October 25th when the paper of P. M. Lincoln on "The Grounded Neutral, With and Without Series Resistance, in High-tension Systems," will be abstracted and discussed.

An outline of the course of lectures on electrical engineering announced in the last issue of the Western Electrician to be given by Prof. Sydney W. Ashe this winter under the auspices of the Association of Employees of the New York Edison Company has been published. These lectures will take up the following 20 topics, each being the subject of a separate lecture: Magnetism; electromagnetism; batteries, primary and secondary; electromagnetic induction, theory of the dynamo; electrolysis and electrolytic corrosion; practical management of shunt motors; practical management of series motors; Ohm's law applied to distribution problems, the three-wire system; Ohm's law applied to electrical measurements, ammeter and voltmeter methods; Ohm's law applied to electrical measurements, galvanometer methods; physics of light; the carbon arc and arc-lamp mechanisms; incandescent lamps; principles of recording wattmeters; elementary principles of alternating currents (two lectures); transformers; alternating-current motors; rotary converters; alternating-current measurements.

The work done by the comparatively new Winona Technical Institute at Indianapolis is attracting considerable attention. This institute comprises the technical branch of the Winona schools at Winona Lake, Ind., and is owned and operated by the Winona Assembly of that place. There are schools of printing, carpentry and woodworking, molding, electrical engineering, pharmacy and chemistry, tile and mantel setting, painting, lithography and also a library school. The electrical engineering department and the department of lithography are of chief interest, the latter because of its being the only school of its kind in America, the former because of the excellent facilities placed at the disposal of the electrical student. Included in the large faculty besides President S. C. Dickey and W. C. Smith, general director, are the following-named of the electrical and engineering department: R. M. Murray and Frank M. Seig, directors; George W. Dinkel, Jr., instructor in applied electricity, and Albert F. Haller, director of chemical laboratories. A handsomely illustrated catalogue will be sent on application.

MISCELLANEOUS.

Mr. Charles A. Brown announces a partnership with Lynn A. Williams, for six years past his assistant, for the practice of patent law, under the firm name of Brown & Williams, with offices at 1550 Monadnock Block, Chicago. Mr. A. C. Bell, who has been in charge of the patent department of the Stromberg Carlson Telephone Manufacturing Company, has taken a position with Brown & Williams, and will give attention chiefly to the work of patent soliciting. Mr. Bell is a graduate of Cornell University and has had practical experience as a mechanical and electrical engineer, in addition to several years' work in soliciting patents.

The London Times Engineering Supplement is responsible for the statement that "it is now possible to purchase liquid air in Berlin for about three shillings (73 cents) a liter, and it can be conveyed over long distances in the well-known double vessels with an intervening vacuum which were designed by Sir James Dewar."

TRADE NEWS.

C. H. and J. S. Warner of Beloit, Wis., and M. E. Palmiter of Rockford, Ill., have incorporated as the Warner Instrument Company, capitalized at $30,000. The company will manufacture electrical instruments and machinery and will locate at South Beloit.

A meeting of the stockholders of the Western Electric Company will be held on November 5th to vote upon the question of ratifying a bond issue of $15,000,000, authorized by the directors. At present the company has no bonded indebtedness. Its authorized capital stock is $25,000,000, of which $15,000,000 is outstanding.

Some months ago the Cutler-Hammer Manufacturing Company announced its purchase of the Wirt Electric Company of Philadelphia. The Wirt business has now been consolidated with that of the Cutler-Hammer New York plant at Park Avenue and One-hundred-and-thirtieth Street, where the manufacture of Wirt apparatus will be continued. Information concerning Wirt apparatus may be obtained from any of the Cutler-Hammer offices. Particular attention is called to the very complete line of battery charging rheostats developed by the Wirt company and to the Wirt field rheostats. Bulletins covering these and other lines of Wirt apparatus will be furnished on application.

BUSINESS.

