In the hearing before the senate committee on miscellaneous corporations Senator Marshall presented the chief argument. He was supported by Frank S. Gardner, Silas M. Giddings, G. Waldo Smith, D. G. Osgood and L. J. Callanan, representing the New York City Board of Trade and Transportation; Dr. George W. Brush of Brooklyn, Dr. William Murr, representing the New York city druggists, and R. M. Walters, Edward J. Gavegan, Andrew Patterson, William F. Russell and Amasa Lyon, who appeared on behalf of the Merchants and Manufacturers' Board of Trade of New York city. They argued that the present telephone rates could almost be cut in two and still leave a sufficient margin of profit. They urged that the people of the state demanded a reduction in the telephone rates. The other telephone rate reduction bills were also incidentally discussed.

Slump in Bell Securities.

[From the Boston Traveler.]

In the Boston market, which, like Wall street, was strong in the early dealings and then weak, the strength in the Dominion, Coal and General Electric and the slump in Centennial and Bell Telephone were the features.

[From the New Haven Register.]

Bell Telephone, which has been as high as 372 within the last few weeks, has dropped to 360, and to-day did not rise much higher. No assignable reason is to be formed for the decline, well informed telephone men laughing at the rumor that Bell Telephone is being injured by the rival companies starting up.

[From the Worcester Spy.]

Bell Telephone fell 28 points to 335, against highest on this year's rise of 378, also a high record. Bell began the year at 273, rising \$105 per share in six weeks; it sold at 238 11 months ago, as low as 163 exactly five years ago yesterday, and at 76 in 1880. In 1883 it got up to 299; last year's highest was 285, in August. It rallied 12 yesterday to 347, or a net loss of 11 at 2 p. m. for the day.

[From the Des Moines Leader.]

The Bell Telephone company is distributing a circular through the state giving notice that it will increase its capital stock of \$1,500,000 to \$2,000,000 and that a meeting will be held in Davenport to get subscriptions; also that the extra money is for improvements. Rivals of the Iowa company claim that it has not paid dividends on its stock in two years because of the bitter competition it has been waging against the independent exchanges, and that, on the other hand, it has been required to increase its bonded debt and to secure money from other sources to make betterments and carry on the fight.

The Telephone Situation.

[From the Chicago Record.]

The tendency toward trusts among industrial enterprises is strikingly illustrated in the present movement in the so-called independent telephone manufacturing field, having for its object a combination of the companies engaged in this industry. These concerns have been supplying the apparatus for the telephone exchanges which have been established in opposition to the Bell interests, and their popularity has been due in large measure to their attitude toward the old monopoly and their encouragement of the local telephone enterprises which have brought about reductions in charges for telephone service. Competition has worked to the advantage of the public by destroying the old monopoly and preventing the anti-Bell companies from exercising similar power. It has also had a tendency toward securing needed improvements in the exchange service, and this advantage is of as much importance to subscribers as the reduction in prices brought about through the same agency.

The reasons advanced by the promoters of the proposed combination are the disastrous effect that indiscriminate competition has had on the trade and the difficulty experienced in securing the necessary funds for developing the enormous business that has grown up so suddenly. From the beginning the chief difficulty of the independent telephone manufacturing companies has been insufficient capital to develop their business. Many of them have been tempted to extend their operations beyond the limits of safety, as judged by actual cash investment, and as a result they are constantly "hard up," although they are conducting an unusually profitable business. It is this feature that has led them into the scheme for consolidation. A strong combination, it is believed, could absorb all the little plants and run them much more economically than they could be conducted under separate management. The business is increasing steadily and is growing more profitable as methods of manufacture are simplified and systematized. These advantages would enable a trust to place a liberal valuation upon the plants and the business turned over by the several companies, and thus the present owners would be enabled to realize in cash a portion of the money and time they have devoted to the building up of the industry. But the most important feature would be the improvement in the financial standing of the business. The present owners would, of course, receive compensation principally in stock of the trust, which would be listed and have some market value, in striking contrast to the securities of existing corporations. But in placing this stock on the market there would always be the danger that the old monopoly would buy it up, if, indeed, that corporation did not gain control at the outset through connivance on the part of promoters of the trust.

It is evident that those who are engaged in the formation of this trust are not entirely actuated by a desire to serve the public or to promote the interest of the anti-Bell movement, as they have arranged for the placing of securities upon the market far in excess of the present value of the plants engaged in this industry, and for this reason alone the managers of independent exchanges are bound to view the movement with disfavor. There is no doubt that the successful execution of the plans of the promoters of the combination would prove a serious setback to the independent movement, as it would destroy public confidence in it and alienate the sympathy which has proved such a valuable factor in the struggle against the Bell monopoly.

[From the Binghamton Republican.]

The telephone companies outside the Bell monopoly are forming a combination to compete with the Bell. That step has a suspicious appearance. It is probably a step to combine with the Bell, if the Bell can be induced to let them in.

Berliner Litigation.

J. D. Leatherbee, treasurer of the National Telephone Manufacturing Company of Boston, writing upon the Berliner litigation which is still pending between the American Bell Telephone company and the National company, says that "the defense of this suit for three and one-half years has absorbed all of our money and a goodly quantity of our energy," but he adds: "You must agree with us that there is no other course for us to pursue than to fight this thing to a finish. Never for a moment have we despaired of ultimate success, but the prestige, energy and unlimited means of the Bell company require, of course, an adequate and approximate defense. You can readily understand what that means in the matter of expense.

"We trust our efforts will soon be rewarded by an opinion that will relegate this so-called Berliner invention to the oblivion from which it should never have emerged, and this country be freed from the 'club' which this suit has caused to be suspended above the heads of the American people—a weapon intended to paralyze the business of the National Telephone Manufacturing company, while interposing between the monopoly and all manufacturers and users of free telephones."

New England Telephone News.

[From the Boston correspondent of the WESTERN ELECTRICIAN.]

The American Bell Telephone company has bought another piece of real estate, this time on Milk street, Boston, adjoining its present building. The property is a four-story building on 3,395 feet of land. The present occupant has a lease running two years. This gives the company a total area of 19,222 feet at the corner of Milk and Oliver streets. It also looks very much as though the company intended to remain in Boston a while longer, despite the rumors that the offices are to be transferred to New York.

The American Bell Telephone company's statement of instrument output for February, although a record-breaker, promises to be outdone by March statistics, for the orders received during the last four or five weeks indicate that a larger number of instruments have been installed than ever before in a similar period. The gross output for February was given as 49,263 instruments; returned, 13,476; net, 35,787. This makes the total outstanding at the time of the February statement 1,192,862, against 951,180 a year previous, 793,550 two years ago and 627,445 three years back. The net gain for the current month is expected to exceed 40,000.

The Cambridge, Mass., Board of Aldermen on March 7th referred a petition for a franchise from the Massachusetts Telegraph and Telephone company to the committee on roads and bridges.

Farm Telephone Service in Illinois.

[From the *Agriculturist*.]

It may please the farmers and others to know something about the working of several lines of our farm telephones here in Mason County, Illinois. Our telephone service was inaugurated March, 1897, by Ralph Bowser, a young man but 20 years old, an enthusiast in electrical work, who connected his father's house and nearest postoffice by a line a mile and a quarter in length. The upper wire of a barbed-wire fence was used at first, and worked so well that I remember hearing distinctly a watch tick over this line. From this small beginning has grown a system of seven separate lines, 21 miles in length, using 38 telephones, and more are wanted. Our telephones cost \$8 each, wire three cents per pound or \$4.50 per mile. The battery with each telephone is effective six months without attention. The use of our telephones is free to all. The practical utility is evident, but the use as a means of social entertainment is not so well understood or appreciated as it deserves. We frequently listen to piano solos and songs, also to Sousa's last marches played by a graphophone before a telephone three miles away, and by simply turning a switch two lines are united and the graphophone can be heard at 24 telephones.

Public-spirited Promoter.

An incident in the controversy over granting a new telephone company in Topeka, Kan., an ordinance enabling it to compete with the old Bell company illustrates the fact that movements of this kind are in the interest of the public and not entirely money-making ventures. J. S. Bear, manager of the new company, has made the following proposition: "I stand ready to treat the people of Topeka with entire fairness, and I now propose that the City Council adopt the suggestion of Councilman Skinner, with reference to the Bell company reducing rates, and I hereby agree to enter into an agreement to withdraw from the field and not to ask for a franchise. My only condition is that the Bell company shall enter into a contract with the city to reduce the rates to \$24 for business and \$18 for residence telephones, and that it bind itself by an irrevocable agreement to keep the rates at these figures for 10 years."

Crippling Competition.

The Bell interests are utilizing their influence with other large corporations, especially those controlled in the East, to cripple the service of independent companies in small places. An example of this kind is furnished in central New York, where local companies have been ordered to remove their instruments from railroad, freight and express offices. The *Chenango Union* furnishes the following particulars of one fight:

Mr. J. B. Marquis, manager of the Marquis telephone system in Norwich, N. Y., has received from A. C. Salisbury, superintendent of the Utica and Binghamton division of the Delaware, Lackawanna and Western railroad, and W. C. Hartigan, superintendent of the northern division of the New York, Ontario and Western railroad, notices, similarly worded, conveying the information that the Central New York Telephone and Telegraph company had made contracts with their respective railroads, under the terms of which the company is entitled to the exclusive privilege of placing telephones in the offices and stations of the railroads. Mr. Marquis is ordered to remove his telephones from railroad property. This is a new attempt on the part of the Central New York company to strike at the Marquis system. The first attempt was made nearly a year ago, when the Marquis telephones were ordered out of the offices of the United States and Adams express companies in this village. The owners of telephones in the Marquis system caused such a commotion at this time, and coincident with the order there was such an increase in freight traffic and decrease in express traffic, that the express companies speedily revoked the order. The second attempt has a more secure foundation. It is based upon a contract between the telephone company and the railroads, whereby the telephone company grants to the railroads the free use of the system in case of emergency when telegraph wires are down, etc., and in return for which the telephone company is granted exclusive right to place telephones in the railroad offices and stations. In justice to Mr. Hartigan, who is a resident of Norwich, it should be said that he was not a party to the agreement, and was simply obeying instructions in sending the notice referred to by Mr. Marquis. The order removing the Marquis telephones from the railway offices, especially from the freight offices, will cause some inconvenience.

ANNUAL MEETINGS.

The stockholders of the Interstate Telephone company, Durham, N. C., have elected L. A. Carr president, George W. Watts vice-president, J. S. Carr treasurer and W. W. Shaw secretary.

The Xenia, O., Telephone company has selected the following named officers for the first year: President, E. H. Schmidt; vice-president, H. M. Barber; secretary, J. C. Conwell, and treasurer, Marcus Shoup.

The following named officers have been elected by the Scuyler Telephone company of Iliou, N. Y.: President, Rufus H. Smith; vice-president, John M. Budlong; secretary, William Sterling, and treasurer, Dr. S. S. Richards.

At the annual meeting of the stockholders of the Richmond (Va.) Telephone company March 6th John C. Robertson and Warner Moore were re-elected president and vice-president, respectively, with substantially the same board of directors. A most encouraging report was presented of the company's operations during the fiscal year.

At the annual meeting of the Cumberland Telephone and Telegraph company in Hopkinsville, Ky., March 2d, it was decided to increase the capital stock from \$3,000,000 to \$6,000,000. The additional stock will be sold to present stockholders in proportion to the amount each now holds. The board of directors elected the following named officers: James E. Caldwell of Nashville, president; W. Litover of Nashville, vice-president, and Leland Humes of Nashville, general manager.

The sixteenth annual report of the New York and New Jersey Telephone company shows that the earnings over operating expenses amounted to \$625,000.87, the gross earnings being \$2,058,477.21. The treasurer shows resources of \$9,048,413.26 and a surplus of \$1,710,342.61, exclusive of \$116,560, reserved for January dividends. Between 1897 and 1898 the gross earnings increased \$268,190 and the operating expenses \$196,656. Last fall the company increased its capital from \$5,000,000 to \$8,000,000 and made a new issue of stock at par to the stockholders amounting to \$1,165,500. The investment in plant amounted to \$885,918, principally in subway construction and putting wires underground.

The annual report of the Hudson River Telephone company shows total gross receipts for the year to be \$377,057.75, expenses \$253,628.80, making a net revenue of \$123,374.95, against \$113,917.22 last year. The capital stock of the company is \$2,000,000; surplus, \$190,338.07; reserve for unearned rentals, \$1,128.00; reserve for outstanding toll tickets, \$5,421.70; bills and accounts payable, \$133,355.37; total, \$2,339,253.74. The officers are: President, James H. Manning of Albany; vice-president, Joseph P. Davis; secretary and auditor, Walter B. Butler; treasurer, James J. Fitzsimmons; general manager, Henry E. Hawley; directors, Joseph P. Davis, New York; James Bigler, Newburg; John G. Myers, Albany; David B. Parker, Randolph; C. Jay French and John E. Hudson, Boston; James H. Manning, Albany, and John E. Adriance, Poughkeepsie.

TELEPHONE LEGISLATION.

The bill taxing telephones has been passed by the Indiana Legislature.

The Delaware Legislature has passed the Donahue bill, regulating telephone tolls for Wilmington, and providing that no company or combination of companies can increase the present tariff.

A bill to regulate telephone charges has been introduced in the California Legislature, in which the charge for one telephone is placed at \$3 per month, and when more than one is used by the same subscriber, to \$2.50 for each instrument, this sum to be in full for all telephone service. Nickel-in-the-slot attachments are prohibited. Connections with places outside the county may be charged for at special rates.

The concurrent resolution passed by the Legislative Assembly of North Dakota relating to the assessment of telephone companies and other quasi-public corporations, known as House bill No. 112, has passed the Senate and will be certified on the official ballot at the next general election. The constitution does not provide for the assessment of property of that nature, and the amendment is for the purpose of remedying that defect.

The Walkerville, Ont., council is considering a measure aimed at the Bell Telephone company. It is claimed by the town electrician that the wires of the telephone company are not sufficiently isolated to protect the buildings in the town, and that, although the company has been repeatedly asked to place its lines in better condition, all of the requests have been ignored. Now it is proposed to pass a new by-law which will compel the company to do so.

The committee on mercantile affairs of the Massachusetts Legislature has listened to the opinions of a number of prominent business men on telephone rates. They all agreed that present rates were excessive. Samuel L. Powers, counsel for the New England Telephone company, contended that competition could regulate rates, but that legislation could not afford relief, and that there was no need of state supervision. He declared that the actual profit of the Bell company in Boston was less than five cents per instrument.

TELEPHONY ABROAD.

The *Chicago Record* correspondent at Gottenburg writes: "The board of manager of the Swedish state telegraph system has asked for an allowance of \$789,000, to be expended during three years for the extension of the telephone system in the kingdom. The government makes about six per cent net profit on the money thus far advanced for such purposes. Still, the state telegraph and telephone lines are managed just as much for the convenience of the people as for profit. The number of interurban telephone conversations during last year exceeded 2,700,000, and the frequency of the telephone call necessitate the building of new lines."

A London correspondent announces that the government asked the House of Commons this week to vote £2,000,000 to enable the Postoffice Department to begin active competition with the National Telephone company, which has a practical monopoly of the business and has carried it on so badly that the service in this country is the worst and dearest in the world. The House of Commons heartily approved the government's resolution, almost the only man to speak against it being Sir James Fergusson. Several bills had been prepared by corporations desiring to engage in telephone service, but these were all laid aside "on account of the announcement made by the financial secretary to the Treasury that the government intends to bring in a telephone bill during the present session."

According to *l'Electricien*, a telephone message counter has been invented by R. Van Kerckhove and will be used for recording and counting the number of telephone messages passed through trunk lines from Brussels, and insuring just charges for service. It is said that the instrument can be manufactured at a very moderate price. On the outside there is a dial with the figures 1 to 5. The needle, when the conversation commences, stands at No. 5, and gradually moves back, indicating how many minutes the speaker still has at his command without extra charge. After 4½ minutes' conversation a stroke on a bell warns the user of the telephone that the time is almost up. An extra charge is made for conversation after the five minutes has elapsed. There is also provided a device by which, during the busiest portions of the day, a change can be made from the five minutes' to a three minutes' conversation.

MANUFACTURERS AND DEALERS.

The Standard Underground Cable company of Pittsburg has received an order from the Japanese government for 16,000 feet of lead-covered telephone cable for an underground system. This is in addition to an order for 40,000 feet of insulated wire for an overhead cable which the company has been working on for some time.

The demand for protection from lightning for telephones and switchboards has become one of considerable importance to telephone exchanges, and those who take the precaution to prepare for the season of disaster to telephone properties will be the ones who will escape not only an enormous expense, resulting from burnouts, but also the exasperating annoyances and inconvenience of not being able to render proper service to their patrons. In this connection announcement is made that the Western Electrical Supply company of St. Louis has a most elaborate assortment of Maxstadt fuses and carbon lightning arresters of every design, such as are at the present time in demand. It is constantly increasing its supply of this class of material, and is always able to take care of its customers in the most satisfactory manner.

TELEPHONE EQUIPMENT.

The Radford Telephone company of Radford, Va., wants to buy telephones, wire and other supplies for a system of 50 subscribers.

David Pruett, secretary of the Winchester and Lexington Telephone company of Pinegrove, Ky., wants a number of toll switchboards to be used in connection with an exchange to operate from four to 12 drops; also at junction points to operate from two to six connections.

NEW COMPANIES.

J. F. Gemelich, J. S. Sanfert and E. W. Chilton are among the incorporators of the Boonville, Mo., Telephone company.

Corning, Ia., has organized a telephone company, with Hon. Bury Brown, Attorney Meyerhoff and Editor Junkin as directors.

Col. H. P. Farrow and associates will organize a company for the establishment of a telephone system from Dahlonga to Gainesville in Georgia.

The Alma, Mich., Telephone company has been incorporated, with a capital of \$25,000, by G. S. Aldrich of St. Louis and F. C. Brown of Alma.

The incorporation of the Raton Telephone company with capital stock at \$10,000 is reported from Albuquerque, N. M. J. L. and C. F. Laub are the promoters.

The City Council of Wilmington, Del., has granted a franchise to the Wilmington Home Telephone company, composed of Miletus Garner, S. R. Mitchell,

C. R. Fisher, L. J. Walker and S. G. Smith, for the building of a new telephone system. The capital stock is \$15,000.

The Radford Telephone company of Radford, Va., has been incorporated with an authorized capital of \$5,000 by D. D. Hull, B. Laughon, George M. Holstein and B. F. Garnett.

A commission for a charter was issued on March 4th to the Orangeburg (S. C.) Telephone company. The incorporators are W. Hampton Dukes, W. C. Wolf and A. C. Andrews.

A telephone company has been organized at Geneva, N. Y., with R. H. Smith as president, John M. Budlong vice-president, Willard Sterling secretary and Dr. S. S. Richards treasurer, to construct a line to Schuyler.

The Lake Park and Ulm Telephone company, to operate an exchange in Lake Park, near St. Paul, has been incorporated by R. T. Gilmore, John Nelson, T. C. Hawley and others of Lake Park.

The People's Telephone company of Luzerne County, Pa., announces that it will have its lines in operation from Scranton to Hazleton by May 15th. The officers are Abram Nesbitt, president; Irvin A. Secarns, vice-president; Samuel C. Wayland, manager; John W. Hollenback, W. A. Lathrop, C. A. Stegmaier of Wilkesbarre and A. Markle of Hazleton, directors.

Wilmington, O., has granted the Home Telephone company a franchise, and it will actively compete with the Central Union company. The new corporation promises telephones to business places at \$1.50 a month and to residences at \$1. The capital stock of the company is \$15,000, and the incorporators are Milesus Garner, S. R. Mitchell, L. J. Walker, C. R. Fisher and S. G. Smith.

Articles of association of a new telephone company for Meriden, Conn., have been filed. The new company is the Connecticut Automatic Telephone Exchange company, which has the exclusive right in Connecticut of the Strowger automatic telephone-exchange system. The capital stock of the new company is \$250,000, and the stockholders are Charles W. Royce, Edward L. Allen and Stephen C. Wolcott of Newton Center, Mass.; William G. Nash and Ira B. Cushing of Brookline, Mass.

EXTENSIONS AND IMPROVEMENTS.

A new telephone service is proposed at Puebla, Mexico.

The Oregon Telephone and Telegraph company will build a line between Salem and Albany.

The Massachusetts Telephone company has applied to the council of Beverly, Mass., for a franchise.

The Nelson and Vernon Telephone company has decided to install a local system in Greenwood, B. C.

Agents have closed a contract for a telephone line from Fullerton to La Hebra Valley.

It is reported that the telephone line from Port Orford, Ore., will be completed through to Wedderburn.

Telephone exchanges are to be established at Trail, Rossland, Cascade, Grand Forks and Republic, according to the Spokane (Wash.) *Chronicle*.

Rust Brothers of San Angelo, Texas, will build a telephone line from San Angelo to Robert Lee, a distance of 35 miles. They will also extend the Sterling City line to Colorado City.

The city of Earlville and La Salle County have granted franchises to the Lee County Telephone company of Dixon, Ill., which proposes to extend its lines as soon as the weather will permit.

The Columbia Telephone-telegraph company of Rossland has closed a contract with Messrs. Davey and Donald of Grand Forks for the construction and equipment of a telephone-telegraph line from Trail to Cascade, Wash.

The county of Jo Daviess, Ill., and the incorporated villages of Stockton, Nora, Warren and Apple River have granted franchises to L. D. Pitcher of Dixon and his associates for a county telephone system to connect with Carroll and other counties in the northwestern part of the state. Work will be commenced at once.

Colonel E. K. Baker, superintendent of the South Texas division of the Southwestern Telegraph and Telephone company, has closed a deal for the erection of a relay station at Houston. Work will be commenced immediately, and it is hoped to have the station in active operation in a short time. Some of the wire needed has already been strung. The object of the relay station is to prevent interference with the long-distance lines of the company in case of a fire or other accident which might render the wires of the local exchange useless. Under the present arrangement, Galveston would be entirely cut off from telephonic communication with all parts of the state and with all points to which the long-distance wires extend in case such an accident occurred in Houston. In connection with the new station, a belt line around the city will be erected, and, no matter what conditions exist at the up-town exchange, the company will be enabled to operate its long-distance wires without trouble, the operators at the relay station being given access over the belt line to all of the numerous connections.

Patent Systems of the United States and Foreign Countries Compared.

[Continued from page 157.]

frequently results in the issuance of a patent which fails to secure to the inventor his just rights. In England the patent is granted for that to which the inventor considers himself entitled, and the patent when litigated is usually sustained for so much of the invention as appears from the evidence to be novel, the patent being thus more or less elastic in its nature, broadening or narrowing to meet the true measure of the inventor's real invention.

While the English system is advantageous in this particular, the advantage is greatly overborne by the fact that the issuance of a patent is not a prima facie proof of novelty or validity, while in the United States, where examination is made, the inventor when he receives his patent knows the scope of his invention and is able to judge of its validity. In the English system the inventor receives no more assistance in this regard than though the patent had not been granted. Nor is the liability of receiving too narrow claims by the American system the fault of the system. The inventor or his attorney should present claims commensurate with the true scope of the invention in view of the prior art as disclosed by the examiner's search, and if the examiner is considered obstinate in his refusal to allow the same, the inventor should avail himself of his right of appeal. Where an evident mistake has been made by the inventor or his attorney through accident or inadvertence the mistake can be corrected by reissue if timely application therefor is made. The best evidence of the efficiency and advantage of the examining system is that the foreign countries are one by one adopting this practice; and, moreover, inventors, foreign as well as domestic, avail themselves of the efficient corps of examiners in the United States Patent Office to determine the real scope of their inventions and then apply for patents in the foreign countries on the inventions as developed in the United States Patent Office.

Considering the third of the above-mentioned differences, the foreign countries do not permit the knowledge or use of the invention to become public within their borders prior to the application for the patent. Such prior knowledge or use does not preclude the grant of the patent, but the patent when granted is invalid, and if contested, this fact being proven will prevent recovery for infringement. The United States wisely provides a probationary period of two years within which the inventor may use his invention in public and introduce it into commercial use, if he sees fit, to try the demand and determine whether or not it is successful mechanically and commercially. He may then go into the Patent Office and secure a patent on his invention. This provision is not only an assistance to the inventor but is a benefit to the public, since it does not compel the inventor to rush into the Patent Office with a crude idea, but encourages him to wait until he has demonstrated the practicability of his invention, when by disclosing such a structure in his letters-patent he gives something of real value to the public.

As to the fourth difference above referred to, the foreign countries with the exception of Great Britain usually provide that the invention shall be worked or put into use in the country within a certain period after the application is filed, usually from one to three years. This is a hardship to meritorious inventors, since it is often difficult for a poor man to enlist capital in so short a time to place the invention in a marketable condition before the public, and fails to reach the parties at whom it is apparently aimed. Parties who are placing an inferior article on the market frequently make improvements which would greatly benefit the public if placed on the market, but such devices when patented and thus withdrawn from the use of the public generally are shelved, since there is more profit in the sale of the inferior articles. These provisions contemplate the forfeiture of the patent for failure to work such inventions; but the intent of the law is readily circumvented by the practicing of the invention on a small scale at stated intervals to comply with the requirements of the law. Such provisions, therefore, while apparently failing to operate effectively where they would serve to advantage, impose a very material obstacle in the path of the struggling and usually meritorious poor inventor.

Considering the fifth difference, relating to importation, the United States places no restriction upon the enjoyment of the invention in this particular, and a foreigner after taking out a patent in this country need not manufacture here, but can manufacture abroad and import the articles into this country to supply the demand here. This, of course, is an economic disadvantage to this country and is a derogation of the rights secured to home manufacturers by a protective tariff, but is an illustration of the respect paid to patent property.

Referring to the sixth difference referred to, the foreign countries usually provide for a graduated tax payable yearly throughout the life of the patent and increasing from year to year, so that the patent becomes an increased burden as its life is prolonged. The spirit of this provision is to spur the inventor to reap a reward from the invention as soon as possible by putting the same on the market and thereby giving the public the benefit thereof, and to discourage the prolongation of the life of the patent when the invention is not put into public use or has

not proven remunerative. This is another of the provisions of foreign countries tending to discourage the inventor by placing obstacles in his path. To wealthy parties the tax is not a burden, and while the real injury to the public arises from the withholding of important inventions from the public while being supplied with inferior goods in which there is more profit to the maker, these taxes do not attack this evil, as is their evident intent, since such parties are abundantly able to pay the consideration necessary for withholding the invention from the public, and the whole burden of the provision falls upon the poor inventor who, in addition to the difficulty of enlisting capital to exploit his invention, finds himself in constant danger of losing all of his rights by failure to raise the necessary amount to pay the frequently recurring taxes. The patent system is the fortune field of the poor inventor, and while a heavy tax upon unused inventions would undoubtedly be an advantageous provision if discriminatingly applied, it seems that the only effect of a general provision to this effect is to work a hardship upon the very inventors who should rather be given assistance.

Adverting to the seventh distinction above mentioned, we find that some of the countries, particularly Germany and Canada, provide for a compulsory license where the inventor or owner of the patent does not or is unable to supply the market. In Germany any party wishing to utilize a patented invention which is not being put upon the market to supply the demand or a probable demand can apply to the government for a compulsory license, which, in proper cases, is granted by the government after the giving of proper guarantees and security for the payment of royalties. This is apparently a good provision, and might be applied to advantage in this country.

As to the eighth difference mentioned, the practice of the foreign countries is to limit the term of the monopoly from the date of the application, whereas in the United States the term begins to run from the date of the grant of the patent. Where no examination as to novelty is made the practice of the foreign countries is undoubtedly a proper one. Where, as in the United States, examination as to novelty is made, often necessitating appeals and long delay, such a provision would be manifestly unjust, since the course of appeal frequently occupies a number of years, while several years is not infrequent in the absence of an appeal, due to the overworked condition of the examining corps. Then, too, several applications, claiming the same invention, necessitate the declaration of an interference to determine who is the first inventor, and this process, subject to many appeals, consumes considerable time, so that if the term were to date from the filing of the application a considerable period of the term would often elapse before the commencement of the monopoly, and this, frequently, without fault on the part of the applicant.

But, on the other hand, the United States practice often results in great injustice to the public, by permitting an application to lie in the Patent Office for a long period of years, while another and former patent is securing a monopoly, to issue at last just as the earlier patent is about to expire, thus securing an increased monopoly for practically the life of a new patent. Such an instance is the now famous Berliner case, the injurious effect of which upon the public and upon our patent system has not as yet been determined. Since it is apparent that it would be unjust to the inventor, on the one hand, to adopt the foreign practice and limit the term from the date of application, and since the present practice is, on the other hand, unjust to the public, it has been proposed to adopt a mean between the two and provide for the running of the term, as at present, from the grant of the patent, but to provide that in no case shall the monopoly extend beyond a period of, say, 20 years from the filing date of the application. This would give three years for the prosecution of the application, and would seem to solve the present difficulty.

The ninth difference is one which arises from a law which went into effect in the United States the first day of January, 1898, and which provides, in effect, that the life of the United States patent shall not be affected by the previous expiration of a foreign patent for the same invention, whereas prior to that date in the United States, as well as at present in many foreign countries, the foreign patent first to expire determines the life of the domestic patent. The spirit of this provision seemed to be that since the monopoly is in the nature of a tax on the public, the removal of the tax in a foreign country by the expiration of the patent there would subject this country to a disadvantage, and that in consequence the tax should be removed here at the time it is removed from the first of the foreign countries. But this would hold good only in case patents were taken out in all the foreign countries, which is practically never the case, so that the argument is apparently not sound, and after wondering for some time what was the real advantage of the provision, and concluding that it really had no reason for existing, Congress repealed this restriction to the proper enjoyment of the monopoly by the inventor.

It is thought that it will appear from the above that the system of the United States is the most liberal to the inventor in that it not only assists him to determine the scope of his invention, but also removes all checks from his enjoyment of the monopoly. While it is apparent that in our system some

objections and abuses may arise, they are not due to the general provisions of the system, but rather to the lack of specific provisions for checking the particular abuses, and these will, it is believed, be in time remedied, but not by radical changes or the adoption of the cumbersome provisions of foreign systems, although we may derive suggestions from their practice. As to the practical effect of the American system, a comparison of the patents granted by the United States and foreign countries shows

FIG. 1. HERCULES BATTERY.

that up to the year 1898 the United States had granted 626,327 patents, France 297,166, Great Britain 265,870, Belgium 146,772, Germany 118,694, Austria-Hungary 82,933 and Canada 65,489. The United States thus stands head and shoulders above all the other nations, having granted more than any two of the other countries.

During 1898 there were over 36,000 applications for patents filed in the United States, while in Great Britain there were about 30,000 applications filed. Practically, all of the applications in Great Britain

FIGS. 1 AND 4. WESTERN ELECTRIC INSTRUMENT SWITCH.

mature into patents, many of which are invalid by virtue of previous patenting, since no examination as to novelty is made. During the year 1898, 22,207 patents were issued in the United States, after examination, and at the end of the year there were 6,824 applications allowed and awaiting the payment of the final fees, while 4,363 applications had been allowed, but had been forfeited for the non-payment of the final fees.

Just how much of the great activity of American inventors is to be attributed to the encouragements offered by our liberal patent system and how much mechanically determined, but it is safe to say that the is to be attributed to the inherent inventive faculty of the American people cannot, of course, be mathe-

FIGS. 2 AND 3. WESTERN ELECTRIC INSTRUMENT SWITCH.

rewards offered by our system have been the fundamental cause which has produced, as a result, a people, every member of which is a born inventor and is accustomed to the practice of mechanical ingenuity from early childhood.

Seymour, Iowa, will vote on the proposition to issue bonds for electric lighting on March 27th.

Hercules Battery.

In placing the Hercules battery cell (Fig. 1) on the market, the Peru Electric Manufacturing company of Peru, Ind., aimed to produce a high-grade battery at a moderate cost, and it feels confident that all users will agree that the object has been accomplished.

This cell consists of a fluted cylinder (Fig. 2) made of selected carbon, filled with a depolarizing compound. The zinc (Fig. 3) is cylindrical in form and made of the best rolled zinc and thoroughly amalgamated. The cover is of porcelain and forms a perfect lid for the jar, preventing evaporation or the climbing of salts.

The manufacturer recommends the Hercules as being one of the best batteries on the market, and says that it is without an equal for gas-lighting and gas-engine work, and in fact for all open-circuit work where the conditions are most severe. The data given are: Electromotive force, 1.47 volts; internal resistances, .11 ohm; current on short-circuit, about 13.4 amperes.

Western Electric Instrument Switch.

The cuts show a new switch designed and placed on the market by the Western Electric company to meet the demand for a substantial voltmeter and ammeter switch. Fig. 1 shows a front view of the switch unmounted. Fig. 2 is also a front view, but showing the device mounted on the switchboard. Fig. 3 is a sectional view through the board, and Fig. 4 a rear view of the unmounted switch.

The contact points of opposite polarity are mounted on separate slabs of white marble, which are fastened on the back of the switchboard. The switch is controlled from the face of the board by a neat hand-wheel and index plate. It has a positive knife-switch contact capable of carrying 15 amperes. This feature specially adapts it for use as a multiple shunt ammeter switch, as uniformly low-resistance contact is necessary for accurate results.

The hand-wheel and index plate are regularly fur-

nished with a polished copper finish. All switches are provided with removable collars on the screws which hold them to the switchboard, so that they may be mounted on marble or slate, one, 1 1/4, 1 1/2 or 2 inches thick. The space occupied on the back of the switchboard is 6 1/2 by 6 1/2 inches, and the switch projects six inches behind the rear surface of the board. Switches are furnished for from two to 12 circuits, inclusive.

Varley Spark Coil.

The Varley Duplex Magnet company of Jersey City, N. J., has recently placed on the market, for ig-

nitiation purposes, the special Ruhmkorff coil herewith illustrated. This coil is built to give a spark from one inch to 1 1/2 inches in length. It is especially adapted for gas and gasoline-engine work. The company states that it has made a special study of the wants of gas-engine builders and believes that its new igniting apparatus is far superior to the imported coils which are largely used in the United States for this purpose.

Bates Ceiling Fan.

The accompanying illustration shows one of the many new designs of electric fans brought out by the firm of D. L. Bates & Bro., Dayton, Ohio. The mechanical arrangement of the fan is such that there is but a single bearing running in oil. The bearing extends the entire length of the motor, making it impossible to get out of line and obviating all danger of the armature striking the pole piece. The fan is also provided with a switch which is completely incased in the housing at the bottom of the motor

FIGS. 2 AND 3. HERCULES BATTERY.

casing, but which is accessible for turning the current off or on.

While the illustration shows the fan with switch and with electric-light attachments, these may be dispensed with if desired. The general external finish of these fans is nickel, oxidized copper or polished brass, but they are also furnished in the black-enamel finish with polished brass trimmings. The same firm has also placed on the market a 12-inch and a 16-inch desk fan, also an adjustable bracket fan for 110, 220 or 500 volts direct current, the

VARLEY SPARK COIL.

fields of which are made of forged steel. These fans are guaranteed to run on less current than any other fan of corresponding size. The firm also manufactures alternating-current ceiling fans and water-motor buzz fans, which give excellent satisfaction.

Municipal Electricians at Wilmington.

Indications are that the next convention of the National Association of Municipal Electricians in Wilmington, Del., in the week beginning September 14th, will be a pronounced success. President J. W. Aydon of the association has secured Pyle's Cycle

BATES CEILING FAN.

Academy for an exhibition hall, and free space will be given to exhibitors. The Board of Trade of Wilmington has appointed a committee of five to interest the business men of Delaware in the meeting. The association has now members representing 110 cities in the United States.

B. Perry and B. H. Dyer are applicants for an electric-light and power franchise in Santa Ana, Cal.

The Motor Vehicle in Commercial Operation.¹

By G. HERBERT CONDUCT.

Having covered over 250,000 miles of actual and commercial service, the electric vehicle in New York has proved itself no longer a toy to be played with by the wealthy, but a practical thing, which is to come to the aid of the dwellers in our great cities, who are anxiously beholding the vast congestion of traffic in the streets and wondering what is to become of it in the future. The modern Rip Van Winkle goes to sleep for much less than 20 years and when he awakes what does he behold? The streets of the city are clean; no rails cut up the smooth surface; no horse or any other beast is here—they are prohibited within the city limits. The pedestrian wends his quiet way along the sidewalks elevated to the second story with bridges over the street, while below the agile electric darts at good speed back and forth, on its noiseless, easy-riding pneumatic tires, carrying all manner of humanity and its goods and chattels, and delivering them, not at the curbstone, but at the doorstep. The elevated train, the cable and the trolley car have disappeared, but far below the surface glides the electric local and express in light and well-ventilated subways. The streets, made wider by the absence of sidewalks on the same level, allow a free movement of vehicular traffic, and the second-story stores are free from the dirt and turmoil now so overpowering.

The men who organized the company operating the electric-vehicle station in New York looked at the crude and inefficient apparatus which was at their disposal and saw in it the possibilities of a great industry. They decided to put sufficient capital at work to develop their ideas, and the present success of electric cabs bears abundant testimony to the wisdom of their decision. This station was equipped with the most approved battery-handling apparatus then obtainable, and no expense was saved in procuring the very latest improvements in all of the various parts which go to make up a vehicle which could be depended on to do the work required of it. The supply is so absurdly inadequate to fill the demand that operation is carried forward under great disadvantages, considering the many component parts that are altogether incomplete and experimental. It has been impossible to make accurate tests of the efficiencies of motors, batteries, gearing, bearings, etc., although data are now being obtained. There is still much to be desired, and in future equipment most material improvements will be made.

Outside of the consideration of large weight in proportion to power delivered, the battery has been giving excellent service. Up to the present time there has been practically no expense for maintenance, and the old-time troubles of buckling, short-circuiting, sulphating, disintegrating are as yet entirely absent.

The tire situation is at present the absorbing subject of our day thoughts and night dreams. Were the streets in this great metropolis paved in an up-to-date manner, there would be comparatively little cause for anxiety on this score, but with the antiquated and despicable cobble the case is far different. Over 20 separate and distinct types of tires have been tried or are to be tried in the near future, and others will probably follow. Solid, single and double-tube pneumatic, cushion, clincher, sectional, protected and unprotected have all had or are to have a trial. Their faults are many, their virtues few, and we are still on the search. We have heard of some eminent authorities in the motor-vehicle field who say that the solid is the only tire. They are rendering judgment without full knowledge of the facts and from a purely local standpoint. They are evidently not acquainted with the streets of Manhattan. A very satisfactory combination for broughams is that of rear pneumatics and front solids.

The wheels also require most serious consideration. The severe strains unavoidable in crossing railroad tracks and other inequalities and running up against curbstones speedily put out of service even the most substantial constructions. Everything from the light and airy bicycle-wheel construction to the dishpan wheels, now so familiar on our streets, have been tried, and still there are more to follow. I mention these few items to indicate some of the most important and particular directions in which the work is progressing.

Another Storage-battery Report.

When new papers have for some time asserted that the Electric Storage Battery company of Philadelphia had been absorbed by a Whitney syndicate, the story being that the particular absorbing company was the New York Gas and Electric Light, Heat and Power company, with its \$36,000,000 capital. But according to the New York correspondent of the *Country Record*, there is a larger scheme afoot. The *Record's* dispatch is dated March 14th and is as follows: "W. C. Whitney is the head and shoulders of a syndicate trust which has consolidated with the storage-battery companies and will control the electric cabs of New York, build thousands of others, install electric delivery-wagon lines and omnibus routes, run the Holland submarine torpedo boat, launch electric launches and ferry boats. The capital is \$100,000,000."

¹ Address: 1144 Broadway, prepared for the New York Electrical Society last month.

Development of Niagara Power on the Canadian Side.

[Special correspondence of the WESTERN ELECTRICIAN.]

The question of the development of the power on the Canadian side at Niagara Falls has reached that stage of public interest that on Friday, March 3d, the people of Niagara Falls, Ont., and vicinity ran a special excursion train to Toronto, Ont., carrying between 300 and 400 persons, who went to make a demonstration before the Ontario Legislature that day at the time a resolution on the power-development question was to be brought up by W. M. German, the member from Welland, in which the Niagara territory is located. All members of the party wore badges bearing the inscription, "Canada no place for monopolies." These words referred to the exclusive agreement between the Ontario government and the Canadian Niagara Power company, in regard to the development of power in Victoria Park on the Canadian side of the Niagara River. By section 10 of that agreement it is provided that the company shall have, by November 1, 1898, completed water connections for 25,000 horse power, and 10,000 horse power actually developed. In November last the courts decided that the company has until November 1, 1899, to do this work. By clause 13 it is provided that if the company shall neglect for one year effectually to generate electricity or pneumatic power its license shall be forfeited. Up to this writing the Canadian Niagara Power company has not taken any steps in Victoria Park to lead the people to believe that it will try to have the above-mentioned water connections made and power developed by November 1st next, and the opposition to the company alleges that it will be an utter impossibility for it to live up to the agreement mentioned.

Mr. German's resolution was as follows:

Resolved, That in the opinion of this House the sole and exclusive right to the use of the waters of the Niagara River within the limits of the Queen Victoria Niagara Falls Park, under the agreement set out in chapter 8 of 55 Victoria (Ontario), between the commissioners for the said park and Messrs. Shaw, Steetsen and Rankine, or the Canadian Niagara Power company, as provided by section 9 of the said agreement, should be forfeited and terminated immediately upon default by the company in complying with sections 10 and 13 of the said agreement, and that no performance of the work, expenditure of money or letting of contracts in part performance of the work to be done in generating electric power under said sections should be considered to save such forfeiture.

And this House is further of opinion that all necessary steps should be taken to bring about at the earliest date the largest possible development of Niagara power.

The resolution was adopted.

Has a Smoker Inalienable Rights?

John M. Wallace of Brooklyn says that he is going to get an opinion from the Court of Appeals, if necessary, in order to set at rest the question of whether or not he has a right to smoke on the rear platform of a Brooklyn trolley car.

In the Myrtle avenue court Wallace complained against John Arkwright, a conductor of the Gates avenue trolley line, whom he charged with assaulting him. On the night of February 17th, according to the report in the *New York Tribune*, Wallace said that he was on the rear of the defendant's car, smoking a cigarette. Arkwright requested him to stop, and referred to the rule of the company prohibiting smoking. Arkwright offered the smoker his nickel back and told him to get off the car. Wallace dared the conductor to put him off the car. Arkwright told him he didn't want to have any trouble, but if he allowed smoking on the car he was likely to lose three days' pay if it should be reported to the company.

The discussion became warmer, and Arkwright cut the argument short by knocking the cigarette out of Wallace's mouth. This act Wallace resented, and the men engaged in a scuffle. Wallace alleges that the conductor kicked him in the ribs. Magistrate Teale advised Wallace to drop the case, as the company had the right to make rules of its own about smoking on its cars.

Wallace said that he would never give in. The magistrate dismissed the charge against Arkwright, and Wallace left the courtroom just as angry as ever.

Postal and Western Union Dispute Over Cable Rights to Cuba.

The attorney-general of the United States gave a hearing recently on the question of the right of the Commercial Cable company of Cuba, a corporation organized on February 15, 1899, in New Jersey, by officers of the Postal Telegraph-cable company, to land and operate a submarine cable between the United States and Cuba. This right is contested by the International Ocean Telegraph company, now under management of the Western Union Telegraph company. It was contended on behalf of the International Ocean Telegraph company that by the specific terms of a royal decree issued by the Spanish government in 1866 it acquired the exclusive right and privilege for the term of 40 years to land a cable in Cuba, to be operated between that island and the United States. It was argued further by the terms of the treaty of peace between this country and Spain the United States bound itself to respect all private rights of ownership of property of whatever character in the island, and disavowed any intention permanently to exercise sovereignty over it, and hence it had no authority to abrogate the decree or interfere with the full enjoyment of the company's rights under its concession. On behalf of the Commercial

company it was said that the original franchise from Spain had been secured through misrepresentation and fraud, and also that the continuance of the monopoly was contrary to the public policy of the United States. It was also contended that under its general authority over conquered territory the United States had a right to inquire into and abrogate such concessions as were found to be subversive of the rights of others and against public policy. A copy of "The Official Gazette," containing the decree of 1866, was filed with the attorney-general. This copy, it was said, showed that the concession was obtained through false representation that the United States had also granted an exclusive monopoly for 40 years. Counsel for the International Ocean company contended that the allegation of fraud was not sustained, as the royal order of 1889 fully confirmed the concession of 1866 for the full term of 40 years, and says in specific terms that the franchise granted by the United States was for 14 years. Therefore there could have been no misunderstanding as to the length of time it was to remain in force. The attorney-general took the matter under advisement.

Pan-American Exposition.

[From the Niagara Falls correspondent of the WESTERN ELECTRICIAN.]

The plans for the Pan-American Exposition, which is to be held near Buffalo in 1901, are gradually assuming definite shape. Congress has appropriated \$500,000 and the Legislature of the state of New York \$300,000 for exhibits, and other states of the Union have been called on to take action looking to proper representation at the great event. The incorporators have met and elected a board of 25 prominent Buffalonians as directors, their names being as follows: Mayor Conrad Diehl, C. W. Goodyear, Capt. J. T. Jones, George L. Williams, J. J. Albright, Major T. W. Symons, W. Caryl Ely, John G. Milburn, Frank B. Baird, William Hengerer, George Bleistein, H. M. Gerrans, E. G. S. Miller, J. N. Scatterd, George K. Birge, W. H. Hotchkiss, J. M. Brinker, George Urban, Jr., John B. Weber, Harry Hamlin, Carlton Sprague, Henry J. Pierce, F. C. M. Lantz, H. P. Bissell, Robert F. Schelling. One of these, J. J. Albright, announces that he does not care to be on the board.

The directors have selected rooms in the Ellicott Square building, Main street, for permanent headquarters. Edwin Fleming has been elected secretary and George L. Williams treasurer of the board. A president has not yet been elected. It may be that this office will be in the main honorary, and that the hard work of the exposition head will fall upon the head of the executive committee. A director-general has not been selected. A committee on by-laws has been appointed and is now at work. The by-laws will tell the scope of the exposition and the various offices to be filled. It is already known with reasonable certainty that outside of the officers above referred to there will be an auditor-general, an executive committee of seven, a finance committee of the same number and similar committees on grounds, publicity and promotion, foreign affairs and exhibits, and on tariffs and transportation. The executive committee will be the hard-working committee, and the members will have to give about all their time to the exposition matters. The president of the exposition will be expected to receive the distinguished guests and make the speeches. There is talk of increasing the capital stock of the company to \$2,500,000. The present capital stock is \$1,000,000. The grand total of subscriptions to date is \$1,353,980, and the total number of subscribers is 11,976.

All who seek for positions or concessions should wait until the various bureaus are perfected, for until then no one will be in position to give information or make contracts.

Power and Light Exposition at Austin.

In connection with the annual meeting of the Southwestern Gas, Electric and Street-railway association at Austin, Texas, an exposition of apparatus used for lighting and power will be held from April 19th to May 1st. A large building will be constructed, and power for exhibits will be supplied without cost. Manufacturers are promised liberal treatment and are urged to exhibit. There is a large water-power electrical plant at Austin, and for this reason the city is thought to furnish a particularly appropriate site for an exhibition of power-transmitting machinery. George A. Hill, the secretary of the Austin Commercial Club, or E. L. Wells, Jr., the secretary of the association mentioned above, can supply further information.

Information Wanted.

[From the *American Machinist*.]

The autotruck is to transform the city [of New York]. We have a great boom on for compressed air. There is an American Air Power company with a capital of \$7,000,000, an International Air Power company with a capital also of \$7,000,000, a New York Autotruck company, \$10,000,000, and a Chicago Autotruck company, \$10,000,000. Such eminent engineers as Richard Croker and Joseph Leiter are operating the machinery, stock is selling, and its "value" is advancing. Some of it has been quoted above 70; but where is the truck, and what can it do? Where is the first truck, and where is there any promising record of its practical performance?

There is a truck which has hauled castings around a factory yard in Worcester, Mass., and that, we are given to understand, is all that there is as yet to show. Two factories are ready to rush out the trucks, but are they yet invented? We are not here implying that they are not; but the question would seem to be a proper one. When stock is for sale the stock buyers should know what they are buying. Do they know in the present case?

CORRESPONDENCE.

New York Notes.

NEW YORK, March 13.—Tammany's "holy war" on the Manhattan company has, from all present appearance, passed into history, without any result whatever. At last Tuesday's meeting of the Municipal Assembly the council recalled from the mayor the resolution requiring the Manhattan Railway company to run cars on all its tracks on a five-minute headway at all hours of the day. This is the procedure suggested by the mayor and adopted by the council. It is the same as that by which the drip-pan ordinance was disposed of the week before and sent to a committee of the Board of Aldermen, where it still remains. The resolution requesting the mayor to recall the ordinance was moved by Vice-president Oakley, who then moved that it be referred to the railroad committee. There were no explanations and no discussion, and the resolution was quietly referred. Mr. Baker, the new electrical superintendent of the Manhattan company, is now at work. He says that the company will use the third-rail system. The work of installing the system, building a power house and constructing the motor cars to be used on the road will be begun as soon as possible.

