Abstract: A multi-position ferroelectric switch is proposed which can accomplish many of the switching tasks in an input handling system; in particular, it can select among rows and columns of a ferroelectric memory. The logical circuitry of the ferroelectric switch can be painted directly onto the two sides of a thin ferroelectric sheet.

The non-linear electric displacement-versus-field characteristics of a ferroelectric dielectric can be utilized to construct a condenser whose capacitance is a function of the applied voltage. This phenomenon, which makes possible solid-state amplifier operation, is the basis for operation of the switch as here described. Figure 1 illustrates the operation of the basic switch element—a simple R-C filter which uses a non-linear capacitor as its series branch. With no direct voltage across the condenser (Fig. 1a), the circuit behaves like any ordinary R-C filter with the exception that distortion will result if the input voltage is large enough to drive the dielectric out of its linear region. Transfer characteristics are shown for sinusoidal excitation. If a bias voltage, $V_b$, is inserted in the circuit as shown (Fig. 1b), the operating point for the transfer characteristic is shifted to a new point on the charge-versus-voltage characteristic of the non-linear condenser. At this new point, the condenser has a much lower capacitance, and therefore, the $R-C$ characteristics are changed in such a way that the circuit behaves, in amplitude, like a linear $R-C$ circuit. Input voltage, $V_i$, the output voltage can be changed by varying the bias voltage, $V_b$. For ferroelectric dielectric operation, if the bias voltage $V_b$ is large enough, the switch will only conduct for a limited period and will remain switched off during this time. The charge $V_i$ is then available to conduct $V_b$ and the input voltage, $V_i$, is no longer available. The switch is thus effective as an electronic switch.

The non-linear condenser can be made as a single unit by etching a large electrode to one of two glass sheets and then coating these sheets with a dielectric. The switch is thereby constructed to be inherently effective as a switch.
In the opposite position, output 2 is ON.

Figure 2B illustrates an eight-position ferroelectric switch. Operation of the first stage, controlled by \( S_1 \), is the same as the two-position switch. Subsequent stages, however, have the lower ends of their resistors connected so that the even resistors are connected to ground when the odd resistors are connected to \( V \), and the even resistors are connected to \( V \) when the odd resistors are connected to ground. There are eight possible paths through the switch (Fig. 3) only one of which will have all of its condensers ON. With \( S_1, S_2 \) and \( S_3 \) of the eight-position switch set as shown, output zero is ON. Outputs 1, 3 and 7 have one condenser OFF, outputs 2, 4 and 6 have two condensers OFF, and output 5 has all three condensers OFF. The number of OFF condensers among the outputs follows a binomial distribution:

<table>
<thead>
<tr>
<th></th>
<th>All On</th>
<th>One OFF</th>
<th>Two OFF</th>
<th>Three OFF</th>
<th>Four OFF</th>
<th>Five OFF</th>
</tr>
</thead>

</tr>
</tbody>
</table>

Successful operation of the switch postulates that a single OFF condenser leading to an output will cause that output to be OFF. To test this, an eight-position switch was constructed (Fig. 4) using a thin (.025") sheet of barium titanate ceramic (Glenco body "X-18"). All of the non-linear condensers are placed on the same sheet by firing electrodes on the two sides as shown. The signal enters the sheet via a large fired electrode (back view). Two electrodes match this input electrode on the opposite side (front view). Among the two condensers thus formed, one will always be OFF and one will always be ON. Each of these two electrodes is enlarged to match up with two electrodes on the opposite side which are alongside the input electrode. One of each pair of this third set of electrodes will be OFF. Finally the signal goes through the dielectric a third time coming out on one of the eight small electrodes (front view).

The operation of the switch is illustrated graphically by Fig. 5. With a constant-amplitude, sine-wave input of variable frequency, the RMS output at terminal 7 was measured as a function of frequency for each of the eight possible combinations of \( S_1, S_2 \) and \( S_3 \). At 800 cps, the best operating frequency for this particular design, the ratio of ON voltage to the highest OFF voltage is greater than three to one. This operating frequency can be shifted higher or lower by changing the size of the condensers and resistors. Both steady-state and pulse tests on this dielectric indicate that the operating frequency can be shifted up to several megacycles per second. If the resistors are replaced by inductors, the output-versus-frequency characteristics can be improved and losses are lowered.

For pulsed operation of this switch, a non-linear condenser is used in both the series and shunt arms of the filter. Fig. 6A illustrates such a switch which is so arranged that when the series condenser is ON, the shunt condenser is OFF (Fig. 6B); and when the series condenser is OFF, the shunt condenser is ON (Fig. 6C). The filter looks like a condenser voltage-divider...
to the rising edge of a pulse. The divider has either a large condenser in its upper leg and a small condenser in its lower leg or vice-versa, depending on whether the switch is ON or OFF.

The ferroelectric switch is proposed as a means for driving the rows and columns of a ferroelectric memory and for switching within an information-handling system. Its unique packaging makes it promising in applications where size, weight and cost are important considerations.