Much attention has been attracted by the six Beck flaming-arc lamps which illuminated the exterior of the Madison Square Garden during the Electrical Show. The effect of this illumination was favorably commented on. In addition a 12,000 nominal candlepower arc lamp was installed by the New York Edison Company on the corner of Madison Avenue and Twenty-sixth Street. This lamp was suspended about 50 feet above the street level from the small corner tower on the Garden and illuminated a large section of Madison Square. Beck flaming-arc lamps have been ordered for the new Terminal Station in Washington, D. C., by the Pennsylvania Railroad. They will operate two in series on 60-cycle alternating current.

The Wright demand indicator has been extensively adopted in determining load factor, the maximum output of generators, transformers, feeders, etc., and the demands of individual customers. It consists of a small differential thermometer having one of its bulbs surrounded by a heating band carrying all or a definite shunted part of the total current. The expansion of air in this bulb forces the liquid in the "U" tube of the differential thermometer into the opposite leg and causes it to overflow into a central or index tube connected to the upper end of the "U." The height of the liquid in the index tube is read on the indicator scale and marks the maximum demand of the circuit. Bulletin No. 4533 issued by the General Electric Company describes and illustrates the several sizes of instruments manufactured, together with capacities, prices, dimension diagrams, scales, etc.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued (United States Patent Office) October 8, 1907.

867,564. Advertising and Illuminating Device. James E. Auclair, St. Marys, Pa., assignor to the Novelty Incandescent Lamp Company, St. Marys, Pa. Application filed February 26, 1906.

An incandescent lamp has a bulb shaped in a striking manner and provided with projections to form feet for it to rest on. A preferred shape is in the form of a pig.

867,575. Process of Reducing Formic Acid. Carleton Ellis, White Plains, N. Y., and Karl P. McElroy, Washington, D. C. Application filed May 2, 1907.

This process of reducing formic acid consists in electrolyzing it in the presence of sulphuric acid, removing a portion of the bath from time to time, distilling out reduction products and returning the residual liquid to serve anew. (See cut on next page.)

867,579. Electrical Condenser. Léon Gerard, Brussels, Belgium, assignor to Percy Thompson, East Orange, N. J. Application filed June 14, 1905.

This condenser is mounted in a cylindrical case filled with oil. The plates are composed of hollow concentric cylinders with outwardly flared ends. The lengths of the cylinders are made progressively shorter as their diameters are increased. (See cut on next page.)

867,608. Photographer's Car. Jean Schmidt, Frankfort-on-the-Main, Germany. Application filed August 16, 1906.

A car equipped with photographic outfit carries a storage battery for propulsion and lighting. A drum carries a conductor wound on it that serves to connect the battery to a distant charging circuit.

867,624. Switch Box. Harry J. Warthen, Washington, D. C. Application filed July 28, 1906.

A wall box adapted to carry switch mechanism has internally and externally screw-threaded sleeves adapted to be adjusted inwardly and outwardly. A wall plate closing the box is secured to the sleeves by screws.

867,627. Induction-coil Apparatus. Ernest C. Wilcox, Meriden, Conn., assignor to the Connecticut Telephone and Electric Company, Incorporated. Application filed June 19, 1907.

The vibrator of an induction coil is provided with adjustments and an indicator for showing the correct adjustment corresponding to normal conditions.

867,635. Electric Sign. William A. F. Becker, Chicago, Ill. Application filed October 26, 1906.

This sign has a base board upon which are supported a number of removable illuminated letters and characters provided with plugs for connection to any sockets of a set of rows of closely spaced sockets mounted on the base board. The letters can thus be grouped to form any words desired.

867,658. Process of Making Electric Conductors. William Hoopes, Pittsburg, Pa., and Norman A. Robertson, New York, N. Y. Application filed January 16, 1905.

This is a process for manufacturing a compound conductor having an envelope of aluminum and a longitudinal reinforcing core of stronger metal and consists in extruding the aluminum upon this core through a die while maintaining the aluminum at approximately a dull red heat and also heating the die during the period of extrusion.

867,659. Electric Conductor. William Hoopes, Pittsburg, Pa., and Norman A. Robertson, New York, N. Y. Original application filed January

16, 1905. Divided and this application filed May 11, 1906.

This is a compound electric conductor and consists of a core of iron wire or wires about which, and in intimate contact with which is an extruded envelope of aluminum.