The City Lighting company of New York city has been incorporated with a capital of \$1,000,000 to furnish electricity for light, heat and power purposes, to light public streets and dwellings, and to manufacture and supply both illuminating and fuel gas. The company is to operate in New York, Kings, Queens, Richmond and Westchester counties. The directors are John M. Ryan of New York city and Frank L. Hearn and John S. Griggs, Jr., of Brooklyn.

Mr. W. J. Johnston, the late owner of the *Electrical World*, is enjoying a trip to the West Indies after his release from the cares of electrical journalism. Before his departure a number of friends and acquaintances presented him a silver loving-cup. It is announced that the Johnston electrical directory has been sold to Mr. E. L. Powers.

It is expected that before the close of the month the two big trolley systems of Brooklyn (Rapid Transit and Nassau) will be operated as one. Some radical changes in the management are contemplated, which will materially reduce the operating expenses. All the Nassau cars will be painted the same color as those of the other road.

Public notice was given on Saturday by the New York and Staten Island Electric company that the company might discontinue the lighting of the streets of Richmond borough, because it had not been paid by the city of New York for the service already rendered. In his announcement, General Manager Swinerton says: "The New York and Staten Island Electric company wishes the public to know that since its organization and the assumption of the public street lighting of the entire borough of Richmond, now over one and a half years, it has not received one cent of payment for the service; that in addition to lighting streets it has in the past done more free lighting of churches, public buildings, and even private property, than any such company can stand and remain solvent, and to have the borough refuse to pay for its public lighting inflicts upon the stockholders of the company the last blow."

M. S.

PERSONAL.

R. H. Bouslog, the secretary and treasurer of the Peru (Ind.) Electric Manufacturing company, was in Chicago a few days ago.

Mr. Patrick Nally, the father of Mr. E. J. Nally, assistant general superintendent of the Postal Telegraph-cable company, died at the latter's residence in Chicago last week at the ripe age of 82 years.

At last week's meeting of the New York Electrical society the following-named members were elected: Albert C. Jahl, T. E. Crossman, W. H. Lawrence, C. J. Field, George M. Warner, George C. Anthon, Charles Klein.

The new manager of the Western Union office at Milwaukee, M. W. Hamblin, has been in the service of his company since 1877. He has been manager of the offices at Janesville, Wis., Bloomington, Ill., and Davenport, Ia.

George Westinghouse presented to Union College, Schenectady, N. Y., some time ago, a 20 horse power gas engine of the latest type. It is now set up in the engine room of North College, and furnishes power for illuminating the whole college.

Samuel W. Schwab, head of the time department in the Edison works in West Orange, N. J., died at his home in Orange on Saturday last. He was born in New York in 1873, and educated in the public schools. He entered the employment of the Edison Manufacturing company in 1886, as an office boy,

and gradually rose till he became the head of the time department of all the works. He married Miss Martha Kruse in 1892, and she survives him, with two children.

ELECTRICAL SECURITIES.

The Commercial Cable company has declared a quarterly dividend of 1 1/4 per cent., payable April 1st.

The Columbus street railroad reports gross earnings for February of \$52,697, an increase of \$4,546 as compared with the same month of last year, and net \$28,831, an increase of \$4,018. For the two months ended February 28th the gross earnings were \$110,688, an increase of \$8,249 as compared with the corresponding period of last year, and net \$60,627, an increase of \$6,717.

First-mortgage five per cent. gold bonds of the Cincinnati Edison Electric company are placed on the market by N. W. Harris & Co. of Chicago. The issue is \$1,000,000, and the banking firm states that "prior to our purchase of the bonds, the plant and business of the company were carefully investigated for us by Samuel Insull, Esq., president of the Chicago Edison company, who states that the property represents an actual cash investment of approximately \$2,027,000 (total amount of bonds outstanding only \$1,100,000), and that the large fireproof central station recently completed by the company is one of the most modern and best equipped in the United States."

Fifty-year five per cent. first-mortgage gold bonds of the Trenton (N. J.) Gas and Electric company to the amount of \$1,500,000 are offered for sale by Redmond, Kerr & Co. of New York. They are dated March 1, 1899. The company is a consolidation of the Trenton Gas Light company, the City Gas Light company, Trenton Light and Power company, People's Electric Light company, Trenton Electric Light and Power company and Edison Electric Light and Power company. In addition it owns the entire capital stock of the People's Gas Improvement company and the Delaware River Improvement company, thereby controlling either through actual ownership or ownership of stock all of the gas and electric-light plants in the city and suburbs of Trenton, N. J.

Alexander Brown & Sons of Baltimore offer \$18,000,000 of first-mortgage, four per cent., 50-year gold bonds of the United Railways and Electric company of Baltimore at 102 1/2 and accrued interest from March 6, 1899. This company has capital stock of \$38,000,000 and an authorized consolidated bond issue of a like amount. It is of this issue that the \$18,000,000 mentioned is offered for sale to the public. The United Railways and Electric company owns all the lines formerly operated by the Baltimore Consolidated Railway company, 207 miles; the Baltimore City Passenger Railway company, 56 1/2 miles; the Central Railway company, 36 1/4 miles; the Baltimore and Northern Electric Railway company, 38 1/2 miles, and all the bonds of the Baltimore, Middle River and Sparrow's Point Railroad, 14 1/2 miles, thus controlling all the passenger railways in the city of Baltimore and its vicinity.

MISCELLANEOUS.

It is said that Thomas A. Edison, Jr., and William Holzer have discovered a process for hardening steel, which, while it costs less than half that of the Harvey process, gives much superior results. To operate the new discovery the Thomas A. Edison, Jr., and William Holzer Steel and Iron Process company has been organized.

A. H. Belo & Co., publishers of the *Dallas News*, are having plans prepared for a three-story-and-base-ment, thoroughly fireproof, modern newspaper building, and their architect, H. M. Greene, Gaston building, Dallas, Texas, would like to get any information regarding novel electrical devices—any novelty that will attract attention.

There is a large amount of available land in Guatemala especially suited for the growth of the rubber-tree. In addition, there are large numbers of wild rubber-trees in the forests of the coast region. The government is desirous of fostering the cultivation of rubber, and late decrees not only protect the wild rubber-trees, but offer premiums of land for groves of rubber-trees planted after January 14, 1899.

TRADE NEWS.

The Western Electric company, prior to the recent rise in copper, greatly increased its stock of rubber-covered wire, and is prepared to meet the demand of the spring trade with reasonable prices and prompt shipments.

Roth Bros. & Co., who were recently burned out, have resumed business at 88-02 West Jackson street, Chicago, and are equipping their new factory with machinery, getting out patterns and making all necessary preparations to resume business. They expect to be able to fill orders with their usual promptness within the next two or three weeks.

Eugene Munsell & Co. of New York have opened a large mica factory in Ottawa, Canada. It is the intention to forward the mica direct from the mines to the factory in Ottawa, where it will be prepared for shipment to the United States. Ottawa as a mica center is perhaps the best known in Canada, and a large business has been carried on between

concerns in that city and firms in all the large cities of the United States.

The Warren Electric and Specialty company of Warren, Ohio, makes direct-current fan motors and transformers as well as incandescent lamps. All are known under the name of Peeries, and the new specialties are said to justify the title. Both 9067 and transformers are said to have exceptional efficiency, and they are put on the market at very reasonable prices.

F. V. Young has opened an office at 331 I. O. O. F. building, St. Louis, as a manufacturers' agent. He represents the Cleveland Electric company, which makes switches, cutouts and other appliances, having the exclusive agency for lower Illinois, Missouri, Kansas, Arkansas, Iowa, Nebraska and Colorado. Mr. Young is looking for a line of lamps, sockets, wire and other electric specialties.

With other carbon companies the Partridge Carbon company of Sandusky, Ohio, was recently absorbed into the carbon combination, and it will be interesting to the host of friends of the Partridge company's recent secretary and treasurer, J. S. Speer, to know that he has deemed it advisable to sever his connections with the absorbed company. Mr. Speer is one of the most aggressive and progressive young business men of the Middle West, and his successful efforts, with Mr. Partridge, in building up the company in Sandusky, Ohio, are well known. It is now announced that it will be but a few weeks before he will start again as a manufacturer of motor and generator carbon brushes. It is stated that Mr. Speer will have plenty of capital with which to back his new enterprise. Although he has not yet decided as to location, it is believed that his plant will be at Pittsburg of some point farther east. With a man of Mr. Speer's experience in the carbon trade at the head of this enterprise, it is safe to say that the new business will be successful from the start.

The interesting announcement is made that Mr. M. E. Baird, the general manager of the Eddy Electric Manufacturing company of Windsor, Conn., has opened a western office for the business of his company at 837 and 838 Marquette building, Chicago. The outlook for the electrical business in the West is so bright that the Eddy company has reached the conclusion that a branch office in Chicago will be necessary to handle the trade. The Eddy dynamos and motors have the record of years of successful operation and are known throughout the length and breadth of the country. In motor work, especially, the Eddy business is firmly established, and the list of plants in which power is supplied by Eddy motors is a long and imposing one. For some time, at least, Mr. Baird will give his personal attention to the affairs of the Chicago office, and as he is equally well known and equally at home in New York, Chicago or San Francisco, his presence in the western metropolis will be of great advantage to the company. Mr. Baird's business and social qualifications are so highly esteemed that his welcome to the electrical circles of Chicago will be unaffectedly sincere and cordial.

BUSINESS.

The Buckeye Electric company, through its western representative, J. H. Cooke, 753 Monadnock building, Chicago, reports many orders for the Buckeye incandescent lamp from Illinois, Wisconsin and Iowa. Mr. Cooke says that it is the purpose of the Buckeye people to camp on the trail of central-station managers everywhere.

An attachment for electrically igniting Welsbach burners is a desirable improvement, as the old method of lighting them with a taper always causes more or less of an explosion, which is detrimental to the burner mantle. The Electric Appliance company is pushing the sale of the Advance attachment for the Welsbach burners and finds that it sells very rapidly.

Seymour Swarts, president of the Swarts Metal Refining company, Chicago, reports a gratifying increase in the business of his company. As is well known, the Swarts company makes a specialty of buying old copper wire of any description, for which it pays the highest market price. It is said that those who have had scrap wire for sale have found the Swarts company very prompt and satisfactory in its dealings.

The L. B. Allen company, 6350 Star avenue, Chicago, exclusive manufacturer of the Allen soldering stick, is reported to be doing a larger business than ever before. Through the able management of C. A. Scott the Allen soldering stick is being used in every state in the country, and its worth is known to almost every electrical worker. It is said to be non-corrosive and very effective. A pamphlet will be mailed to those interested.

The Crescent Chemical company, 185 Dearborn street, Chicago, is sure that it will pay users of belts to look into the merits of Never Slip pulley covering, which it manufactures. This pulley covering is said to be a power, fuel and money saver; its chief object is to prevent belts from slipping. The many claims made for this pulley covering are set forth in a neat circular, which the Crescent company will be pleased to mail to anyone on application. The manufacturer exhibits a large number of testimonials from users.

Cass & Co. of Chicago state that they are in a position to furnish dynamos and motors, both new

and second-hand, as well as gas and gasoline engines. They have been appointed general western agents for the S. E. I. company's switchboard instruments

and for the Moloney transformers. They are also general western representatives for Perfection brushes, and have the agency for the Onondaga

Dynamo company. They will be pleased to see their friends at any time at their office and works at 54 and 60 South Canal street.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 7, 1899.

620,503. Electrical Storage Battery and Plate Therefor. Rankin Kennedy, Bradford, England. Application filed September 9, 1897.

To plates for electrical storage batteries a central solid lead sheet is painted on one side with litharge and dilute sulphuric acid and on the other side with red lead and dilute sulphuric acid, with one or more layers or thicknesses of perforated lead sheets also painted with the same mixtures of litharge and red lead and sulphuric acid on each side of the central sheet, the litharge-painted sheets being placed on the litharge-painted side of the central sheet and the red lead-painted sheets on the other side thereof, the whole being in electrical contact and made solid around the edges by fusing or soldering

620,609. Motor. Edwin S. Pillsbury and Ferdinand Schwedtmann, St. Louis, Mo. Application filed March 18, 1898.

Claim is made for the combination with field magnets of an armature and its windings, a commutator therefor, brushes co-operating with the commutator, an insulation ring on the commutator, pivotally mounted centrifugally operated short-circuiting plates which normally rest against the insulation ring, and centrifugally operated devices for drawing the plates into engagement with the commutator segments when the motor has attained speed.

620,626. Electric Measuring Instrument. Clarence R. Weymouth, Alameda, Cal. Application filed November 30, 1898.

The combination in an electrical measuring instrument, having fixed and movable coils of a divided circuit, one branch containing a fixed coil, the other branch containing another fixed coil and a movable coil.

620,640. Electric Incandescent Lamp. Francis M. F. Cazin, Hoboken, N. J. Application filed September 11, 1895.

A three-part electric incandescent vacuum lamp is described, consisting of a suitable base, an air-exhausted glass bulb and a body or structure of solid matter, which constitutes a cohesive entirety and as such consists of two main constituents, namely, of a continuous linear semi-conductive, current-passing filament, which resists to a passing electric current to the effect of giving off light and heat, and which filament is electrically and chemically insulated from the other constituent by a protecting stratum, and a stratum of matter, which by the heat given off by the filament becomes luminous.

No. 620,640.

620,654. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa. Application filed October 21, 1889.

The method of operating an electric railway consists in supplying high-tension currents of alternately increasing and decreasing potential to a circuit extending along the railway, converting by induction the high-tension currents into alternating currents of lower potential at intervals along the railway, delivering the low-tension currents to a single common continuous conductor, and delivering the low-tension currents from the conductor to independent electric motors upon a series of independent cars, so that the motors are in parallel, and independently controlling the current flowing through the motors.

620,665. Electric Arc Lamp. Moses S. Okun, New York, N. Y. Application filed January 16, 1896. Renewed August 11, 1898.

A carbon rod or feeder has several sections pivoted together, two of the pivots extending in one direction and two in the opposite direction, and a carbon holder pivotally connected with one of the sections by one of the pivots.

620,628. Apparatus for Controlling Operation of Motors. Clinton E. Woods, Chicago, Ill. Application filed February 12, 1898.

The controller is designed for varying the condition of a circuit, including a motor with a brake for engaging and checking the motion of a portion driven by the motor, operating mechanism for actuating the brake and controller, the controller being adapted to open or render ineffective the circuit through the motor, the operating mechanism being adapted, after having actuated the controller, to open or render ineffective the circuit through the motor, to disengage itself from the controller and in its further operation to apply the brake, and means for locking the controller in the position it occupies when the motor runs, it is opened or rendered ineffective thereby.

620,627. Process of and Apparatus for Reducing and Oxidizing Salts. Theodore A. Uehling, Cleveland, O. Application filed August 10, 1896.

An electrolytic cell is divided into compartments by means of a partition, having an oxidizable salt in one of the compartments, a reducible salt in the other compartments, and electrodes projecting into or exposed in the compartments, the partition being built up or composed of a substance or material or materials obscuring communication between the electrolyte in the different compartments, but incapable of absorbing and transferring any other element than hydrogen liberated in one of the compartments, and permitting the element to pass therefrom under the influence of an electric current obtaining between the electrodes.

620,715. Connector for Electrical Conductors. Peter Minich, Independence, Mo. Application filed December 5, 1898.

As a new article of manufacture a fish-plate for track rails having a longitudinal groove therein and a recess communicating with the groove, and having its sides extending below the line of the groove in oppositely curved lines adapted to facilitate the unfolding of an extensible folding conductor of electricity, and an extension upon the opposite side of the fish-plate to that having the recess.

620,733. Telephone System. Charles L. Boyce, Detroit, Mich. Application filed April 29, 1898.

A derived signaling circuit is obtained by the combination with a metallic circuit telephone line normally disconnected from earth at subscriber's station, of an inductive resistance permanently bridged across the two wires of the metallic circuit at the subscriber's station, a telephone repeating coil permanently connected to the terminals of the metallic circuit at the central office, a line-signaling relay permanently connected to the neutral point of the line helix of the repeating coil, a source of electricity connected to earth, and means for connecting the neutral point of the inductive resistance at subscriber's station to earth, whereby line-signaling relay will be actuated.

No. 620,746.

620,745. Telephone Central-office Circuit. Henry M. Crane, Boston, Mass. Application filed October 31, 1898.

Claim is made for the combination in a multiple switchboard system, with a grounded test conductor uniting the test pieces of the switch sockets of a telephone line and a cut-off relay contained in the circuit thereof, of a normally disconnected source of test current, a main conductor including a resistance device extending therefrom, a normally discontinuous branch thereof including a signal-controlling relay, and switching devices adapted when operated to close the circuit of the source through the cut-off relay and signal-controlling relay in parallel branches, and to establish a testing potential upon the test pieces of the switch-sockets.

620,746. Means for Impressing Semicycles of Electromotive Force on Electric Circuits. Albert C. Crehore, Hanover, N. H., and George O. Squier, U. S. Army. Application filed January 4, 1899.

Telegraph transmitting apparatus is provided in connection with an alternating generator producing two alternating electromotive forces of the same periodicity and circuit-interrupting devices adapted to make and break circuit at instants when the current flow is actually zero and to impress the electromotive forces on the circuit so as to cause semicycles of current to flow in the desired order or relation and those in immediate succession to be of the same or opposite sign as desired.

620,759. Electric Arc Lamp. Charles Eschwei, New York, N. Y. Application filed February 3, 1898.

The lamp combines a solenoid, a magnetic core in the solenoid having a circumferential flange at its lower end, a lamp frame with parallel suspension rods, a cross piece sliding on the rods and being insulated therefrom, an upper carbon attached to the cross piece, a plate at the lower end of the suspension rods, a clutch provided with a tapering opening and resting at one side on the top plate, and a connecting rod pivoted at one side of the clutch and connected at its upper end with the circumferential flange of the solenoid core.

No. 620,755.

620,778. Transmitter for Multiple Telegraphs. Walter A. Houghtaling, New York, N. Y. Application filed December 22, 1898.

The combination is claimed in a telegraph transmitter of a movable contact, a pair of fixed contacts, suitable electrical connections for the contact with the main line and with a source of electricity respectively, a polarized magnet for controlling the movable contact having two coil windings, a source of electricity, separate branch conductors connected to the source and to the coils, respectively, to produce opposing magnetic effects, and a circuit breaker in one of the branches.

620,783. Electrical Regulator. William H. K. King, Carthage, Mo. Application filed September 20, 1898.

Receiving posts are connected with a suitable source of electricity; a vibrating arm has spring contacts extending between the contact points on the receiving posts; a delivery post is connected with each of the contact springs, and a clock mechanism is connected with and vibrating the arm and springs, whereby they may receive an automatic movement for alternating the current through the delivery posts.

620,806. Electric Train-signaling System. Benjamin C. Seaton, St. Louis, Mo. Application filed February 28, 1898.

An electric train-signaling system comprising the single-track rails having overlapping insulated sections and broken insulated joints, an auxiliary circuit rail and a signal station having for each side of the signal station a switchboard provided with circuit-closing switches for the several sections, a bell or annunciator, a circuit-closing key for communicating a signal from the signal station to a train, a switch for throwing the bell or annunciator in or out of circuit, and a connecting bar common to all the circuit-closing switches, whereby the latter are connected with the bell or annunciator.

620,839. Electric Switch. Walter B. Bernardini, Lakewood, and William Ely, Providence, R. I. Application filed August 11, 1896. Renewed October 6, 1898.

No. 620,759.

This switch has contact posts arranged in pairs or series, and knives or arms carried by a rotatable shaft for connecting the posts in pairs or series, and also having a stationary guideway combined with the parts, an arm pivoted upon the shaft and capable of partial rotation thereon without reference to the movement thereof, a crosshead capable of reciprocating movement in the guideway, a link pivoted to the arm and crosshead and connecting the two, an actuating lever pivoted independently of the shaft and arm, and adapted for engagement with the arm, and an extensible spring connecting the lever and crosshead.

620,852. Electric Railway. James F. Munsie, New York, N. Y. Application filed October 25, 1898.

A contact box for an electric-railway system is provided with two independent circuit-closers actuated at different positions of a traveling car and co-operating with a collector on the car adapted to hold both circuit-closers closed during transit of the car, and connections between a contact point or space in the track and an insulated supply conductor normally open at two points in the box, the points adapted to be closed by the joint operation of the two circuit-closers.

620,855. Thermo-chemical Electric Battery. Melvin L. Severy, Boston, Mass. Application filed April 8, 1895.

There are two electrodes of a material which is chemically inert to the liquids in the cell, and a conducting liquid in contact with each electrode, one of the liquids being a depolarizer. Means are provided for separating the liquids while maintaining the circuit.

620,864. Electric Clock. Joseph Butcher, Melrose, Mass. Application filed September 22, 1897.

One claim is given: In a clock the combination with a bell, its hammer and a rock-shaft to which the hammer is attached, of an electromagnet, its armature carried by said rock-shaft, a normally open electric circuit including a generator and said electromagnet, said circuit having terminals adjacent to the path of some part of the pendulum of the clock, the said pendulum, a movable interposing piece adapted to be moved into the space between the pendulum and one of said terminals, whereby the pendulum is caused to close the said circuit at each of its vibrations, means for regulating the number of strokes of the bell and means independent of the pendulum for operating the said interposing piece.

Western Electrician

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, MARCH 25, 1899.

No. 12

Chester D. Crandall.

Among the men who have contributed to the upbuilding of the electrical industry and assisted in placing it upon a solid commercial basis, Mr. Chester D. Crandall, the manager of the Western Electric company of Chicago, must be recognized as having played an important part. Mr. Crandall has been associated with electrical enterprises for 20 years, comprising his entire business career, and he has witnessed the growth of the industry from a very small beginning to its present leading position. His experience has been entirely with the financial, manufacturing and operating branches, and he has never attempted to engage in technical work, although through his associations and education he has cultivated a naturally keen interest in the scientific developments that have been made in this field.

Mr. Crandall is still a young man. He was born at Sacket's Harbor, Jefferson County, New York, on January 28, 1855, and received his education at the University of Rochester, from which he was graduated in 1879. From a study of the classics Mr. Crandall turned to the exacting duties of commercial life, and while he did not entirely dismiss the subjects which had occupied his early years, he reserved them for his hours of recreation and did not permit them to interfere with the more serious duties which he had assumed.

Upon completing his college course Mr. Crandall came to Chicago and entered the offices of the Western Electric company as a clerk. At that time, July, 1879, the concern occupied a comparatively small place on Kinzie street, and employed about 300 persons in the offices and factory combined—a large force for an electrical manufacturing company. For a year and a half Mr. Crandall was thus occupied in clerical duties, and in that time he had gained a good general knowledge of the business, and what was more to his benefit and credit, the confidence of his employers. He was sent to New York for a year and at the expiration of that time he was transferred to Indianapolis and made secretary of the Gilliland Electrical Manufacturing company, which had been purchased by the Western Electric company. The old corporation was continued until its affairs could be advantageously closed up, and during this period Mr. Crandall remained in Indianapolis as an officer of the company, representing the Western Electric company.

In 1882 the telephone-exchange business offered unusual inducements, and Mr. Crandall, whose familiarity with the manufacturing end of the industry and personal acquaintance among the leading telephone men of the country gave him excellent opportunities to study this field, determined to take advantage of the opening thus afforded. Accordingly, he organized the Missouri and Kansas Telephone company and opened an exchange at Kansas City, Mo. He was secretary and treasurer of the company, and under his immediate direction the business developed into a profitable enterprise. He remained in Kansas City for seven years and then returned to Chicago to re-enter the service of the Western Electric company, having resigned his position with the Missouri and Kansas Telephone Company.

He was appointed assistant treasurer of the Western Electric company in 1889 and was occupied with the financial affairs of the institution for several years. During Mr. Jackson's illness, and from the time of his death to the appointment of a new treasurer, Mr. Crandall was in charge of this important department. For a large portion of that time he had charge of the selling department as well, having been appointed manager upon the retirement of Mr. C. A. Brown. Mr. Crandall now devotes his entire attention to the management of the business of the Chicago end of this great institution.

Mr. Crandall is identified with several enterprises engaged in the development and application of electricity in various branches, the most important of which is an electric power-transmission undertaking in Mexico. This project is known as the Portezuelo Light and Power Company, an American corporation formed under the laws of Illinois. Mr. Crandall is president of this company, and he has given it considerable attention. A valuable water power is controlled by the company, and it will transmit current to Puebla, where it will be used in driving motors in the fac-

ories of that city. The initial installation will have 2,000 horse power capacity, which will be increased to 5,000 horse power. The company easily disposed of the 2,000 horse power before work was begun on the plant.

In private life Mr. Crandall has developed traits that have contributed to his success in his commercial enterprises. Straightforward, earnest, affable and considerate, he commands the esteem and respect of his personal friends as well as the confidence of his business associates.

Mr. Crandall is a member of the Union League club of Chicago and an associate member of the American Institute of Electrical Engineers.

Growth of the Electric-vehicle Industry.

If the New York newspapers are correctly informed, the electric-vehicle companies in New York are making their plans on a magnificent scale. The

CHESTER D. CRANDALL.

New York Electric Vehicle Transportation company, which was organized recently, and took over the 100 cabs of its predecessor, has ordered 200 more, and, it is said, expects to use an additional 1,500 before long. It is asserted also that the parent corporation, the Electric Vehicle company, will order 12,000 cabs this year. There is a question, however, whether the manufacturers can supply that number. Power to charge the electric cabs, it is stated, will be obtained from the plant of the Metropolitan Street Railway company, and it has been proposed to arrange a transfer system with that company, and possibly also with the elevated railway company, by means of which, at a charge, say, of 15 cents, patrons would be carried from their homes on the side streets to the railroad lines, where transfers would be given.

The Buffalo Automobile company is to be incorporated with a capital stock of \$100,000, and through the company an automobile-cab service will be established in the city of Buffalo. Its plan of operation will be similar to that of the New York Electric Vehicle Transportation company, but, in addition, the company will establish a line of automobile busses along West Side thoroughfares not now reached by the street cars. The promoters of the new company are said to be Dr. Truman J. Martin and Jewett M. Richmond of Buffalo.

Electrical Trade Conditions in New South Wales.

(Prepared for the WESTERN ELECTRICIAN by the Philadelphia Commercial Museum.)

There is a good opening for electrical material of every description in Sydney, New South Wales. Electric fans for ventilating purposes, for instance, have been favorably received in Sydney. They are used to a certain extent, and are very highly thought of by the users. Their use, however, has been very much limited, owing entirely to the fact that there are very few large electric supply stations. The majority of those are alternating current, and until recently there has not been a satisfactory small motor offered for this class of work.

In Sydney the Municipal Council holds the rights of electric supply and has taken no steps to erect a central station. Further, the council has declined to grant franchises to any person or company. The result is that the supply of electricity is carried out from small "block" stations, each with a very limited area of supply. Under such conditions the use of fans and electrical conveniences is necessarily very limited. The motor and fan in most general use is the Lundell, manufactured by the Sprague Electric company.

The situation is, however, bound to be changed, and with it will come more rapid electrical development, for which American manufacturers should be prepared. So far Americans have had but little to say in this market. England and Germany have been the source of supply. Out of a total of \$51,255 worth of electrical machinery imported in 1897 the United States contributed only \$1,935 worth, while \$40,025 worth was supplied by England; and out of \$384,290 worth of "electrical, telephone and telegraph materials" imported during the same year, the United States furnished only \$16,135 worth, while \$233,675 came from England and \$58,265 from Germany.

Electric lighting is in the background. The illuminating industry is represented by 30 gas-works, in which is invested \$3,150,000, while the electric installations number less than 30, with a horse power capacity of less than 3,000, of which not 2,000 is used; the invested capital is about \$500,000. An estimate of the extent to which business in the supply of electric materials of all kinds will be developed may be gauged by the fact that the colony possesses 2,027 churches, 3,467 schools, 93 hospitals, 43 places of public amusement, and over 3,000 manufacturing establishments.

Rapid transit in Sydney has been for years accomplished by means of able-bodied locomotives hauling double-deck open or closed cars over some of the principal streets, emitting from their smokestacks the dense, black, sulphurous smoke yielded so plentifully by the Newcastle coal. A few years ago the steam roads were supplemented by underground cable roads, and now both of these systems

are being superseded by the electric system. In fact, the electric traction system may now be said to be fairly started in Sydney, which means that it will ultimately find its way to the other towns, and in time furnish what the colony has so long badly needed, rapid and cheap means of transportation between points in the "Bush," as the country districts are called.

The local authorities would only agree at first to the substitution of the electric system on the George street line, but after the work had been begun they decided to regard the line no longer as an experiment, but as part of a permanent scheme of converting the steam roads into electrical lines, which, they became at length fully convinced, would furnish the most convenient system of traction for the city and suburbs. A power house was therefore built at Ultimo, several miles out from the city, and machinery ordered from the United States. At the last Sydney advices (January 14th) this had nearly all arrived, and the work was being forwarded expeditiously. When the conversion scheme is completed the city will be served by three lines, in addition to a cross-line in King street, and the Ultimo power house will have not alone to supply these lines, but to furnish electric energy for the North Sydney, Mosman and Willoughby systems, and a new line to Gore Hill, which is about to be built.

The cable from Wilson's Point to Ridge street is to be taken up and the whole system worked by electricity, and it is expected that in the near future Sydney will be able to lay claim to as extensive and perfect an electric system of traction as any city in the world. The fare in certain prescribed sections of the city will be two cents.

There is no reason why American makers should not enjoy their proper share of the Australian trade. On the contrary, there is every reason why they should. They have the advantage of a lower freight than their English competitors, and they can more than meet them in the quality, finish, serviceability and price of their goods. Machinery and mechanical appliances are admitted free of duty into New South Wales.

There has long been a supposition that because New South Wales, Queensland and the other Australian colonies were British dependencies, their traders would give preference to the mother country over other nations. In a recent speech the president of the Chamber of Commerce of Brisbane made it clear that this was not so. "For centuries," he says, "England has been the great 'clearing house' of the import and export trade of her possessions, but there is no imperative reason why we should continue to buy from her goods that she does not manufacture, nor sell to her produce she does use, if we can ourselves find a better market elsewhere. In looking out for such a market we are only following her own teachings of unrestricted and untrammelled trade. And, further, if the English manufacturers refuse to adapt themselves to our requirements, while those of other countries give a ready compliance to our wishes, it is only natural that our trade should follow in their direction."

The best way for an American maker of electrical material and supplies to enter the New South Wales market would be by opening up an agency in Sydney and establishing there a competent salesman who could make periodical trips through the adjacent territory to work up business. It is conceded that foreign houses in the colonies carrying stocks of goods have a distinct advantage over their competitors that do not. If it is not feasible to establish an agency in this way, there are many reliable importers of electrical machinery and appliances in Sydney who would be very glad to undertake American business. It may be proper to mention that the names of these, their standing, etc., is on file in the information bureau of the Philadelphia Commercial Museum, through which can also be obtained precise data as to selling terms, freight rates, packing, etc.

Gorge Road at Niagara Falls.

The great and famous Gorge road at Niagara is now in the hands of a receiver, and its future is quite uncertain. For some weeks the cars of the line have not been in operation, and it is reported that the road is likely to become the property of the New York Central Railroad company. Another report states that it will become a part of the holdings of the International Traction company, which is the name announced for the \$25,000,000 syndicate that has purchased the Niagara and Buffalo electric roads.

The trip through the Niagara gorge on this road is one of the most delightful imaginable, but a profitable business is possible only for a few months in the year in the summer season when visitors at the Falls are numerous. However, before the line is again operated it will require a large amount of repair work, and quite an outlay will be necessary to clear the tracks of the debris that has come down from the cliffs during the winter months. In some places the tracks are almost entirely covered with rock, while in other places huge boulders block the path of the cars. Considerable ballasting will have to be done, and in some places cribwork will have to be built. Located as the road is along the water's edge, it forms a resting place for the ice and rocks that tumble down from the cliff in the early spring, and unless this matter is promptly removed it soon gathers in goodly quantities. In the summer, when the dry season prevails, this trouble is not experienced, and the trip is full of pleasure and practically free from danger.

Reported Expansion of the Westinghouse Interests.

It is reported that an important addition to the number of Westinghouse companies is about to be made. The new company will be a European concern, it is said, and it is the gossip of electrical circles in Chicago that Mr. Maurice Coster, at present Chicago manager of the Westinghouse Electric and Manufacturing company, will soon form a new connection, and that his headquarters will hereafter be in Paris. If this prove to be true, Mr. Coster's friends will extend very hearty congratulations, as the advancement is a flattering recognition of his cosmopolitan ability as a manager of electrical sales.

The San Gabriel Electric Power company has applied to the council of Santa Ana, Cal., for franchise to put in a large electric-lighting and power plant in that city. It is claimed that this is the first step toward establishing a line for light and power to all towns from San Gabriel to San Diego, including Whittier, Buena Park, Fullerton, Anaheim, Orange, Santa Ana, Tustin, Oceanside and San Diego.

Trend of Central-station Design.¹

By B. J. ARNOLD.

It is only a little over a decade since the electrical student was told by those who were supposed to be authority that to get a reasonable efficiency in electrical machinery high rotative speed in the moving parts was necessary. While this statement contains an element of truth, it is by no means so important as at first supposed, for our slow-speed generators and motors of to-day are more efficient than many of the high-speed machines of that time. Difficulties in the manufacture of heavy electrical machinery and lack of knowledge on the part of the designers of that time were probably responsible for the false idea; but, be that as it may, the result was to flood the country with electrical plants, consisting of engines, dynamos, pulley shafting and belts, good, bad and indifferent, and thrown together in almost any manner. These, however, performed their functions remarkably well under the circumstances, and enabled the youngest branch of the engineering industry to command the brains, energy and capital necessary to revolutionize the transportation and factory methods of our cities and make itself felt in many of the homes of our smaller cities and towns. But since Darwin's law of "the survival of the fittest" applies equally in engineering and in natural history, the belts and pulleys are gradually becoming extinct; the engines and generators have left off their prehistoric ear-marks and have grown to their responsibilities and to the possession of those elements which make them the bulwarks of electrical industries, the

which simply speaks well for the engineers and designers, and more especially the manufacturing companies who installed them in the earlier days, because at that time there were few engineers skilled in this branch of work, except those employed by the manufacturers.

The points in accepted practice may thus be summarized:

Water-tube boilers, capable of carrying high steam pressures. This probably will be disputed somewhat by the advocates of other types of boilers, and with some reason, but it nevertheless has become almost standard to use water-tube boilers in modern central stations.

Mechanical stokers, or improved furnaces or grates.

Self-supporting brick or steel stacks, usually steel. A steel stack can be put up for considerably less money than a brick stack, and for all practical purposes it is equally as good, and can be maintained a sufficient number of years to warrant its adoption in almost every case, if properly looked after.

High-pressure steam piping is not duplicated, as was thought necessary by engineers eight or ten years ago, practice having proven that one single steam header can be divided so as to make a plant reliable if the engines are properly located with reference to the boilers and the header. I planned one plant in 1891 with a duplicate system of steam piping, and I firmly believed in it at that time, but have never since had occasion to use the duplicate system, and have never since installed one. I think there are few engineers in the country to-day putting in plants with duplicate systems of piping, unless in buildings

GORGE ROAD AT NIAGARA FALLS.—CONDITION OF TRACKS IN SPRING.

same as the older types of steam engines were to the factories which they drove prior to the advent of electrical transmission. To determine how far this development has gone and its probable tendency in the future is the subject assigned me by your committee to discuss to-day.

The problem which confronts the power-station designer is almost invariably that of the operation of arc lamps, incandescent lamps and motors for various purposes, with the greatest degree of economy, and with as little expenditure in first cost of plant as possible. This is strictly true of combined lighting and power stations, which present the most difficult cases to handle. When, however, the problem is simply one of the development of electrical energy for power purposes only, such as railway work or transmission work, it becomes much simplified. Since the question of the design of a station is interlinked with and dependent upon the system of distribution adopted, we find ourselves struggling with many of the old questions and some new ones, such as the alternating arc versus the series arc and the constant-potential arc, the polyphase transmission plant versus the direct current, the advisable voltage, either alternating or direct, to adopt for central-station work.

While I do not in this paper presume to settle these questions, I will endeavor to convey some idea of their probable solution for general cases; otherwise we can hardly expect to speculate on the "Trend of Central-station Design." The old belted station we may consider obsolete, and come at once to the general types which have been recently installed by competent engineers, and which may be considered as embodying the latest ideas of those skilled in this class of work. In all of these stations we find certain main parts which may be considered as accepted practice. Of course, there are many belted stations running and doing excellent service.

¹ Address before the Northwestern Electrical Association at Milwaukee, January 18, 1899.

where it seems necessary to do it, and on account of the peculiar location of the engines with reference to the boilers. Steam piping costs excessively in a power station, and the less of it put in the better, because there is then less radiating surface to waste heat and fewer parts to keep up. The diameters of the steam heaters which are being placed nowadays are somewhat decreased, as compared with those installed four or five years ago.

Large compound condensing steam units. It has become accepted practice to install as large engines as practical, on account of the decreased cost per horse power and the increased economy of a large engine over a small one. They are almost invariably compound engines, where it is possible to condense, and in many cases whether it is possible to condense or not. The tendency toward triple-expansion work is not as strong as it was five years ago. It has been determined that for almost all cases a compound engine will get nearly as good economy as a triple-expansion engine, and in many cases just as good; it requires less investment, is less costly to maintain, and the difference in economy of the triple-expansion over the compound is so slight that it makes it inadvisable to install, except in exceptionally large sizes. On account of the excessive diameters of the low-pressure steam cylinders in large compound engines it is the practice to install triple-cylinder compound engines; that is, to divide the low-pressure cylinder into two smaller cylinders, the combined area of the two being equal to the area of the large cylinder of a single compound engine.

Direct-connected generators of large capacity. What has been said in general regarding large steam units applies equally to electrical generators, because the larger the unit the greater the economy of the combined unit.

To these chief features of design, which have become so generally accepted as to require little or no discussion, there may be added several features which

may be justly called "tendencies" or "trends," which have not yet been universally adopted.

Economizers come under the first heading. Economizers, as you are aware, consist of a series of vertical cast-iron tubes carrying water within them, and around the outside of which the gases pass from the boilers to the smokestack. There is no doubt, in my judgment, but that there is economy in the use of an economizer, ranging from five to seven or eight and sometimes as high as 10 per cent. In order to get the benefit of an economizer, ample draft must be provided. Sometimes an economizer is installed where the draft is poor, the result being no economy and the annihilation of the draft. There is only one solution for this, and that is to increase the height of the stack or introduce mechanical draft to realize the benefits of the economizer.

Mechanical draft. Under this head there are two types, induced draft and forced draft. Induced draft is a device which consists of a large fan or fans, driven by steam engines or electric motors, which are placed between the economizers and the smokestack, or, if economizers are not used, between the boiler flues and the smokestack, the object being to draw or suck the smoke from the boilers through the fan and deliver it into the stack. The advantages of the induced-draft scheme are, first, a lower and less expensive stack can be used; in fact, no stack at all is required except to get the gases above the buildings in the immediate neighborhood of the property; and, secondly, the fires can be handled under any and all conditions. We are all aware that the condition of the atmosphere changes our draft, and in case a stack is no larger than is required, there

of the evaporation. The five per cent, must be added from the city waterworks, or other outside source.

In place of the cooling tower, where real estate is cheap and available, a table can be erected, consisting of a series of boards laid gridiron-shape, upon which the water is delivered by the condenser pumps and is sprinkled down through the boards, and the air from the atmosphere penetrating through underneath the shelves comes in contact with the hot water and cools it. It then forms a pool at the base of the shelves and is taken from there and pumped back in contact with the steam in the same manner as in the cooling tower. This device can be installed for the same, or less, amount than a cooling tower, and it is advisable to install it where there is sufficient real estate to place it upon, because it requires no power to cool the water, and power is required to drive the fan of a cooling tower.

Motor-driven auxiliaries. Many of the most modern plants are equipped with electrically driven air pumps, boiler-feed pumps and cooling-tower motors, if tower is used. There is a question as to whether this is the most economical thing to do or not. Some believe it to be so. Others maintain that the latent heat derived from the exhaust from the steam cylinders of the steam-driven auxiliaries, if run through a surface or closed heater, more than compensates for the wasteful use of the steam by these steam pumps. I incline toward the belief that there is economy in the use of electrically driven auxiliaries, on account of the non-wasting of heat by pipe radiation, if for no other reason, because the primary objects to be obtained in a power station are to generate the steam with as little fuel as possible, lead

quite extensively in Europe, but not in this country. It consists simply of a commutator revolved by an independent source of power, a small steam engine or motor, belted or directly connected. This commutator will take in alternating current on one side and deliver one, two or three-phase current on the other, accomplishing the same result as a rotary converter, without the use of the field coils or any revolving portion except commutators; and it seems to me that we are somewhat behind in not looking into it more thoroughly in this country, for it certainly can be manufactured for less money than the rotary converter. This is mentioned merely as a tendency in transmission work. The efficiency of it is about 97 per cent.

We now come to what is at present known as the combination generator, which wants a name, and the man who can successfully name it and have his suggestion generally adopted, will, in a sense, become electrically immortal. It consists of a machine having two commutators and capable of generating current at two voltages. It may be direct current on each end or alternating current on one end and direct on the other, but, in either case, it is a machine deriving its power from an external source in contradistinction to a rotary converter, which revolves itself by means of the current passing through it. These machines are coming into use for railway work, telegraphy and printing-office work. They seem to be the connecting link between the alternating and direct-current apparatus. A power station installed with such machines is capable of generating polyphase currents and transmitting such current by means of static transformer to a long distance at a high potential, then running through rotary converters and delivering out on the line direct current, thus enabling us to utilize our direct-current motors which are already installed. The efficiency of such a machine is from 92 to 98 per cent., dependent upon its size.

Boosters. Under this head there are two, rotary and static. The rotary booster is a machine consisting of two dynamo-electric machines, one of which is a motor, which may be either alternating or direct current, directly coupled or belted to a generator, either alternating or direct-current or arc. This machine is used mainly at the present time for use on long-distance feeders in railway and central-station work. The generator end of the machine is series-wound, and through it passes all the current which goes through the feeder to which it is attached. It is a low-voltage machine, and increases the voltage on the feeder to which it is attached a sufficient amount to enable current to be delivered at the end of a long feeder at the same pressure that is delivered at the ends of shorter feeders connected with the system. In other words, it is a device to save copper. But when it is used the line loss is increased. However, under conditions where, for short periods of the day, the load is heavy, it pays to do this instead of adding the requisite amount of copper. It is adopted in a number of the Edison central stations of the country at the present time and in some railroad plants. It is also largely used in stations operating storage batteries for increasing the potential when charging. The efficiency of such a machine is from 80 to 85 per cent.

A static booster is practically a transformer, and is intended to help upon the long feeders of alternating systems. It performs the same function that the rotary booster does, by raising the pressure of the long feeder to a higher potential, so as to make the current delivered of the proper potential. It has an efficiency of 90 to 97 per cent.

Storage-battery auxiliary. The advantages of this feature have been so thoroughly discussed of late that it will be unnecessary for me to enter further into a discussion of its merits. While some engineers are not yet ready to consider its use established practice, its adoption by many of the leading direct-current stations of this country should prove its usefulness. I say this impartially, because I have no connection with any battery interests at the present time, although I have had until recently.

There is one type of machine whose future has not as yet been determined, and perhaps no man can at present safely foretell its future, but there seems to be a demand for it. I refer to the multi-current arc dynamo. There is such a machine made to deliver current for four circuits of about 100 lights each, and if the series are to survive, this type, made to deliver current for five to 100-light circuits, will be the arc machine of the future, and it will revolve at the same rate of speed as our present direct connected incandescent or alternating machines do, because we must eliminate belts. I am speaking of large stations, and I believe that if the series are to survive it will be driven by large machines with slow rotative speeds. Such a machine will probably not have an efficiency greater than from 80 to 82 per cent., and that is what militates against it, the same as the low efficiency of the present series-arc machine does.

Having thus enumerated somewhat briefly the principal factors which are working to shape the design of the future central station, I will briefly describe two types of stations which have lately been built, and seem to represent the latest practice.

1. The composite station, consisting of two or more independent steam units, carrying upon the engine shaft a direct-connected generator suitable for giving light or power, and, in addition, a pulley or

GORGE ROAD AT NIAGARA FALLS —SAND AND BROKEN STONE WASHED DOWN DURING WINTER.

are days when it is difficult to hold steam, and it becomes necessary to put more boilers into service than would be necessary if a mechanical-draft fan were used. Where the economizers can be installed in connection with induced draft an economy is always effected.

Then there is the forced draft, which consists in blowing air under the grates of the boiler and forcing it up through the fire and into the stack, which is supposed to perform the same function that the induced draft does. The objections to it are that inasmuch as it creates pressure in the firebox, the gases are liable to escape out into the room and make a distasteful fireroom. Otherwise, the results accomplished are practically the same as with induced draft, and it is considerably less expensive to install, and this is its chief advantage.

Cooling devices. Under this head come cooling towers and cooling tables. In most plants in this country there are probably no facilities or natural opportunities for getting water for condensing purposes, and, until recently, we have thought it was advisable to continue to operate these plants non-condensing. During the last two years there has been a tendency to put in these cooling towers, and when properly put in there is always an economy effected, resulting in a net saving of at least 15 per cent. in fuel. A tower consists of a series of vertical tubes or sheets, usually within a wrought-iron frame, through which air is forced by blowers, driven by steam engines or electric motors, and down through which flows, or sprinkles, or is spread, the water delivered from the condensers. The water coming in contact with the air is cooled and accumulates at the bottom of the tower, and is then pumped into contact with the steam and condenses it. The same water is used over and over, so that only from five to 10 per cent. will have to be renewed on account

it as direct as possible to the steam cylinders where it is to do its work, and exhaust it into the vacuum as quickly, with as little pipe to radiate heat as possible; and electrically driven auxiliaries seem to me to accomplish this result better than any other.

The rotary converter is a machine for converting from one form of current to another, or from one pressure to another pressure of the same form of current. A machine for converting alternating to direct current or vice versa, consists of a single armature revolving in one field, carrying two commutators, one direct on one side, and three-phase, two-phase or single-phase rings on the other, being capable of taking alternating current into the phase or ring side and delivering direct current on the other or commutator side.

These devices are coming rapidly into use for transmission work. A number of the most modern railroads in Europe and in this country have been equipped in this way during the last year, and with excellent results. There is one road where this device has been put in under my own supervision, which has been operating satisfactorily since the first of last July, transmitting three-phase at 5,500 volts and then converting it to direct current and delivering it out on the line of 600 volts. In most cases 95 to 97 per cent. efficiency may be depended upon, if the machine is reasonably large and operated at full load.

Under this head may be classified the synchronous motor driving series-arc machines. One type of modern central station is utilizing its old series-arc machines for supplying other circuits by driving them with synchronous motors, in case it is an alternating plant. This makes a very good combination and eliminates belts entirely from the station. The efficiency of such combined synchronous motor with arc machine is seldom more than 72 to 75 per cent.

One device, known as a rectifier, has been used

flywheel carrying a belt or rope driving a common shaft, to which the other engines similarly drive, and from which small direct-current arc machines or other old-style machines derive their power. This type is admirably adapted for utilizing out-of-date machinery. There have been several large plants of this style installed in the last two or three years by a leading firm of engineers, and the stations, I under-

stand, are giving excellent satisfaction. I refer particularly to the stations at Toledo and Washington, and the solutions of the particular conditions of those cases seem happy ones, because they enable the owners of the properties to utilize all of their old machinery until such times as it may be deemed advisable to change.

current can be obtained from such a plant by making all of the generating units alike, so far as kind of current is concerned, and driving secondary generators by means of motors running from the main generators. This means is often adopted in rebuilding old plants for driving the old series-arc machines, which are directly coupled to an alternating or direct-current motor, driven from the main bus-bars.

advantage of you, I will refrain from discussing the merits or demerits of this system. It is claimed by its advocates to have certain advantages.

The PRESIDENT: We would like to have you explain the system.

Mr. ARNOLD: Gentlemen, I am really sincere in my position.

Mr. NORCROSS: Well, you have gone too far to retreat now. (Laughter.)

Mr. ARNOLD: I thought that possibly, if you cared to know about it, the matter could be brought out in the discussion, but I prefer to refrain from making further reference to the system in my address. I have no desire to advertise it under such circumstances, and wish to present the subject of my paper as impartially as possible.

In conclusion, we all know that our ideal central station will be designed when we have secured an electric generator capable of producing energy for universal use, and the necessary auxiliaries in the way of motors and lights to satisfactorily use this energy for all purposes, when distance is taken into account. Our expectations and our hopes point toward the alternating machine, but before we can accept it as our ameliorator we must ask its advocates to produce a motor which will start and operate successfully on variable loads without seriously affecting the balance of the plant, and of producing a given amount of light with the same energy and cleanliness that is now provided by means of the direct-current arc and incandescent lamp.

I, personally, lean toward the alternating system, but if we are frank with ourselves we must admit that while the promoters of the alternating system have made very rapid strides in the last five years in the perfection of their machinery, and have overcome difficulties which five years ago seemed insurmountable, there are certain elements which they have not overcome, and which we hope they will overcome; but the chief difficulty of the present time is in getting an alternating motor which can be used on such work as printing-press work, which is exacting in the extreme, and upon electric-elevator work, which is one of the chief sources of revenue for central-station plants, especially in large cities, and also an arc lamp which will run upon practically the same energy as a direct series-arc lamp. The alternating arc lamp of to-day has been greatly perfected, and is almost perfect so far as the quality of light is concerned and absence of noise. It, however, has a slight deposit of ashes in the globe, which requires it to be cleaned oftener than the direct-current lamp, and absorbs or consumes somewhat more energy than the other type of arc lamp, and while it is to be hoped that these objections will be removed, and they probably will be, we have not yet reached the point where we can place them exactly on a par with the other type of lamps.

I believe that the connecting link between the present direct-current station and the future alternating-central station lies in what I have mentioned before, in the combination generator. We can install machines to-day which will produce both direct current and alternating current and which will drive our present direct-current motors satisfactorily, until the time comes when the alternating motor is perfected. Then, by simply taking off the commutators of the same machines, you can convert them immediately to do alternating work, without any additional expense. I believe that the central stations of the present, and for several years to come, will be designed on these lines and with combination machines.

DISCUSSION.

Mr. LIVERMORE: I would like to hear Mr. Arnold tell us a little more about his system. I never fully understood it. If he would explain it more fully we would all feel highly gratified.

Mr. ARNOLD: I want to express my appreciation of the invitation, but I was thoroughly sincere in my position of not desiring to take advantage of you under these circumstances, because if the system has any merit to it, it will probably come out of its own accord. The scheme is, in general, this: It is a direct-connected system throughout. There are no belts used. There has recently been a plant installed under this system of 5,000 kilowatts ultimate capacity, 1,500 of which is now running, and I will describe it, and from the description you may get an idea of what the system is. One engine is installed with a shaft terminating in a flange. Then sufficient room is left for two generators, and then another engine is installed, having a flange on each end of its shaft to which to connect generators. Between the two engines are placed two generators having their shafts in line with the engine shafts. These generators are mounted on hollow shafts or quills carried in their own bearings. Beginning at the end of one engine shaft and extending through the quills, but not touching them, to the other engine shaft is an auxiliary shaft carried in two bearings near its center. With this auxiliary shaft, which is independent of either engine or generator shaft, either one or both the generators between the engines can be connected to either engine when in motion or standing still. This interior shaft does not revolve under normal conditions, but lies idle to be taken up in an emergency, and under normal conditions you drive directly connected. You can add machines, generators and engines, in line, if you choose, and when you get another engine you have four generators available

[Continued on page 176.]

FIG. 2. ELECTRIC LIGHTING IN LONDON.

stand, are giving excellent satisfaction. I refer particularly to the stations at Toledo and Washington, and the solutions of the particular conditions of those cases seem happy ones, because they enable the owners of the properties to utilize all of their old machinery until such times as it may be deemed advisable to change.

2. The second consists of independent engines car-

While the stations I mentioned a few moments ago are good engineering, I believe this is better engineering; that is, to eliminate belts entirely, and if we have a number of different types of machines to drive, we had better produce our energy from standard machines of the same character and size, if possible; then drive the older type of high-speed machine, directly connected, from motors; and the effi-

FIG. 3. ELECTRIC LIGHTING IN LONDON.

rying direct-connected generators. This type is admirably adapted for plants where but one kind of current is delivered, but in case two kinds are required, it becomes necessary to have a generator of each type upon each engine shaft, or have double the number of reserve units that would be required if but one kind of current were desired from the plant. In either case the investment in plant becomes excessive to insure reliability. Two or more kinds of

ciency of the combined plant will, I believe, be better than where the belted type is used.

3. There is one other method of construction, which I will not class as accepted, but mention it as a tendency in power-station design, known as the "Arnold system." There have been several of these plants installed, in which the generators are carried on independent bearings and all made available from more than one engine, but as I do not wish to take

Electric Lighting in London.

The accompanying illustrations, which are reproduced from the London *Electrical Review*, show interesting features of the equipment of the City of London Electric Lighting company's works at Bankside on the south side of the Thames. A lofty building has been erected on the wharf, and is connected to the main building by a bridge placed at an elevation of 50 feet. A fleet of barges is employed to bring the coal alongside this wharf, and a complete equipment of hydraulic appliances is placed in the building capable of hoisting the coal and other materials to a capacious bunker and store room on the top of the building. On the ground floor the pumping machinery is placed, for the purpose of drawing water from the Thames for condensing purposes. Centrifugal pumps are employed, two being driven by steam engines; a smaller set is connected to electric motors.

The engine room occupies a long building having a gallery on each side, the dimensions being 430 feet long and 45 feet wide, and contains engines and dynamos of different sizes, numbering 30 sets, the largest being capable of giving an output of 1,500 kilowatts, about 2,500 indicated horse power. The output from these machines is controlled by two distinct main switchboards, placed on the controlling gallery, together with subsidiary switchboards for other purposes. These switchboards are constructed entirely of incombustible material. Three traveling cranes have been installed, each capable of handling 45 tons. These cranes are driven and the several movements controlled by electric motors. The steam gallery on the opposite side of the room provides every convenience for manipulating the steam valves to each engine and also the large valves in the main steam pipes. A feature of the arrangement of the water

As already intimated, the electrical equipment is a heterogeneous collection, containing almost every variety of electric generating plant—continuous-current, alternating-current, high-speed, low-speed, direct-coupled, belted, antiquated and modern. In the long main machinery hall, for example, are to be found eight Thomson-Houston generators direct-coupled to Willans engines; an equal number of open-type Brush engines direct-coupled to Brush alternators, some with the original Mordey coils on them, others with coils of the Ferranti type; while ranged alongside these are a number of direct-coupled exciter sets and steam-driven pump sets. In an adjoining machinery room is to be found a number of Thomson-Houston and Brush arc lighters, belt-driven by steam engines, and, in a smaller machinery room adjoining this, two small continuous-current plants, which have been recently put into operation. In still another machinery room at the farther end of the rambling pile of buildings, there will shortly be erected three large continuous-current direct-coupled plants for dealing with the motor load. The most important factor in the entire combination is the Ferranti apparatus recently installed, comprising two direct-coupled engine-dynamo units of 2,500 horse

pumps) through gearing, which reduces the speed of the vertical shaft to half that of the engine. There are two steam and two exhaust grid valves to each cylinder. The high-pressure steam valves are driven by the Ferranti trip gear, consisting of eccentrics on vertical shafts working a rocker arm which moves a gun-metal cross-head carrying engaging teeth, which strike into catch blocks on the valve spindle. When the rocker is in its two extreme positions, and moves the valve from its central position, it admits steam until disengaged by tripping piece working over a graduated wedge. The position of this wedge is controlled by a dead-weight governor, driven through gearing from the second-motion shaft. The valve, when moved from central position, compresses two springs on the farther end of the cylinder, which, when the releasing takes place, returns the valve to a central position, the blow being fended by a piston on the valve spindle working in an oil dash-pot. The low-pressure steam valves and both high-pressure and low-pressure exhaust valves are actuated by cams on a vertical shaft, which also produce a similar motion. The lubrication to the valve gear is by drip-feed boxes, filled from the main oil supply, the valve-gear boxes draining into the engine col-

FIG. 4. ELECTRIC LIGHTING IN LONDON.

service to feed the boilers enables the whole of the work to be performed from the gallery, entirely distinct from the ordinary work of the stokers.

The boiler house adjoins the engine room, and contains 33 large water-tube boilers, all fed by automatic stokers, which receive the fuel by chutes or tubes from the coal store overhead, containing about 2,000 tons of coal, all of which is transported from the wharf bunker by means of a long-chain coal conveyor, with broad links which push the coal along a trough. A similar conveyor removes the ashes from the boiler house and deposits them in a bucket elevator, which enables them to be deposited on the wharf for removal.

Other buildings contain machines for the arc lighting of the streets of the city and continuous current for motive-power supply.

The original plans of the company provided for two stations, but this idea was abandoned and one central-station plant decided upon, although the city is divided into two portions and the station equipment is likewise arranged into two distinct sections, one half of the station supplying one district of the city and the other half feeding the remainder. The machinery is also controlled from two separate boards, and the working arrangements are so distinct that while one section of the machinery is working at full load, due generally to a fog over a portion of the city, the other is doing practically nothing. A method of intercommunication between the two sections is maintained by means of interconnecting switches, so that a machine from one portion could be connected onto the other side of the works, or, when the necessity arises, such as at times of small demand, the two sections of the city can be supplied from either section of the works. There is no doubt that the conditions of supply are exceptionally difficult, owing, mainly, to the short space of time in which the city occasionally is enveloped in fog. With the exception of street lighting there is practically no summer load, yet even at the end of May, during a fog, the load has been known to rise within a few minutes from 1,400 kilowatts to 5,000 kilowatts.

FIG. 1. ELECTRIC LIGHTING IN LONDON.

power each. A view of one of these units is presented in Fig. 1.

The Ferranti steam engine is of the compound vertical type with high and low-pressure cylinders on opposite sides of the flywheel alternators. The diameters of the cylinders are 38 inches and 68 inches respectively, each with a 30-inch stroke, and the normal speed is 150 revolutions per minute. The cranks are overhung, there being no outside bearings. Thus the shaft of each set runs in two main spherical bearings, white-metalled, one carried on the high-pressure and the other on the low-pressure bedplates. The weight of the wheel, complete with shafts, disks, bolbins and bolts, is 60 tons, and is taken on two roller bearings hung on springs resting on brackets on bedplates. The over-all periphery of the armature is 20 feet. The wheel is cast in two halves with eight cast arms. The halves are held together by steel links shrunk on bosses cast on to the inside of the rim. The whole wheel is connected to its shaft by two steel rings shrunk on turned registers of the cast boss of the wheel. Throughout, forced lubrication is distributed from pressure tank to the bearings at a pressure of 50 pounds. The oil leaking cut falls into the center of the bedplate, where it is strained before passing into oil tanks under the bedplates. The valve gear is driven from a vertical shaft by a second motion shaft driven from the crank pin (which also drives valveless oscillating oil

um. The clearance spaces for steam are reduced to a minimum, being limited to the actual piston clearance, the valves admitting and exhausting direct onto the top or bottom of the piston. The pipes connecting the high-pressure and low-pressure cylinders form a low-pressure receiver.

The direct-coupled alternator is of the usual Ferranti non-inductive armature type. The armature consists of 80 Ferranti coils, made up in pairs and carried on ebonited bolts sulphured into pockets cast in the rim of the wheel, giving a very high insulation resistance. The two halves of the armature are in parallel. From the collector gear two concentric cables lead away to the switchboards, the outer of the concentric main again being connected to the low-pressure bedplate, and thus a complete earthing of all parts of the plant is insured. The field coils are of bare copper wound on edge, and the pole-pieces are capped with micaite caps molded on. The coils are magnetized from a separate exciter of 30 kilowatts, driven off a rope pulley mounted on the boss of the wheel from the high-pressure side. The switch gear is of the 500-ampere Ferranti single-pole type.

The switchboard controlling the alternators is shown in Fig. 2, and the back of the board is illustrated in Fig. 3. One of the direct-coupled Thomson-Houston generators and Willans engines is shown in Fig. 4.

It seems to be the universal law that man must make compensation in some form for every benefit received. One cannot enjoy the fruits of civilization without accepting the defects and limitations of civilization. This homely old truth must come with redoubled force to the people of Florence just at present; they have enjoyed the rose of electric transportation and now are pricked by the thorn of a street-car strike. Modern inventions make way more slowly in Italy than in the United States, but they are followed, it appears, by modern discomforts just as surely. The brief news dispatch has a very familiar sound—the men want shorter hours and more pay; the system is practically tied up; the few cars that are running are under the protection of the police. The experience has been undergone by almost every large city in this country. It is very uncomfortable for the traveling public, but with the great extension of modern transportation systems and the everlasting selfishness of the human animal, there seems to be no help for it. Strikes are in theory an economic

absurdity, but intelligent end-of-the-century workmen believe them a practical necessity to remedy wrongs, nevertheless. So that they are as much a part and symptom of present-day civilization as the electric-railway car itself. Therefore, the Florentines, in trudging through their first street-car strike, may take such comfort as they can from the reflection that if they are inconvenienced it is from an industrial ill that attacks only the modern methods of living and getting about. With a strike on the trolley lines, Florence is strictly up-to-date.

The electrical and allied interests are deeply interested in the Chicago municipal elections this spring. All parties are playing with the municipal-ownership fad, although ex-Governor Altgeld is endeavoring to make that the chief feature of the Bryan followers' campaign. Mr. Harrison very sensibly contends that the city is not in position at this time to assume ownership of the street railroads, and that until the civil-service regulations are firmly established it would be folly to attempt such an undertaking. Mr. Carter, the Republican candidate, favors civil service and municipal ownership and is opposed to the 50-year franchise scheme. Mayor Harrison's principal strength among independent voters is based on his record in the street-railway fight and his part in bringing about the defeat of the obnoxious Allen law.

Judging from the attitude of the several candidates and the platforms of their respective parties, the street-railway companies will find little favor at the city hall during the next two years, without reference to the personality of the mayor.

Promoters of the combination or trust of independent telephone companies should not lose sight of the fact that much of the success which has attended the anti-Bell movement is due to the sympathy which the public has extended in the fight against that monopoly. These interests cannot hope to sustain the same relations with the public after a consolidation has been effected, as the new combination will practically be in the same class as the Bell company, and the public will not discriminate between trusts.

Exchange managers view with alarm the proposed combination, for they recognize in it a step toward placing them directly within the power of the manufacturers. At present they have many reliable manufacturing establishments from which to purchase apparatus, and this competition has tended to keep prices within reasonable limits and at the same time to stimulate the improvement and refinement of equipment.

In spite of the inducements offered by the promoters of this trust it is admitted that several important concerns have refused to enter the combination. These companies have come to the conclusion that they will be in better position to secure business as perfectly independent companies, unhampered by the restraints and restrictions of a consolidation. They contend that if there is enough money in the industry to warrant the formation of a trust upon the terms proposed there should be larger profit in their business conducted independently under their personal management than when put in the pool.

From the present outlook, it may be said, there is no reason why the independent telephone exchange managers should feel alarmed. There will be independent telephone manufacturing companies with sufficient capacity to furnish all their demands in spite of the present attempt to consolidate these companies into a trust.

English electrical engineers have been occupied with the subject of standard frequencies for some time, and the matter has been under consideration in the engineering societies. At a recent meeting of the Institution of Electrical Engineers it was announced that the committee appointed to consider the question of uniformity in electrical engineering practice had reached a conclusion on the question of a standard frequency for alternate-current working, after having collected information and ascertained the opinions of a number of manufacturers and of consulting engineers on the continent and in America, as well as in England. As a result of these investigations the committee recommended for general purposes the adoption of a frequency of 50 periods per second, as, on the whole, the best suited

to ordinary cases of mixed distribution of alternating currents for incandescent-lamp, arc-lamp and power supply; but for the exceptional purpose of transmission of power on the large scale it recommended the standard frequency of 25 periods per second. The committee suggested for the exceptional cases of house-to-house transformer supply, as preferred in districts where the houses are scattered, a standard frequency of 100 periods per second, but this is not favorably considered. The London *Electrical Engineer* makes the following comment upon this feature of the report: "We think that the committee would have shown itself more than in touch with the profession generally if it had left out the saving clause allowing a frequency of 100 periods per second in certain districts. The very few cases in which, with a well-organized and well-supported electric-lighting undertaking, a house-to-house-transformer system is really advantageous render it useless, in our opinion, to start a special class to gain a slight efficiency in the transformers. Even then, if motors are to be considered at all, it would be better to adhere to the frequency of 50 complete periods per second." It is not improbable that an effort will be made to have this clause eliminated, although the report was unanimously recommended by the committee.

The Brundage telephone bill introduced at Springfield and passed by the lower house ought not to become a law. Good telephone service can not be furnished in a large city at \$60 a year for business telephones and \$30 a year for residence instruments. If these rates are established, as is proposed by the new bill, Chicago will be obliged to put up with a second-rate telephone service, and the Chicago Telephone company will not be able to earn a dividend on its capitalization or secure a profitable return upon its actual investment. In fact, it is pretty likely to go bankrupt should it try to operate under such rates, and we presume that even the Springfield statesmen do not aim to kill off the company entirely. It is more likely that they are poorly informed and are laboring under the misapprehension that if such rates will answer in the country they will also do for large cities. The fact that the bill was introduced by a Chicago man only makes more apparent the lack of practical information possessed by its promoters. In addition to killing off the old company the Brundage bill, should it become a law, would probably result in putting a stop to the plans of the Illinois company for building a competing exchange in Chicago. If let alone by the Legislature the new company promises to give Chicago a magnificent exchange equipped for 30,000 lines and to furnish a service at \$85 and \$45. For rates lower than these good telephone service cannot be furnished at a profit in a city the size of Chicago.

The fact that neither the Chicago Telephone company nor the Illinois Telephone and Telegraph company has interposed any serious objection to the bill is taken to indicate that these companies look upon the bill as a harmless measure. In the light of recent decision, affecting the practical confiscation of property by legislative regulations, it may be assumed that the telephone interests regard the law in its present form as invalid.

No reasonable explanation can be offered for loading the bill down with conditions that should have been the subject of another measure if, indeed, their enumeration is considered necessary and desirable. It has already been pointed out that the courts are divided upon the question as to whether telephone companies should be classed among common carriers, and one authority very significantly remarked in an opinion upon this point that the mere enactment of a law did not affect the matter at all. Such questions were to be determined logically by the conditions that prevailed, and that the courts would be governed by the facts. It would seem, therefore, that if telephone companies are not common carriers by reason of the nature of their business the Brundage bill will not affect them, and if they are common carriers there is no necessity for the formal declaration on this point contained in that measure.

Altogether, the bill may be considered ill-advised and hurtful to the independent movement rather than in the interest of honest reform of the present telephone service.

Development of Electric Power in Southern California.

(From the *Los Angeles Times*.)

This has been called the electrical age. There is no part of the world in which electricity is destined in the future to play a more pronounced part than in Southern California. The conditions which exist here make electricity almost essential to advancing civilization. Cheap fuel has been the one element most lacking as an aid to progress, and this finds a substitute in electrical power. What nature has denied in the way of fuel she has more than made up in opportunities for the development of electricity from mountain streams. In this respect the past year has seen the completion of two great systems bound to affect the industrial activity of all Southern California, while several other electrical projects are now in process of incubation.

Water power has taken on new features in the past few years, the old-fashioned water wheels which utilized the fall of water of but a few feet having been replaced by wheels which use water under pressure of hundreds of feet. The volume of water in the streams of Southern California during the summer months is not sufficient to afford any great power under the old system, but when it is confined in pipes and brought under pressure of from 400 to 700 feet and thus thrown against a wheel, the power developed is magnified almost marvelously, for there is hardly a work of man or nature which could withstand a stream of water coming from a nozzle, under a pressure of 700 feet. A pressure of 300 feet is considered about the maximum for fighting fires, and it was not until recent years that it was thought possible to confine water in pipes under a pressure of even 500 feet. The wheels in use for developing the power of the streams have cups set about their circumferences, and nozzles direct the irresistible force of water under confinement against these cups on the under side of the wheels, the water having free escapement immediately after striking the cups.

The mountain streams of Southern California frequently fall as much as 3,000 feet in the course of 10 miles. It is possible to divert the waters of these streams into artificial channels and carry them with gentle fall along the mountain side to some point where they will have a precipitous fall of hundreds of feet, down which they are conveyed in pipes terminating at the water wheels in power houses. From these houses power is transmitted to distances as great as 90 miles.

When such long-distance transmission was first suggested as a possibility in California, many experts declared it impossible of accomplishment. The Redlands Electric Light and Power company was the first to attempt it, and received much discouragement from experts. Nothing so great had ever been accomplished in any part of the world. The question of the possibility was referred to Edison, and that wizard declared his faith in the possibility of the project, basing his belief on the lack of humidity in the atmosphere of California. Water is a conductor of electricity, and in countries with humid atmosphere the project would have been impracticable. The results have demonstrated the correctness of Edison's views, and the long-distance wires work with but a trifling loss of electric fluid. As a result of its accomplishment in this direction, the Redlands plant became famous the world over among electricians, and has set the pace for the utilization of water and the development of other features of electric plants in many foreign countries, as well as through the United States. The pioneer in the development of electricity from water in California, it has been the object of study by contractors of all the other systems which have since been built up in this state.

Electrical authorities have long maintained, and still maintain, that it is impossible to generate electricity by water power economically, as all water systems are so uncertain that it is necessary to supplement them with steam plants, and the duplication of the plant robs water power of its elements of economy. Evidently this is true in countries where cheap fuel is to be had. Here, as elsewhere, it is necessary to duplicate the water plants with steam plants, for use in an emergency, though the use of the latter may extend through only a few days of each year. Experience has demonstrated that these systems can furnish power at a profit at rates based on coal at \$4 per ton, which is about half the price of coal in California. The authorities on electricity are evidently correct in their statements that water power for the development of electricity does not represent economy, if they limit their remarks to countries where coal is to be had in large quantities on the basis of coal at \$4. This state is given power at about the cost in the eastern states, where there is a cheap supply of coal, and we are thus for the first time put into a position to compete with eastern manufactures, in lines where power, but not heat, is required, while in the latter cases the supply of petroleum for fuel purposes has made great progress.

The greatest utility of electricity thus far in Southern California is in the driving of electric cars. The Los Angeles, Pasadena and Ontario systems, which in each case far surpass those of most towns of the same size, are examples of the possibilities as well as present accomplishments along the line of electricity developed by water power.

Outside of the use of power is the great value of

electrical development in the supply of lighting systems, the effect of which is seen in almost every town in Southern California of over 2,000 inhabitants.

In most cases these towns are lighted by private corporations. There are three notable exceptions to this rule, however. The Riverside and Colton municipal governments have their own distributing system, buy electricity in bulk of the Redlands company, and serve it to the individuals of the cities for either light or power purposes. Anaheim has a steam plant, owned by the municipal government, and generates an abundance of electricity for all uses, the system being one of the best in the state.

There is a utility of electricity which is characteristic to Southern California. This is its use by the farmers in pumping water for irrigation purposes. While this is a new use of it, its advantages have been thoroughly demonstrated, and it seems certain that it will be but a few years before the farming districts will be thoroughly covered by systems for this purpose. At Colton, for instance, during the last summer, the water supply has been pumped by electric power at a cost of only two cents per miner's inch for 24 hours, a cost but one-fifth as great as the average cost by gasoline engine.

It is proper to speak of the development of the past, present and future about Mill Creek, Lytle Creek and the Santa Ana River as the Redlands group of systems, as they are the direct outgrowth of the Redlands Electric Light and Power company's success, and have been projected by the same citizens of Redlands, in much the same locality, as was the parent system. This first project utilized the power of Mill Creek for the generation of electricity, which it first supplied to Redlands, then to the large ice factory of the Union Ice company at Mentone, and finally extending the system to Riverside, Colton and Highland, at which latter point it furnishes lights to the state insane asylum.

Regarding the work which has already been accomplished by this company, it is not necessary to enter into details, as the story is an old one. The company, however, is laying its plans for further development, and is acquiring lands and rights-of-way for another plant immediately above its old plant for a supplemental system, which is expected to develop 1,500 horse power to meet the demands of its increasing business.

After the completion of the Redlands system, as outlined above, the promoters of the project turned their attention to a still greater project, which had lain dormant for a number of years, though often considered as a possibility. This was the development of the power of the Santa Ana River, an undertaking which presented some great engineering problems, the river being a wicked stream after mountain storms and difficult to bring under subjection. This was finally accomplished, however, the water being turned into the canal last October. The company which accomplished this great work, under the management of the Redlands men, prominent among whom were Henry Fisher and H. H. Sinclair, was the Southern California Power company, which has become a part of the Edison Electric company of Los Angeles. The canal in which the water is diverted from the Santa Ana River has a capacity of 7,000 inches, and it extends 14,715 feet from the intake, at the junction of the river and Bear Creek, to the head of the pipes. There are two of these pressure pipes, each 30 inches in diameter, with a length of 2,200 feet and a fall of 728 feet. The power house, situated on the north bank of the river above the mouth of Kellar Creek, contains six Pelton water wheels, each of 1,200 horse power, divided into two teams, either of which, or both, can be operated at a time, affording opportunities for cleaning or repairing when necessary. From this system 4,000 horse power is being transmitted under contract with the Pasadena Electric company, the Pasadena and Los Angeles Railway company and the Los Angeles Railway company. During the construction of this plant from 300 to 400 men were employed for months. Among the materials used were 14,000 barrels of Portland cement, 350,000 feet of lumber and 4,000 poles.

Another stream which the Redlands men look forward to harnessing, and on which some work has been done, is Lytle Creek, a stream considerably smaller than the Santa Ana, but comparing favorably with Mill Creek, and the precipitancy of which offers opportunities for great pressure.

A project which has been discussed for a number of years is that of Dr. Baldwin, the site being on Mill Creek, above the plant of the Redlands system. A small force of men has been at work on this system for a number of years, and there is reason to believe that it will be completed at an early time, probably during the present year. Dr. Baldwin here contemplates putting in pressure pipes with a fall of about two thousand feet, the great power from which he expects to utilize almost wholly in pumping water at Perris, San Jacinto, Lake View and Elsinore from the large number of wells which have been developed in the past year or two. This would be of great value in the development of Southern California.

The second group of electric projects in Southern California centers about the San Gabriel River, which emerges from the mountains near Azusa. The only plant yet completed began rendering service early last summer. It is that of the San Gabriel Electric company. The plant is throughout one of the most substantial and modern to be found in this country. The electricity from this plant is brought to Los

Angeles and Pasadena, for use in all ways for which electricity is adapted, including the propelling of street cars and the lighting of houses and streets. In this city the wires of the company have been laid underground, thus avoiding the defacing the streets with more poles.

The canals of the company, used in transmitting the waters of the river to the power house, are about 30,000 feet in length, of which over 20,000 feet runs through tunnels in solid rock, the remainder being of concrete pipe and redwood-stave pipe. The tunnels are lined with concrete throughout. The water is taken finally through a hill by tunnel, from which it drops through a pressure pipe down a bluff to the power house below, the perpendicular fall being 400 feet and the length of the pipe 800 feet. This pipe is 48 inches in diameter and the lower portion is composed of steel a half inch in thickness. The capacity of the plant is 4,000 horse power. The water is directed against eight Pelton water wheels, divided into four teams, each operating independent of the others, for facility in cleaning or making repairs. Each set is capable of developing 550 horse power. From this power house the electricity is transmitted to the sub-station in Los Angeles, from which point it is distributed. The machinery of the system, both at the power house and in the city, is of the best, and embraces a number of the most modern appliances for changing voltage and transmitting electricity. The stock of this company is all held in Los Angeles.

Another project in connection with the waters of the San Gabriel River, which it was thought would be completed before this time, is that of the Los Angeles Power company, in which Redlands and Los Angeles capitalists are interested. This project looks to the development of power at a point above that of the San Gabriel company. This means the most extensive work yet undertaken in Southern California, in that it implies the gathering of the waters from many streams which unite before being used by the San Gabriel company. There would of necessity be very extensive canals for the purpose of uniting the streams at a point above that at which they unite naturally. This has raised a question of considerable importance, it being claimed that the convergence of the waters by artificial means would leave a large body of land now naturally irrigated, and on which much vegetation exists, without moisture for the preservation of plant life, and that as a consequence a large area would be denuded, to the detriment of the irrigation systems lying below the mountains. This mountain land is a part of the San Gabriel timber reservation, and the federal government has been petitioned not to grant a right-of-way for the system. Such right has not yet been acquired, which has delayed the building of the plant. The end of this matter is not yet in sight, and it may be some time before the system is completed, if it ever is to be.

Still another project connected with irrigation on the San Gabriel River is that of the Silver Lake company, composed of residents of Glendora. While this is not as large a project as the others, it is quite important. The seat of the system is above that of the Los Angeles company, and it is only proposed to utilize a portion of the tributaries of the river. This is designed more especially for local use, yet has the power of adding to the prosperity of the country near the San Gabriel Cañon. A large amount of work has been done on the plant during the past two years, but it is not known that a date has been set for its completion.

For several years there has been talk of the development of power of the Kern River and the transmission of the power by electricity to Los Angeles, a distance of 108 miles. Much work has been done on this plant, and it was thought it would be completed during the past year. Little has been heard from the project of late, and the rate of progress being made on the plant at present is not known, though it is probable that the completion of the system will not be much longer delayed. The project is a large one, rivaling anything in the southern counties. The electrical supply from this source will add materially to the possibilities of this city.

Ontario, a little city of 2,500 inhabitants, has set a hot pace in the matter of electrical development for local use, a water-power plant having been developed for the propulsion of a complete car line.

The San Antonio company of Pomona has been furnishing light for a number of years to Pomona and San Bernardino, the electricity being developed by a water-power plant with many modern features.

There are through Southern California many projects along this line, and the future will bring forth many developments, giving to all the southern counties an abundant supply of electricity to keep the country fully abreast of all demands which can be made upon it.

In Honor of Volta.

The telegraphers of Italy are soliciting funds to purchase a bronze crown to be placed at the foot of the statue of Volta. The monument of the great scientist is located in the city of Como, Italy. It is proposed to have a grand celebration in May, 1899, at Milan and Como, Italy, in honor of the 100th anniversary of Volta's discovery of the voltaic cell. The bronze crown is to be paid for by popular subscriptions of telegraphers of the world. Mr. Walter C. Burton of New York has been selected as the American delegate at the celebration.

DEVELOPMENT OF THE TELEPHONE FIELD.

Telephone Legislation in Illinois.

The question of regulating telephone charges is the subject of several bills prepared for the consideration of the Illinois Legislature, but little attention has been given them until the present. On March 16th the House passed the Brundage bill by a unanimous vote, 123 members being present and all voting in the affirmative. The bill, as originally introduced by Mr. Brundage, fixed the rental of telephones at \$85 per year for instruments in business houses and \$45 for private residences, but it was amended in the committee so as to read \$60 and \$30, and in this shape it was called up as a special order last week. From the start there seemed a practical unanimity of sentiment on both sides of the House in favor of passing the bill, and long before the end of the roll-call was reached there was no doubt but that it would go through. An important feature of the measure is the conditions it imposes upon existing companies and the declaration that telephone companies shall be considered common carriers. The text of the bill follows:

Be it enacted by the people of the state of Illinois, represented in the General Assembly, that it shall be the duty of every telephone company, or person, firm or corporation engaged in the business of leasing telephones to the public or supplying the public with telephones and telephonic service, or operating a telephone exchange, to receive and transmit without discrimination messages from and for any other company, person or persons upon payment or tender of the usual customary charges therefor; and upon payment or tender of the usual or customary charges or usual or customary rental, the amount of which shall not exceed the sum herein provided, it shall be the duty of every telephone company or person, firm or corporation engaged in the business of leasing telephones to the public or supplying the public with telephones and telephonic service, or operating a telephone exchange, to furnish without unreasonable delay, without discrimination and without any further additional charge, to the person, firm or corporation applying for the same, all the proper or necessary wires and fixtures, and the use of such telephones, wires and fixtures, as well as connections with the central office, or telephone exchange, if desired, and to connect the telephones of such person, firm or corporation with the telephone of any other person, firm or corporation having connection with the same, or a connecting exchange or central office, whenever requested so to do.

Provided, the charge, price or rental for the leasing or supplying of a telephone for use in offices, stores or other places of business, including connections, both by day and night, together with such wires, fixtures and apparatus as shall be necessary to transmit vocal messages between the patrons, subscribers or customers of any telephone company within the limits of this state, shall not exceed a rate of \$60 per annum, which charge, price or rental shall be pro rata for shorter periods, and the charge, price or rental for leasing or supplying of a telephone for use in private residences, including connections, both by day and night, together with such wires, fixtures and apparatus as shall be necessary to transmit vocal messages between the patrons, subscribers or customers of any telephone company within the limits of the state, shall not exceed a rate of \$30 per annum, which charge, price or rental shall be pro rata for shorter periods.

Provided, further, the charge or price at public or pay stations or places for local messages or conversations shall be not to exceed five cents for the first five minutes after connection is made, and if the conversations be continued beyond five minutes, five cents for each five minutes or part of five minutes thereafter.

Every company, person, firm or corporation neglecting or refusing to comply with any of the provisions of this act shall forfeit all right to transact a telephone business in this state, and may be enjoined therefrom, and from leasing telephones to the public, from supplying the public with telephones and telephonic service, and from operating a telephone exchange, by bill of complaint filed in any court of competent jurisdiction, by any person, firm or corporation injured, interested or denied of any of the rights herein given; or such company, person, firm or corporation neglecting or refusing to comply with any of the provisions of this act shall forfeit not less than \$25 nor more than \$100 for each and every day such neglect or refusal shall continue, one-half to the use of the person, firm or corporation prosecuting therefor.

In the construction of this act public telephone companies are hereby declared to be common carriers.

The fact that the Chicago Telephone company made no serious objection to the passage of the bill is looked upon as indicating that it does not fear that the measure will apply to it.

Regulating Telephone Charges.

[From the Chicago Tribune.]

The House has passed, by a unanimous vote, a bill declaring telephone companies "common carriers" and regulating their charges. Those companies are not to be allowed to charge more than \$60 a year for business and \$30 for residence telephones. At present the Chicagoan who has an instrument in his house has to pay at least \$125. The case with which this bill has gone through the lower house shows that the Chicago Telephone company has not lifted a finger to retard its progress. Evidently that company is not afraid of it. Neither is the new telephone company which the council recently allowed to do business in Chicago. The terms it promises subscribers, though lower than those of the old company, are higher than those set forth in the bill the House has passed. The new company proposes to charge \$50 for residence telephones.

If those rates which have met with the approval of the House were to be enforced the old Chicago Telephone company would not have sufficient revenue to cover its operating expenses and would have to stop doing business. The new company would abandon at once the idea of starting exchanges here. Men will not put their money into an enterprise which they know will be unprofitable and will become increasingly unprofitable as the volume of business increases.

The telephone people view with unconcern a measure which, if enforced, would ruin them, because they know that that measure, though it should receive the vote of every member of the Legislature and the signature of the governor, will be knocked in the head by the courts whenever an attempt is made to enforce it. The courts, while conceding the right of the Legislature to regulate telephone charges, will

inform the General Assembly that it has not the power to destroy the property of the telephone companies under the pretense of regulating their charges. The courts will hold that the rates prescribed by the Legislature must be "reasonable," and that rates such as those set forth in the House bill are unreasonable because they are too low.

The courts will not, while declaring the legislative rates unreasonable, attempt to make rates. To do that would be to invade the legislative domain. The court will not say that \$30 is too little, but that \$40 or \$50 will be about right. It will simply declare the entire law invalid, and the attempt to regulate telephone charges will come to a sudden end. And then some thoughtless persons, suffering from telephone exactions, will allege that the courts are "on the side of the monopolists," and berate them for declaring unconstitutional a law enacted to benefit the people.

Measures which are on the face of them impracticable are not framed or passed to benefit the people. They are passed to make the people believe the legislators are zealous guardians of their interests, when, as a matter of fact, those legislators have been shamefully derelict. The General Assembly enacts some law which most of its members know is good for nothing. The courts set it aside. The members of the Legislature say to the people, "We did the best we could, but you see what the courts have done."

The Senate has yet to pass on the House telephone bill. It should amend that measure by inserting rates which the courts will not be obliged to decide are unreasonable. It will be much better to enact no law on the subject than to enact one which cannot be enforced and thus deceive and then irritate the people.

Ohio Telephone Association.

Representatives of the independent telephone companies of Ohio met at Cleveland on March 15th to form a close association of the independent interests of the state for the purpose of co-operation and mutual protection. It is said that the association will promote a scheme for giving long-distance service, connecting Cleveland, Chicago, Cincinnati, Columbus, Toledo and a number of other cities. Eventually it is proposed to complete an arrangement with the Indiana and Michigan toll-line systems, thus effecting a comprehensive service.

The first practical step toward carrying out this plan was the signing of an agreement to connect the independent exchanges and toll lines with the United States Telephone and Telegraph company. This will give the independent movement 121 exchanges, 2,500 miles of local toll lines and 1,000 toll stations.

A permanent organization was effected under the name of the Ohio Telephone association. J. M. Thomas of Chillicothe was elected president, Kora F. Briggs of Tiffin vice-president, Edward Kibler of Newark second vice-president, A. A. Whitney of Mount Gilead third vice-president and H. D. Critchfield of Mount Vernon secretary and treasurer.

Independent Telephone Interests in Iowa.

[Special correspondence of the WESTERN ELECTRICIAN.]

The Iowa Telephone association, including the independent lines throughout the state, met recently in Des Moines in annual convention. Uniformity of rates and the connection of toll lines were the principal subjects discussed.

The following officers were elected for the coming year: President, Charles E. Wells; vice-president, G. N. Bandy; secretary, J. W. Hill; treasurer, H. E. Teachout; executive committee, D. N. Smith, Clearfield; A. A. Moore, Marshalltown; C. F. Bennett, Waterloo; W. W. Pritchard, Spirit Lake; legislative committee, Judge J. L. Stevens, Boone, and A. A. Moore, Marshalltown.

The attendance of exchange managers was encouraging, and many leading manufacturers and dealers were represented. The proposed combination of independent manufacturers was discussed informally, and the tendency toward encouraging competition was plainly marked.

The Telephone at the Paris Exposition.

According to *l'Industrie Electrique*, there will be a lack of telephonic facilities at the exposition of 1900, the prospective demand threatening to exceed the coming supply. By the present arrangement the central stations of the exposition grounds should be tributary to a central station, which hardly exists up to the present except on paper, while they are actually dependent on a central in the boulevard Saint-Germain and another in the Rue Lecourbe, both already overcrowded and insufficient for present needs. The city is possessed of a proper location in the Avenue de Saxe, and it is prepared to erect a central there to cost 1,700,000 francs. The work has been already commenced, but the authority quoted, while approving the project, calls attention to the fact that in about 14 months the exhibition will be in full blast, while in the coming fall months there will be a constant, imperative halloing from the army of constructors busy on the ground.

"It will be a perfect miracle," says that journal,

"if, with the ordinary well-known sloth of the government, the station will be in readiness for the rush. We shall wait without confidence and without hope."

Telephone News from the Northwest.

[From the Minneapolis correspondent of the WESTERN ELECTRICIAN.]

The council of Duluth, Minn., has granted a franchise for a telephone exchange to R. H. Evans of Detroit, Mich. The new company offers long-distance connection, low rates, metallic circuits and first-class service. The Bell company's franchise expired March 9th, but it continues under act of Congress applying to postroads. The new company will also apply for a franchise in Superior, but the indications point to a stormy time. Some members of the council declare that they favor a municipal exchange.

The telephone exchange at Detroit, Minn., now has 56 connections, and already an enlargement of the switchboard has been necessary.

The Wisconsin Telephone company has put in a new switchboard at Onalaska, Wis.

A local telephone company is projected at Corning, Iowa.

The Lineville (Ia.) Telephone company may extend its wires to connect with the Clinton township and Warsaw line.

The Iowa Telephone company is working to put in a telephone exchange at Montezuma, Ia.

The Greene and Western company has bought the telephone system at Clear Lake, Ia., and will make numerous extensions.

A telephone exchange is being constructed at the new town of Titonka, Ia.

The Finch Telephone company of Escanaba, Mich., is building toll lines to neighboring towns.

A local telephone exchange has been established at Mellen, Wis.

The Chequamagon Telephone company expects to have its exchange at Ashland, Wis., in operation before the end of April.

The Fairmont (Minn.) Telephone company contemplates extending its wires to Spirit Lake, Ia.

The Spirit Lake Telephone company has made connection with Sutherland, Ia., and established an exchange there.

By June 1st a new metallic-circuit telephone line will be in operation between Spokane, Wash., and Republic and Camp McKinney.

The Dakota Southern Telephone company of Woonsocket, S. D., has been incorporated with \$50,000 capital stock.

The Cedar Valley Telephone company contemplates establishing an exchange in Clarksville, Ia.

A new building will be erected for the telephone company at Algona, Ia. Chase & Achatz of Preston, Minn., have just bought the system.

The Jefferson (Ia.) Telephone company will make connection with Scranton, Ia.

A telephone exchange is projected for Northwood, Ia., if a franchise be granted.

The new telephone-exchange building is progressing toward completion in St. Paul, and on April 1st the company will issue a new directory, with the new system of calling in vogue. The calls will then be "Main," "Dale" and "Selby," followed by the number.

The Dakota Central Telephone company contemplates establishing a local exchange at Big Stone, S. D.

A telephone company has been formed at Allerton, Ia., to put in a local exchange.

The Northfield (Minn.) Chess club played a game of chess with the St. Paul Chess and Whist club by long-distance telephone. The game was an entire success, the wires working perfectly.

The Northwestern Telephone Exchange company will rebuild its exchange at Grand Forks, N. D., in the spring. Materials for the work are being received.

The Mankato (Minn.) Citizens' Telephone company has declared a three per cent. dividend out of the earnings for the quarter ended April 1st. A fund was also established to improve and extend the lines. The company has 275 instruments in use.

Assemblyman Albrecht of St. Paul proposes to have the telephone and electric wires banished from the business portion of the city. Those which cannot be put underground, he thinks, can be changed to side streets, and as soon as he determines the owners of the objectionable wires he will introduce a resolution directing their removal.

There is talk of building a telephone line from Kenosha, Wis., to Racine and other points.

The Northwestern Telephone Exchange company may erect a building for its exchange in Fargo, N. D.

J. J. Greaves of the telephone exchange in Glen-coe, Minn., contemplates extending a toll line to Lester Prairie.

The Clearfield (Ia.) Telephone company will establish connection with Afton, Ia., soon.

Arrangements have been completed for telephone connection between Winterset, New Virginia, Osceola, Woodburn, Lucas and Chariton, Ia. Work will be begun in the spring.

The Southern States Telephone company of Norfolk, Va., will issue bonds for the enlargement and extension of its system.

ANNUAL MEETINGS.

The stockholders of the Alexandria Telephone company, New Orleans, have elected seven directors to serve for the ensuing year, as follows: B. Weil, S. Warshauer, G. W. Bolton, A. Albert, Thomas Clements, J. M. Barrett, R. W. Bringham. A dividend of 10 per cent. was declared.

At the meeting of the new board of directors of the Iowa Telephone company in Davenport, Ia., the following-named officers were re-elected: President, C. E. Yost; vice-president, F. H. Griggs; secretary and treasurer, August A. Balluff, and auditor, C. A. Dalzell. President Yost told a reporter that the company would expend \$1,500,000 on improvements.

The annual meeting of the stockholders of the New Telephone company was held at Indianapolis March 9th and the following-named directors were elected: A. H. Nordyke, Louis Halloweg, W. N. Gates, L. P. Walker, M. B. Wilson, D. M. Parry, H. B. Gates, S. P. Sheerin and D. E. Parrott. The directors elected the following-named officers: President, A. H. Nordyke; vice-president, S. P. Sheerin; secretary, H. B. Gates; treasurer, M. B. Wilson.

The organization of the Green River Telephone and Telegraph company was completed in Henderson, Ky., on March 9th, to do toll-line business in that locality where independent local exchanges are in existence. Officers were elected as follows: President, J. H. Hickman, Owensboro; vice-president, O. W. Rash, Henderson; general manager, H. K. Cole, Henderson; executive committee, J. W. Carter, Owensboro; A. Waller, Henderson; J. W. Walker, Morganfield.

The sixth annual meeting of the stockholders of the Western Telephone Construction company was held at Chicago March 13th, and was characterized by the entire harmony of the stockholders present. The same board of directors was re-elected for the ensuing year, and the thanks of the stockholders were unanimously voted to the officers for the results of the year's business. The statement showed a remarkable increase in the earnings of the company and in the extension of its property, the balance-sheet showing assets of about \$200,000 in excess of its liabilities. The orders on the books were said to be greater than at any time in the history of the company, and it is working its factory night and day to catch up with orders. Within the last 30 days it has been enabled to increase its output by 50 per cent. through the addition of considerable machinery and new tools. It was announced that the company six months ago made very extensive contracts for raw materials involved in its product for the year 1899. The extent of this may be better shown by the fact that in one line of materials alone the advance in the market price amounts to nearly \$30,000. It is intimated that a considerable amount of additional cash capital has just been added to the resources of the company, enabling it to largely increase its output and place upon the market some very valuable devices which have been withheld from production until now.

MANUFACTURERS AND DEALERS.

The American Hardwood Manufacturing company of Grottoes, Va., manufacturer of telephone wood-work, has issued a new price-list which should particularly interest telephone manufacturers. This company has done business with many prominent concerns, and its facilities enable it to turn out work promptly.

A representative of the Evans Telephone company was in Duluth, Minn., lately, for the purpose of preparing the specifications of the telephone plant for West Superior under the franchise which the company holds there. Experienced solicitors are getting subscribers for telephones for the new company in West Superior.

NEW COMPANIES.

The City Council of Marshal, Ind., has granted a telephone franchise to C. W. Shmel.

The Interior Telephone company of Vienna, Ill., has been incorporated by H. De La Rue, J. W. Eaton, Jr., and C. H. Gray.

The Dakota Southern Telephone company has been incorporated in Woonsocket with a capital stock of \$50,000. The incorporators are Charles M. Hopkins, G. Dzlewanoski and Robert S. Vassar.

The Pee Dec News Transit company, N. C., has applied for a telephone charter. The company's capital stock is \$25,000 and the incorporators are W. H. Smith and J. I. Dunlop of Wadesboro, N. C., and J. L. Bundy of Rockingham.

Papers of incorporation have been issued to the Zanesville, O., Telephone and Telegraph company. The incorporators are S. M. Winn, F. H. Southard, A. T. Brennan, J. G. England and J. B. Rhodes of Zanesville, O. The capital stock is \$10,000.

The Harrison, Ky., Telephone Toll Line company has filed articles of incorporation, the incorporators being Ike C. Adair, John J. McHenry and John W. Carter. The principal place of business is Owensboro, and the capital stock is \$3,000, divided into 120 shares of \$25 each.

The Portland Telephone company of Brockton, Chautauqua County, New York, has been incorporated, to operate in Brockton, Westfield, Fredonia; capital, \$15,000; directors, S. Fred Nixon and H.

Kent of Westfield, George Frost of Buffalo and T. C. Moss, G. W. Fuller and Augustus Blood of Brockton.

The Mayville Telephone company of Mayville, Chautauqua County, New York, is a new organization, which will operate in Mayville, Westfield and Chautauqua. The capital is fixed at \$15,000. Directors have been elected as follows: S. Fred Nixon, V. A. Kent and C. J. Bannister of Westfield, C. H. Frost of Buffalo, A. T. Baldwin, C. L. Cipperly, L. B. Bixby, E. C. Fish and E. J. Griswold of Mayville.

TELEPHONE LEGISLATION.

The Assembly committee on state affairs heard arguments recently in the Wisconsin Legislature on the bills to compel long-distance telephone companies to connect with local exchanges for the transmission of messages. Henry C. Payne of the Wisconsin Telephone company contended that it would be special legislation intended to benefit a few persons at the expense of the subscribers of long-distance telephones. Mr. Payne said that for five years the Wisconsin Telephone company had paid only seven per cent. on an investment of more than \$1,200,000. The *Milwaukee Sentinel* says: "The object of these bills, as of many others presented at preceding sessions, is to enable business rivals of the Wisconsin Telephone company to use the company's property. If the bills are passed a subscriber of the rival company at Madison, for example, will be able to call up Milwaukee by means of the long-distance lines belonging to the Wisconsin Telephone company. When he is using the line subscribers of the Wisconsin Telephone company will not be able to use it. Thus there is an injustice, not only to the Wisconsin company, but to its customers. There is a widespread, and we believe a reasonable, desire to introduce competition into the telephone business. There is a general impression that this business could be conducted profitably if lower rates were charged. But the bills now before the Legislature are plainly unjust."

TELEPHONE LITIGATION.

Two suits have been started in the Circuit Court in Paterson, N. J., in consequence of the decision of the Court of Errors and Appeals, mentioned last week, declaring that telephone and telegraph poles and wires do not come under the definition of a public easement. Both are for \$2,000 and against the New York and New Jersey Telephone company. The plaintiffs allege that the telephone company erected poles and strung wires on their land in Wayne township without their consent and against their wish. The Court of Errors has decided that owners must be compensated when telephone and telegraph companies exercise their statutory privileges against the consent of the owner.

EXTENSIONS AND IMPROVEMENTS.

A telephone line will be built from Lewiston, Idaho, to Pomeroy.

The Central Union Telephone company will construct a line from Galena to Freeport, Ill.

George Grange has organized a company for the establishment of a telephone system at Alvin, Texas.

The East Radford, Va., Telephone company has been granted a franchise for the erection of a telephone system.

The American Telephone and Telegraph company has purchased 7,000,000 pounds of copper wire for extensions of the long-distance service.

The Central Union Telephone company has filed with the city clerk of Springfield, Ohio, its acceptance of the franchise allowing it to place its wires underground.