867,664. Governor. Clinton R. Lanphear, Midland, Mich. Application filed December 6, 1906.

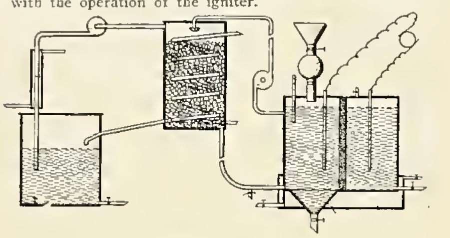
Contacts are mounted on insulating blocks on the base of the governor. As the speed increases and the fly-balls move further out, they raise a rod which closes the contacts at the base.

867,681. Automatic Fire Alarm. Charles Smith, South Croydon, England. Application filed July 9, 1907.

A cord has one end fastened and the other end passing over a pulley and connected to a weight, which is provided with contacts adapted to be closed if the weight descends. Between the ends of the cord is a fusible metallic member, about which the cord is wrapped. In case of fire this melts, the cord is lengthened and allows the weight to drop far enough to close the contacts and ring an alarm.

867,696. Igniting Means for Explosive Engines. Boris Botkowski, New York, N. Y., assignor to the De La Vergne Machine Company, New York, N. Y. Application filed August 27, 1903.

Stationary and movable electrodes are provided in proximity to a supplemental fuel injecting outlet. The valve in this is first opened and then closed simultaneously with the operation of the igniter.



NO. 867,575.—PROCESS OF REDUCING FORMIC ACID.

867,707. Coin Collector. Edward B. Craft, Wilmette, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed February 11, 1907.

This coin collector for telephones is a combination with coin-actuated toll-indicating mechanism arranged to receive a coin deposited in the coin collector, a line-signaling mechanism and means controlled by a deposited coin, in the operation of the first-mentioned mechanism, for governing the transfer of the coin to the line-signal mechanism.

867,721. Electric Belt and Appliances Therefor. Michael Hatzenbuehler, Chicago, Ill. Application filed January 7, 1907.

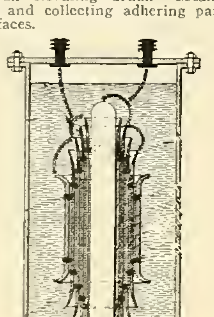
An electric belt is provided with body electrodes connected with studs to which the battery is connected.

867,743. Plug-in Switch. Henry D. Murdock, New York, N. Y. Application filed March 21, 1907.

A circular box has a central contact terminal and spring, and an annular spring contact mounted on an insulating base. A plug provided with corresponding terminals is adapted to fit into the neck of the box.

867,744. Magnetic Separator. James B. McCabe, Buffalo, N. Y. Application filed November 13, 1906.

This separator has a rotatable magnetic drum surrounded by an elevating drum. Means are provided for detaching and collecting adhering particles from the magnetic surfaces.



NO. 867,579.—CONDENSER.

867,746. Coin Collector. James L. McQuarrie, Oak Park, Ill., assignor to the Western Electric Company, Chicago, Ill. Application filed February 11, 1907.

A coin collector for a telephone consists of a combination with a cash box, of coin-actuated toll-indicating and line-signaling mechanisms, means controlled by a coin, in initiating a call for a connection, for governing the transfer of the coin to the line-signal mechanism, or to the cash box, and automatically operated means for preventing the transfer to the line-signaling mechanism of a coin subsequently used in the payment of toll.

867,758. Electric Stop-motion. Frank A. Sandford, Adams, Mass. Application filed June 27, 1906.

A stop motion for looms is controlled by the filling and has a filling fork and a weft hammer. An electromagnet on the weft hammer attracts the filling fork, and is controlled by a contact in the guide for the warp thread.

867,809. Series-parallel Controller. Arthur C. Eastwood, Cleveland, Ohio. Application filed September 6, 1906.

This is a controller in which the circuit is opened in changing the motor connections from series to parallel. Means are provided for inserting resistance in series with the motors concurrently with the opening of the circuit in passing from series to parallel.

867,810. Automatic Accelerating Controller. Arthur C. Eastwood, Cleveland, Ohio. Application filed January 15, 1907.