The Rocky Mountain Bell Telephone company will erect a line from Weiser to the Seven Devils, and from there to the Buffalo Hump country, according to the *Boise (Idaho) Statesman*.

The San Diego, Cal., *Tribune* says: "A subscription is now being raised for the purpose of constructing a telephone line from Banner to Julian. It is probable that the line will be commenced in a short time."

A franchise has been granted to D. C. Demarest to construct, maintain and operate a telephone and telegraph line between the towns of Jamestown, in Tuolumne County, Cal., and Altaville, in Calaveras County.

The Winthrop, Me., Telephone company wants to run its lines through that town and through Monmouth to Augusta. The Nash Telephone company wants similar rights, and both are opposed by the New England Telephone company.

The Douglas Telephone company will construct a telephone line and exchange in Lawrence County, Kan., in opposition to the Kansas-Missouri Telephone company. S. J. Bear is president of the Douglas company and J. D. Lemon secretary.

The Missouri and Kansas Telephone company will improve its toll-line service this spring. A line between Kansas City and Omaha will be established. It will have six wires, and a similar addition will be made to the Kansas City and Topeka line, while the line to Liberty will be rebuilt at a cost of \$25,000

and the service increased by the addition of four circuits.

The Massachusetts Telephone company applied on March 8th for a franchise at Lynn, Mass., agreeing not to charge more than \$3.50 for telephones in business places and \$2.50 in residences. Another petition for a telephone franchise was received from "Frank R. Marsh, trustee," and both were referred to a committee.

Among the conditions imposed in the franchise granted the Pittsburg and Allegheny Telephone company is one that the rate for business houses shall not exceed \$48 and for residences \$36; also that the company shall not sell or transfer its franchise.

S. B. Hill, manager of the Independent Telephone company at Fairmount, Ind., announces that his company will build a toll line to Matthews. The Independent Telephone company at Hartford City will also build to Matthews, joining the Fairmount company there.

The American Bell Telephone company will make improvements to its central exchange in Newport News at a cost of \$10,000. These improvements will include a new switchboard, which will have facilities for connecting 600 subscribers. The company has at present 350 subscribers.

The Cumberland Telephone and Telegraph company has completed its long-distance telephone line from New Orleans to Memphis. At an early date New Orleans will be in communication with practically all that portion of the United States east of the Mississippi River.

The local telephone company of Bath, N. Y., announces that it will make a flat rate of \$20 a year for the use of telephones for business places and \$12 a year for private residences on a three-year contract. The present rate of the Bell company is \$36 for office and \$30 for residence.

The People's Telephone company has applied to the Worcester, Mass., council for a franchise, and its application was favorably received. I. C. Currier of Worcester is at the head of the company, and it is said that the Boston and New York Telephone company is ready to back it financially.

T. S. Ingram, special agent of the Bell interests, has recently made arrangements to install a new telephone plant in Tampa, Fla. He is pushing to completion also a long-distance telephone line to connect Tampa with other important cities of Florida, and also with cities of the North, East and West.

The Bell Telephone company is soon to have a rival in Hamburg, N. Y. A new enterprise, including Jacob Peffer, John Schoepfkin, Fish & Kronenberg and H. G. Pierce, is being organized to give service in Hamburg at a much lower figure than that given by the Bell company. The local company proposes to give an all-night service at \$12 a year.

The Mount Whitney telephone system in California has been sold to the Sunset Telephone company. The Mount Whitney has offices in every town in Tulare County, and has reached far into the mountains south and east since its formation in 1844. The Sunset extended its line to Porterville, and reduced its local telephones in Visalia, Tulare and other towns from \$4 to \$1.50, to compete with the Whitney system.

The New York Telephone and Telegraph company has bought from the estate of Silas Brown the five-story brick building, 25 by 110 feet, at 14 Cortlandt street, New York, adjoining its present building, for about \$200,000. The building was badly damaged by fire a few weeks ago. It will be torn down and a 12-story addition to the company's present quarters will be erected on the site.

Springfield, Mo., has secured telephone connection with 100 towns and stations in Southwest Missouri through the Interurban Telephone company. The central office is at Greenfield, and the lines connect with Barton, Dade, Polk, Cedar, Lawrence and Greene counties, having nearly 300 miles of wire. The principal towns on this big circuit are Greenfield, Springfield, Bolivar, Humansville, Arcola, Fair Play, Dadeville, Golden City, Stockton, Lockwood, Everton and Ash Grove.

Aluminum Telephone Lines.

D. H. Fitch, manager of a telephone exchange at Cozenova, N. Y., has had some experience with aluminum wire in telephone work, and he declares that the results have been entirely satisfactory. Mr. Fitch says:

"All thus far has served its purpose splendidly. I was a little apprehensive of the last, on account of being so soft, but it has stood the storms thus far without the least impairment. The last wire put up had about 450-foot spans. The long span of nearly 600 feet has now stood through two winters and is in perfect condition—just where I put it—and has not stretched or sagged. I have an inquiry from Canada, and I have said in reply that my use of aluminum is most satisfactory, and if I had this exchange to build to-day, I would use aluminum wholly for line work."

In this connection it is interesting to note that the Pittsburg Reduction company announces that it has furnished the Bell Telephone company with aluminum conductors for foreign business, and has also furnished considerable aluminum for conductors in Japan and other foreign countries.

The "Ever Ready" Electric Light.

The cut and the title of this device explain themselves fully. The manufacturer, the American Electrical Novelty and Manufacturing company of 235 Center street, New York, offers an electric hand-lamp, consisting of lamp and battery combined, so connected that the lamp burns as long as one presses on the ring on the band. Three sizes are made, the lamps taking from 3½ to 5½ volts. The smallest outfit is 1½ inches in diameter and 8½ inches long. It will, it is said, give from 6,000 to 8,000 light flashes before the battery needs renewal. The advantages of this light in dark places, particularly out of doors, or in localities where an open flame might cause an explosion or be otherwise dangerous, are obvious.

Space Telegraphy.

A London newspaper correspondent asserts that "wireless" telegraphy has been put to a really practical test, which has proved how valuable it will be in the future saving of life at sea. "Last Saturday," says the account, which is dated March 18th, "a barkentine got ashore on the treacherous Goodwin sands, and signals of distress were fired from the south Goodwin light. These were heard on the east Goodwin lightship, where a wireless telegraphy apparatus is fixed, and by that means a message was sent to the south Foreland lighthouse, whence other messages were passed on to Kingsdown and Rams-gate for life boats. It often happens that when the

Trend of Central-station Design.

[Continued from page 170.]

from each large or interior engine. By making the end engine extra strong, so that it will carry 100 per cent. overload, which can very easily be done with slight increased cost, in case the large engine lets down you can run two generators at full capacity from the small engine until the large engine is again ready for work. This requires much less investment in plant than would otherwise be necessary to meet this emergency with independent units of power.

I have just received a report on a new magnetic clutch, three of which were designed by me for this plant, which may be of some scientific interest. These clutches are designed to transmit 1,500 horse power each and are to go between the engines and generators. These being the largest magnetic clutches I have ever attempted to design, I allowed ample reserve, and the test showed that these clutches will transmit 3,000 horse power each, with a consumption of energy of eight-tenths of an ampere at 500 volts, or less than one-half of a horse power going through the coils. The clutch is 10½ inches in diameter and carries cast-steel rings or armatures with coils in them, and by pressing a button the armatures move up to place against springs and transmit power purely by the friction of the surfaces in contact. The only energy consumed is what goes through the coil. Inasmuch as the system contemplates the bringing up of the generator arma-

The PRESIDENT: Could you use it on a jet condenser?

MR. ARNOLD: Yes; you could.

The PRESIDENT: Would it be proper to use water at a temperature of 80 or 90 degrees on a jet condenser? I should think it would require too much water to get your vacuum.

MR. ARNOLD: We are doing this right along; as, for instance, at the Englewood plant.

The PRESIDENT: It takes a good deal of water, doesn't it?

MR. ARNOLD: Not water, but power, for we use the same water over and over again, and add probably five per cent. to that water, as stated, to make up for loss by evaporation. I did not fully answer your question, but I will do so now. Where you can place your cooling tower on the ground it is advisable to do so and use the jet condenser, because it is cheaper to do so.

MR. HINE: I understood Mr. Arnold to say that the net efficiency of a combined synchronous motor and arc-machine outfit was something like 72 per cent., where the efficiency of the rotary converters was 90 per cent. or more. Do I understand you to say or to mean by that that there is any inherent disparity in efficiency between the synchronous motor per se and the rotary converter?

MR. ARNOLD: No; I did not mean that.

MR. HINE: Was not the apparent disparity due to the fact that the arc machine was necessarily less efficient than either of the other machines, and that the arc machine was perhaps a 75-kilowatt machine,

THE "EVER READY" ELECTRIC LIGHT.

FIGS. 1 AND 2. ADVANCE GAS LIGHTER.

wind is blowing off shore guns on lightships cannot be heard on land, and it is in such cases that wireless telegraphy will be of inestimable value in saving life. The Ramsgate town council is now pressing the Trinity House for installations of wireless telegraphy between all lightships and the shore."

In this country the Marconi system is to be thoroughly tested by the War Department at Washington. Two experimental stations have been selected, the roof of the State, War and Navy building and Fort Myer, the army post, on the west side of the Potomac, opposite Washington. The distance between these stations is six miles. The government has purchased the necessary instruments. The experiments will be conducted by Col. James Allen and Lieut. George O. Squier, both from the regular army. On the success of the experiments will depend the adoption of the system for the Signal Service.

Advance Gas Lighter.

A new electric gas lighter, made by the Advance Specialty company of 119 La Salle street (room 68), Chicago, is shown in the accompanying cuts—in position on the fixture in Fig. 1 and with the novel features in detail in Fig. 2. The characteristic feature of this gas lighter is that no wiring is required. Each fixture has its own source of electric supply in the small drum shown in the upper part of Fig. 1, and enlarged, with parts detached, in Fig. 2. The drum for the battery is made to be readily attached to the fixture in sections, and can be easily placed on fixture in use. It is shown at the right in Fig. 2, which also illustrates, in the central figure, the bottom plates of the drum, and on the left the ornament that conceals the joint of the two sections. The system is simple and cheap, and the manufacturer is confident that it will be favorably received.

ture as a motor to the same speed as the engine before it is clutched in, the two surfaces move together when running at the same velocity, and there is no grinding and no wear, and therefore the cost of maintenance should be very low.

The PRESIDENT: I would like to ask Mr. Arnold in regard to the apparatus for condensing, whether he uses a jet or a surface condenser?

MR. ARNOLD: It depends upon the location of the cooling tower. It is usually necessary when a cooling tower is used, on account of the value of real estate, to place it upon the roof of the building, and then, by all means, use a surface condenser, for by using a surface condenser you get a closed column of water; that is, the condensing water can never come in contact directly with the steam, and in that way you avoid the danger of the flooding of your engine cylinder, which is liable to happen when using a jet condenser if you had a great body of water on the roof and your jet condenser should fail.

The PRESIDENT: How many degrees can you reduce the temperature of the water in the cooling tower?

MR. ARNOLD: That depends entirely on the size of the tower and the speed at which you run the fan, which means consumption of energy. In winter this water leaves the condenser at about 100 degree Fahr. and is reduced to about 65 or 70 degrees Fahr., while in summer it leaves the condenser at about 120 degrees and is reduced to about 80 to 90 degrees. You can get it as low as the temperature outside if you use power enough on the fan, but it is not advisable to attempt to get too great a reduction of temperature in that way, because it takes too much power, so that if you get down to 80 degrees in the summer it is sufficient, because to cool the water from this temperature down the power required on the fan increases very rapidly.

and therefore naturally of lower efficiency than a large-sized rotary converter would be?

MR. ARNOLD: That is partially the explanation. The reasons for the discrepancy in the efficiency of the two machines are two, viz., the low capacity of the arc machine, and its consequent lower efficiency than the other larger machine, and the efficiency of the small synchronous motor. When we have a combined unit of that kind, a synchronous motor driving a series-arc machine, we have two small machines. Into the motor we feed the alternating current. That is simply a motor, and it has a certain efficiency, probably not over 92 per cent. It then drives mechanically an arc machine which has an efficiency of only about 80 per cent., possibly less. So that the combined efficiency of the two machines is much less than that of a rotary converter, the latter consisting of one machine, of a single armature, of a single field, the armature having a direct-current commutator on one side and three-phase collector rings on the other, the current going into one end of the armature and coming out at the other end; that is the reason that it so much more efficient.

MR. HINE: But the synchronous motor taken by itself would be just as efficient as a rotary motor of the same size, would it not?

MR. ARNOLD: Yes, sir.

MR. HINE: There is one other matter that I would like to mention. The statement was made regarding the alternating arc lamp, to the effect that as there was a deposit of ashes formed in the globe, it became necessary to clean the alternating lamp more frequently than the ordinary direct-current lamp. Is it not a fact that the alternating-current lamps burn so much longer than the direct-current lamps that they actually require less cleaning?

MR. ARNOLD: I should probably have stated in

my remarks that I was comparing the alternating arc lamp and the modern enclosed arc lamp. On that basis, I think, my remarks would be correct, but as I spoke extemporaneously I will make it clear now. Comparing the series arc lamp with the alternating, I think you are correct, because the series lamp requires attention oftener than the alternating lamp would.

Mr. KORST: Can either end of the rotary converter be used as a motor and the other part as a generator, as made to-day?

Mr. ARNOLD: You can feed the direct current into the direct-current end and take the three-phase current out of the other end, and you can feed the three-phase current into the three-phase end and take the direct current out of the other end. It is completely interchangeable in that respect.

Giant Transformers at Niagara Falls.

The Niagara Falls Power company has awarded another important contract for electrical machinery. It is for seven 2,500 horse power transformers, involving the largest units that have ever been manufactured. The transformers will be of the Westinghouse standard oil-insulated, water-cooled type. The cooling is effected by the circulation of water through coils of brass pipe immersed in the oil, so that no fans, blowers, pumps or motors will be required. This construction, therefore, eliminates any loss of power in the revolving elements of auxiliary devices.

These transformers will be of the same type and of the same general appearance as the four 850-kilo-watt transformers which were built by the Westinghouse Electric and Manufacturing company for the Cataract Power and Conduit company, and installed about a year ago in the Ohio street sub-station in Buffalo. The satisfaction given by these transformers and by others of similar design, which have been in use for several years at Niagara Falls, led to the selection of this type of transformer for the new installation in the Niagara company's power house.

The efficiency of these transformers, the Westinghouse people say, will be remarkably high. At full load it will be considerably over 98 per cent., at half load over 98 per cent. and at quarter load over 97 per cent.

At present these transformers will be used in stepping-up the two-phase, 2,200-volt current from the generators to three-phase, 4,400-volt current for supplying the Union Carbide company. They may also be used in stepping-up to 11,000 and 22,000 volts, three-phase, these being the voltages used in transmitting the power to Buffalo, or they may be employed as reducing transformers, lowering from 11,000 or 22,000 volts, three-phase, to 2,200 or 4,400 volts, two-phase or three-phase.

It is interesting to note the growth of the Westinghouse company's oil-transformer business, the total output of which for the seven years ended December, 1898, was 146,540 horse power. In 1898 about 90,000 horse power was installed.

CORRESPONDENCE.

New York Notes.

NEW YORK, March 20.—Such has been the absorption and consolidation and interlacing of electrical companies in New York and Philadelphia by a single group of capitalists that some people are beginning to think that the Whitney syndicate will soon have a predominating influence in everything electrical in this part of the country. Things have not reached that stage yet; but the statement that the Metropolitan Street Railway company will install \$3,000,000 worth of storage batteries directs attention again to the far-reaching extent of the operations of Mr. Whitney and his associates. The statement that the value of storage batteries to be put into the Metropolitan plant is \$3,000,000 may not be exact, but the order is certainly a very large one—the largest the Electric Storage Battery company ever received. Now Mr. Whitney and his business friends are in control of the Metropolitan company and also of the Electric Storage Battery company, without much doubt. They also own the New York Gas and Electric Light, Heat and Power company, formed to consolidate the lighting and power companies of this city, and are back of large electric-vehicle and electric-boat interests. It is believed that the storage batteries that have been ordered are to be used to enable the syndicate to operate all these interests in conjunction, with a steady load on the generating plants, and therefore more economically. The scheme is of the first magnitude, but all the steps taken by the syndicate so far seem to tend in the direction of its consummation.

On Wednesday of last week the Assembly at Albany, after a three hours' debate, passed the bill giving the Astoria Light, Heat and Power company authority to build a tunnel beneath the East River and to condemn land, if necessary, in Astoria for the purpose of running gas mains from works it contemplates building there to the tunnel. The intent of this bill is declared to be to concentrate in Astoria the works of the Consolidated Gas company, now in New York. On the same day Senator Fells-worth introduced a bill which some persons think is a companion measure to the Astoria bill. Others think it has an intimate relation to the great scheme of the capitalists of New York who seem to be attempting to unite all the electrical companies of New

York into one company. It provides that any company which manufactures electricity may also manufacture steam and place its pipes in the streets, with the consent of the local authorities.

The Assembly cities committee has reported favorably the New York city rapid-transit bill, with the amendments asked by Alexander E. Orr, president of the Rapid Transit Commission. Mr. Orr said that the bill was needed to give the Rapid Transit Commission authority to have an underground rapid-transit system built by private capital if city money could not be secured. The commissioners were unanimous in their opinion that the system should be built by city capital, but city money had not been available owing to the constitutional debt limit being nearly reached and for various other reasons. The commissioners intended to continue to seek city capital, but if they were unable to get it they did not want the construction of a rapid-transit system held up for an indefinite length of time. The amended bill has not been opposed so far by the Tammany authorities, which is rather surprising, in view of the previous attitude of Mr. Croker and Mayor Van Wyck.

I noticed among the incorporations at Albany last week that of the McGraw Publishing company of New York. The capital of the new company is placed at \$400,000, and the directors are E. E. Higgins and J. Aspinwall Hodge, Jr., of New York and C. E. Whittlesey of Madison, N. J. A good guess would be that this company is formed to take over the business of all of Mr. McGraw's publications—the *Street Railway Journal*, *Electrical World* and *Electrical Engineer* and the *American Electrician*.

The United Gas Improvement company of Philadelphia, which already controls the Yonkers gas plant, as well as gas plants in many other cities in the country, including Philadelphia, proposes to branch out farther in Westchester County. It will, it is said, take in the following-named electric-light companies: East Chester Electric company, which is operating electric-light plants at Mount Vernon, New Rochelle, East Chester and Pelham; Port Chester Electric Light company, operating plants at Port Chester and Rye; Larchmont Electric company, operating plants at Larchmont, Mamaroneck and New Rochelle, and the White Plains Gas and Electric company, operating at White Plains. M. S.

PERSONAL.

T. W. Ness, representing the Holtzer-Cabot Electric company of Boston, was in Chicago last week.

W. D. Packard of the New York and Ohio company of Warren, Ohio, passed through New York on Tuesday of last week en route for Europe. Mr. Packard expects to remain in foreign parts several months, and will make a combined business and pleasure trip.

John G. Milburn, a prominent lawyer of Buffalo, has been elected president of the Pan-American Exposition company. In accepting the position Mr. Milburn said that he believed the real purpose of the exposition should be an educational one, and that the merely "show" features should not predominate.

Mr. L. K. Cushing, the secretary of the Illinois Electric company of Chicago, has been afflicted by the loss of his wife, who died at the family residence on March 14th. Mrs. Cushing, who was but 25 years of age, was well known in South Side society and left many friends to mourn the departure of a charming personality. Electrical men in Chicago and elsewhere will sincerely sympathize with Mr. Cushing in his bereavement.

A complimentary dinner was given in Liverpool, England, on March 4th, to Prof. Oliver J. Lodge, B.Sc., F.R.S., in recognition of his having received the Rumford medal, which is awarded every other year by the Royal Society for the most important discoveries in heat and light. The company included Sir William Crookes, Sir John T. Brunner, Bart., Prof. Rucker, Prof. Fitzgerald, Principal Glazebrook, Prof. Hele Shaw and Mr. A. Bromley Holmes.

Mr. E. J. Spencer is the chairman of the committee of electrical men of St. Louis which has been appointed to solicit stock subscriptions from electrical manufacturers and business men for the exposition to be held in St. Louis in 1903 to celebrate the centennial of the Louisiana purchase. The project contemplates a stock company with a capital of \$5,000,000. In all, by subscriptions, loans and appropriations, it is proposed to raise \$17,500,000. The electrical industry will be benefited by the fair, it is said, and is therefore urged to contribute. Mr. Spencer's address is 24 Laclade building, St. Louis.

ELECTRIC LIGHTING.

The city of Louisburg, N. C., is in the market for a complete electric-light plant.

A franchise has been granted to Chicago men for the establishment of a complete system of water-works, electric lights and telephones at Wills Point, Texas.

A San Diego, Cal., paper says that E. C. Sharpe of San Francisco has arrived in San Diego and will probably put in a bid for installing an electric-light plant. Two years ago he offered to build it for

\$48,000, but now he says he could not build it for less than \$60,000, owing to the advancement in the prices of material.

The city of Rosland, B. C., has been authorized to borrow \$150,000 for the purpose of procuring light and water plants.

The contract for reconstructing the building of the Citizens' Light and Power company of Houston, Texas, has been awarded. It is said that the new plant will cost \$150,000.

Citizens of Ferris, Cal., have organized for the purpose of securing a water plant and an electric-light plant. It is believed that an electric plant can be installed for \$10,000.

The Consolidated Electric Light and Power company of Birmingham, Ala., is preparing to make extensive improvements and additions to its plant and will extend its lines to all the suburban points.

An ordinance has been accepted in Redwood City, Cal., calling for the construction of a system of electric-light works to be owned and maintained by the town. D. R. Stafford is the town clerk.

The committee appointed by the trustees of Ukiah, Cal., to investigate the question of an electric-light plant (municipal) recommends that the town be bonded for \$18,000 to raise money to erect the plant.

Robert Morrill is installing an electric-light plant at Nelson, Wash., and is pushing the work with vigor. The power house will be built on Deep Creek, and power will be transmitted over the mountains by wires.

It is intended to make an especial feature of the electrical illumination of the streets and business blocks of Chicago at the coming autumn celebration, of which Chicago Day (October 9th) will be the distinguishing date.

Sealed proposals will be received until April 1st for furnishing materials and constructing an incandescent electric-lighting plant in Palo Alto, Cal., in accordance with plans and specifications on file with the town clerk. The bids are to be addressed to H. W. Simkins, clerk.

The Peninsula Electric Light and Power company of Newport News, Va., is engaged in making improvements to its plant to cost \$30,000. The new apparatus includes one 400 horse power engine, four incandescent-light dynamos with capacity of 1,000 lights each and an ice plant of 10 tons a day capacity.

The Houma (La.) Lighting and Ice Manufacturing company has closed a contract for the erection of an electric-light plant of 1,000-light capacity for furnishing lights and power to the city. The plant will be operated in connection with the company's ice factory, the capacity of which will be increased to 12 tons a day.

An application has been made to the council of Napa, Cal., for a franchise for 50 years to construct and operate systems of poles, wires, etc., for electric-light and power lines in Napa City. The council proposes to grant the franchise, and will meet on April 17th, at 7:30 p. m., and open and read all bids therefor. H. H. Thompson is city clerk.

The United States Treasury Department is inviting sealed proposals, until March 28th, for the installation of a system of conduits and wiring for electric lighting in the United States courthouse and post-office building at Kansas City, Mo. Plans and specifications can be had upon application to O. L. Spaulding, assistant secretary of the Treasury, Washington, D. C.

The electric-light plant at Belleair, Fla., has been enlarged and placed in first-class order, and is now considered the finest electric plant of its size in the South. It has recently been supplied with duplicate machinery, so that if any part of the equipment breaks or gets out of order the other can be brought into service in a few minutes. The plant has a capacity of 3,000 lights.

In 1898 the gross station earnings of the Edison Electric Illuminating company of New York were \$2,868,026. The net income was \$1,277,129, from which were paid interest and dividends amounting to \$867,743, leaving a surplus of \$409,386. The net income was over \$150,000 greater than in 1897. The installations in connection with the service of the company approximate nearly 1,000,000 16 candle power lamps, and the maximum output of the Edison stations exceeded on December 22d 112,000 amperes.

The commissioner of Indian affairs is inviting sealed proposals until March 27th for furnishing the necessary materials and labor required to construct and complete an electric-light system at the United States Indian school at Santa Fe, N. M., in accordance with plans and specifications to be seen at the United States Indian warehouse, No. 1602 State street, Chicago, Ill. Any additional information can be obtained upon application to A. H. Viets, superintendent of the school.

A short time ago the sheriff sold at public sale the Rutherford, N. J., electric-light plant, under foreclosure proceedings instituted by the Franklin Trust company of New York, which held a mortgage of \$37,000 on the plant. The bidding was brisk during the early part of the sale, but it narrowed down

to Mr. Copeland, counsel for the electric company, and Mr. Levan, for the Franklin Trust company. Mr. Copeland bid to \$60,950 and quit. Mr. Levan went \$50 better and obtained the plant.

The directors of the North Hudson Light, Heat and Power company, which enjoys a monopoly of furnishing electricity for lighting purposes and motive power in Hoboken, N. J., and the North Hudson towns, has decided to expend \$250,000 to improve and enlarge the plant in Hoboken. The company is also considering the advisability of placing all its wires underground. The promoters of the North River Light, Heat and Power company, which was organized several weeks ago for the purpose of competing with the old company in Hoboken and vicinity, are said to be not meeting with much success in their efforts to secure franchises in the different towns.

The electric-lighting plant recently installed by L. N. Fowler for Austin Kimball of Clearwater, Fla., for lighting his residence, is one of the most complete and efficient private plants in the South. The generator is a 4½-kilowatt C. & C. machine, and the current is conveyed from the power house, 200 feet from the residence, by a lead-encased underground cable. There are 65 lamps of 16 candle power each connected in the residence. There are distributing boards on the first and second floors of the building, and all wires are run through brass-covered conduits, and each circuit is separately fused. The motive power of this plant is a Hornsby-Akroyd oil engine.

ELECTRIC RAILWAYS.

An electric railroad is to be built to connect Portland, Ore., to Oregon City.

The San Diego (Cal.), Pacific Beach and La Jolla Railway company has given up the idea of electrically operating its road.

Work has been begun on the Tacoma-Seattle electric-railway line. Franklin Riffle of Victoria will have charge of the work.

Papers have been filed with the secretary of state of New Jersey increasing the capital stock of the Havana Electric Railway company from \$5,000,000 to \$10,000,000.

Blackall & Baldwin, 39 Cortlandt street, New York, have postponed the time for receiving bids for building the 23 miles of electric trams in Shanghai from March 15th until June 30th.

It is understood that the Glenwood Street Railway company has purchased the Arlington Heights railroad of Fort Worth, Texas, and contemplates making a number of important improvements on it.

An electric street-car line is to be erected for Kern and Bakersfield, Cal., to cost about \$60,000. Money is on hand for the enterprise. Work will be commenced as soon as preliminaries are arranged.

It is reported that an electric railway will be built, starting at The Dalles, Ore., and following the Columbia River and tributaries to a point near Gooseberry, thence running to Hardman, which place will be the end of the road.

The commissioners of Cook County, Ill., have passed an ordinance granting the Northern Electric Railway company a 20-year franchise, that will carry one of the projected lines from Chicago to Elgin as far as the limits of River Grove.

The War Department has given to the Westinghouse company a contract for building an electric railroad at the Indian Head proving grounds. A commission decided that this would be the best way to avoid danger of fire.

The Southwest Missouri Electric Railway company is reported to be contemplating the erection of a large power plant in Galena, Kan. This would indicate the possibility of an extension of this admirable system to some point farther south.

On March 20th Alderman Bennett introduced an order in the Chicago City Council providing that the receiver of the Calumet electric railroad be compelled to operate cars in St. Lawrence avenue, between Seventy-first and Seventh-fifth streets, on tracks now unused.

Henry Elling of Dillon, Mont., is said to be contemplating the construction of an electric railway from the terminal of the Gaylord and Ruby Valley road at Twin Bridge, up the Ruby Valley, to some convenient point, probably the mouth of Alder Gulch, near Laurin, and possibly Virginia City.

The Freeport General Electric company of Freeport, Ill., has passed into the hands of a receiver. Judge Groscup entered the order on the application of several complainants, who alleged that the company is insolvent and unable to pay the \$78,500 bonds held by it. William O. Johnson of Chicago is named a receiver.

An amended ordinance granting to A. F. Burleigh, W. Smith and A. Stone a franchise to build a street railway upon the same streets now occupied by the trolley way cable line has been adopted by the council of Seattle, Wash. The present cable line will be abandoned and reconstructed with double trolley to be operated by electricity.

Hon. Thomas Forster, C. E. Tisdall and others had an interview recently with the provincial government of British Columbia, in which they urged the

construction of an electric railway from Vancouver to Steveston at the mouth of the Fraser River, and thence up the river, to secure all the available trade from canneries and farmers. The cost of the enterprise is estimated at \$145,000. Mr. Tisdall is taking a leading part in the matter.

There is about to be built in San José the first electric railroad in Costa Rica. H. T. Purdy, chief engineer, is in charge of the work, and D. M. Anderson of Washington, D. C., is first assistant to him. The company that is building this road is the Costa Rica Electric Light and Transportation company of San José. The material for the line is now practically all in that country.

The Niagara Falls and Suspension Bridge Railway company has applied to the Common Council of Niagara Falls for permission to extend its tracks through several of the streets of that city. If the right is granted the company will extend its tracks outside of the city to the north on Sugar street to Lewiston avenue, and then south on Lewiston avenue to connect with the Whirlpool and Northern tracks, thus making a new belt line in the northern section of the city.

It is said that arrangements have been completed whereby the suburban trains of the Evanston branch of the Chicago, Milwaukee and St. Paul railroad will be run downtown in Chicago from Sheridan Park on the Northwestern elevated railway, now building, and thus around the Union loop. This plan will make necessary the electrical equipment of the cars of the Chicago, Milwaukee and St. Paul Railroad company employed in this service and an inclined connection at Sheridan Park.

A call has been issued for a meeting of the stockholders of the Redlands (Cal.) Street Railway company, to be held May 25th. This is because the subscriptions to the proposed issue of bonds are such as to encourage the hope that the balance needed before any further steps are taken will be subscribed by that time. If the subscription is completed by the date of the meeting, the bonds will be issued promptly, and the work of changing the road to an electric line will be begun immediately.

The new Indianapolis Street Railway company has presented a proposition to the city. The company offers to pave between the tracks, expend in the extension and improvement of its plants, cars and lines of street railway all sums that shall be necessary, to pay the city the sum of \$750,000 in installments, carry passengers for a fare of five cents for a single ride with suitable transfer privileges and sell six tickets for 25 cents and 25 tickets for one dollar. In return the company asks a 34-year franchise.

Early in the month the Cleveland (O.) and Warren Electric Railway company was incorporated, with a capital stock of \$10,000, with the right to increase the capital to a larger amount. Among the incorporators are Hon. Martin Dodge, C. B. Lockwood, J. E. Phelps of Chagrin Falls, C. E. Thorp, Maysmills, and J. B. Corlett. The intention of the company is to build a line, 50 miles long, passing through the counties of Cuyahoga, Geauga, Portage and Trumbull. The temporary officers are: President, J. W. Conger; general manager, Martin Dodge.

The New Orleans City Railroad company has been incorporated as the reorganized New Orleans City and Lake Railroad company. The capital stock of the new company is \$7,500,000, of which \$2,500,000 is preferred and \$5,000,000 common stock. The old company had been a part of the New Orleans Traction company, which, with its constituent companies, is now being reorganized. The new board of directors and officers of the new company are: Albert Baldwin, J. C. Denis, F. T. Howard, C. H. Hyams, R. E. Craig, J. B. Levert, A. B. Wheeler, J. C. Russell, R. M. Walmsley. Mr. Walmsley is president and Mr. Baldwin vice-president.

The Tarrytown, White Plains and Mamaroneck Railway company has secured a franchise from Highway Commissioner John T. Creavy to construct its lines through the town of East Chester as a part of its proposed extension from White Plains to Mount Vernon, N. Y. The franchise is for 99 years, and the company must have cars running in six months. Another applicant was the New York, Westchester and Connecticut Traction company. The traction company has purchased the North Mount Vernon railroad, which, it asserts, has a franchise from Mount Vernon to White Plains, and President Boland said that if the commissioner decided against his company the fight would be carried into the courts.

The Tennis Construction company of Philadelphia has been awarded the contract for building the 40 miles of road for the Cincinnati, Lawrenceburg and Aurora Electric Street Railway company. The latter company was incorporated last November, with a capital stock of \$10,000, which has since been increased. There will be two power houses, each equipped with two 500 horse power Hamilton-Corliss engines, two 400-kilowatt Westinghouse generators and four 250 horse power tubular boilers. Besides building the road and the power houses, the contract requires the Tennis company to furnish the rolling stock. J. C. Hooven, Hamilton, O., George H. Helvey and Fred D. Shaefer are among those interested in the company. The Hamilton county commissioners have granted a franchise and right-of-way for 25 years from Anderson's Ferry to the Indiana state line.

TECHNICAL SCHOOLS.

Fire started by an explosion in the mechanical hall of West Virginia University at Morgantown, W. Va., early in the month, burned the building to the ground. The loss was \$52,000.

The senior class of the Massachusetts Institute of Technology recently made two tests, each of 88 hours' duration, on the battery of boilers in the engineering boiler house. During the first test three boilers were run; in the second test the two new boilers only. It happened that the second test was made during extremely cold weather, and the two boilers were run at the rate of 255 horse power, this being about 80 horse power above rating. The students were divided into squads of four, each squad working eight hours. Particular attention was given to the analysis of fine gases, and the fire was regulated in accordance with the results of the different analyses.

ELECTRICAL SECURITIES.

The American Bell Telephone company has declared a quarterly dividend of three per cent., payable April 15th.

On March 15th \$950,000 worth of 30-year, five per cent. gold first-mortgage bonds of the Niagara Falls and Lewiston railroad, better known as the Niagara Gorge road, were sold at auction in New York. They brought 50 cents on the dollar. They are due in June, 1925. The bonds were held as security by the Equitable Life Assurance society for a note for \$760,000.

INDUSTRIAL COMBINATIONS.

The street railways and electric-lighting companies of Easton, Pa., have been purchased by Stern & Silverman of Philadelphia, Pa. The various companies will be consolidated.

The *Chicago Record* asserts that a combination of manufacturers of gas and electric-light fixtures is being formed, with a capital of \$6,000,000 6 per cent. cumulative preferred and \$9,000,000 common stock.

A dispatch from Washington to the *Newark Advertiser* says: "Ex-Senator James Smith, Jr., has, it is reliably reported, secured an option on the gas and electric-light plants of the District of Columbia, and will consolidate them in one big trust. It is understood that he is backed by millions in local capital and the United Gas and Improvement company of Philadelphia."

The International Traction company is the name taken by the big syndicate that has purchased the electric roads in Buffalo, Niagara Falls and vicinity. It has been incorporated under the laws of New Jersey with a capital stock of \$15,000,000. Benjamin W. Franklin of New Jersey is the president, and C. McVeagh secretary. This organization is believed to be temporary, the expectation being that Hon. W. Caryl Ely will be the president in the permanent organization. Of the capital stock \$5,000,000 is preferred and \$10,000,000 common. The preferred is to bear 4 per cent. cumulative dividends.

Consolidation of the electric and cable street-railway lines of Denver was effected recently under the name of the Denver City Tramway company. Articles of incorporation were filed. The capital stock is \$5,000,000. The directors are Rodney Curtis, G. E. Ross-Lewin, James H. Blood, Samuel N. Perry, Dr. W. F. Accleman, Charles B. Whitehead, William N. Byers, Charles F. Musgrove and William G. Evans. The officers are: President, Rodney Curtis; vice-president, W. N. Byers; treasurer, G. E. Ross-Lewin. The cable lines will be changed to electric, provided the consent of the city can be obtained, and other extensive improvements will be made.

Some interesting figures about the rush of incorporations of new companies under the laws of New Jersey are given by a Trenton correspondent of the *New York Tribune*. The records of the secretary of state for the month of February show that it has been the greatest in the history of this state in the incorporation of large trusts and companies, and, as New Jersey leads all the other states in the number of incorporations, these records indicate that the combination of large industries and the organization of companies with enormous capital have been greater in the United States in the last month than ever before. In the last three months the amount of money received by the state in fees for incorporating companies under its laws exceeds the amount received in the whole 12 months preceding. The sum of \$71,631.96 was received in February for fees, and will be turned over to the state controller for deposit in the state treasury. January comes second, with \$68,830.50. To show how rapid has been the increase of incorporations formed under the New Jersey laws, the amounts of the state fees since October 1, 1898, the first month of the fiscal year, are given as follows: October, \$5,645; November, \$11,704.72; December, \$46,312.81; January, \$68,830.50; February, \$71,631.96; total, \$204,124.99. These figures show only the fees paid on the filing of the articles of incorporation, and do not include the receipts from the tax on corporations. The total amount received by the state in fees for the filing of certificates of incorporation in the last fiscal year was only \$164,000. If the average rate of incorporating of the last five months continues until the end of the present fiscal year, the state will receive nearly \$500,000, or about three times as much as last year, in fees for incorporating these concerns."

MISCELLANEOUS.

The 353-foot chimney, with 22-foot core, which has just been completed at the Ninety-sixth street station of the Metropolitan Street Railway company, New York, is said to be the largest in the world and the tallest on the continent. This stack gives draft to a 70,000 horse power station.

The United Pneumatic Fire Alarm Telegraph company, with a capital of \$100,000, has been incorporated in Trenton, N. J. The incorporators are Michael C. Bouvier, Albert Goldstein and Max Radt of New York, Bernard M. Irving of Wyckoff, N. J., and John Bouvier of Nutley, N. J.

The Bureau of Yards and Docks of the Navy Department is inviting sealed proposals, until April 8, 1899, for enlarging the existing three-wire, 220-volt, electric-light and power plant at the Norfolk, Va., navy yard. The specifications call for two boilers, one feed-water heater, one feed pump, two electric generating sets, one switchboard, two steam separators, two injector condensers and two steam condenser pumps. There will be four compound-wound, direct-current, constant-potential dynamos. Specifications and blank forms of proposal will be furnished intending bidders upon application to Mordecai T. Endicott, chief of the bureau, Washington, D. C.

The Chicago Edison company has secured the contract for wiring the new *Evening Star* building in Washington, D. C. The work includes the wiring for about 1,400 16 candle power lights and for 250 horse power in motors; also bell-signal system, telephone wiring and telegraph piping. It is to be done in iron-armored interior conduits. The contract also includes a very elaborate switchboard, with cable connections to storage battery. The switchboard has three dynamo panels of 75 kilowatts each, besides the various feeder panels for the lighting and power feeders. The building is to be located on Pennsylvania avenue, opposite the new postoffice building. It will be 10 stories high. The general contract was awarded to the George A. Fuller company of Chicago, which sub-let the electrical construction to the Chicago Edison company.

The Philadelphia exposition of manufactures suitable for export, which will be held in September, October and November, will furnish manufacturers of electrical machinery and appliances with an excellent opportunity of meeting the representative business men of Australia and neighboring colonies and exchanging views with them, that may result in opening up valuable trade connections. The second International Commercial Congress of the leading commercial men in the chief cities of the world will meet in Philadelphia during the progress of the exposition, and the visitors will naturally devote considerable time to an examination of American goods. The delegation from the Australian colonies will be a full and representative one. The display of electrical material is expected to form one of the leading features of the exposition.

A Rochester dispatch to the New York *Sun* relates that Frederick Owen of Pittsburg, representative of the Westinghouse Electric and Manufacturing company, who has had charge of establishing the electric-lighting plant recently contracted for by the village of Charlotte, met a severe accident at the power house of the plant. Mr. Owen was working on a large Westinghouse alternating-current generator when his arm came in contact with a live wire, and 1,500 volts passed through his body. The strength and path of the current are not stated. The man was thrown twenty feet and narrowly escaped being caught in the flywheel of the engine. When picked up he was unconscious. His fellow-workmen carried him out of the building, stripped him and laid his body on the wet ground. He began to revive, and in half an hour was conscious. The next morning he was able to be up, and in the afternoon he was apparently entirely recovered from the shock. It was noticed, however, that during a severe electric storm that prevailed at Charlotte on the day after the accident Mr. Owen suffered again the pains that racked his body while lying on the wet ground outside of the power house.

TRADE NEWS.

A New York financial publication makes the rather startling assertion that the General Electric

company does about 85 per cent. of all the electrical business in this country.

William W. Northcott, purchasing agent for the city of Victoria, B. C., will receive bids for arc-light carbons and globes until April 4th at 4 p. m.

The Knapp Electric and Novelty company of New York is removing its office and factory from 47 Warren street to 125 White street, where its facilities will be doubled.

The Martin J. Insull company of Chicago has been incorporated with \$6,000 capital by A. H. Reece, G. E. C. Johnson and Robert L. Elliott. The new company will be closely associated with the General Incandescent Arc Light company of New York and will deal in enclosed arc lamps, switches, sockets and other electrical specialties.

One of the busiest concerns on John street, New York, is the Standard Paint company. Purchasing Agent Vandewater recently stated to a representative of the *WESTERN ELECTRICIAN* that the company was literally overwhelmed with business. Outside of the electrical business, as is well known, the Standard Paint company does an enormous general trade. And when it is realized that the company's electrical department, handling a very large amount of insulated tape, compound, etc., is but a branch of this flourishing establishment, the present condition is easily understood.

The Smith & Hemenway company of 20 Warren street, New York, has purchased of the Malby-Henley company of the same city the latter's entire hardware business, good-will, trademarks, etc., and also all unfilled orders for hardware. The new company will take pleasure in receiving and executing all orders on goods of this nature formerly manufactured and sold by the old concern. Among other things the Smith & Hemenway company deals in Swedish carbons for all purposes. The Malby-Henley company will still continue business, devoting its entire attention hereafter to the silver-plated ware and kindred lines and steel-tin spoon branch of its business.

When a company receives daily unsolicited, testimonial letters from those using its product there must certainly be some merit in the article used. The Crescent Chemical company, Chicago, is one of the concerns thus pleasantly situated; it is constantly receiving the strongest kind of testimonials from electric-lighting companies using its Never Slip pulley covering. This covering is used all over the country, and is said to be giving the best of satisfaction. It is a liquid, is inexpensive and is absolutely guaranteed. The Crescent company will send a supply of its covering on 30 days' trial, and if not entirely satisfactory the sample may be returned at the company's expense.

The Western Electrical Supply company of St. Louis, Mo., has made arrangements with the Emerson Electric Manufacturing company for the sale of the latter's motors for this season. The long-established reputation which the Emerson company has enjoyed, due to its efforts to maintain a strictly high-grade product, has been demonstrated by the results obtained in the past. The Emerson '99 model electric fan, among other improvements, has an entirely different blade from the one formerly used, having a tendency to cut the wind without causing the incessant buzzing of most desk fans. The Western Electrical Supply company is in an excellent position to make prompt shipment of these fans and anticipates a very large fan-motor business this season. It is also again introducing its well-known Paragon fan, which met with much success last season. The Paragon fan is made only for direct current, whereas the Emerson is made for the alternating current. These two fans make a good combination and place the company in a position to supply the wants of prospective purchasers, irrespective of the current they are using. The new type Paragon ceiling fan promises flattering returns for the coming season, and will probably meet with general approval. The Western Electrical Supply company will take pleasure in making prices on both types of fans, in either alternating or direct current, for desk, bracket or ceiling types, on application.

BUSINESS.

W. C. Sterling & Son, Monroe, Mich., have a large stock of cedar poles for telephone, electric-light and street-railway lines and call the attention of electrical men to their prices and facilities for

prompt shipment. They also supply ties for railway work, cross-arms and pins.

Henry C. Adams, Jr., secretary of the Phillips Insulated Wire company of Pawtucket, R. I., is just starting on the western trip which he makes about this time of the year. His business is in excellent condition, as is shown by the fact that the new double factory is running full blast.

The Petite arc lamp of the Western Electric company is made in a number of different styles, so that it is suitable for use under different conditions. It is suitable for street-railway plants, power circuits and isolated plants. A handsomely illustrated catalogue of this lamp is sent on application to the company at Chicago or New York.

The Lombard Water-wheel Governor company has received an order for three additional type "B" governors for the plant of the St. Anthony Falls Water Power company of Minneapolis. These governors are for the three additional units of four Victor turbines each, which are now to be installed. This will make in all 10 Lombard governors in the plant, regulating 40 water wheels.

For a man that never had an idle moment to spare in the usual routine of business, it is not to be wondered that Capt. F. S. DeRonde of the Standard Paint company now finds the day short. Soon after his recovery from camp fever, contracted during the war, Capt. DeRonde made a western trip and was welcomed by many of his old friends. But his return to New York, after his protracted absence, finds him in the position of the man who wishes every day had 48 hours.

The Jandus Electric company has recently placed on the market a continuous globe enclosed arc lamp, 25 inches in length, which is attracting much attention. The method of trimming is ingenious, and is said to be the quickest yet devised. Ready accessibility to the lamp mechanism is another good feature. The western trade will be supplied with information, catalogues, etc., by addressing the company at 753 Monadsnock building, Chicago.

The Bryant bracket weatherproof socket, which is, it is claimed, an absolute weatherproof socket supplied with a brass cap, with either 1/2-inch or 3/4-inch thread, is an article which has been looked for for some time, and will undoubtedly find a large demand. This socket also has the advantage of being grooved to take a special 2 1/2-inch shade-holder, which is an advantage which has not been generally possessed by weatherproof sockets heretofore. The Electric Appliance company is carrying a large stock of these sockets.

Charles H. Besly & Co., 10 and 12 North Canal street, Chicago, Ill., report that they are very busy in the tap and die department at their factory, Beloit, Wis. They are making many shipments of their new Badger non-adjustable die stock, which cuts the same size every time and full thread at one cut. These die stocks are made complete in the bicycle sizes, as well as in the machine-screw and regular bolt sizes. Recent shipments of taps and dies have been made to Rockford, Milwaukee, Rock Island, Moline, Pullman, South Chicago, Joliet, Omaha, London, Lima, Rio de Janeiro and other points.

The many friends throughout the western and southwestern states of W. N. Matthews, who was so long identified with the success of the St. Louis Electric Supply company of St. Louis, Mo., are watching with interest his new venture. Mr. Matthews is at present handling a large line of second-hand electric and steam machinery, with headquarters at 312 Commercial building, St. Louis. This machinery is all in first-class condition, and is only for sale in consequence of its having been discarded through the consolidation of several small plants into a large plant, and also through the change from overhead to an underground system. In a word, although nominally "second-hand" machinery, this lot is considered practically as good as new. Mr. Matthews' present plan is to further prosecute the business of handling second-hand electrical machinery. With his enviable reputation for square and straightforward dealing and his long experience in the supply business among the central-station people of his section, it is safe to say that he has only to continue this business to make it a success. Mr. Matthews is at present in New York, where he has secured several valuable agencies for his territory.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 14, 1899.

620,900. Means for Lighting Fountains, etc. August Engelsmann, Stuttgart, Germany. Application filed December 11, 1897.

Features of this arrangement include the drum, the colored glass and light therein, the U-shaped rim on the upper edge of the drum, and the drum cover having a glass and having a flange extending down into the channel formed by the U-shaped rim, so as to leave an air space for the passage of air to and from the interior of the drum.

620,907. Trolley Ear. Henry Geisenhoner, Schenectady, N. Y. Application filed August 5, 1898.

The trolley wire has grooves, a trolley ear has lugs, and a wire laid in the grooves and passing around the lugs secures the ear and trolley wire together.

620,930. Circuit Breaker. Thomas J. Johnston, Schenectady, N. Y. Application filed October 19, 1898.

This circuit breaker comprises a switch, a trip, an electromagnet and armature for opening the trip, and a device for altering by steps or aliquot portions the pull necessary to actuate the armature and trip and open the switch.

620,965. Alternating-current Motor. Edwin W. Rice, Jr., Swampscott, and Charles P. Steinmetz, Lynn, Mass. Application filed July 29, 1893.

The motor includes an inducing or primary element, comprising coils or sets of coils connected in series and angularly displaced so as to have different axes of mag-

netization, an adjustable resistance connected in multiple with one of the coils or sets of coils whereby the magnitude and phase of the current therein may be varied, and a secondary or induced element in inductive relation to the primary coils as set forth.

620,966. Induction Motor. Edwin W. Rice, Jr., and Charles P. Steinmetz, Schenectady, N. Y. Original application filed July 29, 1893. Divided and this application filed October 16, 1897.

Claim is made for the combination with single-phase mains of an alternating current motor containing three angularly displaced windings, one of which receives current by inductive action from the other two, and all of which receive energy derived from the single-phase mains, and means for shunting one winding by a device adapted to shift the phase of current in the winding.

620,986. Frequency Changer. Charles P. Steinmetz, Schenectady, N. Y. Application filed January 31, 1895.

A frequency changer is composed of two dynamo-electric machines of the rotary-field type, connections being made from one of the machines to a supply system, and from the frequency changer to a secondary system, and means provided whereby the speed of one of the machines is so modified by the action of the other that the currents induced in its secondary member, and fed therefrom to the secondary system, are of a definite frequency different from the frequency of the currents in the supply system.

620,987. Frequency Changer. Charles P. Steinmetz, Schenectady, N. Y. Application filed January 31, 1895.

The method of changing the frequency of alternating-current circuits or systems consists in supplying currents of given frequency to the primary of an induction or transformer motor maintained in rotation at a speed different from that corresponding to the frequency of the supplied currents, feeding one circuit with currents induced in the secondary of the motor, and a second circuit with currents generated in a generator mechanically coupled with the motor, and representing the mechanical energy consumed by the motor.

NO. 620,965.

620,988. Self-starting Alternating-current Motor. Charles P. Steinmetz and Ernst J. Berg, Schenectady, N. Y. Application filed September 10, 1895.

An alternating-current motor has exciting windings connected directly to the supply mains of the system, phase-modifying devices consisting of a device having capacity and a device having inductance, connected across the mains in parallel to the first-named exciting windings, and other exciting windings connected to the first-named exciting windings at an intermediate point, and connected at their free end to a point between the device having capacity and the device having inductance.

620,989. Starting Device for Electric Motors. Charles P. Steinmetz and Ernst J. Berg, Schenectady, N. Y. Application filed January 26, 1897.

In a single-phase alternating-current system of distribution it is proposed to use an alternating-current motor having main and supplemental inducing windings, the main windings being directly connected to the supply lines in parallel to the first-named exciting windings, and the supplemental inducing windings to the supply lines, one of the phase-modifying devices consisting of a phase-advancing device in the secondary circuit of a step-up transformer.

620,990. Frequency Changer. Charles P. Steinmetz, Schenectady, N. Y. Application filed January 30, 1895. Renewed February 5, 1897.

The combination is claimed of a transformer or induction motor and a synchronous generator geared to run in unison therewith, with a source of alternating currents of given frequency supplied to the primary of the motor and a circuit for supplying current to translating devices connected in multiple with the generator terminals and with the secondary of the motor.

620,996. Electric Arc Lamp. Joseph T. Tsachieret, Levallois-Perret, France. Application filed May 9, 1898.

The claim is reproduced: An arc lamp comprising two rigidly connected frame plates, sheaves revoluble in bearings secured to the upper plate, a guide rod depending from the upper plate, tubular guides arranged diametrically opposite each other respectively rising and depending from the lower plate, a tubular carbon holder working in the tubular guide riser from the lower plate and on the guide rod depending from the upper plate, a carbon holder working in the tubular guide depending from the lower plate, a flexible connection passing over the aforesaid sheaves and connecting said carbon holders, which latter are provided at their lower ends with a horizontal arm projecting toward each other to hold the carbons in the vertical axial plane of the frame or substantially so, in combination with a solenoid, its core or armature, the lever pivoted to said core and terminating in a sleeve through which one of the carbon holders passes, the spring, means substantially such as described for limiting the movement of the lever in one direction, suitable electrical connections connecting the carbon holders with a supply circuit, and a shut circuit including the solenoid.

NO. 620,990.

620,997. Self-acting Annunciator-indicator. Francis C. Van Dyck, Jr., New Brunswick, N. J. Application filed March 20, 1897.

A horizontal series of vertically movable indicators, each provided with a hook having a beveled face, and a transversely disposed screw retaining rod for all the hooks provided with a beveled face, a second horizontal series of annular magnets in a different horizontal plane from the first series, provided with similar hooks, a similar transversely disposed retaining rod for the hooks, and operative connections between the transversely disposed bars for insuring their simultaneous movement.

620,998. Electrical Device Involving Hierarchically Insulated Conductors. Nathaniel G. Warth, Indianapolis, Ind. Application filed December 7, 1897.

In an electric cable there is an impermeable and hermetically sealed sheath containing fibrous insulating

material and rarefied air, which latter in part forms the dielectric for the conductors when the cable is in use.

621,005. Electric Meter. William S. Weston, Chicago, Ill. Application filed July 1, 1898.

This meter consists of an electric motor having an alternating or to-and-fro rotative movement, a pole changer adapted to reverse the torque of the motor after it has passed the center of movement, and a registering train for recording the total movement of the motor.

621,008. Electric Storage Cell. Chaimsonovitz P. Ellicson, London, England. Application filed May 9, 1898.

A plate for an electric accumulator comprises a series of parallel perforated and corrugated plates, the corrugations of one plate being arranged at an angle to those of the adjacent plates, the exterior plates being formed of one piece bent to surround the interior plates and having its ends secured together and rivets of the same material as the plates uniting the same, the several plates being united by autogenous soldering.

621,080. Underground Electric-railway System and Traveling Collector Therefor. Nestor Henquin, Schenectady, N. Y. Application filed March 8, 1898.

A conduit of the character described and a collector consisting of a yoke, wheels journaled upon the yoke, the wheels having a conducting center and insulated sides, conductors leading from the axles of the wheels, a housing secured to the under side of the car, copper plates fitted within the housing, and means for maintaining the collector in its proper relation to the housing are described.

621,084. Method of Applying Preservative Coatings to Objects or Structures of Iron or Steel. Henry L. Hollis, Chicago, Ill. Application filed April 20, 1898.

The method of applying a preservative coating to iron objects consists in subjecting the iron object to be treated to an oxidizing reagent, passing a current of electricity from the object through the oxidizing reagent to furnish oxidizing conditions at the surface of the iron object and cause the union of oxygen with the iron, and subjecting the coated iron object to an annealing temperature.

621,093. Fire-alarm Box. James W. Johnson, Chicago, Ill. Application filed December 7, 1896.

The first claim is given: In a signaling apparatus the combination of a starting device, motor mechanism responsive to the starting device, a signaling device adapted to be operatively connected with said motor mechanism, a signal-arresting device, a motor-stopping device independent of the length of time the motor is in operation and normally held to an inoperative position, but adapted to be rendered operative in response to abnormal conditions.

NO. 621,005.

621,104. Electric and Combined Electric and Gas Chandelier or Bracket. Willy H. Lau, Chicago, Ill. Application filed June 6, 1898.

A combined electric and gas distributor comprises a gas distributor, rings of non-electric conducting material surrounding the gas distributor, such rings having grooves therein forming holes through which gas arms can be inserted to be secured in the gas distributor, metal plates, one of such plates having lugs extending peripherally of the rings, bolts extending through the metal plates and the rings and securing the plates and rings rigidly together, and a bracket secured to the electric distributor in combination with gas arms secured to the combined electric and gas distributor by being extended through holes in the electric distributor and into the gas distributor, and electric arms secured to the combined electric and gas distributor by extending into the peripheral lugs.

621,126. Electrical Switchboard Signal. William E. McCormick, Chicago, Ill. Application filed January 11, 1898.

The combination is made in a switchboard casing having a series of openings arranged one above another in the front thereof and doors or shutters for closing the openings, of means—such as an incandescent electric lamp—located within the casing near the front thereof for illuminating the interior of the same, a series of frames having shelves in the rear and open spaces at the front thereof, so that rays of light can pass therethrough, the frames being arranged one above another within the casing and in the rear of the openings through the front thereof, electromagnets on the shelves, and an armature for each magnet adapted to engage and operate a shutter corresponding thereto.

621,150. Process of Manufacturing Active Compositions for Secondary and Primary Battery Elements. Alexander Schanschiff, London, England. Application filed January 3, 1898.

A process for the production of active material compound for battery elements consisting in intimately mixing finely powdered carbon with formic acid, tartaric acid and sulphuric acid, when the mixture has cooled adding the active material and when cooled making the mixture into a dough-like paste, with sulphuric acid solution, whereby the paste after it has dried and been "formed" is in a highly porous condition and has its pores filled with highly porous gas absorbent and conductive matter.

622,295. Automatic System for Preventing Collisions on Electric Railways. Charles F. Bancroft, Lowell, Mass. Application filed November 3, 1898.

The combination is shown in an electric railway of a feed wire, a trolley line, provided with turnouts, having in each branch an insulated section, and means whereby the moving of a trolley or equivalent device over one branch of one of the turnouts will render the insulated section of the opposite branch of the next turnout in advance dead and prevent an approaching car from passing over the last-named turnout.

621,210. Apparatus for Supporting Electric Wires and Automatically Cutting off Current on Breakage of Same. Ralph Bostock and Frank A. Cheetham, Brighouse, England. Application filed November 29, 1898.

In apparatus for supporting electric wires, there is a frame, a block capable of sliding in same, and insulated therefrom a shield pivoted at one end and below the frame and adapted to make contact with the wire carrying the current, means for normally connecting the shield and block and means for withdrawing the block and thereby disconnecting it from the shield when the wire is broken, so that the shield may fall by its own weight.

NO. 621,048.

621,241. Electrical Controller. Nathan K. Garhart, Indianapolis, Ind. Application filed August 8, 1898.

An electrical controller includes a suitable frame, a horizontally rotatable lever adapted to be actuated by the foot, a horizontal rod rotatably mounted in the lever with an upturned end that engages the frame when the rod is oscillated, and a pedal piece secured to such rod for oscillating it.

621,263. Electric Switch. Andrew E. Maccoun, Braddock, Pa. Application filed March 28, 1898.

An electric switch is described comprising a rotatory drum having a series of conducting sections laterally insulated from each other, a bar to which the current is led, the bar having electrically connected conducting fingers arranged to bear upon the sections and split up the current, and another bar having electrically connected fingers arranged to bear upon the sections and collect the split-up current.

621,267. Magnetic Lifting Device. Ambrose Monell, Homestead, Pa. Application filed May 12, 1898.

In a magnetic carrying device there is a series of electromagnets, the lifting power of the series being proportioned to lift the heaviest weight desired, and each individual magnet being proportioned so that the magnetic lines between its poles will be practically completed through the smallest thickness of article to which it is applied, means for energizing and de-energizing the magnets, and an equalizing support for the magnets arranged to distribute the lifting strain equally among them.

621,291. Electric Incandescent Lamp. Francis M. F. Cazin, Hoboken, N. J. Application filed October 29, 1895.

In an electric incandescent lamp there is a luminous body which consists of two cohesive parts, of which a linear, uniformly sectioned, continuous filament of suitable material and section is the one, or inner part, and sheets or webs or pseudo fabrics, made of rare metal oxide, as their main substance, form the other or outer part, which two parts are adhering to one another.

NO. 621,084.

621,292. Electric Incandescent Vacuum Lamp. Francis M. F. Cazin, Hoboken, N. J. Application filed October 15, 1897.

An electric incandescent vacuum lamp, having an extra glass housing, surrounding the inner air-exhausted glass bulb and leaving space between the inner and outer glass walls, and having a part of the inner bulb projecting through the housing into the surrounding atmosphere.

REISSUE.

11,724. Electric Vehicle. Karsten Knudsen, Chicago, Ill. Application filed December 16, 1898. Original number 613,420, dated November 1, 1898.

A vehicle frame comprising a rear axle is described, upwardly extending brackets mounted thereon, a pair of longitudinal tubes secured in the brackets, a cross piece, an electric motor frame journaled to the rear axle and resiliently suspended from the cross piece, a cross piece joining the longitudinal tubes at the forward end of the frame, a center bracket upon which the cross piece is supported, tubes extending laterally from the center piece, each carrying brackets upon the ends, and a pair of axles mounted upon the brackets to rotate about vertical axes.

CHICAGO, APRIL 1, 1899.

No. 13

An Electrical Sawmill.

A sawmill built from the ground up for electrical operation is still a novelty, rapid as has been the introduction of electric power for factory driving. Such a plant is to be found in Chicago, however, in the large establishment of the Edwin S. Hartwell Lumber company on Elston avenue, near Humboldt boulevard. The yards extend along the north branch of the Chicago River, opposite the Deering harvester works, and are of large extent and traversed by special tracks of the Chicago and Northwestern railroad. The manufacturing plant is new and consists of a planing mill and saw-sheds. The power house (Fig. 2, page 182) is placed between them. Power from a 500 horse power engine is transmitted mechanically to the planing mill and electrically to the saw-sheds. In the latter every machine is driven by an electric motor, and the whole sawmill was designed and arranged for electrical operation.

Five tubular boilers (Fig. 3) of 100 nominal horse power each constitute the steam-raising equipment. Shavings and sawdust are burned as fuel under them in external furnaces or Dutch ovens. This fuel is collected in the planing mill and saw-sheds by two steel-plate exhausters and delivered to a cyclone head on the roof of the planing mill. From this receptacle the shavings are fed through pipes to the furnaces. The galvanized-iron chutes used for this purpose are plainly shown in Fig. 3. The boilers have suspension settings. The breeching leads to a self-supporting steel-plate stack, 110 feet high above foundation and having a 60-inch flue. The top of the foundation for the stack is two feet above the boiler-room floor, and the breeching enters

room and supplies current to the motors in the saw-sheds. The shaft has two friction clutches—one attached to the pulley driving the dynamo and the other, a friction-clutch cut-off coupling, connecting the long shaft in the planing mill.

Fig. 4 (page 183) shows the power generator and switchboard. The dynamo is a Westinghouse, 250-volt, 225-kilowatt, multipolar machine. The switchboard is of white marble, with Wagner instruments and Bergmann switches. There is a separate switch for each of the six circuits leading from the board, whether light or power, and provision is made for extension. Lightning arresters are being placed on all outdoor circuits. A 110-volt lighting dynamo, driven by its own engine, is to be installed, but in the meantime all lights in the mills, both arc and incandescent, are run on the 220-volt circuits, with

types of saws, an exhauster and groups of machines. Four of the motors, of 15, 25, 30 and 50 horse power each, are multipolar; the others are bipolar. Each motor is elevated on a platform, and, with the exception noted, enclosed in a room or large box of its own, with door and window, starting apparatus and fuses. The wiring is all open and is well done.

Exceptionally good service has been given by this plant, and Mr. Hartwell is well pleased with the electrical system. It enables the machinery to be arranged in any position desired, without reference to line shafts, and is economical of power, as there is no idle shafting to be driven when one group of machines has ceased work for lack of material or other cause. The electrical plant is to be extended to the installation of more enclosed arc lamps throughout the yards and the erection of an electric hoist at the wharf on the river, to be used in unloading lumber barges.

When the sawmill motors were first put into service some of them were installed temporarily, as the machines to be driven were not in their permanent positions. In consequence several of the machines were compelled to carry overloads, and this afforded opportunity for some interesting tests, which were made by Mr. S. G. Neiler of Pierce & Richardson, the consulting mechanical and electrical engineers for the plant. Under the running conditions, it was found that a 20 horse power motor driving a resaw ran for three consecutive days with 76 per cent. overload. This machine behaved admirably, there being an entire absence of sparking at the brushes. Two of the eight horse power motors were run continuously for over

FIG. 1. AN ELECTRICAL SAWMILL.—A FEW OF THE MOTORS.

the chimney at a height of 10½ feet above the foundation. The stack is lined throughout, above the breeching, with curved firebrick, and there is an opening in the base to make easy the removal of soot.

The engine that operates the power plant has a single cylinder 30 by 48 inches and turns at 70 revolutions per minute. It was built by Filer & Stowell, and has a heavy-duty frame and a specially built-up flywheel 22 feet in diameter and weighing 55,000 pounds. It is now running non-condensing, but is fitted with double eccentrics, permitting a better distribution of steam and thus increasing the economy at full load. It is usually run at 90 pounds steam pressure, and then gives an output of about 500 horse power, but at 100 pounds pressure and at the latest point of cut-off it has a capacity of 800 horse power.

The engine drives an elevated jack-shaft, supported by extra heavy standards. This shaft extends into the adjacent planing mill and drives all the machinery there. To it, also, is belted the electric power generator, which is located in the engine

room and supplies current to the motors in the saw-sheds. The planing mill and saw-sheds are well lighted, many of the lamps being attached to pendant lamp-cords, so that all parts of the machines may be supplied with ample illumination. The switchboard is arranged so that when the new dynamo is installed the lights can be easily carried on separate 110-volt circuits. Then the lighting and power outfits will be independent and may be run separately.

In the saw-sheds there are 19 220-volt Holtzer-Cabot motors, ranging from five to 50 horse power in capacity. They are all belted machines, and, with the exception of the two placed on balconies in the second story of the building and shown in the upper view in Fig. 1, they are all completely housed in, as indicated in the lower picture in the group. There are four motors of five horse power each, four of eight horse power, three of 10 horse power, three of 15 horse power, one of 20 horse power, two of 25 horse power, one of 30 horse power and one of 50 horse power—in all, 19 motors with a combined capacity of 277 horse power. The smaller motors drive elevators and conveyors; the larger ones conveyors, various

two weeks with a 30 per cent. overload. The 50 horse power motor, which was installed to run a group of machines, was obliged to carry an overload of 40 per cent., as one of the steel-plate exhausters was connected to the shafting. This machine carried this overload for a week, at the end of which time a motor was installed for driving the exhauster. The 30 horse power motor was subjected for an entire day to an overload of no less than 100 per cent. The machine behaved very well indeed under this excessive overload, neither the armature nor the fields becoming overheated and there being very little trouble at the commutator. Under no condition was there any injurious sparking. The small eight horse power motors ran along with their overload exceptionally well for such small machines. One in particular, which was driving a saw, was experimented with. It was found that when ripping one-inch boards at the highest speed 34 amperes was required. This is 10 per cent. overload. With two saws on the same shaft, making two cuts in one-inch board, 56 amperes was required, the machine under these conditions carrying an overload of about

87 per cent. With one saw cutting two-inch board, the motor required 60 amperes, which was 100 per cent. overload. The latter experiment was made to determine whether a change could be made and a larger saw put in the outside saw-shed, but as this machine when operating under normal load required just eight horse power no change in the saw was made.

These tests again demonstrate the endurance and flexibility of the electric motor and its peculiar adaptability for factory use.

Electric Street Lighting.¹

By ALBERT SHEIBLE.

The efforts made toward street lighting by that early electrical student, Benjamin Franklin, make it particularly fitting that our streets should be lighted electrically. And when we consider how readily we can supply electrical energy to lamps distributed over wide areas, how a given amount of gas will produce nearly three times as much light when used to run a gas-engine dynamo supplying incandescents as when consumed in fish-tail burners, and how we can easily support our electric lights in positions and under conditions that would bar out both oil and gas lamps, we may well expect lighting by electricity to closely approach the ideals of street lighting and to most fully meet its prime objects. This it has done sufficiently to hold its own for nearly a score of years, yet we can hardly say that the average electric street-lighting installation has made the most of its possibilities. The reasons for this will be more plain when we look back over the last score of years and trace the causes which have molded electric street lighting into the present common forms.

Street lighting, as a whole, had become quite common for large cities before the advent of electric-lighting practice; indeed, Pompeii had its street lamps, and even the use of gas for street lights dates back almost to the time when Davy discovered the electric arc. Paris was lighted with gas as early as 1817, while Berlin and Dresden followed nine and 10 years later, so that the extended street lighting of large cities from a central point had passed the experimental period more than half a century before the days of electric lighting. What is more, our larger cities 20 years ago seemed to be well aware of the two prime objects of street lighting, namely, path finding and crime preventing. They wanted to give the pedestrian enough light to see others approaching him and to avoid his stumbling over irregularities in the sidewalks or streets. They endeavored to give enough light at the crossings for teamsters to see holes or obstructions in the roadway, and they knew that the highwaymen would be greatly handicapped by the lighting of the dark nooks and alleys which formerly harbored them. Had the incandescent lamp come first it probably would have been immediately set to work at helping

went up immediately for electric street lamps, powerful street lamps, dazzling street lamps. Mr. Brush himself likes to tell of the first electric street lighting in this country, when a dozen tower lamps were placed on the Public Square at Cleveland, and when many in the crowds that gathered brought dark spectacles with them! It was not so much the illumination that they were watching for, but rather the dazzle, the glare; and having once seen these

FIG. 2. AN ELECTRICAL SAWMILL.—POWER HOUSE

dazzling lights and noted the intense illumination near them, the people were not satisfied with anything less brilliant, so that high candle power of lighting units became a requisite of lamps for street lighting.

The result was twofold; first, the cost of the high candle-power lamps made it necessary to get along with a much smaller number of lighting units than had formerly been used; and, secondly, the impression made on the general public by these intense lamps led to emphasizing the show or display feature. These new factors have been affecting street lighting ever since, and besides influencing the trend of

FIG. 3. AN ELECTRICAL SAWMILL.—BOILER ROOM, SHOWING CHUTES CONVEYING SHAVINGS TO FURNACES.

street lighting to more readily fulfill these two prime objects.

But it was the arc lamp that came first here and the Jablochkoff candle in Europe. Both of these were lamps of high candle power, and in admiring their great brilliancy, the people forgot the formerly well-known objects of street lighting. Wherever the arc lamp or the Jablochkoff candle was shown, the high candle power made the old gas or naphtha lamps seem very dim and ineffective; hence the cry

street lighting, they have done a great deal toward introducing electric-light systems into towns which otherwise might still be without them. This very show feature appeals to the pride of the citizens of the average town, when electric lights are proposed for use on their streets, so that even to-day we can find items like this in the local papers: "If we can get a telephone system and electric lights, this will indeed be the metropolis of the county." No doubt, the presence of a good street-lighting system and the show created on the business streets by an intensely bright lighting during the evening have drawn

trade toward towns thus lighted; and happily so, for there are hundreds and hundreds of cities in this country that have been blessed with electric-lighting and power circuits for years that even now would not have them were it not for the encouragement given to the proposed lighting company in the shape of a city lighting contract.

The rapidity with which electric lights were introduced has shown a very marked effect on the character of the devices used in connection with them. In the early days the many problems connected with the successful building of the generators, regulators, lamps and switches left the makers no time for paying proper attention to the means for supporting the lamps, for protecting them from the weather or for reflecting the light so as to distribute it over a wide area. Nor were the purchasers particular; almost any sort of arrangement would do if ready in time. The result was immediately seen in the crudeness of many of the street-lighting devices brought out at that time, and, unfortunately, a large share of those still on the market are merely copies of these early examples. Even to-day the number of manufacturers who have made a real study of the needs in this line is very, very small, and naturally so, as the devices represent quite a small part of the cost of a plant. These few have already done much toward equipping both new and old plants with a better class of devices, and can do more just in proportion to the support given them by electrical engineers, city officials and the general public.

Having taken this glimpse at the causes that have molded street lighting in the past and are still molding it, let us now look briefly at some of the changes due partly to the general progress in electrical work and partly to these peculiar influences.

As for the lamps themselves, electric street lighting has, for the most part, been done with just the same types of arc lamps that have been used indoors, the works of the arc lamp being somewhat protected from the weather by means of a sheet-iron hood over it. Only within the last half-dozen years have there been lamps with a proper weatherproof casing so as not to need this hood. The so-called 2,000 candle power (460 watt) and 1,200 candle power (300 watt) arc lamps are used almost entirely, though here and there we find some smaller sizes, which I believe will be used more largely in the future. The term "2,000 candle power" in itself impressed the people in the towns lighted as something worth having, and if they happened to find out that the lamps really gave only about a quarter of this candle power, the electric-light men had no difficulty in convincing them that "the 2,000 candle power lamp is one which sends 500 candle power in each of four directions from its place over the street crossing." Incandescent lamps have been most commonly used in the 25, 30 and 32 candle power sizes, with a few of 50 or 75 candle power, and some of only 16 or 20 candles. However, the distribution of the light from these lamps has almost always been aided by the reflectors over them, which is not the case with the arc lamps.

As a distribution system, the series circuit still holds almost a monopoly for street lighting. It lends itself so readily to the connecting of lamps scattered over a large territory that it was used with the Brush arc lamps just as soon as the differential winding made the operation of arcs in series a possibility. The number of lamps on a circuit and consequent voltage was limited only by the ability of the dynamo builders to properly insulate the parts of their machine. Eighteen years ago a circuit of 16 or 18 arcs was a high-voltage circuit, although the lamps then used were the so-called short arcs requiring only 25 to 30 volts each. Bare copper wire was used at that time, but sad experiences with it led to the "underwriters" and later to the so-called "weatherproof" wire, which is still used almost exclusively except for wires leading into the casing of weatherproof arc lamps, for which purpose rubber-covered wires are now preferred.

The size of the dynamos was at first larger in Europe than in America, as the 48 Jablochkoff candles installed 21 years ago in the Place de l'Opera at Paris were run on multiple circuits from three alternators (each with its own exciter), driven by three 20 horse power engines. This meant 16 lamps per generator, while the earliest Brush arc dynamos built at about the same time were made for a single arc lamp, and the two-light and four-light machines which followed them had the lamps in multiple. Then when the series lamp was perfected circuits of 12 to 18 lamps became common and dynamos gradually increased in size up to the so-called 60-light or 50-kilowatt type, which for years has been the accepted unit. However, the development of much larger constant-potential generators, and the evident increase in efficiency with the larger sizes stimulated the builders until we now have arc machines supplying as many as 150 of the 2,000 candle power lamps, or 200 of the 1,200 candle power. Some of these are so arranged that the lamps, while all in series, are distributed over three circuits, so that the voltage on any one circuit is only about a third of the total. Meanwhile there have been great improvements in the alternating-current arc lamps, and the perfection of such lamps for use on series circuits seems close at hand. When it comes, we shall be able to run both our arcs and incandescents from the same machine, so as to use the 200 or even 500-kilowatt generators (which already have reached such high efficiency) without needing the rectifiers

¹ Read before the Chicago Electrical Association, March 10, 1899.

now used to some extent in England for supplying current from alternators to arc lamps in series.

Incandescents for street lighting are usually connected in series across the primaries on the alternating generator, each lamp being provided with a suitable cut-out device (either in the base of the lamp or in the socket) to automatically close the circuit when the filament gives out. An exception to this is the Westinghouse plan of having an inductive or so-called "kicking" coil in shunt with the lamp, the coil being of too high resistance to consume much current ordinarily, but which will offer an inductive counter-electromotive force equal to the voltage of the lamp when the latter gives out.

The method of supporting the lamps varies from place to place, and, as a rule, has not had the proper amount of thoughtful attention paid to it. In the early days, when the number of arc lamps used was very small, these were put up on tall masts or towers so as to form an imitation moon, which was supposed to light a wide area. Such towers are still in use altogether at a number of places, and have also been retained in parts of other towns. They have the great advantage that they hold the lamp high enough not to glare into your eyes when walking toward them, but tall trees or buildings of any considerable height usually interfere with the distribution of light from them. Such towers generally had from two to six arc lamps each, and the next step was the placing of each of these lamps over a tall pole, so that the lamps could be distributed over the area to be lighted. The poles, being set inside the curbing, brought the lamp so close to the line of the shade trees as to cut off most of the light from the walk on the nearer side. To overcome this, lamps were hung out at the end of iron mast-arms, these being 10, 12, 15, or even 20 feet long, and, as a cheaper substitute, the cross-suspension wire method was then introduced (though mast-arms can now be put up as cheaply as the cross-suspension). Each of these methods has given good average results, yet there have been objections to each when universally used.

For a wide distribution of light from a lamp, the latter ought to be not less than 30 feet above the street, hence the mast-arms or cross suspensions were at first made to support the lamp over the center of the street and some 30 or 35 feet high. This brought the lamp above the foliage which shaded and darkened the walks, so the lamps were lowered to the common height of only 18 or 20 feet, bringing them so nearly on a level with the eyes of teamsters as to seriously dazzle them when driving toward the lamp. Reducing the candle power of the lamp reduces the intensity of this glare, so that a 340-watt or 240-watt lamp is less offensive than the 460-watt arc, and a 105-watt incandescent lamp still less so. (The energy required for the 460-watt arc will supply four or five incandescents scattered like our gas lamps, to give a more even distribution of lighting units.) Happily, the enclosing globes used

The distribution of lamps in a town, while still affected by the political influence of adjoining residents, is no longer done entirely in accordance with the clamor of the local constituents. The question used to be, Where shall we put a certain number of lights? Now it is, Where do we need the lights, and how shall we support them to avoid deep shadows? One recent installation had 14 per cent. of the arc lamps on mast-arms, 25 per cent. on short pole brackets, 60 per cent. on cross-suspension wires and one per cent. on pole tops. Even in this case

ALUMINUM AT NIAGARA.

many of the cross-suspension arcs might better have been replaced by four or five times as many incandescents, as is now frequently done.

Reliability of service is now insisted upon, and the contracting plant has to pay a rebate for every hour's lamp outage reported by police or by inspectors appointed for the purpose. Hence the adoption of such construction as will withstand high winds and sleet storms, of safety pulleys and pole-locks that will avoid accidents to the lamp, and of loop switches to cut out a portion of the circuit for repairs without interfering with the rest of the lamps.

From an artistic point, electric street lighting still leaves much to be desired. Only a small portion of the fixtures and lamps used have been designed on lines of beauty, and the average circuit is all but sightly. Still the lamps and fixtures are better looking than formerly, and the adoption of pole-locks has done away with the unsightly bundle of rope at each arc-lamp pole, leaving the loosely dangling wires leading to the center-supported lamps as the chief eyesore. Even this will be doomed as soon as an automatic cut-out pulley enables us to run the line wires taut to the lamp support, which we shall be able to do on the morrow.

To sum up the changes in street-lighting practice: Yesterday the cry was for large lamps and intensely bright illumination of some picked spots, regardless

Aluminum at Niagara.

One of the peculiar sights to be seen quite frequently on the streets of Niagara Falls, N. Y., is a great wagonload of aluminum passing from the lower plant of the Pittsburgh Reduction company to the upper works. The metal is of snowy whiteness, and as such a sight has never been witnessed by many people before, it immediately attracts attention, for it looks like a wagonload of silver. The aluminum glistens in the sun, attracting the attention of all. In the accompanying illustration there is shown a wagon loaded with about three tons of aluminum in "pig" form. It is being taken to the upper works of the company mentioned, where there is a remelting furnace, and the pigs will be remelted and run in the form of rolling bars, slabs, wire bars, waffles and different forms of ingots, and then shipped to the manufacturer of the various aluminum wares. Niagara Falls is the greatest aluminum center in the world, and it is little wonder that it should have some such novelties to offer.

C. S. Knight.

Chicago's latest acquisition to its list of prominent electrical men is C. S. Knight, the newly elected vice-president and general manager of the Siemens & Halske Electric company of America. Mr. Knight has taken his headquarters in Chicago and will direct the policy of the company and the operations of its forces from this city. He has long been closely identified with the electrical interests of Chicago and the West, and the new trust reposed in him will tend to promote this relationship.

Mr. Knight was born at Columbus, O., and passed his early life there. Thirty years ago he entered the service of the railroad system that is now merged

C. S. KNIGHT.

into the Pennsylvania lines west of Pittsburg. He continued in the transportation department until 1881, when, for five years, he engaged in the gas business at Fort Wayne, Ind., and then became interested in the Fort Wayne Electric company. When this concern was thrown into the hands of a receiver in June, 1894, and the Fort Wayne Electric corporation organized for the purpose of operating the business under contract with the receiver, Mr. Knight was chosen a director of the new company. This connection continued until February 1st, when he resigned the vice-presidency of the corporation and accepted his present position with the Siemens & Halske interests.

Mr. Knight has enjoyed unusual opportunities of familiarizing himself with the electrical interests of all branches throughout the country and he has kept in touch with them. Under his energetic direction the Siemens & Halske company may be expected to take a commanding position among the electrical manufacturing concerns of the country.

Negotiations have been completed by Tucker, Anthony & Co., Boston, Mass., whereby they will build and finance the Peoria and Pekin Traction railroad, which will be 10 miles long, between Peoria and Pekin, Ill., using both electricity and steam—electricity for passenger traffic and steam for heavy-freight traffic. The power house will be located midway between Peoria and Pekin, and it is proposed to put in three engines of 325 horse power each, and room will be provided for a 650 horse power engine as an auxiliary engine. The company has a 50-year traffic agreement with the Central street railway of Peoria, which road controls all the surface lines in that city. The following-named officers have been elected: President, Theodore J. Miller of Peoria; vice-president, W. T. Trumbull, Salem, Mass.; secretary and general manager, Louis E. Myers, Peoria, and treasurer, P. S. Saltonstall, Boston, Mass.

FIG. 4. AN ELECTRICAL SAWMILL.—POWER GENERATOR.

on long-burning arcs are reducing the glare, and the same is true when ground, opal or fluted globes are used.

The hours of street-lighting service vary, some towns being lighted from dusk till midnight, others until dawn, and a large share having the lights turned off when the calendar says that the moon will shine brightly. This means darkness whenever fogs or clouds hide the moon, but recent contracts avoid this by calling for the light every night and allowing lamps to be turned off when the moon is not hidden.

of the equally intense shadows intervening. To-day there is the tendency to have the rays of light overlap and to use lower candle-power lamps in the alleyways and other dark nooks and on the streets of the outlying districts. To-morrow we may look for smaller units and a great many more of them.

Yesterday the type of lamp and method of support picked for the business district was used throughout. To-day many towns use the bright dis-

Electric Appliance Company in Its New Home.

Honestly won success challenges the admiration of every fair-minded person. No one with a spark of magnanimity begrudges the well-earned reward of merit. So when a clean, well-managed business enterprise like that of the Electric Appliance company of Chicago gives unmistakable evidence of successful growth by appropriating to itself a large new five-story building especially arranged for it, it is entitled to hearty congratulations from all interested in the progress of electrical industries in the West.

The steady and healthy development of the company in its seven years of life shows that it has a reason for being, that it has satisfied the needs of a constantly increasing number of customers, and that

occupies the space to the left of the general offices. In the rear of the offices and store, and occupying the remainder of the first floor, is the room devoted to outgoing and incoming freight and express.

On the second floor the manager of the shipping department has his offices. His assistants' desks and the benches for assembling and for the packers take about one-half of the space on this floor, the rest being used for bins for shades and shade holders, sockets, switches and miscellaneous stock.

The third, fourth and fifth floors, with the exception of the list of goods stored on each, may be well described in the same paragraph. They are arranged with bins, racks and shelves to best suit the stock carried in them. The telephone department is located on the third floor, as well as the office of Mr. S. A. Dinsmore, the manager of this department.

Last, but by no means the least important part, is the basement, with its accommodations for heavy goods

Mr. Chapman is receiving applications for space, and it is desired that intending exhibitors indicate the character and dimensions of the space they will require. Secretary Penington has issued a circular explaining the conditions imposed by the association and giving the necessary directions for shipment and installation of exhibits. Allotment of space will be made on September 1st.

General Meeting of the Institute to Be in Boston.

At the meeting of the American Institute of Electrical Engineers in New York on March 22d a paper was presented by Dr. M. I. Pupin of Columbia University on "Propagation of Long Electrical Waves."

Willard W. Low, President Electric Appliance Company.

Mr. Low's Private Office.

General Offices.

ELECTRIC APPLIANCE COMPANY IN ITS NEW HOME.

Thomas I. Stacey, Secretary and Treasurer Electric Appliance Company.

Mr. Stacey's Private Office.

it has been well managed. This success is the more noteworthy, as at least four of the company's seven years of existence were a period of marked business depression. The outlook for continued progress is excellent, and Messrs. W. W. Low and Thomas I. Stacey, who founded the business and made it what it is, have good reason to be proud of their work. These gentlemen are still attending strictly to business—President Low to the sales, Secretary Stacey to the office management—and their active personal efforts are a guaranty that the company's standard of achievement will be borne steadily onward.

It was on December 1, 1891, that the company started in business, using one floor of the building at 242 Madison street, with 2,500 square feet of space. One year later another floor was added. In the latter part of 1894 the entire building, or 8,000

—armorite and armorduct tubing, "O. K." bare copper and iron wire, cross-arms, brackets, polesteps, etc.

On each floor is a stock clerk, who must be thoroughly posted on the stock under his immediate control. All bins and shelves are lettered or numbered, classified and indexed in such a manner that the assembler can at once place his hands on the article wanted. Every arrangement or device which would in any way help toward the desired end—a quick shipment—has been employed. The quick-running elevator and lifts, the extensive house telephone system connected at the switchboard on the first floor with the city exchange and with the long-distance lines leading from Chicago, perform an important part in the dispatch of business.

To all its friends, to all electrical people everywhere, the Electric Appliance company extends a

The paper was discussed by Messrs. Bradley, Carty, Kennelly and Steinmetz.

At the meeting of the council in the afternoon the following-named associate members were elected: Tom Howard Gregg, Tompkinsville, N. Y.; Harold J. Horn, Trenton, N. J.; Howard S. Johnson, Columbus, O.; Herbert S. Miller, Elizabeth, N. J.; William D. Pomeroy, Akron, O.; Thomas Byrd Whitted, Schenectady, N. Y.

The returns from the nomination blanks sent in by the membership were canvassed, and the following-named gentlemen were announced as the council nominees:

For president, Dr. Arthur E. Kennelly; for vice-presidents, J. W. Lieb, Jr., Charles F. Scott, L. B. Stillwell; for managers, C. O. Mailloux, S. Dana Greene, C. S. Bradley, W. D. Weaver; for secretary,

City Sales Department.

Work Room in Telephone Department.

ELECTRIC APPLIANCE COMPANY IN ITS NEW HOME.

square feet was required. The new building has 30,000 square feet of floor space.

Now well settled in its new building, which is at 92 and 94 West Van Buren street (corner of Jefferson street), the Electric Appliance company has provided an attractive and well-arranged quarters, as pictures on this and the next page show very clearly. The company is enabled to carry a larger stock than before, and every facility is provided for filling and shipping orders with speed.

Passing through the main entrance on Van Buren street, the visitor notes on his left the private office of Mr. W. W. Low, the president of the company. To the right and opposite is the office of Mr. T. I. Stacey, secretary and treasurer. To the right of this again, and extending back about 70 feet, are the general offices. The store, or city sales department,

hearty greeting, with the invitation to visit it in its new home.

American Street Railway Association.

The local representatives of the American Street Railway association have perfected their organization and completed their plans for the annual meeting and exhibition in October. A general committee will have charge of all matters pertaining to the gathering. It will be composed of the chairmen of the several sub-committees as follows: M. K. Bowen, banquet; George A. Yuille, finance; J. M. Roach, entertainment; George O. Nagle, halls and hotels; H. M. Sloan, reception and ladies; H. H. Windsor, publicity and information; F. L. Fuller, transportation; James R. Chapman, exhibits; T. C. Penington, representing the administration of the association.

Ralph W. Pope; for treasurer, George A. Hamilton. The regular election will proceed after the distribution of the ballots early in April, and the result will be determined at the annual business meeting, which will be held in New York city May 16th.

The following-named local honorary secretaries were appointed: H. F. Parshall, London, for Great Britain; James S. Fitzmaurice, Sydney, for Australia; Prof. Robert B. Owens, Montreal, for Canada.

The council appointed Dr. F. A. C. Perrine to fill out the unexpired term of Lieutenant W. F. C. Hlasson, who has resigned from the office of manager on account of his removal to the Hawaiian Islands.

The council decided to hold the fifteenth general meeting at Boston during the last half of June, the exact date to be fixed by the executive committee.

Big Companies in Patent Litigation.

After a period of comparative quiet in the patent litigation between the prominent electrical manufacturing companies, the contention has been reopened by suits brought against the General Electric and Western Electric companies by the Westinghouse Electric and Manufacturing company.

The action between the Westinghouse and General Electric companies seems to be based on a misunderstanding of the contract between these companies, entered upon three years ago, for "a recognition of the patents of each company by the other, and the right, subject to certain exclusions, to a joint use thereof." The patents which have caused the present dispute are those of Tesla on the multiphase system. The Westinghouse company, which is the plaintiff, alleges that the General Electric company is negotiating contracts for use of the multiphase system, in violation of the contract between the two companies. The action was brought in the United States Court at Utica, N. Y., on March 21st, and is set down for trial, according to an Associated Press dispatch, for April 4th. Particulars of the exact grounds of the suit are not obtainable in the West. The New York Tribune asserts that "it is understood on good authority that the bringing of this suit does not signify that the friendly relations between the Westinghouse and General Electric companies will be broken off." On the other hand, the New York Sun, in an article reviewing the situation on March 23d, takes the view that the relations of the companies are less cordial than formerly. The greater part of the Sun's article is given:

Both companies maintain that their differences have their origin solely in the varied interpretation of a contract entered into in 1896 between the companies providing for an exchange of licenses. Three years this month [March, 1896] the companies entered into an agreement to allow each other to use their several patents under conditions restrictive of territory and customers. The allegation of the Westinghouse company is that the General Electric company has violated the terms of this agreement by contracting to furnish the Edison Electric Illumination company with the multiphase generators, whereas the United Electric Light and Power company of this city is the exclusive licensee of the right to use this apparatus.

The General Electric company maintains that a different interpretation of the agreement allows it to supply these generators to the Edison company. It declares, and the Westinghouse company does not deny it, that it has sold these generators to the Edison company before. No protest was made at the time by the now plaintiff company, and this fact lends color to the report current in Wall street yesterday that the suit is an entering wedge in a coming split in the pool of patents between the Westinghouse and General Electric companies. The plaintiff company and its licensees, the United Electric Light and Power company, by antagonizing the Edison company, place themselves in opposition to William C. Whitney's new \$25,000,000 electrical concern, the New York Gas and Electric Light, Heat and Power company. This new company recently absorbed the Edison company and with it the Manhattan Electric Light company. It has control of the subway system of the Empire Subway company. The Mount Morris Electric Light company is controlled by the Light, Heat and Power company, and the Block Electric Light and Power company is a more recent acquisition. There was a report that the United company was about to be consolidated into the new concern, but the negotiations never came to a successful conclusion. Another Wall street report is that the Westinghouse

company and its officers is for alleged patent infringement, but is of entirely different character from the suit against the General Electric company. The Western Electric company is charged, in a bill filed by Gifford & Bull of New York, the Westinghouse company's solicitors, with infringing patent No. 573,009, granted to Benjamin G. Lamme of Pittsburgh on December 15, 1896, and assigned to the Westinghouse Electric and Manufacturing company. This patent is for a direct-current dynamo-electric generator, and the claims cover methods of construction. The defendant is charged with general infringement. Suit has been brought in the United States Circuit Court for the Southern District of New York. Mr. George P. Barton, the patent attorney for the Western Electric company, said, in answer to the question of a representative of the

NEW BUILDING OF THE ELECTRIC APPLIANCE COMPANY.

Western Electrician, that he had not had time to examine the bill of complaint carefully, and that he was not now prepared to give an opinion on the merits of the case.

ELECTRIC VEHICLES.

The New England Electric Vehicle and Transportation company, with a capital of \$25,000,000, has been incorporated in New Jersey. The company is authorized to manufacture appliances for operating vehicles and to manufacture and operate vehicles themselves. The incorporators are James E. Hayes, Camden, and Arthur Phillips and Augustus Treadwell, Jr., of New York.

The Nassau County (N. Y.) Motor Coach company has been organized, with a capital of \$150,000. The directors are all stockholders in the electric railway which is to operate in Nassau County. The trolley road and the coaches will make connections. The motor company was formed in order that the Merrick road and other thoroughfares can have better transportation facilities. Legislative

ready. It is expected that during the next year over 1,000 motor cars and hackney will be running and that by degree the 3,500 cabs or cabs now in use will be replaced. The new cabs are to be supplied with batteries capable, it is claimed, of working over about 37 miles without need of replenishment. Four kinds of vehicles are to be put in circulation. First come the landaulet, open or closed, with four places, and to be hired at two francs the journey, or two francs 50 centimes the hour. Next comes a coupé or ordinary sort of cab or four-wheeler, then the vehicle with rotund interior for four persons, and the imitation of the existing hackney, with a large shelf seat or strapontin, in addition to the usual accommodation. All these vehicles, with the exception of the landaulet, will be run at the tariffs now in use. The delay in getting out the new vehicles has been caused by the difficulty of finding a proper type of accumulator. The drivers of the vehicles will be smart-looking fellows, unlike most of the existing Paris cabsmen, who seem rather ponderous and clumsy in their high hats and long coats. The motor conductors are to wear white-glazed flat caps, black jackets and trousers, with yellow piping and gilt ornaments, bearing the company's monogram.

Argentine News Items.

[Special correspondence of the Western Electrician.]

The rumor that the General Electric company of the United States intends to open a branch house in Buenos Ayres for the supplying of electric materials and machinery has been verified. This will insure a thoroughly up-to-date supply house and goods always in stock at reasonable prices. It also proves that the American electrical houses are beginning to appreciate the development that is now taking place in all parts of the Argentine Republic, and that they are going to compete with the Germans and English for the trade.

The following shows what change of traction from horse to electric has done for the Capital Tramways company of Buenos Ayres, and the managers say more promising results are in sight. The Capital Tramways company's gross receipts, converted into gold, at average rates, were as follows: Aggregate gross receipts from January 1 to November 17, 1898, \$229,650, corresponding period 1897, \$130,450; increase, \$99,200. Mileage open in 1898, electric, 17.64 kilometers; horse, 6.63; total, 24.27; in 1897, horse, 14.79.

The Concordia municipality has contracted with Señor Pablo Sabrega for an electric-light station in that city. The works will be situated in Salto Grande, so as to utilize the water power of the River Uruguay. As this is the fourth or fifth time the concession has been granted, it is hoped the works will now be carried out.

Enginer Marengo, the new chief of the public lighting department of Buenos Ayres, has reported to the mayor on the clause in the electric-tramway companies' concessions requiring it to give free lighting. His report condemns the clause as impracticable, but he is of the opinion that in exchange the companies might be taxed one per cent. on each \$1,000 per kilometer revenue. Instead of encouraging the remaining tramway companies employing horse traction to change to electric, which is conceded by all to be beneficial to the city, the authorities are discouraging them by every means in their power.

One of the most novel requests for a concession that has ever been made to any municipality in the world has just been received by the Buenos Ayres municipality. The would-be concessionaire desires a 20-year franchise for placing electric bells at the vaults and tombs in the Recoleta cemetery, so as to enable the owners to call the "peons" when they are wanted.

The municipality has resolved that, in future, all applications for electric-tram concessions must be accompanied by full technical data concerning construction materials, etc. This will prevent a number of would-be concession-mongers from appearing on the scene.

The director of public lighting has been authorized to contract with the German Electric Light company for the placing of 150 arc lamps in hitherto unlighted portions of the city of Buenos Ayres. When these new lights are in operation the city will be one of the best lighted in the world, and will be able to determine soon whether the alternating or the continuous-current arc gives the better result, and which is more suitable for street lighting, as both are now being used.

The Pacific Railroad company is now advertising in the local papers for a capable man to look after the electric plant in its coaches. In this connection it may be mentioned that there is a lack of capable electricians in this country, and that many really good openings are constantly occurring for young men who have had an electrical training. A large number of the so-called electricians now holding responsible positions with the electric-light and traction companies of this city have had no more training or experience in the field in which they are now posing as experts than was to be obtained in placing electric bells or performing the duties of linemen. This will explain the large quantity of electrical machinery that has broken down and the armatures that have burnt out. These so-called electrical engineers have pronounced this apparatus defective, whereas, in reality, its failure was solely attributable to their inexperience and consequent lack of attention.

ELECTRIC APPLIANCE COMPANY IN ITS NEW HOME.—VIEW IN BASEMENT.

company, which has the contract to equip the Third Avenue railroad with the underground trolley system, has failed in its endeavor to get the \$18,000,000 contract to equip the Manhattan elevated railroad with electricity.

The neglect of the Westinghouse company to attempt any restrictive measures against the General Electric company hitherto when it supplied the Edison company with the multiphase generators is given as a basis for the report that the new litigation is begun for other reasons than merely to protect the rights of the licensee. Current with the talk that the Westinghouse people had lost the Manhattan contract was the report that the General Electric company was practically assured of the contract.

If the suit of the Westinghouse company is successful, Mr. Whitney's company will be unable to use the Tesla multiphase generators, which are admitted to be the most economical. It is known that the new Light, Heat and Power company intends to transmit power on an enormous scale, and to be deprived of the use of this apparatus will, it is said, seriously cripple the operations of the company.

The suit brought by the Westinghouse Electric and Manufacturing company against the Western Electric

acts prevent the laying of tracks for a surface road on these thoroughfares, and on this account the motor coaches will be used.

Articles of incorporation of the Columbia Automobile company, with a capital of \$3,000,000, were filed in Trenton, N. J., on March 23d. The company is authorized to manufacture and operate vehicles propelled by electricity, compressed air or other power. The incorporators are Elliott Mason, Andrew H. Scoble, John M. Scoble, Louis R. Moore, Anthony N. Jeshera, Sherman N. Granger, Francis R. Foraker, Roland B. Harvey of New York; W. B. Greely of New Rochelle, N. Y., and E. S. C. Young of Jersey City.

A Paris correspondent says that the General Company of Vehicles is about to send out 110 electric carriages, the number being increased as other cars are

Mr. Medill had good ability and great energy, which was rewarded with success, and he delighted in patronizing art, literature and science and performing public service.

A press dispatch from London says that on March 28th Marconi successfully carried out his experiment of telegraphing across the English Channel, between Dover and Boulogne, without connecting wires. A message sent to England by Marconi was promptly answered from Dover. There was not the slightest hitch. Messages were passed and repassed quickly and easily. The distance was 32 miles, and the greatest previous distance covered had been 18 miles. Marconi has found that the distance to which signals may be sent varies according to the square of the height of the vertical conductor at each station. For signaling 18 miles he used a conductor 80 feet high, and in his application to M. Lockroy, French minister of marine, he contended that with a conductor 114 feet high he could establish communication between points on opposite sides of the Strait of Dover, and even go 10 miles farther. Marconi seems to have proved that when a proper vertical wire or conductor is employed, no hindrance to signaling is caused by hills or other obstacles or by the curvature of the earth. The experiments were conducted with the Morse code, which was read as distinctly, it is said, as if the termini had been connected by wires. The London Times printed a 100-word dispatch, the first press message by the Marconi system of wireless telegraphy, describing the experiments between Dover and Boulogne.

Those who are studying the problem of introducing automobiles and auto-trucks into general use in this country should watch the forthcoming experiments at Liverpool to test the capacity and adaptability of motor vehicles for heavy traffic. The trials will begin on the morning of Monday, July 31st, and will conclude on the evening of Wednesday, August 2d. Trial runs will be made from Liverpool over distances from 30 to 40 miles. There will be four classes of vehicles eligible, the minimum loads being two tons, 3 1/2 tons, five tons and six tons. The vehicles must be propelled by mechanical power alone. No restrictions will be placed upon the methods employed in utilizing this power or the form in which the energy is applied. The contest will be conducted under the direction of the Self-propelled Traffic association of Liverpool. Special efforts will be made to induce American manufacturers to send specimens of their carriages and wagons to the test, as the claims made for them have attracted universal attention and have encouraged the hope that they might be compared in operation with the French and English product. The specifications governing the competition have been carefully prepared and are now ready for distribution. The United States consul at Liverpool says that "the hope has been officially expressed that vehicles from the United States will take part in the competition." There is ample time to prepare for the event, and it is to be hoped that American manufacturers can see some commercial advantage in being represented on this occasion.

Mention has been made frequently of the great value of the searchlight to the American squadron in the naval operations before Santiago harbor that resulted so disastrously for the Spanish admiral's ships. In preventing the egress of the Spanish cruisers from the harbor entrance at night the beams of light from the American men-of-war had a twofold value—they would have revealed the presence of the enemy's vessels and also, by blinding the Spanish navigators, seriously interfered with the handling of their ships in the difficult channel. The latter point has not been dwelt upon so much as the value of the searchlights in apprising the Americans of the actual presence of the Spanish ships. But it was of great importance, as is shown by a chapter in W. A. M. Goode's book, "With Sampson Through the War," contributed by Admiral Sampson himself. The admiral says: "Had it not been for the use of the searchlights by our ships to illuminate the channel by which the Spaniards must necessarily come out, they probably would have selected the darkness. After the destruction of the Spanish fleet many of the captured prisoners freely expressed their opinion

that it was impossible to pilot their ships out through the narrow channel with such a powerful light shining in the eyes of the officers." However, Admiral Sampson expresses the opinion that Cervera would have had a better chance had he chosen the night time to make his escape, "especially had the hour been set to coincide with a passing storm, which would have diminished the intensity of our searchlight and would have greatly increased the intensity of the darkness."

The awakening interest in foreign trade among American manufacturers of all lines, and especially of the higher class of machinery, corroborates the claims that had been made regarding the advancement of this country among the great trading nations of the world. This is especially true in its application to the electrical manufacturers of this country. The question of securing foreign markets to take the surplus stock which they are now producing and the greater surplus which they might produce with their natural and mechanical advantages if they enjoyed a larger share of the world's export trade is one of the first importance. That electrical manufacturers are alive to the possibilities of commercial expansion is indicated by the fact that during the year 1898 the exports of electrical machinery reached the enormous value of \$2,523,644, as compared with \$917,453 in 1897. Notwithstanding the fact that the demand of the home market upon American manufacturers has been unusually large, electrical manufacturers increased their foreign trade to the extent of \$1,606,191 in 1898. The result proves that the skill of the American workman is universally recognized and the reliability of his work accepted. American electrical exports increase year by year, and find their way to more distant localities, where they would only be acceptable upon the assurance given by actual experience that they can be relied upon to perform their duties in unfamiliar hands, and without supervision or care from those skilled in their production.

The opportunity thus presented should be accepted and its advantages reaped by the country at large. The reputation which American products have already established has but to be maintained in order to command the trade of the most profitable markets of the world to-day.

Attorney-general Griggs has rendered an opinion on the application of the Commercial Cable company of the United States for permission to land a submarine cable in Cuba and Porto Rico, holding that the right could not be granted. The decision is based both on the position of the executive branch of the government and on the declaration of Congress in the Foraker amendment to the army appropriation bill of the last session. The position of the executive departments of the government on the general subject of franchises in Cuba as established in previous cases is outlined as follows: "In all instances heretofore, where applications have been made to this government, exercising the temporary control and government of the island of Cuba, for grants or concessions which usually flow from the depository of sovereign power, the executive departments have taken the ground that under the circumstances by which the United States came into the temporary administration of affairs in Cuba, and in view of the fact that it is the declared purpose of the United States, when a stable government shall have been there established, to retire from the island and leave the government thereof to the inhabitants, it would be inexpedient to grant such applications except in case of absolute necessity."

Concerning the Spanish franchises under which the present cables are operated, the attorney-general says: "The conclusion which I have arrived at renders it unnecessary for me to discuss or decide the objections raised on behalf of the Western Union Telegraph company, lessee of the International Cable company of New York, which companies claim an exclusive grant under a concession from Spain, made in 1867, which exclusive grant, it is claimed, has not yet expired." This leaves the whole question of privileges granted under the old Spanish regime undecided, and the government's attitude toward companies now conducting public enterprises in the new American possessions is still problematical.

Joseph Medill, the distinguished editor of the Chicago Tribune, who died recently at San Antonio, Texas, was a great admirer of Benjamin Franklin, and on June 6, 1896, caused an imposing monument to be erected in Lincoln Park, Chicago, in memory of the great philosopher, statesman and scientist.

FOREIGN EXCHANGE NOTES.

A company formed in Brussels under the name of *Compagnie Hongroise des Tramways et de l'Éclairage Electriques d'Oedenbourg et de Steinamanger* will soon commence work at its new branches, among which are the supplying of electric light and tramcars to the towns of Sarvar, Steinamanger, Ikerver and Oedenbourg. Power will also be supplied to run mills and agricultural machinery, plows and threshers.

The manager of the Yokohama agency of Siemens & Halske sent the *Japan Times* the following news: "As published by you some months ago, we secured a contract with the Chinese government for the construction of an electric railway in Peking. We have now received telegraphic advice that another contract for a central power station for lighting the city by electricity has been given to us. The ground on which this building is to be erected has already been bought."

According to the *Oesterreichisches Handels-Journal*, the Brussels *Société Internationale d'Enterprises Electriques* has formed, with the *Paris Société Generale*, a Russian electrical company, capitalized at 10,000,000 francs. This Franco-Belgian electricity and tramway trust has organized three sub-companies to supply Reval, Kronstadt and Sophia with electric cars. It has further taken a contract to supply the horse trams in Wilna, Tula, Samara, Woronesch and Minsk with electric motor power.

The *Société Electrique de la Méditerranée* has taken several contracts to supply electrical plants in Greece. The contracts were first given to a German company, which, however, forfeited them. One of the contracts is with the town Kephallonia, to supply an electrical center, comprising 300 incandescent lamps and three arc lamps. The electric light for houses will probably require more than 1,000 incandescent lamps. The excise duty has been hypothecated as a guarantee for payment. The contract is to run 60 years, at the end of which the plant becomes the property of the town. Another contract is to supply the town Kalamata with electric light and an electric line between the town and the port, lying two kilometers away. Contracts have also been made with Syra, Patras, Etion and Kalavryta.

A writer in a recent issue of the *Oesterreichisches Handels-Journal* of Vienna says that it has generally been supposed that incandescent lamps could not set anything on fire. On the basis of this they have been used among tapestries in a very careless way. But after several fires had been caused by incandescent lamps, it became necessary to investigate whether the lamps were dangerous or not. The result is shown that the amount of heat given out by an ordinary incandescent lamp is sufficient to cause the fire. If an incandescent lamp is put in a bowl filled with water and the current turned on the water will get warm and soon commence to bubble. An experiment with cotton showed a better result. A lamp was put in among some cotton, and in a short while the cotton was set on fire. Celluloid will begin to burn in five minutes after the lamp has been placed next to it. Incandescent lamps have therefore been declared dangerous, and are subject to the same rules of precaution observed by other lights.

Large Arc Lamp.

[From *Fachblatt*, Vienna.]

The firm of Siemens & Halske, in Charlottenburg, near Berlin, completed the other day a 100,000 candle power arc lamp. The lamp was set up and decorated in the lamp-testing room.

Electric Car Lines in Germany.

[From *Electrotechnische Zeitschrift*.]

The number of towns in Germany with electric car lines is reported as 68, and in 35 more similar enterprises are projected or under construction. The total capacity of dynamos and accumulators driving the 68 lines is 38,451 kilowatts. The average kilowatts required for one kilometer of track (ranging from 9.6 to 50.2 kilowatts per kilometer) is found to be 20.7, while the average number of kilowatts required per car (ranging from 6.2 to 46 kilowatts per car, according to local conditions) is 14.2.

Electric Cars in British Guiana.

[From the *Daily Gleaner*, Kingston, Jamaica.]

Mr. W. B. Chapman, who was recently in Jamaica as a promoter of the new electrical car undertaking, has been exploiting British Guiana on behalf of a Canadian syndicate. He has just bought out the British Guiana Electric Lighting and Power company.

In his opening speech at the Combined Court, last month, the governor of the colony said: "I should also not omit to mention the near prospect of a great extension of the means of communication in the city of Georgetown through the acquisition by a syndicate of Canadian capitalists of the property

and privilege of the existing tramways company. A bill has already been introduced and read the first time in the Court of Policy for affording the necessary legislative power required by the new company, who propose to introduce a system of electric tramways and also to take over the whole business of supplying electricity, whether for lighting or for motor purposes."

Automobiles in Europe.

[From *Continental Exchange*.]

Belgium and France have hitherto been prominent mainly in the development of the automobile industry. Now a company is being formed in these countries to establish a complete network of electrical stations, which will gradually branch out and take in all of Europe. According to *Neues Wiener Tageblatt*, Vienna, the stations for the charging of accumulators and the sale of materials and supplies for the automobile traffic are to be established along the large roads, at a rate of one station for every kilometer. Twenty stations are already under construction between Paris and Brussels, and within a short time work is to be commenced on some other more important lines. It is intended that these stations shall supply the neighborhood with electric light. The capital of the company, 5,000,000 marks, has been nearly all taken up.

Electrical Development in Burma.

[From the *Rangoon Gazette*.]

At the works of the Burma Ruby Mines, Limited, Mogok, there has just been successfully set to work a large electrical power and light installation, and as this is the first of its kind to be introduced into Burma, a short description will be of interest.

Owing to scarcity of wood and other causes, the annual fuel bill at the mines has always been a very important consideration, and it was in order to reduce this heavy item of cost as much as possible that Mr. A. H. Morgan, the company's able engineer, first directed his attention some two years ago to the feasibility of utilizing some of the water power which abounds in the vicinity for working the mines. After an inspection of some of the leading mines in South Africa which have adopted electricity as a form of power, an order was placed with Messrs. Johnson and Phillips of London for a complete plant, comprising turbine, dynamo, transformers, line material, motors, pumps, arc lamps, etc., and the whole of this has now been erected and is working with the greatest satisfaction.

Power is taken from a neighboring river at some falls about a mile and a half from the mines. A strongly built house has been erected on the river bank, and in this the turbine and dynamo are placed, which are capable of delivering 130 brake or useful horse power at the mines. The turbine is of the Pelton wheel class and runs at a speed of 110 revolutions per minute, under a head of water of 60 feet. It is provided with a large grooved fly-wheel for rope driving. The dynamo is a two-phase, alternating-current machine of special design for power work, and runs at a speed of 450 revolutions per minute.

From this power house the current, at a pressure of 2,200 volts, is taken overhead (long bare copper wires, supported on large porcelain insulators, fixed to poles placed at suitable distances apart) to another building known as the transformer house, erected in a convenient position at the mines, where it is transformed down to a lower and safe pressure for working the motors. These motors are employed in driving pumps and other machinery about the mines, and, owing to the highly increased economy attained by this system, it is expected that steam power will shortly be done away with altogether and electricity substituted in its place.

Several arc lamps, each of 2,000 candle power, are used for lighting the mines and are found to be a great improvement over the old method of oil lighting, while a telephone service connects the power and transformer houses, so that communication between the two can be readily established at any time.

Mr. H. Shaw Dunn, the assistant engineer, was responsible for the erection of the plant, which was finally supervised and started at work by Mr. F. M. Short, who is a member of the American Institute of Electrical Engineers, and is the electrical engineer for Balmor, Lawrie & Co. of Calcutta, who are the sole agents out here for Johnson & Phillips.

Three-wire Patent Litigation.

The Imperial Electric Light, Heat and Power company of St. Louis, which is the competitor of the consolidated local electric-lighting interests in St. Louis and which has built up a large and successful business in supplying light and power to customers throughout the principal part of the city, has been sued by the Edison Electric Light company upon patent No. 274,200, which is the so-called "Edison three-wire patent."

This patent has been considered a powerful weapon by the General Electric company for a long time, but there has never been a decision of any court upon its merits. All decrees which have been obtained have either been consent or default decrees, and the patent, so far as the courts are concerned, stands exactly as if it had never been before the

courts at all, except so far as the particular defendants in the several suits are concerned. It is well known also that there are a considerable number of plants operating with the so-called "three-wire system" described in Edison's patent and not licensed thereunder. It has been the policy of the General Electric company to threaten with suit anyone who starts to use the system set forth in this patent, and then, if the threat failed and the plant was installed and operated, the threatened suit has been either withheld, or, if brought, has been allowed to go by default unless some settlement was secured after suit was begun. The three-wire Edison patent, therefore, is a shining example of the old saying that "He who fights and runs away may live to fight another day."

The patent is now near its expiration, and the General Electric company has determined to put it to a test in this case. The defendant, the Imperial Electric Light, Heat and Power company, claims to have anticipations of the Edison patent which completely destroy its validity.

The hearing on the motion for preliminary injunction is now set for April 10th. The complainant is represented by Messrs. F. P. Fish and R. N. Iyer; the defendant by George H. Knight and Charles A. Brown.

The Gambler's Electromagnet.

Among the battered flotsam and jetsam that has accumulated in a second-hand store not a great distance from Jackson Square, says the *New Orleans Times-Democrat*, is a shabby round table with a curious secret, and no doubt a still more curious history. The top was once covered with green billiard cloth, which now is worn to tatters, and discloses a steel plate set in the center and perhaps to inches square. The whole top is loose and can be removed, revealing an interior space containing a horseshoe magnet wound with wire and connected with an armature very much like that of an ordinary telegraphic instrument. A close examination shows an insulated wire running down one of the legs to a small knob or button, protruding on the outside. When the top is in place the steel plate rests directly over the magnet. This strange device is explained clearly enough by its present owner. "It is a dice table," he said, "on which a lot of money has been won. When it was in order there was a good-sized battery inside, connected with the magnet. When the knob on the leg was pressed the current was turned on, and that made the steel plate magnetic. The dice they used with it had small metal disks on one face, and as long as the current was on they naturally fell that side down. When the knob was released they would fall any way they chanced to come, so all that was necessary for the operator to do was to keep his knee on the button and he could absolutely control his play."

Changes in Westinghouse Personnel.

Mr. Maurice Coster, for three years manager for the Westinghouse Electric and Manufacturing company at Chicago, has accepted the position of agent-general of the *Société Industrielle d'Electricité Procédés Westinghouse*, the French company newly formed to manufacture and sell Westinghouse electrical machinery and apparatus on the continent of Europe. After May 1st Mr. Coster's headquarters will be at No. 45 Rue de l'Arcade (Boulevard Hausmann), Paris. The new company is erecting a factory at Havre. Mr. Coster expects to leave Chicago on April 8th, and, after spending a few days in Pittsburg, will probably sail from New York on April 16th. A farewell dinner in his honor is announced by the Technical club, of which he was an active member, for Thursday evening, March 30th.

Mr. Coster is exceptionally well qualified for his new position. He has wide experience, both as a mechanical and electrical engineer and as a manager of electrical sales. He is a native of Holland and speaks Dutch, French, German and Spanish as well as English. He came to this country in his youth and is a graduate of the Stevens Institute of Technology. He has had practical experience in American machine shops and on railroads, managed a sugar refinery in South America and traveled in Europe. Since 1888 Mr. Coster has been connected with Westinghouse interests. He was first employed as an engineer and erected several important central-station plants. In 1891 he was transferred to the selling department, and soon after he was placed in charge of the territory served by the Pittsburg office of the Westinghouse Electric and Manufacturing company. After the death of his wife, in 1895, Mr. Coster was, at his own request, transferred to the Chicago office, and in January of the following year he was made manager of it. In Chicago Mr. Coster has made a fine record. He has brought about many important sales, built up the business of the company generally and made many friends for himself and his company. His departure will cause real regret.

Mr. Arthur Hartwell succeeds Mr. Coster as manager of the Chicago office of the Westinghouse company. Mr. Hartwell comes from Pittsburg, and, like his predecessor, is experienced in the affairs of the Westinghouse company. He was Mr. Coster's successor as manager in the Pittsburg office and now follows him in Chicago.

DEVELOPMENT OF THE TELEPHONE FIELD.

Formation of the Independent Telephone "Trust."

Preliminary arrangements were completed at Chicago last week for the organization of a new telephone manufacturing company, with the avowed object of absorbing the principal companies now manufacturing and dealing in apparatus and supplies for the equipment and operation of independent telephone exchanges and private lines. The promoters of this proposed trust are William T. Blaine and Sterling L. Bailey of Chicago, and they have been assisted by William P. Williams, assistant treasurer of the United States, who is in charge of the sub-treasury at Chicago. Mr. Williams is supposed to have secured the financial backing for the undertaking. P. C. Burns, president of the American Electric Telephone company of Chicago, and owner of the Keystone Electric Telephone company of Pittsburgh, the Northwestern Telephone Manufacturing company of Milwaukee and the Laclede Battery company of Kokomo, Ind., has also been actively interested in the formation of the combination, and it is generally believed that his influence will predominate in the management. Mr. Burns, Mr. Blaine and Mr. Williams are now in the East, and it is understood that before their return the formal organization of the new corporation will be accomplished.

It was announced last Saturday by Mr. Burns that 21 companies would be included in the consolidation and that the capital stock would be \$7,000,000, half preferred and half common; that the combination would be known as the American Independent Telephone company, and that it would be incorporated under the laws of New Jersey. Mr. Burns furnished the following list of names of 20 companies that, as he said, would be included in the combination:

American Electric Telephone company, Chicago.
Northwestern Telephone Manufacturing company, Milwaukee.
Keystone Electric Telephone company, Pittsburgh.
Laclede Battery company, Kokomo, Ind.
Victor Telephone Manufacturing company, Chicago.
Western Telephone Construction company, Chicago.
Stromberg-Carlson Telephone Manufacturing company, Chicago.
Sterling Electric company, Chicago.
Farr Telephone and Construction Supply company, Chicago.
Schmidt & Bruckner, New York.
De Veau & Co., New York.
Phoenix Electric Telephone company, New York.
Viaduct Manufacturing company, Baltimore.
Williams & Abbott Electric company, Cleveland.
Holtzer-Cabot Electric company, Boston.
Utica Fire-alarm Telephone company, Utica, N. Y.
Central Telephone and Electric company, St. Louis.
Standard Telephone and Electric company, Madison, Wis.
Pennsylvania Electric company, Lancaster, Pa.
Mason Telephone Pay-station company, Ludington, Mich.

The first four are controlled by Mr. Burns, and one of them is a battery company. Of the remaining 16 concerns six have already positively denied that they have entered the combination, one (De Veau & Co.), in the absence of the manager, was unable to give an answer, and others are undecided as to what position they will finally take. This would indicate that not more than 10 companies, including the Victor, had joined the Burns interests in this movement.

In response to an inquiry from the Western Electrician, six of the largest companies mentioned denied positively that they had entered into the combination, as will be seen by the following statements from representatives of these interests:

Holtzer-Cabot Electric company, Boston: This company has entered into no agreement with the trust, nor given any options.

Stromberg-Carlson Telephone Manufacturing company, Chicago: This company has not joined the combination, but has emphatically declined to do so.

Standard Telephone and Electric company, Madison: We have not entered the trust, nor have we seriously considered the matter.

Western Telephone Construction company, Chicago: The Western Telephone Construction company has not entered into any agreement to go into any combination or consolidation.

Sterling Electric company, Chicago: We are not looking for a purchaser for our business. We are too busy to consider the question of consolidation.

Farr Telephone and Construction Supply company, Chicago: We have given no one authority to use the name of our company in connection with this movement, as we have never entertained any thought of joining a trust or going out of business.

The promoters of the combination have endeavored to create the impression that the principal interests involved in the independent field had joined the movement and that 85 per cent. of the apparatus manufactured for independent exchanges was made in the factories that would be controlled by the trust. This view is entirely erroneous. The following list includes the concerns that have not entered the so-called trust. It does not, however, include the numerous companies making and selling batteries to independent exchanges:

MANUFACTURERS OF TELEPHONE APPARATUS NOT IN THE "TRUST."

Automatic Telephone Switch company, Parker, S. D.
Automatic Telephone Exchange company, Washington, D. C.
American Hard Wood Manufacturing company, Grottoes, Va.
Boardman-Tucker company, Boston.
Bauerle & Stark, Chicago.
Fisher-Taylor company, Ravenna, O.
George C. Bell Manufacturing company, La Crosse, Wis.
Cosmo Electric company, Chicago.
Cleveland Telephone Exchange company, Piqua, O.
Cabinet Manufacturing and Supply company, Cleveland, O.
Chicago Telephone Supply company, Chicago.
Connecticut Telephone and Electric company, Meriden, Conn.
Century Telephone company, Boston.
Central Manufacturing company, Chattanooga, Tenn.
S. S. Creider, Sterling, Ill.

Chicago Electric Manufacturing company, Chicago.
Danbury Electric Works, Danbury, Conn.
Detroit Switchboard and Telephone Construction company, Detroit.
Decker Automatic Telephone Exchange company, Oswego, N. Y.

Erskine Telephone company, McConnellsville, O.
Ericsson Telephone company, New York.
Eastern Electric company, Tonawanda, N. Y.
Electro Manufacturing company, Brooklyn.
Eureka Electric company, Chicago.
Eastern Telephone Manufacturing company, Meriden, Conn.
Electrical Appliance company, Cincinnati.
Farr Telephone and Construction Supply company, Chicago.
H. M. Fisk Manufacturing company, Wheaton, Ill.
Garl Electric company, Akron, O.
Gilliland Electric company, Adrian, Mich.
A. Y. Gordon, Massillon, O.
Holtzer-Cabot Electric company, Boston, Mass.
Hunnings Telephone company, Elkhart, Ind.
Holyoke & Holyoke, Chicago.
Hammacher, Schlemmer & Co., New York.
Hipwell Manufacturing company, Allegheny, Pa.
Indianapolis Electric company, Indianapolis.
D. A. Kusel Telephone and Electric Manufacturing company, St. Louis.
Kokomo Telephone and Electric Manufacturing company, Kokomo, Ind.
Kellogg Switchboard and Telephone Supply company, Chicago.
Logansport Telephone Manufacturing company, Logansport, Ind.

McDermid Manufacturing company, Chicago.
George M. Mayer, Chicago.
Charles Martin, Detroit, Mich.
Moon Manufacturing company, Chicago.
J. H. McFarlan & Co., Flint, Mich.
Mianus Electric company, Mianus, Conn.
Maryland Telephone Manufacturing company, Baltimore, Md.
Maryland Electric company, Hagerstown, Md.
George F. Mims, Edgefield, S. C.
Menominee Electrical and Mechanical company, Menominee, Mich.

William J. Murdock & Co., Boston, Mass.
Northwest Engineering company, St. Paul, Minn.
National Telephone Manufacturing company, Boston, Mass.
North Electric company, Cleveland, O.
National Automatic Telephone company, Chicago.
E. J. Nohlet, Chicago.
Phoenix Telephone Manufacturing company, Chicago.
Pennsylvania Telephone company, Philadelphia.
Rawson Electric company, Elyria, O.
E. Rubel, St. Louis.
O. H. Rugh, Rock Island, Ill.
Rousseau's Electric Works, New York.
Reliable Electric Manufacturing company, Worcester, Mass.
Russell Tomlinson Electric company, New York.
Standard Telephone and Electric company, Madison, Wis.
Stone City Telephone Manufacturing and Construction company, Joliet, Ill.
Swarts' Switchboard and Electric company, Knoxville, Tenn.
Smith-Vasson Telephone company, New York.
Stromberg-Carlson Telephone Exchange company, Chicago.
Simplex Interior Telephone company, Cincinnati, O.
Southern Telephone company, Fayetteville, N. C.
Stromberg-Carlson Telephone Manufacturing company, Chicago.

Sterling Electric company, Chicago.
Springer Electric company, McCordsville, Ind.
Taber & Mayer, Boston.
J. W. Thomson, Jr., & Co., Mitchell, Ind.
Tucker Electric Construction company, New York.
Telephone Manufacturing company, Sumner, S. C.
W. S. Tobie, Augusta, Ill.
Union Electric company, Cleveland.
H. C. Underwood Manufacturing company, Wabash, Ind.
United States Automatic Telephone company, New York.
Western Telephone Construction company, Chicago.
Whitman & Couch, Boston.
W. F. Warner company, Muncie, Ind.
Wilhelm Telephone Manufacturing company, Buffalo.
M. B. Wheeler Electric company, Grand Rapids, Mich.
Williams Electric company, Cleveland, O.

DEALERS IN TELEPHONES AND TELEPHONE SUPPLIES NOT IN THE "TRUST."

Julius Andrae & Sons company, Milwaukee.
American Hard Rubber company, New York.
Allen-Hussy company, Chicago.
E. Bissell & Co., Toledo.
Electrical Engineering company, Minneapolis.
Gay & Thwaites, Philadelphia.
Harvard Electric company, Chicago.
Harrison Bros. & Co., Philadelphia.
Matthias Klein & Son, Chicago.
McFell Electric company, Chicago.
Mississippi Telephone company, Hazlehurst, Miss.
Manhattan Electrical Supply company, New York.
C. H. McEvoy, Lowell, Mass.
National Automatic Fire Alarm company, New Orleans, La.
Plummer, Ham & Richardson, Worcester, Mass.
J. D. Randall, Memphis, Tenn.
St. Louis Electrical Supply company, St. Louis, Mo.
Stanley & Patterson, New York.
Thermo-electric company, New York.
Varley Duplex company, Jersey City, N. J.
S. S. White Dental Manufacturing company, Philadelphia.

Mr. Blaine authorized the statement that the combination would adopt a liberal policy in dealing with the exchanges and that it would encourage new enterprises and assist those already formed to extend and improve their properties. Eventually, it was hoped, a comprehensive toll-line system would be established, connecting independent exchanges and affording means for subscribers of a local exchange in one place to communicate with those of an adjoining town. Construction work would be undertaken when necessary to insure good service. The most important work to be undertaken is the standardization of telephone apparatus. This, the new company announces its intention to do. Mr. Blaine said that two prominent banking houses, one in New York and the other in Chicago, would underwrite the securities of the new company. He also volunteered the statement that "spot cash" was paid for all the plants taken over. This statement is not entirely in harmony with the reports of companies that were approached in connection with this consolidation.

Mr. Burns confirmed the announcement of the policy of the new company as outlined by Mr. Blaine. He said, however, that no official statement could be given out until the corporation was formed and permanent organization effected, as the officers in charge might modify the plans. It was the intention of the promoters of the company, he declared to give the business a recognized standing in the financial world, which individual plants could never hope to attain.

Annual Meeting of the American Bell Telephone Company.

[Special dispatch to the Western Electrician.]

Boston, March 28.—The annual meeting of the American Bell Telephone company was held in this city to-day. The numerical attendance was small, as usual, but the stock was almost entirely represented.

The annual report of the president, John E. Hudson, contained a satisfactory statement of the condition of the company's business. It showed an unprecedented improvement in many important particulars. The net earnings were \$4,393,966, which is equivalent to nearly 17 per cent. on stock outstanding. The dividends paid during the year amounted to 15 per cent. The growth of the Bell interests during the last year was the greatest in the company's history. New construction work was completed by companies sustaining contract relations with the parent company that amounted to a cash valuation of \$12,105,921. Upward of \$1,000,000 was expended for real estate during that time. The list of subscribers to Bell exchange service throughout the country received more than 80,000 names in 1898, and the toll-line systems were extended to the extent of 61,000 miles of wire.

In the treasurer's report it was shown that the earnings for 1898 were \$5,548,701, as against \$5,130,844 for 1897. The expenses for 1898 were \$1,054,734, against \$961,170 for 1897, and the net earnings \$4,393,966, against \$4,169,674. Regular dividends paid in 1897 amounted to \$3,106,356, an increase of \$166,452, while extra dividends declared in 1898 were \$776,589, an increase of \$33,545.

During the meeting the subject of removal of offices to New York was not mentioned, and there was no official statement made upon the subject, although it was discussed by individual stockholders before and after the regular meeting.

President Hudson, Treasurer Driver and Clerk Hubbard were re-elected, and the old board of directors was also continued for another year.

The meeting was harmonious, and the impending competition and adverse legislation that is threatened in many quarters did not seem to worry the stockholders.

J. S. B.

New England Telephone Notes.

[From the Boston correspondent of the Western Electrician.]

The New England Telephone and Telegraph company has issued notice that the outstanding bonds of the first series, dated April 1, 1889, numbered from 1 to 500 inclusive, will be paid at the office of the treasurer in Boston April 1st. Holders of bonds of the second series, payable April 1, 1900, are also notified that the company will receive tenders, in writing, for the surrender of the bonds numbered from 501 to 1,000 inclusive on the date of payment of the first series, and will accept 50 thereof for redemption and payment on that date. But in no case will more than \$1,020 and accrued interest be paid on any of the bonds.

Beginning April 1st the Southern New England Telephone company will reduce the rate for a single-circuit business from \$120 per annum to \$100. This will make a reduced rate in Hartford, Waterbury, New Haven and Bridgeport, in Connecticut. Friends of the new telephone company, known as the Boston and New York Telephone company, which is seeking to do business in that section, claim that the reduction is intended to head off competition.

The directors of the New England Telephone and Telegraph company have declared a dividend of \$1.50 per share, payable May 15th. The company has also sold \$500,000 debenture bonds, dated April 1, 1890, and payable April 1, 1910, to Adams & Co., interest being stated at five per cent.

The Massachusetts Telephone and Telegraph company is making an active canvass in Boston and vicinity for subscribers to the new service, which will be established under the franchise granted recently by the Boston and Cambridge city governments. The subscriber is required to take a five-year contract, but the prices are lower than the established company in this section has been charging.

Russian Telephone System.

The Revue d'Orient of Budapest says: "The Central Administration of Posts and Telegraphs of Russia intends to proceed during the current year with the construction of a direct telephone line between Moscow, Varsovic, Kiev and Odessa. It will be thus possible to communicate directly between St. Petersburg and Odessa. This is really marvelous, when we consider the enormous distance which separates Odessa from St. Petersburg."

Appeal Against the Citizens' Telephone Company Dismissed.

In the suit on the Gilliland patent, No. 266,806, brought by the Western Electric company of Chicago against the Citizens' Telephone company of Grand Rapids, Mich., the plaintiff, on March 27th, dismissed its appeal from the decision of Judge Sevens.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Wisconsin Telephone company announces a cut to \$1 per month for residence service at Janesville, Wis. The cut will probably be met by the home company, which is just completing a system and has 500 subscribers pledged for five years.

The Michigan Telephone company is purchasing a right-of-way for a long-distance line between Menominee, Mich., and Marquette.

A telephone line will be built between Mercer and Adel, Ia., as soon as the weather will permit.

It is rumored at Fargo, N. D., that the Northwestern Telephone Exchange company may erect a building there for its exchange.

There will be some extensive improvements made to the telephone exchange at Billings, Mont., in the spring. The list of subscribers has grown under Manager Hungerford from 42 in 1895 to 121 now. A switchboard of 200 drops is about to be put in. Mr. Hungerford also has a franchise for an exchange at Miles City, Mont., and has about decided to put in a system.

The telephone office at Belknap, Ia., was burned out.

An exchange, with 30 telephones, has been installed at Titonka, Ia. This town has grown up in three months.

The Duluth Telephone company announces that it will have long-distance connection between Duluth, Minn., and Ashland, Wis., by July 1st. Work will be begun as soon as the frost is out of the ground.

The Monroe County Telephone company of Sparta, Wis., has completed a toll line to Oil City. Numerous other extensions are projected for spring.

The Gilmore City (Ia.) Telephone company is preparing to install an exchange.

The Mesaba Telephone company of Sparta, Minn., contemplates extending its wires to McKinley and Bivabik, Minn. Later connection will be made with Duluth.

The Standard Telephone company is an applicant for a franchise at Dubuque, Ia. The Iowa Telephone company is working to keep the newcomer out. The council is being bombarded with statements of the unpleasant features of having two telephone systems in the same city.

Fargo, N. D., is said to lead all other towns of its size in the world in the number of telephones in use and the calls made. It has 583 instruments in use and averages 6,000 calls daily.

J. B. McBride has sued the Sunset Telephone company, at Tacoma, Wash., for \$25,000 damages for the non-delivery of a message to him at Jerome, Ariz., stating his daughter was dying and in need of funds. The message was sent to J. B. Upright and was not delivered.

The Mississippi Valley Telephone company announces it will have its system in operation in Minneapolis by June 1st.

A telephone line is to be constructed between Amboy, Minn., and Sterling Center.

G. E. Merrill is working to secure sufficient subscribers to establish a telephone exchange at Verdale, Minn.

Senator McGowan has introduced a bill in the Minnesota Senate for the taxation of telephone, sleeping-car, telegraph and express companies. The bill requires the companies to file in July of each year a statement of their business and the extent of their property. The State Board of Equalization then assesses a tax equal to the average taxation rate in the state.

Brookings, S. D., will vote on \$5,000 bonds for telephone and electric plants in the spring.

J. C. Crowley, Jr., has severed his connection with the Eau Claire (Wis.) Telephone company and taken a position with the Stromberg-Carlson company in Chicago.

Business men of Melrose, Minn., have formed the Merchants' Telephone company and propose to construct a line between Melrose and Meire Grove. The system will be extended as rapidly as possible.

The Northwestern Telephone Exchange company has filled its new switchboard, recently put in at Winona, Minn., and has ordered another board. The present board has 500 drops.

The Southern Electric Telephone company of Minneapolis has been incorporated by officials of the Minnesota Central Telephone company of Willmar, Minn., and of the Union Electric Telephone company of Waucoma, Ia. The capital stock is \$30,000.

PERSONAL.

A. L. Waterbury of Houston, Texas, spent several days in Chicago recently, looking into telephone matters.

P. Yensen has been appointed general manager of the Cleveland Telephone company, in recognition of his efficient development of the company's system.

Charles Webster, vice-president and general manager of the Western Electric telephone system, was a Chicago visitor last week. Mr. Webster's headquarters are at Waucoma, Ia., and his telephone system includes the Union, Western Minnesota, Minnesota Central, Northern Minnesota and Western Electric Telephone companies.

J. P. McKinstry has been elected vice-president of the Northwestern Telegraph and Telephone company, which operates exchanges in Minnesota, North and South Dakota, Arkansas and Texas. Mr. Me-

Kinstry has been vice-president of the Cleveland Telephone company for some time, and was recently elected vice-president of the Michigan Telephone company. The companies mentioned comprise the Eric system, which is the largest operating telephone company in the world. The Eric company, on January 1, 1899, had 57,455 subscribers and 12,668 miles of pole line. Mr. McKinstry's headquarters are in Cleveland.

Bell Securities Increased.

An important step was taken by the Bell interests at Albany, N. Y., on March 27th, when the American Telephone and Telegraph company filed a certificate announcing an increase of capital stock from \$25,000,000 to \$75,000,000. The statement shows that the company has already \$23,500,000 stock issued and that its liabilities amount to \$902,736. No explanation is offered by the officers of the company for the extraordinary increase mentioned, and it has been suggested that it is the intention to change the present relations of the several Bell corporations so as to make the present long-distance company the chief factor in the scheme. This would be in keeping with the plans that have often been discussed of bringing about a closer union of the Bell properties.

The American Bell Telephone company, chartered under the laws of Massachusetts, is the parent of the American Telephone and Telegraph company and the numerous Bell exchange companies throughout the country. The American Telephone and Telegraph company has control of the long-distance telephone system of the Bell company.

In financial circles the explanation is advanced that the purpose of the increase is to absorb the parent concern, the American Bell Telephone company, so that the latter could work under the liberal and elastic charter which the American Telephone and Telegraph company holds in New York. The corporation laws in Massachusetts are strict and rigidly enforced, and several times the Bell company has had considerable trouble in carrying out its plans. One example of the friction that has been caused by the enforcement of the Massachusetts laws is recalled by the step taken at Albany on Monday. In June of 1894 the American Bell Telephone company secured the passage of a bill by both branches of the Massachusetts Legislature permitting it to increase its capital stock to \$50,000,000 from \$20,000,000, an increase of 250 per cent., but when the measure was presented to Governor Greenhalge he promptly vetoed it on the ground that it was a stock-watering scheme, saying that there was no reason why the company should be exempt from the Massachusetts laws as to stock watering. At that time and at frequent intervals since then the company has threatened to withdraw from Massachusetts and establish headquarters elsewhere in order to take advantage of more liberal laws regulating incorporations.

Competition in Connecticut.

[From the Waterbury, Conn., American.]

Beginning with the first of April the Southern New England Telephone company will reduce the price of local service for private wires from \$120 to \$100. This cut is made to head off the threatened competition of the Boston and New York Telephone company, which is planning to establish a telephone exchange here with lower rates for telephone service the coming summer. The new company will furnish private-wire service for \$48 a year and business-wire service for \$25. The Southern New England company is now furnishing similar service for \$120 and \$75 a year, respectively. The cut in rates which the Bell company will make in April will effect private wires only. It is probable, however, that other reductions in rates will be made if found necessary to retain control of the business.

A newspaper dispatch from Winsted, Conn., dated March 22d, says: "Independent telephone companies, with lines in New York, Massachusetts and this state, have decided to connect with one another and compete with the Southern New England Telephone company, the Connecticut branch of the Bell company. The independent companies have a capital of \$100,000. Capitalists in Boston, Providence, Worcester, Springfield, Hartford, New Haven and Meriden have applied for franchises to establish telephone systems in those cities, and in some cases the rights have been granted. The independent companies' rates are 50 per cent. lower than those of the Southern New England company."

Central Union Securities.

The Central Union Telephone company of Chicago decided some time ago to issue \$6,000,000 of five per cent. gold bonds accruing in 20 years. Of this bond issue \$2,500,000 will be held in the treasury to retire the first-mortgage six per cent. bonds which are subject to call at 105 on any interest day after January 1, 1909. There will be issued at once \$1,000,000 of these bonds, the proceeds of which will be used in extensions and betterments. The remaining \$2,500,000 will be held for future extensions and improvements. These consolidated bonds are second lien upon the property of the company, but on the retirement of the first-mortgage bonds as provided in the plan of the issue they become a first security.

NEW COMPANIES.

The Axtell (Mo.) Telephone company has been incorporated with a capital of \$2,500 by George Delaney and associates.

The Prairie Queen Telephone company of Edgerton, Wis., has been organized. All of the incorporators are Scandinavians.

The Virginia and Little India Telephone company of Little India has been incorporated in Illinois, with capital stock placed at \$600, by Marquis L. Crum, Frank Virgin and L. L. Fox.

A new telephone company has been organized at Concord, Mich., to be known as the Concord Telephone company. The capital stock is placed at \$5,000, \$1,700 of which is already paid in. At the last meeting of the Village Council a 25-year franchise was granted. All the stock is owned by business men of Concord and farmers in the immediate vicinity, and the work of constructing the system will be commenced at once. The lines will extend about the village of Concord and connect surrounding towns.

TELEPHONE LITIGATION.

The question whether a telephone company is bound either by common law or statute to furnish service equally and impartially to an individual or corporation who might apply for it was argued in the Appellate Division at Albany, N. Y., on March 16th. The appeal was made by the Onida Telephone company against the New York Telephone and Telegraph company, because the latter refused to place one of its instruments in the office of the plaintiff. The court sustained the demurrer of defendant upon the ground that mandamus proceedings are not the proper legal steps in the premises, but did not pronounce on the question at issue.

Argument was heard in Philadelphia on March 14th by Judges Acheson, Dallas and Kirkpatrick in the United States Circuit Court of Appeals on the appeal of Millheim Electric Telephone company and others of Millheim, Pa., from the decision of Judge Buffington, in the United States Circuit Court of Pittsburg, in favor of the Western Electric company of Chicago. The lower court had upheld the validity of the "bridging" patent issued to John J. Carty, which it was claimed the defendants infringed. The defenses are that the alleged improvements claimed in the patent in suit did not amount to a patentable invention, and that it has not been infringed. Decision was reversed.

MISCELLANEOUS.

During the meeting of the independent telephone companies of Ohio at Cleveland recently a letter was received from J. P. McKinstry, representing the Bell interests, inviting the independent managers "to visit the main exchange of the Cleveland Telephone company at such time during your stay in the city as may best suit your convenience. Upon being advised of the time of your visit a suitable escort will be in readiness to attend you."

Commenting upon the proposition to introduce government telephone service in England in competition with the National Telephone company, the Boston News Bureau makes the following statement concerning the financial aspect of the case: "This government scheme for developing telephonic competition has had for result a sharp fall in the prices of the National Telephone company's securities. The proposition of three months ago to buy out the National Telephone company on the basis of the average prices of its securities during the preceding three years was deemed extravagant. This basis would have been on a value of \$34,250,000 (calling it \$5). The value to which said securities declined under that proposition was \$29,045,000. The decline in market prices since the government's scheme has been proposed has been to a value of about \$27,500,000."

TELEPHONE LEGISLATION.

The bill providing for a reduction of telephone rates has been rejected by the Tennessee Legislature.

The Chicago City Council is considering a resolution requesting the Chicago Telephone company to enclose all public telephones with sound-proof booths to insure privacy to users of these instruments.

Telephone subscribers in New York failed to gain relief from the Legislature in the matter of regulating telephone charges. On March 22d the Senate killed the only bills lowering telephone charges, those of Senator Marshall and of Senator Wagner, which had any prospect of receiving favorable action. Senator Marshall's bill provided that the state controller, the attorney-general and the state engineer should establish telephone rates, after careful investigation of their justice and injustice, except that the maximum rate in New York should not be above \$125 a year; in cities between 100,000 and 500,000 population \$48 a year, and so on down the scale. Senator Wagner's bill declared that it should be unlawful for a telephone company in New York to charge a subscriber more than \$50 for any number of messages less than 1,000 transmitted in one year, or more than five cents for each additional message. The

Senate committee on miscellaneous corporations reported both the bills adversely. Senator Marshall at once moved to disagree with the unfavorable report, and made a speech in support of his favor, depicting the unjust charges of the telephone companies. The Senate rejected Senator Marshall's motion to disagree with the adverse report by 15 to 34. This was substantially a vote on the bill itself, for the rejection of Senator Marshall's motion killed the measure, and the adverse committee report was then adopted without a division. Senator Wagner made the same motion to disagree with the adverse report upon his bill, and made a speech, arguing that his bill was a just one. His motion to disagree with the adverse report was defeated by a vote of 18 to 32.

In the New Jersey Legislature on March 20th Mr. Marks presented a resolution, which was defeated by a vote of 20 to 35, providing for the appointment of a special committee of five to investigate the earnings, rates, charges, expenses, cost of maintenance and other matters concerning the public welfare in connection with all individuals, corporations and associations owning, leasing or operating telephones in this state, the committee to have full power to investigate the telephone companies and report to the governor the result of the investigation, together with any proposed legislation and such recommendation as in its judgment the public interests require in the premises, and that the report be transmitted by the governor to the next Legislature, to the end that proper legislation may be enacted to safeguard the interests of all concerned.

MANUFACTURERS AND DEALERS.

Holyoke & Holyoke, manufacturers of telephone switchboards, Chicago, report a large increase in their business. This firm has recently doubled its force and is located in new and commodious quarters, at the southeast corner of Clinton and Van Buren streets. It has recently shipped one of its switchboards to British Columbia.

The Varduct Manufacturing company is turning out large quantities of its regular telephone sets and great numbers of standard magneto bells. Its factory is running full time on telephone work, district telegraph messenger call boxes, and on specially constructed telephones for railway use. Since the consolidation of a great many of the street railways, it has been found important to have a good signal apparatus to facilitate the movement of cars, and this company supplies a special outfit for the purpose.

EXTENSIONS AND IMPROVEMENTS.

The Bell company does not admit visitors now at the Detroit exchange.

It is expected that a telephone line will be extended from Albion, Idaho, to Elba and Almo.

S. P. Haney is constructing a telephone line from Ione, Ore., to Gooseberry, a distance of 18 miles.

The Southwestern Telegraph and Telephone company contemplates erecting a telephone exchange at Sherman, Texas.

Right-of-way has been secured for a new state telephone line from Jackson to Lansing. There will also be a station at Leslie.

The private telephone line between Columbus and Sugar Grove, O., operated by the Columbus Natural Gas company, is to be reconstructed, and 47 miles of new wire will be strung.

The Michigan Telephone company has recorded a mortgage aggregating \$5,000,000 at Bad Axe. It required \$2,500 in revenue stamps. Another mortgage for the same amount was filed at Owosso.

The Sunset Telephone and Telegraph company has volunteered to furnish telephones for the police-signal service at Los Angeles, Cal., for \$5 per year instead of \$7.50, and to rent the loop wire at \$1.50 instead of \$2.50.

The City Council of Houston, Texas, has granted a 15-year franchise to A. L. Waterbury and W. Bucklin, Jr., for a telephone exchange in that city. They have accepted the ordinance and deposited \$10,000 with the city treasurer to insure the prompt execution of the contract.

The People's Telephone company of Wilkesbarre, Pa., recently expended \$50,000 for apparatus with which to equip its system. The line is expected to be in operation by July 1st. Poles are being placed, and the work of laying the underground wires will begin as soon as all the frost is out of the ground. The number of subscribers is nearly 600.

A representative of the Trans-state Telephone company of Philadelphia has been in Cincinnati soliciting subscriptions for that company as a competitor of the Bell interests. An ordinance has been presented to the Board of City Affairs providing for a franchise. The same company has commenced operations in Springfield and Columbus, O.

H. A. Everett of the United States Telephone company is after the franchise to operate in Columbus, where the Bell company occupies the ground. He stated that the roof would be on the Cleveland telephone building which the Cuyahoga Telephone

company is erecting by July, and the Cleveland system would be in operation in the fall. "We are doing much inside work now, wiring buildings," said Mr. Everett.

R. A. Knight, counsel for the Massachusetts Telephone company, asked for a franchise in Springfield, Mass., on March 21st. G. S. Halbrooke, whom he introduced, said the company would furnish connection with New York and the West 50 per cent. cheaper than was given by the Bell interests. Judge Long, in behalf of the New England Telephone company, opposed the granting of a franchise. The Board of Aldermen took the matter under advisement.

The establishment of a comprehensive system of local independent telephone lines, all interchanging business, is now being completed in Western Pennsylvania, and will form the nucleus of an anti-Bell system. The work of connecting the lines has begun, and the new system will shortly be in use throughout Pittsburg, Allegheny and the surrounding territory within a radius of 50 miles. The Pittsburg and Allegheny Telephone company is the name of the principal concern, and the following towns will be included in the new system: McKeesport, Braddock, Carnegie, Greensburg, Uniontown, Connellsville, Canonsburg, Oakmont, New Kensington, Parnassus, Verone, Homestead, Sewickley and Macdonald. This system is to be extended westward and north to Cleveland, to connect with the lines of the United States Telephone company of Cleveland, the big anti-Bell concern which proposes to build long-distance lines between a number of large cities and ultimately secure connection with Chicago.

Electric Street Lighting.

[Continued from page 183.]

play lighting only in the business section and a milder one for the residence portion. To-morrow we may look for a mild but uniform illumination, both

FIG. 2.

FIG. 1.

for the residence district and for the business portion after midnight.

Yesterday the lower efficiency of the incandescent lamp kept it back. To-day our ability to distribute light more uniformly with the incandescents has caused them to be used in many places, and to-morrow we may look for small arcs or incandescents of higher temperature (and therefore higher efficiency) to bridge the gap.

Yesterday the naked arc, being all the more dazzling, was welcome. To-day enclosing globes are mellowing the effect on the eye. To-morrow the use of naked arcs out of doors and less than, say, 30 feet above the ground ought to be prohibited by law.

Yesterday only large cities felt the need of street lighting. To-day even towns with a population of less than 1,000 have their streets electrically lighted.

Yesterday a thousand towns secured the advantages of electric light and power by giving lighting contracts at a fair profit to proposed plants. To-day the same towns begrudge the help they have given toward modernizing their city, hesitate to pay even the actual cost for lighting by contract, and make the central stations look to the sale of exhaust steam and like sources of extra revenue.

Yesterday towns were lighted either with arcs or incandescents. To-day both are used in the same city, each in its proper place. To-morrow we may have some lamps of intermediate candle power (perhaps semi-incandescents of the Nerst or allied types) to supplement the arcs and incandescents.

Yesterday every circuit of one or two dozen arc lamps required its own generator. To-day we have from 100 to 200 run from a single generator, and to-morrow we may have four or five hundred arcs (or the equivalent of part of them in incandescents) all run from the same alternator.

Yesterday a circuit of a thousand volts was hard to insulate, and might have to be shut down during rainstorms. To-day we have circuits of 7,000 to

8,000 volts giving uninterrupted service, in spite of wind and weather.

Yesterday little attention was paid to the fittings as long as the lamps, dynamos and circuits were all right. To-day they must be firm and durable. To-morrow the lamps, supporting fixtures and all parts of the circuit will need to be good-looking.

Last, but not least, electric street lighting has become an object of careful study and is receiving skilled attention. Yesterday the size and distribution of lamps and the methods of supporting them were determined chiefly by the salesmen of the firms supplying the material. To-day such organizations as the American Society for Municipal Improvements and the National Association of Municipal Electricians are making a serious study of street lighting in its general bearings and are getting back to due consideration of the prime objects of all street lighting—path finding and crime preventing. What is more, while some manufacturers and consulting engineers have made a specialty of long-distance power transmission, others of the lighting system for modern buildings, and still others of the applications of electric motors to special classes of machinery, we also have some who have been studying the problems of electric street lighting. It is only by such special study, both on the part of the engineers in charge of the work and of the makers of

the needed devices, that we can expect to raise the present standard of effectiveness of our street lighting. And I think it is high time that both the general public and our electrical fraternity were made aware of the importance of these problems, so as to help us all in having electricity become by far the best means for properly lighting our outdoor pathways.

Fan-motor Outfits.

The problem of designing a fan motor that is both efficient and economical when run by battery power is one of much importance. The Edison Manufacturing company of New York and Orange is placing on the market several fan outfits that are superior to anything it has produced up to the present time. The ironclad outfit carries a seven-inch fan with a guard and is operated by a battery of three Edison Lalande cells. The speed is about 1,200 revolutions a minute. The motor is efficient, and the battery will run for 150 hours before needing to be recharged. The nine-inch Edison fan motor, shown in Fig. 1, has been greatly improved this season. The motor is much more efficient and will run at about 900 revolutions a minute on a little less than two amperes of current when using the battery supplied with it, consisting of four Edison Lalande cells in a polished oak case.

The greatest attention has been paid to the elimination of all unnecessary friction in the moving parts, and the motor now placed on the market is said to be the most efficient battery motor that has yet been constructed. The company has also a nine-inch fan motor similar in construction to the battery fan motor, and is wound for 110-120-volt direct-current circuits. It is provided with three speeds—1,400, 1,600 and 1,850 revolutions per minute.

An improved and convenient outfit for use in a

telephone booth is a late novelty exploited by this company. Its use is not limited to any time or season, as every telephone booth is apt to be close, hot, ill-ventilated and uncomfortable at all times. Its many points of superiority have won for it great favor from a large number of New York firms who have used these fans. It has also been indorsed by the Long-distance Telephone company and several of the local Bell Telephone companies, who are using it quite extensively. The outfit, as shown in Fig. 2, is designed for use with either 110-120-volt direct current or a primary battery. It is said to be noiseless and to produce no vibration—two important features for recommending it for the use for which it was designed. It has self-aligning, self-oiling bearings and is suspended by a double spiral spring from an ornamental bracket easily adjusted to the interior woodwork of a telephone booth.

In motors for the 110-volt circuit connection is made from the stop-and-start switch on the motor by means of the connecting cord to the nearest

THE CARY SPRINGS.

electric light. The lamp bulb is unscrewed from its socket and the current tap is inserted. The connecting cord leads to the binding posts on the sides of the current tap. The switch on the motor is so arranged that the lighting of the lamp will start the fan, or the lamp can be lighted without the motor running, if so desired. It costs no more to run both the lamp and the fan motor than to run the lamp only, and as neither need run while the telephone booth is not in use, the economy of the outfit is most apparent.

The Cary Springs.

It is a recognized fact that inquirers for mechanical specialties, Yankee novelties, and even some ordinary devices, are in many cases referred to New York, New England and other eastern manufacturing centers. At present an effort is being made to develop this business in the West, and among the enterprising manufacturers of "mechanical refinements" engaged in this line is the Cary Spring Works of New York city. This company manufactures a full and complete line of springs for machinery, motors, clocks, music boxes and all kinds of electrical purposes, and its springs are said to have always met with universal favor. This concern is sending thousands of springs to Germany and England, and many to the city of Sheffield, which is supposed to be the center of the finest tempered steel in the world.

A New Interlocking Speaking Tube and Whistle.

Electrical contractors will be interested in the new interlocking speaking tube and whistle which is diagrammatically illustrated herewith. This device

A NEW INTERLOCKING SPEAKING TUBE AND WHISTLE.

Telegraphic Extensions in Africa.

The German minister of foreign affairs recently announced in the Reichstag that an agreement had been made between the government and the Trans-African Telegraph company in relation to the construction of a telegraph line in the German East African protectorate as a connection with the existing South African line, in which the German supremacy of interests will be safeguarded. The Trans-African company by this arrangement, he said, receives permission to construct the line at its own cost, the work to be completed within five years. The officers and workmen are to be subject to German laws while in the East African protectorate. The company undertakes, in addition, to build a separate line of two wires between two stations in Rhodesia, nearest to the frontier and British East Africa, which shall be the property of the German government and kept up at the government's expense.

In relation to the proposed extension of the tele-

graph up the Nile to Fashoda, Slatin Pasha, interviewed at Vienna recently, says that the construction will be difficult, owing to the sudden closing of navigation on the Nile. To transport poles and other materials by camels is too costly.

Triumph Power Fans.

The Triumph exhaust fan (Fig. 1), made by the Specialty Manufacturing company of Indianapolis, Ind., presents some novel features. The flat, square back reduces the trouble and expense of placing the fan in position, it only being necessary to bolt or lag the flat back up to the opening, and the fan is ready for service. This fan is said to be the only fan made with perfectly adjustable self-oiling boxes and phosphor-bronze (not babbitt) bearings, thus insuring a fan of the most durable character, as the bearings represent practically the only wearing parts of a fan. The manufacturer claims high efficiency for the Triumph, due to neatly fitted bearings, proper number of blades, correct angle and accuracy in balance, and the maker is willing to ship this fan to any responsible person on 30 days' trial, and simply asks that it be returned if not fully satisfactory. This fan is made for belted service only, as most customers have power of some kind, and if it should be necessary to use an electric motor, any first-class motor and a Triumph exhaust fan complete can be bought and belted together.

The Junior water-blow fan, manufactured by the Specialty company, is shown in Fig. 2. This fan is operated by water pressure. It has its own motor and can be used in cities or towns where a water pressure of 30 pounds or over is attainable. It is neat, attractive, efficient and economical in water consumption, as it requires a jet only one-sixteenth inch in diameter to run it. It is made with ground

FIGS 1 AND 2 TRIUMPH POWER FANS

MORRIS ARC LAMP.—FEEDING MECHANISM.

is manufactured by H. A. Paquette & Co., 53 Dearborn street, Chicago. It has a number of special features. One half of the drawing gives a side view of the whistle and elbow. A is a small covering over the spring which holds the whistle so that plastering cannot come in contact with it. The other half shows the elbow whistle bottom side up. C represents a slot cut in on both sides of the whistle, which is held to the elbow as represented by B. The whistle is so constructed that children and others cannot steal it. The blowing off of the whistle when too much force is used is also an impossibility. Paquette & Co. state that only the best material is used in their device. It might be added that although only recently placed on the market this speaking tube is already in great demand and is said to be recommended by architects all over the country. It will be handled by electrical supply houses as well as hardware dealers.

A stock company has been organized at Hope, N. D., to establish an electric-light plant.

tool-steel shaft and hard-brass bearing, and has 13-inch blades of spring brass, nickel plated and protected with neat wire guard. The body and base are neatly enameled. The fan weighs only nine pounds complete. The inlet is provided with thread to which the ordinary three-quarter-inch hose coupling may be attached, thus enabling the purchaser to fit up this fan with rubber hose for both waste and supply, at a very small cost. The manufacturer of the Junior is the maker of many other water fans, and has placed the Junior on the market in response to a demand for a reliable and serviceable fan at a price that will be within the reach of all.

Morris Arc Lamp.

The Morris Arc Lamp, made by the Morris Arc Lamp company of Chester, Pa., is designed to meet the demand for a long-burning arc lamp for use on constant-potential circuits, constructed without the complicated mechanisms which, to quote the language of the manufacturer, "have been as unnecessary as they are disastrous to every-day use

in the hands of any but expert electrical men." The carbon feeding device of this lamp, which is in the cut, consists of a single column of rigid carbon core of which directly emerges the carbon rod by means of a washer clutch, and sudden movement of the carbon is checked by means of a self-aligning dash-pot, provided with a graphite plunger. There are absolutely all the parts of the feeding mechanism, there being no clockwork, escapements or racks, and in practice it is found to control the arc perfectly, it is said.

These lamps are made for use on all the standard constant-potential circuits, 110, 220 and 550 volts. The lamps constructed for use on 110-volt circuits are for multiple connection with about 80 volts at the arc; those for 220 volts are for either multiple or two in series, and those for 550 volts are for five in series connection. The four cardinal points of merit claimed for the Morris arc lamp are insulation, economy, simplicity and steadiness.

Great care has been devoted to make the insulation perfect, and the liability to burn-out has been almost entirely eliminated. Those having experienced the annoyance and expense attending incomplete insulation in arc lamps will appreciate this point.

The "economy" refers to the cost of operation as well as to the first cost of the lamp. The saving in carbons and time expended in trimming will, it is claimed, more than pay for the lamp in a year.

Simplicity is a very desirable feature and one that will be fully appreciated by those having had experience with the clockwork mechanisms in arc lamps. There are no working parts to get out of order and all the attention required is to trim the lamp and keep the globes clean.

Steadiness is accomplished by patented features controlled by the company. With even voltage there is no jumping of the light, and by the use of proper inner and outer globes there are no shadows.

Electric Lighting in Massachusetts.

The fourteenth annual report of the Massachusetts gas and electric-light commissioners for 1898, just issued, covers the operations of 138 corporations, 68 of which are electric-light companies and 24 others operating gas and electric-light plants combined. The earnings of these companies are summarized separately from those doing a gas manufacturing business only, and compare with 1897 figures as follows:

	1898	1897	Increase.
Gross.....	\$4,841,779	\$4,510,134	\$331,645

Cable Communication in the Philippines.

The Signal Service Corps of the United States army is hard at work in the Philippines, and cable communication is being rapidly opened among the islands. On March 22d the War Department at Washington received from General Otis information that came by cable to Manila from Iloilo. The opening of the cable from Manila to Iloilo was announced the day before in a message to General Greely from Manila, which also reported the proposed extension to the island of Cebu. A cable has heretofore run from Manila to Capias, on the island of Panay, and communication with Iloilo was maintained by a land telegraph from that point before the insurgent uprising. The station at Capias has now been discontinued, and the cable has been swung from there around the northeast end of the island of Panay, so that it reaches Iloilo, making a direct line between Iloilo and Manila. General Greely has also been informed that the cable has been opened from Iloilo to Baccolod, on the island of Negros, and it is hoped to open soon the land line from Baccolod, on Negros, to Escalante, from which place a cable extends to Suburan, on the island of Cebu.

Trouble in Syracuse.

The trouble between the city officials and the Rapid Transit Railway company, controlling all of the local surface lines of Syracuse, N. Y., culminated on March 20th in the stoppage of traffic on the entire system. The conflict started last week on account of the refusal of the company to pay certain taxes due the city. The company recently adopted some new rules regarding transfers and the running of cars, which proved unsatisfactory to the public. It was asked by the mayor and Chamber of Commerce to change these rules, but it paid no attention to the request. The mayor then gave notice that he would enforce every ordinance touching the speed of the cars and their sanitary condition, and would bring into effect many laws which have for a long time been considered dead letters. There was a timely snowfall of over six inches, and this gave the mayor an unlooked-for opportunity. In the morning the company had out its snow plows, which resulted in the piling of the snow beside the tracks to a considerable height. An ordinance says that the snow shall be carted away, and this not being done, the commissioner of public works was ordered to get out his men and shovel the snow back

on the tracks. So effectually was this carried out that in less than an hour after the order was issued almost the entire system was tied up. When the motormen and conductors attempted to move their cars they were arrested and taken to police headquarters for violating a city ordinance. All of the cars carried small plows, which would shove the snow from the track as fast as it was shoveled on. The men were afterward released on bail, and were allowed to run their cars into the various barns, but this was as far as they were allowed to go.

CORRESPONDENCE.

New York Notes.

New York, March 27.—An important development in the rapid-transit situation in this city came to light to-day, when the Rapid Transit Commission received an application from the syndicate of capitalists headed by William C. Whitney, offering to construct an underground railway according to the plans prepared by the commission and lease it in perpetuity to the Metropolitan Street Railway company. The board voted to instruct its counsel to prepare an amendment to the rapid-transit act which will empower it to consider and act upon such a proposition. The proposal submitted is that a company shall be organized to build the tunnel, work to begin on the first section, from the city hall, at the southern end of Manhattan island, to Fort George, at the northern end, within three months after the right is acquired, and to be completed within three years from the beginning. The second section is to be built within two years after the first has demonstrated its capacity to earn for the tunnel company five per cent. on the actual cost of construction and equipment. On completion the road is to be leased in perpetuity to the Metropolitan Street Railway company for a yearly rental of five per cent. of its actual cost. The city is to receive from the Metropolitan company five per cent. of the gross receipts of the road, after taxes and the rental to the construction company are paid. The Metropolitan company will bind itself to run express and local cars, the fare on express trains to be 10 cents, entitling persons to transfer to all surface lines. The fare on local cars is to be five cents, and transfers to or from surface lines are to cost three cents extra. It is said that both Richard Croker and Senator Platt are backing the proposed deal with their political influence, and that, therefore, little or no opposition is expected from the Legislature. The Whitney syndicate has almost unlimited capital at its back, and possesses one of the largest power houses in the world, capable of furnishing power to the tunnel trains in addition to that required for its surface lines. The cost of the road has been variously estimated at from \$30,000,000 to \$60,000,000.

The new Park Row building, just completed, is 26 stories high, and it is significant that electric elevators are relied upon where quick, reliable service is so essential.

The students in electrical engineering at the Johns Hopkins University of Baltimore will take a trip in the Easter vacation to New York, Brooklyn and Philadelphia for the purpose of inspecting the working of power houses, machine shops and electrical works. Dr. Hermann S. Hering, instructor in electrical engineering, who lectures upon central-station equipment, will have charge of the party. While in New York, says a Baltimore correspondent of the Tribune, the party will visit three stations of the Edison Illuminating company—the storage-battery sub-station at Bowling Green, the Pearl street station and the Twenty-sixth street station. The students will also go through the large Kent avenue station of the Brooklyn Heights Railway company and the Bay Ridge station of the Brooklyn Edison company. They will also see the Waldorf-Astoria plant, which is said to be the largest private electric plant in the world. In Philadelphia visits will be made to the power house of the Union Traction company and the Baldwin Locomotive Works, where the students will see the large 100-ton electric crane. The Cramp shipyards will also be visited.

The Brooklyn and Brighton Beach railroad, long in the hands of a receiver, was sold under foreclosure last week. The syndicate headed by R. P. Flower, which is attributed with the purpose of consolidating all the railroad interests in Brooklyn and Long Island, bought it for \$711,000. The railroad is to be equipped with electricity before long, and Colonel F. S. Williams, secretary of the Brooklyn Rapid Transit company, says that it will be run on a five-cent through fare to Brighton Beach. The first mortgage bondholders will be paid in full, with interest to date, out of the proceeds of the sale. The holders of both the preferred and common stock of the company will get nothing, both entire issues having been wiped out under the receivership.

Corporation Counsel Whelan gave an opinion to the Board of Public Improvements on Wednesday last that contracts made by town officials in the borough of Queens for lighting, water and public improvements just prior to consolidation are not binding upon the city. The opinion will affect \$2,000,000 worth of contracts. Bridge Commissioner Shea reported that the comptroller had discovered that fraudulent methods were used to get the required number of names on petitions for all sorts of extravagant improvements for which contracts were afterward let. The method was to get signatures for the opening of new roads, and then attach the

names to petitions for additional electric lights, gas lamps and water mains. One of the results was, Mr. Shea said, that some farms in Queens County were better lighted than many streets in Manhattan. M. S.

PERSONAL.

Henry C. Adams, Jr., secretary of the Phillips Insulated Wire company of Pawtucket, R. I., is in Chicago.

Mr. Charles E. Brown, secretary of the Central Electric company, Chicago, has been taking a week's rest in Virginia. He returns with renewed vigor to handle the arduous duties of his position.

Mr. W. R. Mason and Mr. William M. Moran of St. Louis were Chicago visitors early in the week. Mr. Mason is in charge of the St. Louis office of the Siemens & Halske Electric company and Mr. Moran is the engineer of the St. Louis, Belleville and Suburban Railway company.

ELECTRIC LIGHTING.

The council of Prineville, Ore., has granted a franchise to H. V. Gates of Hillsboro, Ore., to furnish and operate an electric-light, power and water-works in the city of Prineville.

The committee appointed to ascertain the cost of an electric-light plant to be owned and maintained by the city of Mendocino, Cal., recommends that the trustees call an election at once to vote on the question of bonding the town for \$18,000 for that purpose.

The High Falls Electric company of Malone, N. Y., has been incorporated to produce electricity for public and private purposes. The capital is \$20,000, and the directors are Joseph F. Wright and Frederick O. Kilburn of Malone and J. Henry Abbott and Morton P. Abbott of Gouverneur.

The Interior Department is inviting sealed proposals, until April 20th, for-furnishing the necessary labor and materials required to construct and complete an electric-lighting system at the Genoa Indian School, Nebraska. Full information will be furnished upon application to J. E. Ross, superintendent of the school, or to W. A. Jones, commissioner of Indian affairs, Washington, D. C.

ELECTRIC RAILWAYS.

Two parties of surveyors are locating the line of the Seattle-Tacoma electric road. The contracts for the bridges will probably be let first. The bridges will be of the latest pattern of steel work.

The Fresno (Cal.) Railroad company, with capital stock of \$500,000, has been incorporated by S. W. Jones, Alexander Gordon, S. N. Griffith and others, to build a road from Fresno to Clovis, with laterals. The road will be 20 miles long and the principal place of business will be Fresno.

Governor Pingree has signed the bill authorizing the city of Detroit to purchase the street railways of the city. A citizens mass-meeting was called to protest against the measure, on the ground that it contains no provision for submitting the municipal-ownership proposition to a popular vote.

The property of the Akron (O.) Street Railway and Illuminating company was sold on March 28th to the reorganization committee, represented by Attorney J. H. Dempsey of Cleveland. The price paid was \$1,050,000, but this was subject to an underlying issue of bonds amounting to \$200,000, so that the real purchase price was \$1,250,000.

Now that satisfactory arrangements with the Jackson aldermen seem to be assured, the 38-mile electric railroad between Adrian and Jackson, Mich., will be built this year. The right-of-way for the whole distance, outside of Jackson, has been secured. The line will be operated summer and winter, and the rate of fare will be 1½ cents a mile, with a minimum of five cents. One power house will be in Jackson.

Judge Swan of the United States Circuit Court for the Eastern District of Michigan has enjoined the Detroit Citizens' Street Railway company from infringing the General Electric company's series-parallel car-controller patent, known as the Condict patent, No. 393,323. The car equipments held to be infringing were sold to the street-railway company by the Steel Motor company. There are about 500 of them, and they must be removed by May 27th.

The Elizabeth (N. J.) Street Railway company has applied for permission to change its motive power from horses to electricity. The company wants to construct its line from the Elizabethport and Staten Island ferry to Cranford township, and have the cars running by June 1st, and if the Elizabeth Council acts promptly this can be done. The intention of Senator Kean is to build the road through to Plainfield, but that part from Elizabethport to Cranford is to be undertaken at once.

A trolley car of the Stratford avenue line of Bridgeport, Conn., pulled into the station at the end of the line recently with William Steadman, the conductor, lying dead on the rear platform. He must have died after the car left the East Main street junction, as the passengers said that he was alive at that place. There was a terrific thunderstorm rag-

ing at the time and the car made no stops for a long distance. The lightning struck in several places and the trolley wires were ablaze along the line as the car passed along. Steadman's death was due to heart disease, but was probably caused by the excitement occasioned by the action of the lightning.

A strike which may tie up every street railway in Cleveland is threatened. The employees of the Big Consolidated company declare that unnecessarily severe rules are being harshly enforced with them, and the men of the Little Consolidated companies, while having no complaints of their own, say they will stand by their fellow-workmen.

A company has been formed by Nassau County (N. Y.) men to operate a trolley road throughout the county. The capital stock is \$300,000. Two lines will be maintained. One will start from Mineola, near the county building, and run through Garden City, Hempstead village, Freeport, Baldwins, Ocean Side and East Rockaway. The route will be through public thoroughfares and private property. The other line will start at Hempstead, and run through Rockville Center and East Rockaway, where it will connect with the other line. A loop will be extended so as to take in Long Beach and Lynbrook, and, altogether, 30 miles of road will be operated.

The Long Island Railway company has let contracts for the equipment of a portion of its suburban system, running between Far Rockaway and Rockaway Park, a distance of seven miles. The trolley system will be employed, and both electric and steam cars will use the same tracks the electric cars running during the intervals between the regular steam trains. At present there is only a single track between the two places, but it is intended to lay a second track and equip both tracks with the overhead wire. There is also in contemplation the extension of the electric system through the streets of Far Rockaway, so as to connect with the electric service on the Long Island road proper.

The people of New York, it seems, are slow in taking advantage of improvements, or, at any rate, of that particular improvement which consisted in placing electric push-button signals on the surface railway cars. "One in authority" is quoted as follows in the *Sun*: "The buttons were put in to accommodate passengers, who are not always able to catch the conductor's eye when they want the car to stop. But thus far the push signal in our system has been a failure. Passengers rush out to find the conductor or grab the bell-rope or sometimes the rod that rings up the fares. There is an electric button at every window. When it is properly used the car will stop at the next crossing."

It is very evident that Hon. W. Caryl Ely of Niagara Falls is to be the official head of the International Traction company, when its organization is perfected. At a meeting of the Buffalo Railway company, held March 24th at the office of J. P. Morgan & Co. in New York city, the following new organization of the company was perfected: President, W. Caryl Ely; vice-president, Daniel S. Lamont; general manager, Burt Van Horn; secretary-treasurer, Richard F. Rankine; directors, Charles H. Coster, T. De Witt Cuyler, Daniel S. Lamont, Francis Lynde Stetson, William B. Rankine, W. Caryl Ely, Burt Van Horn, Henry M. Watson, Cornelius C. Cuyler, Robert L. Fryer, John N. Scatcherd, George Urban, Jr., Daniel O'Day.

A. A. Talmage & Co., New York, are about to incorporate the Michigan Street Railway company and the Michigan Heat, Light and Power company, each with a capital stock of \$25,000, the minimum amount allowable in Michigan. The ultimate capitalization of the company, according to the *Railroad Gazette*, will probably be about \$10,000,000. This company has secured nearly all necessary right-of-way and franchises for 85 miles of electric railroad. The road will begin at Flushing, Shiawassee County, running southeast 12 miles through Genesee County, to Flint, which will be the headquarters of the company; then the road will parallel the Flint and Pere Marquette railroad to Grand Blanc, where two branch lines will be built, one running east to Atlas, the other southwest to Fenton, via Long Lake, probably needing three bridges. From Atlas it is intended eventually to build a line through to Pontiac and connect with an electric railroad to form a continuous line to Detroit. With trackage arrangements with other roads now in operation and building, this new road will pretty well cover the territory between Bay City and Detroit. In Flint about six miles of road will be built to give a local service. The company will do its own building. H. A. Lloyd is president pro tem. Other persons interested are A. A. Talmage, R. D. Talmage and William J. Schaefer.

INDUSTRIAL COMBINATIONS.

The articles of incorporation of the International Steam Pump company were filed on March 17th with the secretary of state in Trenton, N. J. The capital stock is placed at \$27,500,000, and the incorporators are Wilson P. Marchbank, Charles N. King and B. B. Schiff of Jersey City. This is the company formed to take over the business of the steam-pump companies of the country.

It is said that an effort is making to combine the manufacturers of pulleys and other mechanical devices for power transmission. The names of the

companies invited into the combination are given as follows: Reeves Pulley company, Columbus, Ind.; Keasey Pulley company, Toledo, O.; Dodge Manufacturing company, Mishawaka, Ind.; Menasha Pulley company, Menasha, Wis.; Saginaw Manufacturing company, Saginaw, Mich.; Ohio Valley Pulley company, Maysville, Ky.; Buckeye Pulley company, Marion, O.; Fulton Pulley company, Fulton, N. Y.

POWER TRANSMISSION.

Work will be begun at once on the electric plant near San Bernardino, Cal., to be erected by the Lytic Creek Power company, and it is believed that the plant will be in operation by August or September. Judge Campbell has sent a corps of engineers to the canyon to stake a line for pipes and ditches.

The Woodland, Cal., Mail says that E. H. Winship of Napa has made a statement regarding the proposed electric power enterprise. Cache Creek of Lake County will furnish the water power to generate electricity. The turbines will be on same shafts as the dynamos. A pole line will be constructed from the power house, conveying six wires carrying 40,000 volts, along the most feasible route to Calistoga. From there the line divides, three wires going to Santa Rosa and Petaluma and a three-wire line to St. Helena, Napa, Vallejo and Benicia.

Power from the new plant to utilize and electrically transmit some of the force of the Missouri River is now available at Helena, Mont. Immense smelters, concentrators, mining machinery, mine hoists, street cars, electric-light systems, telegraph and telephone batteries, newspaper plants, and, in fact, almost every power plant in Helena, East Helena and Corbin are either now or will be driven by electricity derived from an electrical plant located at Canyon Ferry, 16 miles from Helena. It is the hope of the company to extend the lines to Butte, distant about 40 miles.

The Clear Lake Electric Power company has asked for a franchise to erect, construct, maintain and operate in Solano County, Cal., a system for the transmission of electricity for light and power purposes, and to exercise the privilege of operating electric-light and power plants in the county. The application was received and the clerk of the Board of Supervisors instructed to advertise that the board proposes to grant the application, and will receive bids for it up to 10 a. m. on Monday, May 1st. The same company has made similar applications in Sonoma, Napa and Lake counties, and bids for the franchise in the last-named county will be received by the clerk of the Board of Supervisors at Lakeport, until 1 p. m. on May 1st.

A dispatch from Stockton, Cal., states that after a tour of inspection of the big power line between that city and the Blue Lakes, Chief Engineer F. A. C. Perrine and Foreman of Electrical Construction E. D. N. Lehe of the Standard Electric company have arrived in Stockton. They report the system completed and ready for operation. This power line extends 42 3/4 miles and has aluminum wire. This is the first division of the system, which will be extended to Oakland and eventually to San Francisco, for it can furnish and power at much lower rates than a company compelled to produce its electricity by coal. Arrangements have already been made with the Oakland Gas and Electric company to distribute the power in that city, while all who wish it in the towns through which the line passes will be furnished directly by the Standard Electric company, with the exception of Stockton, which has a distributor.

ELECTRICAL SECURITIES.

The Twin City Rapid Transit Railroad company reports gross earnings for February of \$178,829, an increase of \$27,003 as compared with the same month of last year, and net \$92,304, an increase of \$19,267. Fixed and preferred-stock charges were \$67,529, leaving a surplus of \$24,775, an increase of \$18,788.

President W. W. Gibbs of the Pennsylvania Electric Vehicle company says that the preferred stock is entitled to a dividend of six per cent. upon the amount paid in upon it before any dividend shall be payable on the common stock. After six per cent. has been paid upon the amount paid in or called upon the preferred stock, then six per cent. shall be paid on the par value of the common stock before further dividends or payments are made on the preferred. After six per cent. has been paid upon the amount paid in on the preferred stock, and six per cent. has been paid upon the par value of the common stock, any further distribution of profits will be made, share and share alike. The capital of the company is \$4,000,000 common and \$2,000,000 preferred.

N. W. Harris & Co. of Chicago, having sold \$1,200,000 five per cent. 30-year first-mortgage gold bonds of the Edison Electric company of New Orleans, now offer \$500,000 more at 106 and accrued interest. The company has a capital of \$1,500,000 common stock and \$2,000,000 preferred. It has outstanding \$2,000,000 first-mortgage bonds and \$500,000 are in the treasury reserved for extensions. The gross earnings of the company have increased from \$152,712 in 1894 to \$550,003 in 1898; net earnings in the same period have increased from \$74,150 to \$262,817. The company owns complete control of the electric-

light business of New Orleans. It is said that its plants have been carefully examined by Mr. Samuel Insull, president of the Chicago Edison company, who estimates that the property represents an actual cash investment of \$2,865,000. The income of the Edison Electric company of New Orleans per capita of population is said to be greater than that of any other illuminating company operating in a city of similar size.

The New Jersey Title Guarantee and Trust company of Jersey City, acting as agent for the United Gas Improvement company of Philadelphia, has issued a circular letter to the owners of stock of the North Hudson Light, Heat and Power company, stating the terms upon which the stock of the latter company can be exchanged for bonds of the United Electric company of New Jersey, which was recently incorporated with a capital stock of \$20,000,000. The United Electric company has issued \$20,000,000 of 30-year four per cent. gold collateral trust bonds. The letter says: "The holder of each \$1,000 of the stock of the North Hudson Light, Heat and Power company will receive \$875 in the bonds upon the surrender of the certificate and by the payment of \$100 in cash on or before May 31st." The United Gas Improvement company agrees to sell to the stockholders of the North Hudson company who avail themselves of the offer stock in the United Electric company to an amount of 25 per cent. at par of their holdings in the North Hudson company at \$30 a share, the par value of each share to be \$100.

PUBLICATIONS.

The Western Electric company, Chicago and New York, has issued its second fan-motor bulletin, 17 F, descriptive of desk and bracket fans.

The Western Electric company, in addition to its handsome 40-page fan-motor catalogue, is issuing a series of four-page bulletins, descriptive of the different styles of fans. Bulletin 16 F, on "W. E. Standard Ceiling Fans For Direct Current," has just been issued.

Dixon's "Teachers' Note Book," issued by the Joseph Dixon Crucible company of Jersey City, N. J., tells all about lead-pencils, their properties and the methods of manufacture. The pamphlet also contains interesting information of a miscellaneous character and blank pages for memoranda.

Locke's line material for high-potential circuits is of approved excellence and widely known. The porcelain and glass insulators, steel pins and other specialties bearing the name of Locke are handsomely illustrated and clearly described in a new catalogue which may be obtained by addressing Fred M. Locke, Victor, N. Y.

A handsome catalogue of electric ceiling and column fans is issued by the Backus Water Motor company of Newark, N. J. The fans described and illustrated are said to be of the highest grade, electrically and mechanically. A special feature is a two-speed switch furnished with fans when desired. The western agent of the company is the Chicago Motor and Fan company.

Lighting has no terrors, we are told, for users of Garton lightning arresters, which are made by the Garton-Daniels Electric company of Keokuk, Iowa, for use on any circuit, either direct or alternating current. A new catalogue, neatly printed with wide margins, tells all about these protective devices and gives pictures of them, with a list of users and testimonials.

Pamphlet No. 4, issued by the Electrical Bureau of the National Board of Fire Underwriters, 157 La Salle street, Chicago, gives the laws and ordinances adopted by various states and municipalities to regulate the installation and use of electrical apparatus. It has lately been revised, and the new edition is brought up to date. It is especially valuable to electrical inspectors, whether for municipalities or fire-insurance companies.

The 1899 fan-motor catalogue of the Western Electric company, Chicago, now out, is complete, with prices, and well illustrated. The pamphlet contains 40 large (10 3/4 by 8-inch) pages, besides the cover, which is of a deep red color. The large pages give opportunity for exceptionally large explanatory cuts, which are a feature of the catalogue. Desk, bracket, ceiling and column fans for direct and alternating-current circuits are described.

The Bates electric fans are shown in a small catalogue issued by D. L. Bates & Bro. of Dayton, Ohio. Especial attention is paid by this firm to ceiling fan motors for either direct or alternating current, which are, it is said, acknowledged to be superior to any others on the market. The fans are furnished with lamp attachments, if desired, making a very attractive electrolier. The lights revolve with the blades, and in winter the blades may be detached. Column, desk and bracket fans are also described.

A recent catalogue of real usefulness to all electrical men is the "Complete Catalogue for 1899 of Weston Standard Electrical Instruments," issued by Meysenburg & Badt of Chicago, the western agents for the Weston Electrical Instrument company of Newark, N. J. It is superfluous to praise the Weston instruments, and it is sufficient to say that the "complete catalogue" describes and illustrates all

types of portable and station instruments to indicate the value of the book. Instructions for placing the instruments in position and diagrams of connections are also given and will be appreciated by practical men.

Students of telegraphy may obtain J. H. Bunnell & Co.'s "Manual of Telegraphy," which is combined with the firm's telephone catalogue, by merely applying to the concern at 76 Cortlandt street, New York. No charge is made for the pamphlet, which consists of 112 pages, with many illustrations, and contains much valuable information. The instruction in telegraphy is clearly written and is practical and helpful. The catalogue portion of the book is useful to all users and dealers in telegraph and telephone supplies.

"Transformer Design and Operation," published by the General Electric company of Schenectady, N. Y., is a pamphlet from which the station manager can obtain much valuable information. Two recent papers on transformers in service—that of Mr. W. F. White before the Omaha meeting of the American Institute of Electrical Engineers and that of Professor Goldsborough at last year's convention of the National Electric Light association—are reprinted, and the "type H" transformers of the General Electric company are exploited. The advantages and economy of substituting modern large transformers, supplying groups of customers, for a number of small house-to-house transformers are pointed out.

Nash gas and gasoline engines are described in a new catalogue issued by the National Meter company of New York. Pictures show all the distinguishing features of the engine, and all needful information, tables of sizes and data of power and cost are given in the text. The Nash engine is believed to be especially well adapted as a prime mover for dynamos, and several direct-connected sets are illustrated. On the interesting subject of the direct connection of gas engines and dynamos the company says: "The principal difficulty met in producing a satisfactory direct-connected electric-lighting plant operated by a gas engine has been to secure the requisite close regulation in speed of both engine and dynamo. To explain how this has been accomplished, it may be said that we use, for all our larger engines, the Beau de Rochas system, commonly known as the four-stroke cycle, and govern by the principle of missed ignitions. * * * We may state that our method of direct connection secures a practically unvarying speed for the generator, and therefore produces a light so steady that the eye is unable to detect any flickering in the lamps, while the fluctuations of the voltmeter are almost imperceptible under changing loads. This regulation, so essential to a commercially successful electric-lighting system, is, we believe, unapproached by any other gas-engine combination, and it is due, in large measure, to the fact that the dynamo is not rigidly connected to the engine shaft, but is driven by our special centrifugal clutch coupling, by virtue of which any tendency to variable speed in the generator that would follow a like variation in the engine or the load is at once corrected so as to keep the generator speed constant."

TRADE NEWS.

H. J. Gorke, electrical supply dealer, has found it necessary to secure increased store capacity. His new address is 305 South Clinton street, Syracuse, N. Y.

To accommodate its eastern customers the Cutler-Hammer Manufacturing company of Chicago has opened a New York office at 136 Liberty street, where it will carry a large stock of rheostats. This office will be in charge of Mr. W. H. McGregor.

C. E. Corrigan, manager of the American Electric Vehicle company, Chicago, states that his company is daily booking orders for its vehicles. The business of the company is becoming greater each day and is by no means confined to the United States. Orders from Hawaii, Belgium, Hungary and several other foreign countries are now on hand.

Prof. R. C. Carpenter of Sibley College, Cornell University, is now engaged in making a series of exhaustive tests with Cling Surface compound for belts. A preliminary report, just made, shows most surprising results as to the increase of transmitting power of belts from the use of Cling Surface. A full report, with diagram of curves, will be issued soon.

Mr. Charles McLaughlin, the surviving member of the firm of J. H. Bunnell & Co., 76 Cortlandt street, New York, with his competent assistants in the various departments of the concern, is pushing the business with intelligence and zeal, and customers may rest assured that all orders placed with the firm will receive the same careful attention as heretofore. The concern manufactures, imports and deals in telegraph, telephone, railway and electric-lighting supplies, and Mr. McLaughlin has been the active manager of the business from its inception. The high standard of the firm's apparatus will be maintained under the same firm name, and no interruption of the satisfactory extension of the business is anticipated.

Every spring season the Garton-Daniels Electric company of Keokuk, Ia., is rushed with orders for

its lightning arresters, and, knowing what to expect each year, it endeavors during the winter months to prepare as large a stock as possible. This spring it had twice as large a stock on hand as ever before, but has just doubled its force in order to keep pace with the demand for these goods, and still finds that it is shipping faster than it is manufacturing. Additional force will be employed, however, and all orders will be shipped with the usual promptness, as the company thoroughly appreciates that when a man wants lightning arresters he wants them badly. This company's catalogue No. 22 seems to be in great demand, and a second edition may be required.

BUSINESS.

The Western Electric company, Chicago and New York, is especially prepared to fill all demands for sockets, switches and cut-outs.

The Electric Appliance company reports large sales of the P. & S. junction box, which is an all-

porcelain box for high-voltage service. The P. & S. box seems to meet all requirements and finds a ready sale wherever introduced. The Electric Appliance company carries a large stock of these goods.

Seymour Swarts, president of the Swarts Metal Refining company, Chicago, reports a large and flourishing business. One of the best-known concerns in the business, the company is adding to its large trade from day to day. Electric-light, street-railway and other electrical men who have scrap copper wire for sale will receive the highest market price from the Swarts company.

The Central Electric company, Chicago, is adding physical apparatus to its already complete electrical lines. The company is now sending out an attractive booklet entitled "A Barometer for Weather Conditions." Our present climatic changes are very hard to "guess," with prospects of further hardships; hence it is suggested that all electric-light and street-railway companies request a copy of this booklet, and be independent of weather conditions.

The electrical fraternity will be interested to learn that the Royal Electric company of Peoria, Ill., manufacturer of alternating-current generators, transformers and accessories, has opened a Chicago office in rooms 1201-2 Marquette building, which will be in charge of J. B. Wallace. This step was necessitated by the large and increasing demand for the well-known Royal apparatus, which has found such favor throughout the country. Mr. Wallace will have charge of the sales of the Royal apparatus in the states of Ohio, Indiana, Michigan, Wisconsin and Minnesota, and in Northern Illinois and Eastern Iowa. He will be assisted by Edward Barr. The Royal Electric company, under the able management of G. G. Luthy, has met with gratifying success in pushing its apparatus, the merits of which are becoming better known from day to day. Mr. Wallace has extended experience and a wide acquaintance in the electrical business, and of late years has devoted especial attention to alternating-current apparatus. He should be a valuable acquisition for the Royal company.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 21, 1899.

621,321. Electric Railway System. George L. Campbell, Dushore, Pa. Application filed May 5, 1898.

A trolley comprising a wheeled frame with wheels below the frame and pivotally connected therewith and brushes carried by the frame and engaging the pivoted wheels and a brush on the upper part of the frame is described.

621,324. Combined Pump and Motor. Niels A. Christensen, Milwaukee, Wis. Application filed December 30, 1896.

In a combined air pump and electric motor a motor base is attached to the frame and forms a cover for the oil chamber; an armature is supported upon the base and connected by gears with the crank shaft, and a gear case is attached to the frame and motor base and forming therewith an inclosure for the gears and a receptacle for holding oil, the frame gear case and motor base completely inclosing and protecting the driving connection of the pump and the crank shaft terminating within the gear case, whereby a stuffing box therewith is dispensed with.

NO. 621,324.

621,326. Automatic Telephone Switch. Charles S. Karoly, Aurora, Ill. Application filed November 9, 1897.

A telephone switch comprising a movable plate, a circuit of which the plate forms a part, a push finger having connection with the telephone wire and adapted for engagement with the plate to close a circuit, a receiver-supporting lever in the circuit, and a shoe pivotally connected to the lever for engaging with the plate and moving the plate out of engagement with the push finger.

621,352. Supply of Current to and Governing Arc Lamps. Frank M. Lewis, London, England. Application filed December 28, 1897.

An arc lamp comprising a transformer actuator and means controlled by the transformer actuator for regulating the arc are described.

621,361. Electric Burglar-alarm System. David W. McCaughey, Chicago, Ill. Application filed April 1, 1897.

Claim is made in an electric alarm system for the combination of a contact point, means for insulating the same, a metallic sleeve surrounding and inclosing the contact point and provided with lateral projections, a second metallic sleeve of thin die, and means for yieldingly holding such sleeves or thimbles apart, but arranged to yield when an attempt to drill or break the same is made and form electric contacts and short-circuits between the same.

621,412. Transfer Wattmeter Switch for Storage-battery Circuits. Charles Hewitt, Philadelphia, Pa. Application filed May 13, 1898.

There is a combination of a battery and its conductor, two recording devices, an electromagnet responding to the electrical condition of the conductor, and a polarized armature co-operating with the magnet and provided with means for connecting and disconnecting one or the other of the recording devices.

621,417. Electric Arc Lamp. Emil Hungerbühler, London, England. Application filed December 18, 1897.

A pair of circularly curved electrodes is employed, one of which is excited by a series coil and the other by a shunt coil, with a pair of circularly curved cores mounted on an axle which coincide with their respective centers of curvature, a pulley is mounted on the axle between the cores, and a pair of ropes passes over the pulley and serves to suspend the electrodes as well as to conduct current to them.

621,422. Trolley Catcher. Roswell I. Kroft, Avon Lake, O. Application filed April 14, 1898.

In trolley-catcher apparatus there is a combination with the trolley and adjusting rope and spring-actuated reel having a ratchet and locking pawl, of a trip spring actuated constantly to resist the pawl held in its engagement with the ratchet by the pressure of the reel spring, and a lever arranged to overcome the action of the trip spring and force the pawl into engagement with the ratchet.

621,449. Telephone System. Charles E. Egan, Burton L. Lawton and Ernest C. Wilcox, Meriden, Conn. Application filed February 25, 1898.

Metallic rails are insulated and supported in pairs upon the back of a switchboard, each rail being provided with metallic springs, each spring-jack with rods fitted to register with the springs, there being electrical connections with the rods on the one side and the rails on the other side.

621,471. Switch for Altering Speed and Direction of Revolution of Electric Motors, etc. William R. Edwards and Septimus F. Beevor, London, England. Application filed September 6, 1898.

Claim is made for the combination in a switch for altering the speed and direction of revolution of electric motors, of a spindle turning in bearings in the frame, a switch arm carrying spring brushes insulated from another switch arm, concentric insulated contact pieces below the spring brushes on one side of the central line, concentric insulated contact pieces below the spring brushes but on the other side of the central line, insulated conductors connecting the different concentric contact pieces, and conducting wires and terminals with the poles of the two halves of the batteries with the coils of the field magnets and with the commutator brushes.

621,492. Electric Railway. William J. George, Johnstown, Pa. Application filed June 8, 1898.

A sectional conductor is composed of aligned sections, floating switch plates, housed directly within the contiguous ends of the sections, and normally in metallic contact therewith, and means, carried by the car, for causing the switch plates to move bodily out of contact with the conductor sections.

621,575. Electrical Warp Stop Motion for Looms. Frederic E. Kip, Montclair, N. J. Application filed June 17, 1898.

In an electrical warp stop-motion for looms the combination with the loom frame having the transverse rods fixed therein, the normally open operating electric circuit, having tubular terminals mounted loosely on the respective rods at their respective ends only, whereby distortion of the loom frame is prevented from bending the terminals, and the drops adapted to close the circuit at the terminals when a warp thread breaks.

NO. 621,717

621,594. Electrical Warp Stop Motion for Looms. William H. Baker, Central Falls, R. I., and Frederic E. Kip, Montclair, N. J. Application filed August 6, 1898.

A fulcrum rod extends transversely of the warp, and a contact terminal also extends transversely of the warp, while a series of lever-like drops is interposed side by side on the rod, and a detached removable strip is supported on and carried by the longer arms of the drops.

621,604. Electric Heater. Edward E. Gold, New York, N. Y. Application filed January 8, 1898.

An electric heater comprising an open helix of wire having sufficient stiffness or resilience to retain its helical form, and a support therefor consisting solely of a rod or stiff wire extended within the helix, of materially smaller diameter than the interior thereof, so that the helix is interiorly open for free circulation of air within it, and supporting the convolutions of the helix by tangential contact therewith at single points only of their circumference.

621,631. Section Insulator. Edward J. Cook, Cleveland, O. Application filed March 5, 1898.

Claim one is for a metallic end piece for section insulators having a wire channel, a toothpick end and an arc-breaking flange.

NO. 621,739.

621,661. Insulator. Morton Harloe and Wilton S. Bloes, Peckville, Pa. Application filed February 1, 1899.

An insulator is described having a body portion with means for mounting it to swing, the body portion having located eccentrically thereon three studs separated by grooves, the end studs having overhanging outer ends and the middle stud having an overhanging inner end, whereby upon swinging the insulator the wire may be bent through the grooves and beneath the several overhanging ends of the studs.

621,716. Secondary-battery Plate. Alexander Schan-schieff and Albert E. Hodgson, Halifax, England. Application filed October 17, 1898.

A battery plate formed of two plates each having openings larger on one side than on the other, and V-shaped bars between the openings, the two plates being secured to each other with the pointed edges of the V-shaped bars together and active material filling the openings and V-shaped bars is described.

621,717. Dynamo-electric Machine. Coleman Sellers, Philadelphia, Pa. Application filed October 20, 1897. Renewed October 31, 1898.

In a dynamo having a vertical shaft it is proposed to utilize a frame or armature stand cylindrical in form having its upper and lower surfaces dressed parallel to a plane at right angles to its axis and its inner cylindrical surface bored conically top and bottom, spider frames carrying the shaft bearings having their exterior surfaces dressed conically to fit to the conical borings of the frame and concentric with the shaft, a coupling frame uniting the upper and lower spider frames, and means for drawing the spider frames to place within the frame.

621,733. Electric Belt. Thomas F. Wynne, Lindale, Texas. Application filed October 4, 1898.

The combination is described with cells and a cell-carrying plate of the cell pockets having slots and an outwardly bent tongue, and the wire passed through the slots and under the tongues, and having its ends secured to the plate.

621,739. Automatic Electric Switch. Robert Baumann, St. Louis, Mo. Application filed March 10, 1898.

A suitable base is provided, and pairs of electromagnets are arranged upon the base; an armature is pivoted at one end so as to swing between the cores of the magnets, to the sides of which armature opposite the ends of the cores are formed recesses, a pair of leaf-springs fixed to and extending forwardly from the free end of the armature, and means for making and breaking an electric circuit, which means is operated by the leaf-springs.

No. 14

Electric Power Transmission in Mexico.

An electric power-transmission enterprise with valuable water-power privileges near Puebla, Mexico, is attracting considerable attention among those engaged in the development of the industrial capacities of the southern republic. The project is in the hands of an American company organized under the laws of Illinois and directed by Chicago capitalists. It is known as the Portezuelo Light and Power company, and is under the immediate direction of Mr. Chester D. Crandall of the Western Electric company, who is the president and chief promoter of the enterprise. The plans of the company provide for the building

distance of two kilometers more. The smaller tunnels vary in length from 100 to 600 feet, but the large tunnel, which is an imposing piece of masonry, is 2½ meters high and will admit a man walking erect from one end to the other.

The fall in the upper canal and tunnel is 20 centimeters per kilometer, and in the lower end of the canal 60 centimeters per kilometer. The sectional capacity of the canal is six cubic meters per lineal meter. The actual flow of water during the lowest stage in the dry season of the year is three cubic meters per second, or 3,000 liters. This large volume of water is conveyed through four 42-inch pipes

Chicago, who acted for the Portezuelo company, and is now superintending the installation of an equipment valued at \$275,000 gold. The installation will include four power generators of 1,200 horse power each. The line will comprise six copper wires. A three-phase system operating at 10,000 volts will be employed. The hydraulic installation will be supplied by the Pelton Water Wheel company of New York and San Francisco, and will comprise four water wheels of 1,200 hydraulic horse power each.

It is the intention of the company to furnish electric light and power. Puebla City uses 250 arc and 2,000 incandescent lamps in its city service, and the

Fig. 4. View of Dam.

ELECTRIC POWER TRANSMISSION IN MEXICO.

of a power station in the Atlixco Valley, on the Atoyac River, 12 miles from the city of Puebla. At that point an immense water power has been developed by Sebastian de Mier, under a concession granted by the Department of Public Works of the Mexican government in 1880. The object of this improvement, upon which \$600,000 has already been expended, is to furnish hydraulic works for irrigating Mr. de Mier's immense estate. A system of canals and dams and locks has been built which overcomes the irregularity of the natural supply of the river.

The point of derivation of the water is in the mountains 12 miles south of Puebla, where the diverting dam, shown in Fig. 1, has been built. This dam leads the water from the headwater of the Atoyac into a canal and tunnel system, which continues in a south-westerly direction for 11 kilometers. The waters conducted from the river at the dam pass through a canal four kilometers in length, and then a tunnel nearly five kilometers through the heart of a mountain, and finally through 10 tunnels and a canal for a

from the entrance of the canal down the mountain side, a distance of 2,500 lineal feet, at an angle of 10 to 30 degrees, and a total perpendicular fall of 143 meters. This fall of 3,000 liters will produce 4,000 horse power, and the same water after passing this fall is conveyed four kilometers farther down the side of the mountain until a point is reached 200 feet above the floor of the valley, where the water supply at this point is capable of producing an additional 2,000 horse power, making a total at both falls of over 6,000 effective horse power to be utilized when the electric installation is completed in Puebla. This will then be the largest electrical installation in the republic of Mexico.

A section of the main canal is illustrated in Fig. 3, and the arch where the water enters the canal is shown in Fig. 2. This elaborate gate is a fair specimen of the work that has been done in this installation. The view of the dam, in Fig. 4, gives an idea of the volume of water that is controlled for this purpose.

Mr. de Mier leased the power to J. W. Ebert of

factories and mills in and around the town will take the remainder of the 2,000 horse power at first generated. Calculating coal at \$18 a ton and wood fuel at \$7 a cord, the price of power furnished by this company will be a reduction from one-half to two-thirds the price of steam power.

Puebla enjoys exceptional railroad advantages, being linked with the capital of the republic by two lines, and having a railroad to Vera Cruz and one to the southern city of Oaxaca. These facilities, combined with the cheap power, make it probable that many more factories will locate in Puebla. The city now is the most important manufacturing center in Mexico, and the list of factories which will be supplied with power by the new company includes cotton and woolen mills, shoe and hat factories and cornmeal mills. The company is now considering a proposition to enlarge its plant and secure additional power for transmission to other points. The city of Mexico is another excellent field for electric-power development.

Electrical Spectacular Effects.

The interesting photographs reproduced in Figs. 1, 2 and 3 of the accompanying illustrations show the graceful figures of light traced in the air by swinging electrically lighted Indian clubs in a dark room. The clubs are the property of Mr. George W. Patterson of Chicago, and he was swinging them at ordinary speed when the negatives were made. The time of exposure was from five to ten seconds, and the photographs were made by the light of the incandescent lamps studded on the clubs.

Mr. Patterson claims the distinction of having invented this spectacle, which is part of an electrical entertainment that he gives, and he has been perfecting his electrical club swinging and other "acts" for the last six years. The clubs are made in two parts, the split being lengthwise. A flexible cable of five wires leads into club handles through a rubber tube, the wiring being entirely concealed. Three series of eight, three and one candle power colored lamps are set in small, specially turned brass sockets the length of the club, so that the lamps stand out at right angles to its surface. This gives six series of different colors to the two clubs, with which most beautiful combinations of colors can be made, and rapidly changed, with appropriate music, by a man at a small switchboard behind the scenes. At the tip of each club there is a 32 candle power 50-volt lamp, which is usually run on 110 volts, the result being the brilliant light shown so prominently and distinctly in the large circles of light shown in the pictures outside the many smaller circles of the miniature lamps. These large lamps, either frosted or plain, are too dazzling for the naked eye when lighted and stationary, and are said to illuminate a large church or hall very well. Switches are placed

FIGS. 1, 2 AND 3. ELECTRICAL SPECTACULAR EFFECTS.

inside of the clubs, so that the series can be quickly cut in two for 52-volt circuits.

Another striking feature of the entertainment is the electrical storm, beginning with distant heat lightning, gradually increasing to the fiercest of chain or "zigzag" lightning, with corresponding gradation of thunder, the latter being produced in the usual manner by a "thundersheet" of iron. The heat lightning is simulated by well-distributed Geissler tubes, and the near-by lightning by the direct arcing of carbons in Mr. Patterson's hands. The arc is struck in a small box, and the light is thrown by a lens through a cardboard disk having lightning forms cut in it. The disk is revolved to any form desired and the light flashed out while the lens is pointed to the wall back of platform, on the ceiling or into the audience. The effect is very startling, especially as it is accompanied by the fiercest thunder, the sound of dashing rain and by Mr. Patterson's voice laughing and singing "The Lightning King" through a megaphone. "The Lightning King" is followed by the latter part of "Anchored," in which a perfect double rainbow gradually appears and is dissolved by a water rheostat, by sending the rays of a single-loop-filament incandescent lamp through a prism. The colors come out beautifully; when at their brightest the lamp is run greatly over voltage. By turning the lamp slightly, so that the filament is not in direct line with the prism, light from two points strikes the prism, producing two rainbows, as sometimes seen in the sky.

Mr. Patterson has been hampered for years in not being able to give his electrical effects except in halls or houses wired for electrical illumination, but, after much experiment, he has designed, built and tested a portable storage battery of high voltage and very light weight. The first one had a normal electromotive force of 58 volts, or 10 amperes at 40 volts, when necessary to draw on it so heavily. This weighed 63 pounds. But the style of battery best adapted for the purpose is the small one shown in Fig. 4 (which represents all of Mr. Patterson's "show" apparatus), weighing 35 pounds, with 32 volts normal and a capacity of 10 amperes at about 25 volts. This size may be readily carried by one person on a street car. As made now the small battery will charge at five amperes and throw off so little hydrogen that it can scarcely be detected, thus showing low internal resistance and high efficiency.

There are 17 1/4-pound lead plates, 7 by 10 inches, set on edge with a special separator, the whole bound together. A box is built closely around the plates, and the slight space between the lead and the box is filled with elastic insulating compound. The tops of plates are free to expand, but are well insulated. Each plate gives two volts, but the two end plates are half ones. One side of each plate is positive and the other side negative. This is a cheap battery to construct and weighs very much less than the ordinary battery of the same capacity. In small units it seems to be as efficient as any other battery; what it will do in large units has not been tested. The great trouble found in making this type of battery was to get a semi-elastic compound to seal up the bottom and sides that would stand the acid and allow the plates to expand without springing a leak, but the present compound seems to answer the purpose.

There are also a number of other electrical features, such as telephone with megaphone attachment, through which Mr. Patterson sings from a distant room, and a beautiful exhibition of rotating Geissler tubes of various sizes, forms and colors, operated by an electrolytic interrupter. The power of the electro-magnet is shown in lifting a boy from the platform. Other things shown are musical and fancy club and torch swinging. The music for the entertainment is furnished by good singers and performers through the "graphophone grand," the new instrument which reproduces music or the voice with almost the same volume and quality as the original. The horn of this graphophone is shown prominently on the table in Fig. 4.

Mr. Patterson is now planning to add wireless telegraphy (etherphone), a Nernst lamp, a vacuum lamp without filament, a large coil for X-ray ex-

hibitors and for the production of ozone, which is to be blown among the audience by an electric fan, and perhaps, with the aid of an atomizer and apple-blossom perfume, there can be produced the genuine air of a country orchard in the springtime after a heavy thunder-storm. He also hopes to secure liquid air to cool the churches or halls in hot weather.

Detroit Street-railway Ownership.

Under a new law the city of Detroit may purchase street-railway lines in that city. The City Council has appointed Governor Pingree, Elliott G. Stevenson and Carl E. Schmidt a commission to consider the matter. The commissioners have already conferred informally with Tom L. Johnson, the president of the local companies. Mr. Johnson was pleased, according to a correspondent, at the action of the council in selecting the commission. Governor Pingree, like his fellow-commissioners, protests his entire willingness to submit the proposed terms of purchase at the proper time to the council and the public. He frankly says his previous negotiations with Johnson resulted in his securing an option. This option, he asserted, was a short one, and he was sure the outcome would be three-cent fares with transfers; "and," added the governor, replying to charges of having rushed the act, "I'm willing everybody should know that I'm the 'old cuss' that helped push that bill through."

Proposed Russian Exposition.

The Department of State desires to make correction of an item which recently appeared in some papers, to the effect that the minister of finance of Russia had informed our embassy at St. Petersburg that American products intended for exposition purposes would be admitted free, upon the condition that a sum corresponding to the amount of the duties on the products be deposited as a guaranty; and that this sum would be returned in case the products should be exported within a certain time. The action of the Russian government was not taken in view of a general proposition that American manufactures should be admitted free for purposes of exposition, but was in view of a suggestion previously made that a special exposition in some designated Russian capital, for a limited time only, of American products and manufactures, might be or-

ganized by American exporters with the sanction of the United States government and the permission of the Russian government. The Russian minister's statement to the United States embassy at St. Petersburg had reference only to the treatment of goods sent to that exposition, should the proposed project be realized. It has no reference to any general admission of American goods for purposes of commercial display, and exporters should be cautioned not to attempt to send any goods or valuable samples to Russia on individual account under the impression that they will be bonded for re-exportation in the manner described.

New York Electrical Exhibition.

The management of the coming electrical show at Madison Square Garden, New York, for the month beginning May 8th is most enthusiastic over the prospects of the exhibition. From the following list of exhibitors booked to March 15th it would seem that the company has good reason to feel well satisfied:

American Engine company, Bound Brook, N. J.; American Electric Novelty and Manufacturing company, 255 Centre street, New York; American Vitrified Conduit company, 39 Cortlandt street, New York; American Electric Vehicle company, 1545 Michigan avenue, Chicago; American Miniature and Decorative Lamp company, 255 Centre street, New York; American Circular Loom company, Boston, Mass.; Adams-Bagnall Electric company, Cleveland, Ohio; American Microscope company, 377 Broadway, New York; American Pulley company, Philadelphia, Pa.; Ball & Wood company, 120 Liberty street, New York; Buffalo Forge company, Buffalo, N. Y.; Boston Electro-duct company, Boston, Mass.; Bullock Electric company, 220 Broadway, New York; Bossert Electric Construction company, Utica, N. Y.; Bryan-Marsh company, 136 Liberty street, New York; Clings-surface Manufacturing company, 146 Virginia street, Buffalo; Cincinnati Shaper company, Cincinnati, Ohio; Crocker-Wheeler Electric company,

39 Cortlandt street, New York; Camp company, H. B. Aultman, Ohio; Colliery Engineer company, Scranton, Pa.; Corey, R. B., 26 Cortlandt street, New York; Columbia Incandescent Lamp company, St. Louis, Mo.; Cutter Electrical and Manufacturing company, 1112 Sansom street, Philadelphia, Pa.; Dietz, Schumaker & Boye, Cincinnati, Ohio; Dixon, Jos., Crucible company, Jersey City, N. J.; Dale company, The Thames & Greenwich streets, New York; Emerson Electric Manufacturing company, St. Louis, Mo.; Estey & Saxe, 97 Fifth avenue, New York; Electrical Appliance company, Jersey City, N. J.; Electrical Engineer Institute of Correspondence Instruction, 120 Liberty street, New York; Forbes, W. D. & Co., Hoboken, N. J.; Fayerweather & Ladew, 159 East Houston street, New York; Friok, I. P., 551 Pearl street, New York; Granger, Francis, 26 Cortlandt street, New York; Griffing, A. A., Iron company, 66 Centre street, New York; Gold Car Heating company, Frankfort and Cliff streets, New York; General Incandescent Arc Light company, Thirty-third street and First avenue, New York; International Correspondence Schools, 14 East Seventh street, New York; Indiana Bicycle company, Indianapolis, Ind.; India-rubber and Gutta-percha Insulation company, Glenwood, N. Y.; Kaufman & Alexandre, 1153 Broadway, New York; Lamble, H. V., Rockaway, L. I.; Libbey Glass company, Toledo, Ohio; Machado & Roler, 203 Broadway, New York; McKay Engineering company, 106 East German street, Baltimore; National Gramophone company, 874 Broadway, New York; National Meter company, 118 Chambers street, New York; New York Electric Equipment company, Thirty-third street and First avenue, New York; Northern Engineering company, 39 Cortlandt street, New York; Niles Tool Works, Niles, Ohio; Northern Electrical company, Madison, Wis.; New York Telephone company, 18 Cortlandt street, New York; Orient Electrical company, Youngstown, Ohio; Prindle Pump company, 120 Liberty street, New York; Paragon Fan Motor company, Brooklyn, N. Y.; Pope Manufacturing company, motor carriage department, Hartford, Conn.; Pittsburg Reduction company, Pittsburg, Pa.; Rockwood Manufacturing company, Indianapolis, Ind.; Roebbling's, John A., Sons Co., 117 Liberty street, New York; Risley-Bird Manufacturing company, 91 Fifth avenue, New York; Riker Electric Motor company, 45 York street, Brooklyn, N. Y.; Standard Steam Specialty company, 83 Centre street, New York; Stirling company, The Chicago, Ill.; Safety Insulated Wire and Cable company, 229 West Twenty-eighth street, New York; Warren-Medbury company, Sandy Hill, N. Y.; Williams, J. P., 39 Cortlandt street, New York; White, S. S., Dental Manufacturing company, Chestnut and Twelfth streets, Philadelphia, Pa.; Wagner Electric Manufacturing company, St. Louis, Mo.; Willard & Frick, Rochester, N. Y.

General Manager Marcus Nathan is as "busy as a bee" getting all affairs in shape and he states that contracts have already been closed for space far in excess of those signed at a corresponding date in advance of the 1898 show.

All the exhibits of this year will be shown in the amphitheater, and the scope of the exhibition will include not only electricity, but also the kindred industries. The exhibit of automobiles will be larger than any ever held in this country, the section set aside for this purpose having been already oversubscribed for. Exhibitors of boilers, engines and steam specialties will undoubtedly be pleased with

the arrangement, which brings them up from the basement on to the main floor of the exhibition hall. The space allotted for these lines is almost entirely disposed of at this early date, so that exhibitors interested will do well to make speedy application. A special section will be set aside for patents and inventions, the idea being to enable inventors whose goods are not yet on the market to display them here to the thousands of interested persons, including a number of investors, at small cost.

It is desired that the electrical fraternity understand that in addition to the convention of the National Electric Light association there will be meetings of other engineering societies every day during the show. For the benefit of the industry all these meetings will be scheduled in advance and lists of participating members will be furnished to exhibitors. Special days will be arranged for the exporters and also for the people who will be interested in the development of Porto Rico and Cuba.

Falling Rock on Gorge Road at Niagara Falls.

Cruel fate seems to have determined to injure the Gorge road at Niagara. During the last winter its financial matters were so troublesome that it was forced to pass into the hands of a receiver, and now even the great rocks of the cliffs beneath which it runs appear determined to leave their resting place of centuries to pound it to pieces. Recently the Western Electrician presented two views, showing the fall of rock that had occurred along the line this spring, but on March 31st these conditions were outdone by a veritable avalanche of rock that came

FIG. 4. ELECTRICAL SPECTACULAR EFFECTS—MR. PATERSON AND HIS APPARATUS.

down from the cliff-top 200 feet above. So great was this fall of rock that the earth in the northern section of the city of Niagara Falls fairly trembled from the shock, which occurred about 5 a. m. When full daylight came it was seen that the avalanche had taken place on the south side and close to the Buttery elevator at the Whirlpool Rapids. There, on the tracks of the Gorge road, were piled many hundred thousand tons of rock, all of which had tumbled in one mass from the bank. Part of it had fallen upon the buildings at the base of the Buttery elevator, crushing them into kindling wood, and doing considerable damage. One of these buildings was entirely new, having replaced an old elevator shaft, wrecked by the wind a few weeks ago. About 30 or 40 feet of the foot of the new elevator shaft was broken off by the rock fall, and it was impossible to operate the cars. One mammoth limestone rock had fallen upon the tracks of the Gorge road, full in the center of the roadbed, crushing it down and smashing it out almost into the Whirlpool Rapids. This single rock weighed thousands of tons, and had it gone a few feet further it would have rolled into the rapids. But there is no doubt, despite the great mass of rock on the tracks, that much of the rock that fell with the avalanche went into the river.

An examination of the point from which the rock fell revealed that another great mass was ready to make the plunge into the gorge, and policemen were stationed to warn venturesome people from going near the spot. Later on the loose rock was blasted away and this source of danger removed. This immense chunk from the cliff falling on the roadbed makes still more difficult the work of getting the line in readiness for summer travel. It is a great many years since there has been such an avalanche of rock tumbled into the Niagara gorge, and the strange part of it all is that it was not at a point where such an event was expected, the general idea being that the bank there was quite solid.

E. S. Wilson has been appointed receiver for the Ironton Electric Light and Railway company of Ironton, O.

Annual Report of the Department of Electricity of Chicago.

There is much interesting information in the report of the Department of Electricity of the city of Chicago for the year 1898, just issued. This is the first annual report of the department, which was authorized on January 24, 1898, the electrical work of the city previous to that date having been under the direction of the Fire Department. The wisdom of uniting the various electrical activities of the city government in a separate department is shown by the work accomplished. The department has charge of the municipal street-lighting system, the isolated electric-lighting plants in city buildings, the fire-alarm telegraph, the police telephone service and the work of electrical inspection. Mr. Edward B. Ellicott, the city electrician, has labored with zeal, intelligence and honesty to extend and modernize the electrical plants of the city, and the report shows "a remarkable decrease in the cost of operating the lights and numerous improvements in the fire-alarm telegraph and police telephone systems." Moreover, in no instance was an appropriation exceeded. Credit for these results is shared with the efficient employes of the department by its head.

MUNICIPAL STREET ARC LIGHTING.

The annual city appropriation for 1898 included the net sum of \$140,152 available for extending the system of electric street lighting. Mr. Ellicott shows how this money has been expended. Work was commenced about April 15th. A complete station was equipped at Rice and Lincoln street, in a building formerly used as a repair shop, and the capacity of the station at Halsted street and Blue Island avenue and of that at Fourteenth street and Indiana avenue was materially increased. By December 31st there was in operation from these three stations 2,263 arc lamps of 2,000 nominal candle power each—an increase of 825 for the year. Mr. Ellicott's report ends with the calendar year of 1898, but it may be added that on April 1st of this year the total number of arc lamps operated from the Chicago municipal stations was 2,923.

It is noted that "the prices secured for machinery and supplies were the lowest ever granted for similar articles, and probably never will be duplicated." The contractors carried out the work to the entire satisfaction of the department and in accordance with the guarantees required.

The cost of construction for the new plant and extensions during 1898 is given as follows:

Equipment of Stations.

Steam and electric plant, with erection, at Rice and Lincoln streets.....	\$35,978.98
Additions at Halsted street.....	12,781.00
Additions at Fourteenth street.....	6,256.00

Total amount for equipping stations.....\$55,015.98

Line Equipment.

2,848 cedar poles.....	\$ 9,417.10
129,772 feet of underground cable.....	15,213.82
571,760 feet No. 6 line wire, cross-arms, pins and insulators.....	7,895.17
68,780 feet vitrified clay-pipe conduit.....	1,572.42
21,543 feet two-inch iron pipe.....	1,787.68
20 Columbia arc lamp posts.....	800.00
840 arc lamps and brackets.....	11,760.00
Labor erecting poles, wire, lamps and laying conduit.....	36,689.83

Total for line equipment.....\$85,136.02
Adding the totals together gives the amount of the appropriation, or.....\$140,152.00

The report states that much of the work was done during the most inclement weather, and was necessarily more expensive, "yet the average cost per arc lamp, for boilers, engines, dynamos, lamps and line work only reached the sum of \$166.85, and it is doubtful if ever such a low cost was reached by a municipality or private corporation for a corresponding amount of work and class of apparatus."

The next feature of the report is the one that will attract the most attention. It is on the cost of operation. In introducing his figures Mr. Ellicott makes this explanation: "Appreciating the fact that there is no credit in making misstatements of the cost of operating lights from municipal plants, and desiring to be in a position to prove the correctness of the actual cost to the city of Chicago, a most careful record of expenses has been kept for each month of the year. At the end of the year the added monthly costs were taken as a total cost and then checked with the total amount paid out for operating expenses, repairs and renewal of worn-out or obsolete apparatus." In the general table of costs as presented in the report the figures are given for four plants. The old Chicago avenue plant was operated part of the year, but afterward shut down, being superseded by the station at Rice and Lincoln streets. The three plants mentioned above are the ones now operated. The table of total costs for material and labor for the year in the four plants (average number of lamps, 1,710) is as follows:

Material—	
Coal.....	\$30,605.39
Carbons.....	6,216.90
Oil and waste.....	1,934.69
Globes.....	372.81
Engines.....	2,045.64
Boilers.....	3,493.57
Steam pipes.....	470.08
Dynamos.....	617.95
Lamps.....	4,278.34
Conduits and lamp posts.....	811.00
Underground circuits.....	586.65
Buildings.....	247.95
Rental of real estate.....	2,500.00
Sundry expense.....	3,346.09
Total material.....	\$57,436.85

Labor—	
Engineers and assistant engineers.....	\$ 371.66
Dynamo tenders.....	1,766.88
All-night lamp trimmers.....	2,844.23
All-night lamp trimmers.....	728.49
All-night lamp trimmers.....	15,372.84
Firemen.....	12,022.20
Stablemen.....	720.00
Machinists.....	135.00
Time and store keepers.....	779.99
All-night inspectors.....	429.89
Laborers.....	269.25
Total labor.....	\$42,967.43
Material as above.....	57,436.85
Labor as above.....	42,967.43
Total cost of plants.....	\$102,854.31
Cost of labor testing circuits.....	1,102.86
Cost of labor repairing circuits and conduits.....	5,977.59
Total cost.....	\$109,934.76
Total cost per lamp.....	62.52
Cost per lamp of improvements, average of 25 cents per lamp per month.....	2.98
Cost per lamp of office salaries, average of 25 cents per lamp per month.....	2.98
Grand total cost per lamp.....	\$68.48
Total number of lamp-hours.....	1,018,010
Average lamp-hours, each lamp.....	4,104
Average cost per lamp per hour.....	0.01666

It will be noted that the cost of operation is figured entirely on material and labor, with the excep-

FALLING ROCK ON GORGE ROAD AT NIAGARA FALLS.

tion of rental of real estate (which occurs in only one of the four plants) and office salaries. Other items which would be given in the report of a commercial company, such as taxes, insurance, water, interest on capital, etc., do not appear.

The remaining portion of the report relating to cost of operation is substantially as follows:

"In the above costs appear an item of lamp repairs. This item covers the rebuilding of 80 per cent. of the arc lamps used by the city previous to 1898. The lamps were sent to the manufacturers and made as good as new.

"On engine repairs it was found necessary to rebuild all of the valve stems and eccentric rods of two 600 horse power engines, put in two new pistons, re-babbit main bearings, and several minor repairs; rebuild one Ideal engine and put in two new wrist pins in other engines. These repairs make these engines as perfect as the day they left the shops, as far as operation and life are concerned.

"Extensive repairs were also made to four boilers. "About 75,000 feet of old underground cable was pulled out and new cable for 10,000 volts pressure installed in place.

"In doing this a great deal of cable was saved by rearranging the circuits. The old cable was sold and the difference in price charged to operating expenses.

"The cost per light per year for the different items is as follows:

Table with 2 columns: Item and Cost. Items include Coal, Carbons, Oil and waste, Lamp globes, Repairs to engines, Repairs to boilers, Repairs to steam pipes, Repairs to dynamos, Repairs to lamps, Repairs to conduits and lamp posts, Repairs to underground circuits, Repairs to buildings, Rental of real estate, Incidental expenses, Engineers and dynamo engineers, Dynamo tenders, Night inspectors, trimmers and labor, Lamp trimmers, Firemen, Stablemen, machinist, time and store keeper. Total: \$62.44

"By separating the above figures into two parts we find the cost per year of producing the necessary power for each arc lamp is as follows:

Table with 2 columns: Item and Cost. Items include Coal, Oil and waste, Repairs to engines, Repairs to boilers, Repairs to steam pipes, Engineers, Firemen, One-third of incidental expenses. Total: \$35.02

"This cost of \$35.02 for power alone is too high, and a great saving will be made in 1899, the plans for so doing having been completed the last of December. There will be a saving of at least \$10 per light per year.

"Owing to the rebuilding of so many lamps this year the cost for 1899 should be at least \$1 a lamp less than during 1898.

"The cost of repairing underground circuits has been excessive, for the reason that a great deal of the amount charged has been for rebuilding the circuits—a charge that will not appear this year.

"The most important change made during 1898 was the shutting down of the Chicago avenue station and moving the electrical machinery to Rice and Lincoln streets station, where more economical steam apparatus was installed and the cost of labor was practically no more than before the addition to the station. A pay-roll of about \$500 a month was saved in addition to the coal, amounting in all over \$800 a month.

"The Halsted street and Rice and Lincoln streets stations are modern electric-lighting stations, and have no superior in the United States for economical operation. The Fourteenth street and Indiana avenue station is poorly equipped with engines, and is not economical to operate when compared with the other stations. Plans are completed to change this station during the year of 1899 and place it on a par with the others.

"It has required the best part of two years to bring the plants to their present efficiency and system of operation. There are further opportunities to be taken advantage of.

"The station cost of maintaining an arc lamp for December in 1896, 1897 and 1898 was as follows:

Table with 2 columns: Year and Cost per lamp. Data for 1896, 1897, 1898.

"About the same ratio per month will apply, except during June, July and August, during which time it

FIG. 1. WIRELESS TELEGRAPHY.

will be slightly less, on account of short hours the lights are operated."

FIRE-ALARM TELEGRAPH.

The number of fire-alarm boxes in service on December 31st was 1,296. The total number of alarms transmitted during the year was 6,423. One box was "pulled" 77 times. The total amount of wire in service in fire-alarm and police telephone systems is 3,524 miles. Not a single alarm of fire was lost during the year. Probably the most important change made in this bureau during the year was the substitution of storage batteries for a large number of gravity batteries. This change was made after conducting an exhaustive test to prove the advantages of using storage batteries. The cost of maintenance is greatly reduced, and the advantages of a practically uniform current and voltage are secured. The total number of primary batteries displaced was 2,144, costing for maintenance \$3,354.46 a year. The total number of accumulators installed is 782, costing for maintenance \$1,272.43. The annual saving in maintenance is \$2,292.03. The new motor-generator equipment, used as a relay for a part of the storage batteries, gives satisfactory service. A large amount of old iron line wire was replaced with hard-drawn cop-

per wire, and in a number of places overhead wires were replaced with underground cables.

POLICE TELEPHONE SYSTEM.

The total number of police signal boxes installed is 1,318. The old-style telephone transmitters have been replaced in many instances with modern long-distance transmitters, and the entire system will soon be changed. It is stated that, owing to the almost universal use of the grounded trolley system in Chicago, the old-style transmitter was almost inoperative—a condition that is corrected with the new style. This change was made without cost to the city, except for a small amount of labor.

ELECTRICAL INSPECTIONS.

The report shows a large increase in electrical work throughout the city, with but slight increase in the cost of maintaining the bureau of inspection, and few electrical fires. The cost for inspections has been greatly reduced during the year, and the charges are now made on a sliding scale, giving the advantage

FIG. 2. WIRELESS TELEGRAPHY.

of cheaper inspection to large installations, where the expenses of making inspections are naturally less. The total receipts for electrical inspections in 1898 were \$15,223.97, and the expense of making them was \$12,525.11.

ELECTRICAL FIRES.

A table is given showing that there were 80 fires caused by electricity in Chicago during the year. The total loss was \$13,109.48—certainly a moderate amount. The causes in detail are thus enumerated:

- High-tension grounded by moisture, 18 fires; low-tension grounded by moisture, 8 (loss, \$396); pole broke, 1; concealed low-tension crossed, 5 (loss, \$5,655.92); high-tension crossed with telegraph, 1; high-tension grounded on cornices, roof and ceilings, 4; broken wire grounded, 1; outside switchbox, 4; short-circuit in elevator motor, 1; broken lamps set fire to varnish, 1; elevated railroad (South) troubles, 4; socket short-circuited, 1; (loss, \$253); crossed telegraph lines, 1; low-tension switch short-circuited, 3 (loss, \$5,500); low-tension wires short-circuited, 1 (loss, \$334); low-tension wires outside crossed, 1; low-tension wires crossed during repairs, 1 (loss, \$2,125.06); low-tension wires crossed in pipe shaft, 1; transformer wires left exposed—abandoned, 1; high-tension wires crossed, 2; low-tension poor connection, 2 (loss, \$3,795); waste basket on electric stove, 1; lightning, 1; cable failures, 8; high-tension insulation stripped, drawing in, 1; faulty transformers, 1 (loss, \$45); high-tension crossed with telephone line, 1; window trimmer crossed low-tension wires, 1; fuse block maintained an arc, 1; high-tension grounded by nails, rods and pipes, 3.

STATISTICS OF ELECTRIC LIGHTING.

The number of electric-lighting stations and lamps in Chicago is given as follows:

Table with 4 columns: Type of Plant, Number of Stations, Number of Arc Lamps Operated, Number of Incandescent Lamps Operated Equivalent of 16 Candle Power. Rows include Commercial companies, central stations, Isolated plants, City plants, street lighting, City plants (isolated), in cluding city hall and water works, and Total.

ELECTROLYSIS.

On this subject Mr. Ellicott says: "The question of damage to water pipes and other underground metals which are so situated that they may become conductors of current shunted into them by the electric street-railway circuits using the grounded return has caused a most careful investigation to be made in nearly all the large cities throughout the United States. This investigation in Chicago was commenced nearly two years ago, and the indications shown by the many tests made and a subsequent inspection of pipes demonstrated that the fears of actual damage were well grounded. Over 1,000 tests were made between the street-railway companies' rails and the water and gas pipes and such of the elevated roads as were using electricity as a motive power.

"In many places the voltage shown indicated an extremely dangerous condition existed, and requests were made on the different companies to immediately take the necessary measures to obviate any further damage to the metals not intended to form a part of their return circuit. The requests in some instances have been complied with, and the indications of trouble removed, while in others no attention was paid to the request, and the conditions have become more aggravated. Three six-inch water mains were weakened at points to such an extent that they burst and sections were removed and replaced with new pipe. Over 25 service pipes were destroyed, and when removed samples were kept to be used as evidence in suits which will be started by the corporation counsel for the purpose of recovering damages and compelling a reconstruction of the defective parts of the return circuits."

Wireless Telegraphy.

By G. MARCONI.

"Wireless telegraphy," or telegraphy through space without connecting wires, is a subject which has attracted considerable attention since the results of the first experiments I carried out in this country became known. It is not my intention this evening to give my views on or discuss the theory of the system, with which I have carried out so many experiments, and by means of which I have worked various installations, but I hope to put before you some exact information of what has been done by myself and my assistants during the last 12 months, and also some reliable data as to the means employed to obtain such results. Much has been published on the subject, I must say, with varying accuracy, and there can hardly be anyone here altogether ignorant of the general characteristics of the system. Before I go into this subject further I wish to state that any success I have met with in the practical application of wireless telegraphy has been, in a large measure, due to the efficient co-operation which has been rendered by my assistants. I think it will not be out of place if I give a brief description of the apparatus.

Transmitter.—When long distances are to be bridged over and it is not necessary that the signals should be sent in one definite direction, I employ as transmitter an arrangement, as shown in Fig. 1, in which two small spheres connected to the terminals of the secondary winding of an induction coil are connected, one to earth, and the other to a vertical conductor w, which I will call the aerial conductor. Should it be necessary to direct a beam of rays in one given direction I prefer to use an arrangement similar to a Righi oscillator, placed in the focal line of a suitable cylindrical parabolic reflector f, Fig. 5. The transmitter works as follows: When the key b is pressed, the current of the battery is allowed to actuate the spark coil c, which charges the spheres of the Righi oscillator or the vertical wire w, which discharges through the spark-gap. This discharge is an oscillating one, and the system of spheres and insulated conductor becomes a radiator of electric waves. It is easy to understand how, by pressing the key for long or short intervals, it is possible to emit a long or short succession of waves, which, when they influence the receiver, reproduce on it a long or short effect, according to their duration, in this way reproducing the Morse or other signals transmitted from the sending station.

Receiver.—One of the principal parts in my receiver is the sensitive tube or coherer or radio-conductor, which was discovered, I think I am right in saying, by Professor Calzecchi Onesti of Fermo, and was improved by Branly, and modified by Professor Lodge and others. The only form of coherer I have found to be trustworthy and reliable for long-distance work is one designed by myself, as shown in Fig. 2. It consists of a small glass tube, four centimeters long, into which two metal pole-pieces j' j" are tightly fitted. They are separated from each other by a small gap, which is partly filled with a mixture of nickel and silver filings. This coherer forms part of a circuit containing the local cell and a sensitive telegraph relay actuating another circuit, which circuit works a trembler p, or decoherer, and a recording instrument h. In its normal condition the resistance of the filings in the tube j is infinite, or, at least, very great, but when the filings are influenced by electric waves or surgings, cohesion instantly takes place,

FIG. 3. WIRELESS TELEGRAPHY.

and the tube becomes a comparatively good conductor, its resistance falling to between 100 and 500 ohms. This allows the current from the local cell g to actuate the relay n. One end of the tube is connected to earth and the other to a vertical conductor similar to that of the transmitter, Fig. 1, or, if reflectors are used, a short strip of copper is connected to each end, Fig. 4. The length of these strips of copper must be carefully determined, as good results cannot be obtained unless they happen to be of the proper length, which will cause them to be in tune or sympathy with the transmitted oscillations. All the electromagnetic apparatus in the receiver is shunted by non-inductive resistances in such a manner that there may be no sparking at contacts and no sudden perturbations or jerks caused by the local battery current near the coherer. I find that the relay tapper and telegraphic instrument, if not properly shunted, produce disturbing effects, the result of which is to prevent the coherer from regaining its sensitive condition after the receipt of electrical oscillations. No such trouble is experienced when suitable shunts are used, and I attribute to their action, in very great

1. Read before the Institution of Electrical Engineers, London. 2. See Nuovo Cimento, series 3, vol. xvii., January-February, 1895, and January-February, 1896.

measure, the success which has been attained with this system. Small choking coils k'k' are introduced between the coherer and the relay. They compel the oscillating current due to the electric waves to traverse the coherer rather than waste its energy in the alternative path afforded by the relay. The oscillations induced on the strips k k or aerial conductor w, which acts as resonator, by the radiation from the oscillator affect the sensitive tube. This effect on the tube consists, as we have said, in a great increase of its conductivity, thus completing the circuit and allowing the current from the cell to actuate the relay. The relay in its turn causes a larger battery r to pass a current through the tapper or interrupter p, and also through the electro-magnets of the recording instrument h.

The tapper or trembler is so adjusted as to tap

FIG. 4. WIRELESS TELEGRAPHY.

the tube and shake the filings in it. If, in the instant during which these various actions take place, the electrical oscillations had died out in the resonator, the shake or tap given to the tube by the hammer o would have restored it to its normal high-resistance condition, and the Morse instrument or recorder would have marked a dot on the tape; but if the oscillations continue at very brief intervals the acquired conductivity of the tube j is destroyed only for an instant by the tap of the trembler, and immediately re-established by the electrical surges; and, therefore, the relay tapper and telegraph instrument are again actuated, and so on, until the oscillations from the radiator have ceased. The practical result is that the receiver is actuated for a time equal to that during which the key is pressed at the transmitting station. For each signal, however short, the armatures of the relay and tapper perform some very rapid vibrations, dependent on each other. For it is the action of the relay which starts the tapper, but the tapper by its action interrupts the relay. The armature of the Morse recording instrument being rather heavy, and possessing a comparatively large inertia, cannot follow the very rapid vibrations of the tongue of the relay, but remains down all the time during which the rapidly intermittent action of the receiver lasts. In this way the armature of the inker gives a practically exact reproduction of the movements of the key at the transmitting end, dashes coming out as dashes and dots as dots.

Much has been said and written about coherers being very unreliable and untrustworthy in their action, but I must confess that this has not been in any way my experience. Provided a coherer is properly constructed and used on a suitable receiver, it is just as certain in its action as any other electrical apparatus, such as an electro-magnet or incandescent lamp. I have coherers which were made three years ago that are now quite as good, if not better, than they were at that time, and we have had tubes working for months in most important installations without ever giving trouble. At the installation my company has erected at the South Foreland lighthouse, which, as you probably know, is working to the East Goodwin lightship, the coherer was mounted on the receiver when we first started in December of last year, and has done its work in a most satisfactory manner ever since. I must call your attention to the object and function of the vertical wire w. It has been by means of this addition to the apparatus that we have been able to telegraph over distances which have been so far unattained, I think I am right in saying, by any other method of space telegraphy. The way I came to appreciate the great importance of the addition of the conductor w and earth connection E to the apparatus was as follows: (I take this data from a copy of a letter I wrote to Mr. Preece in November, 1896.) When carrying out some experiments in Italy in 1895 I was using an oscillator having one pole earthed and the other connected to an insulated capacity, the receiver also earthed and connected to a similar capacity. The capacities were in this case cubes of tinned iron of 30 centimeters side, and I found that when these were placed on the top of a pole two meters high, signals could be obtained at 30 meters from the transmitter. With the same cubes on poles four meters high, signals were obtained at 100 meters, and with the same cubes at a height of eight meters, other conditions being equal, Morse signals were easily obtained at 400 meters. With larger cubes of 100 centimeters side, fixed at a height of eight meters, reliable signals could be obtained at 2,400 meters all round, equal to about one mile and a half. These results seemed to point out that a system of transmitter and receiver designed according to the lines on Fig. 1, i. e., a radiator of the Hertzian type having one pole earthed and the other connected to a vertical, or almost vertical, conductor, or to a lofty capacity area, and a

resonator consisting of a suitable receiver having similarly one terminal connected to earth and the other to an insulated vertical conductor, constitute a system of transmitter and receiver capable of giving effects at far greater distances than the ordinary systems of Hertzian radiators and resonators. The results I have referred to also show that the distance at which signals could be obtained varied approximately with the square of the distance of the capacities from earth, or perhaps with the square of the length of the vertical conductors. This law has since been verified by a careful series of experiments and found correct, and has furnished us with a sure and safe means of calculating what length the vertical wire should be in order to obtain results at a given distance. It is well to know that the said law has never failed to give the expected results across clear space in any installation or experiment I have carried out, although it usually seems that the distance obtained is slightly in excess of what one might expect. I find that with parity of other conditions a vertical wire 20 feet long at the transmitter and receiver is sufficient for communicating one mile, 40 feet at each end for four miles, and 80 feet for 16 miles, and so on. An installation is now working over a distance of 18 miles with a vertical wire 80 feet high at each installation station.

Professor Ascoli has confirmed this, and demonstrated mathematically, using Neumann's formula, that the inductive action is proportional to the square of the length of one of the two conductors if the two are vertical and of equal length, and in simple inverse proportion of the distance between them. Therefore, the intensity of the induced oscillation does not diminish with the increase of distance if the length of the vertical conductors is increased in proportion with the square root of the distance; that is, if the height of the wire is double, the possible distance becomes quadrupled. Should it be necessary to rig up an installation at a distance of, say, 32 miles, such as is about the distance between Folkestone and Boulogne, it is easy to find that a vertical wire 114 feet long would be quite sufficient for that purpose.

Such laws are applicable only when apparatus properly constructed is employed. With apparatus in which some or several improved details are omitted I find it quite impossible to obtain any-

FIG. 5. WIRELESS TELEGRAPHY.

thing like the results above mentioned. If, say, the impedance coils k'k' are omitted, the distance (other conditions being equal) is reduced to almost half its original value. I must also call your attention to such cases as when obstacles like hills or mountains, or large metallic objects, happen to intervene between the places between which it is desired to establish communication. With all other forms of Hertzian transmitters and receivers with which I have experimented I find it to be quite impossible to obtain any results if a hill, mountain or large metallic object intervenes in any way between the two stations. I am not aware whether any satisfactory results have been obtained by others where such obstacles have intervened, but when the vertical-wire system is employed it becomes easy to telegraph between positions screened from each other by hills or by the curvature of the earth. In such cases it seems to be a marked advantage if the aerial conductor is thick or if a capacity area is placed at the top of it. I am rather doubtful as to the correct explanation that can be given to this effect. I think there can be very little doubt as to the complete opacity, to electric waves, of a hill three miles thick, or of, say, several miles of sea water. A solution of this difficulty might be given by attributing the results to the effect of the diffraction of such long waves as those radiated by a conductor 100 feet long, but in that case it is difficult to explain why other forms of Hertzian transmitters and receivers also giving long waves do not act when such obstacles intervene. A way out of the difficulty may be arrived at if we suppose that the electrical oscillations are transmitted to the earth by the earth wire E of the transmitter, and travel in all directions along the surface of the earth till they reach the earth wire of the receiving instrument, and by traveling up the said wire to the coherer thus bring about its action. This was the first explanation I came to during my early experiments. I, however, do not wish to say that I hold entirely to this view at present, although I have not yet found any other perfectly satisfactory explanation of the phenomena. It is well, also, to note that a horizontal wire, even if supported at a considerable height from earth, seems to be of little or no practical utility in increasing the range of signals. If, say, a vertical wire 30 feet long is employed at both stations, and to the top of this is added a horizontal length of 300 feet, as shown in Fig. 6, the distance

obtained is greater with the vertical wire without the horizontal length than it would be if both were employed. These results show that with this system it is not sufficient to use a horizontal radiating or collecting wire, as such a wire would be of no utility for long-distance signaling.

I believe that the exceedingly marked advance made by the adoption of the vertical conductor is due to the fact that the plane of polarization of the rays radiated is vertical, and that, therefore, they are not absorbed by the surface of the earth, which acts as a receiving conductor placed horizontally. As the maximum effect is obtainable when the conductors of the transmitter and receiver are parallel, this makes it necessary to have a vertical conductor connected to one pole of the coherer.

Before proceeding to describe the results obtained under various conditions by means of what we may call the vertical-wire system, I think it desirable to bring before you some observations and results I have obtained with a system of Hertzian-wave telegraphy, which was the first with which I worked, and in which parabolic reflectors are used to control the propagation and intensify the effects obtained when comparatively short electric waves are employed for signaling. As in ordinary optics, so also in the optics of electro-magnetic oscillations, it is possible, as has been shown by Hertz, to reflect the waves radiated from the oscillator in one definite direction only. This can be done, as you know, by using convenient reflectors, similar to those used for projectors, but preferably, for economical reasons, made of copper or zinc, instead of silver amalgam or silver. Except when very small radiators of the Righi or Lebedew type are employed, it is desirable to use cylindrical parabolic reflectors, and it is with reflectors such as I here exhibit that the trials to which I am alluding have been carried out. The advantages obtainable by their use are obvious.

In any other system intended for the transmission of telegraphic signals by means of electric waves through space, the waves have been allowed to radiate in all directions and would affect all suitable receivers within a certain radius, which, of course, is dependent on the power of the radiator or transmitter and on the sensitiveness of the resonator or receiver. It is, however, possible, by means of syntonizing arrangements, to prevent, to a certain extent, messages affecting instruments or receivers for which they are not intended, and therefore to select any receiver by altering the wave length of the transmitter. By means of reflectors it is possible to project the waves in one almost parallel beam which will not affect any receiver placed out of its line of propagation, whether the said receiver is or is not in tune or sympathy with the oscillation transmitted. This would enable several forts, or hilltops, or islands, to communicate with each other without any fear of the enemy tapping or interfering with the signals, for if the forts are on small heights the beam of rays would pass above the positions which might be occupied by the enemy. An illustration of the possibility of directing these waves can be shown by the action of the receiver, which in this case rings a bell only when the radiator in the reflector is directed toward it. These results are much more marked in an open space than in a lecture theater, as the walls, gilt hangings, etc., tend to reflect the rays in all directions and may alter the results.

In experiments carried over a distance of 1 1/4 miles I noticed that only a very small movement of the transmitting reflector was sufficient to stop the signals at the receiving end, which could be only obtained within a latitude of 50 feet to the right or left of what was believed to be the center of the beam of reflected radiations. There exists a most important case to which the reflector system is applicable, namely, to enable ships to be warned by lighthouses, light-vessels or other ships, not only of their proximity to danger, but also of the direction

FIG. 6. WIRELESS TELEGRAPHY.

from which the warning comes. If we imagine that A is a lighthouse provided with a transmitter of electric waves, constantly giving a series of intermittent impulses or flashes, and B a ship provided with a receiving apparatus placed in the focal line of a reflector, it is plain that when the receiver is within range of the oscillator the bell will be rung only when the reflector is directed toward the transmitter, and will not ring when the reflector is not directed toward it. If the reflector is caused to revolve by clockwork or by hand, it will therefore give warning only when occupying a certain sector of the circle in which it revolves. It is therefore easy for a ship in a fog to make out the exact direction of point A, whereby, by the conventional number of taps or rings, she will be able to discern either a dangerous point to be avoided or the port or harbor for which she is endeavoring to steer. I have not up to the present

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO. TELEPHONE, MAIN 1746.

Eastern Office: 148 Times Building, New York.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the entire contents of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, \$3.00 for a full year of 52 numbers; in clubs of four or more, \$2.50, with free extra copy for eight subscriptions; foreign countries, \$5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—the only general electrical paper published in the West—thoroughly covers a territory exclusively its own. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers desiring western trade will appreciate the UNQUALIFIED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

of Marconi and his associates. Consul-general Gowdy writes from Paris that he has had an interview with E. Ducretet, the inventor and constructor of electrical apparatus, whose experiments have been described in these columns, and who asserts that messages could then (February) be perfectly transmitted a distance of about 13 miles through space without wire. The messages were dispatched and received between masts 30 meters high at the extreme ends of the distance. One of the principal obstacles encountered was the difficulty of securing automatic registration of the message, but this has been overcome, it was reported, by an instrument of Mr. Ducretet.

The source of atmospheric electricity has proved an attractive subject for investigators, and many interesting experiments have been conducted by students engaged in researches along this line. The work of H. Pellat, described in Comptes Rendus, and summarized by d'Albe in the London Electrician, is the most valuable contribution to the literature of the subject of late. The evaporation of the moisture of the earth's surface has for over a century been considered to account for the electric charge of the atmosphere, but, strange to say, it has been found almost impossible to prove that even a highly charged body of water, in evaporating, loses any of that charge with the vapor that rises from its surface. Lecher, indeed, proved such a loss with a potential of 25,000 volts, but then, as he says himself, the liquid was practically "pulverized," and was at any rate widely removed from ordinary conditions, such as exist at the earth's surface. H. Pellat has now succeeded, however in demonstrating a loss of 40 to 60 per cent. of the original charge in an hour's evaporation from a very shallow dish connected with a quadrant electrometer, and negatively charged by a battery giving 116 volts. Applying this observation to the negative charge of the earth, it appears that there must be a loss of that charge, and a gain of negative electrification by the air, during the first warm hours of the day, and the reverse process must set in after sunset. This is actually the case in all published observations, but these observations also show a minimum at 4 a. m. and a maximum at 8 p. m. Neither of these is yet accounted for, and they are both probably due to some influence as yet unknown. The impetus that has been given these investigations by Pellat's disclosures should stimulate interest in the subject, and it may result in still further valuable discoveries.

Mr. Armstrong's communication on the Brundage telephone bill, now before the Illinois Legislature, explains the action of the proposer of the measure and the attitude of the Bell interests toward legislation that is aimed at regulating the telephone business. It is not strange, however, that the public failed to appreciate the work that Mr. Brundage and his associates have done, inasmuch as the details presented by Mr. Armstrong had not been published, and no intimation of the plans and motives of the promoters of the movement had been given. On the question of compensation, too, Mr. Brundage and Mr. Armstrong seem to agree with the Western Electrician, and if they can bring their associates to a realization of the importance of returning to the original plans, which provided for fair rentals, they will perform a valuable service to the people of Chicago. Otherwise it would be far preferable that the bill be killed, as it will merely insure the Chicago Telephone company uninterrupted enjoyment of its present monopoly in this city. Capital will not invest in an independent company in the face of such a measure, and competition, which has been demonstrated to be the only real solution of the telephone problem, will therefore become impracticable.

Much stress is laid by the framer of the bill and its supporters upon the provision for interchanging service, but as this proposition involves the principle of common carriers, which is far from being established and recognized as applying to the telephone business, it cannot be assumed to affect the present relations of the Chicago Telephone company and the independent interests. It seems injudicious to burden a bill with provisions that invite litigation when the disputed points could be treated in an entirely independent measure. In the present situation, it would seem as if there was really nothing to be gained by the insertion of this matter, for if the law of common carriers applies to telephone companies

the fact must be established in any event by recourse to the courts, and the solution of the problem will not be hastened by the enactment of such a bill as the proposed measure. If, on the other hand, the courts should not accept the view advocated by Mr. Brundage and his associates, the law could be successfully attacked by the Bell interests on this point and thus delay the enforcement of other features that might be equally desirable.

The tendency to attack everything pertaining to the Bell system cannot be encouraged by the independent interests without danger to their own investments, and it is, therefore, well to consider problems of this nature in a conservative spirit and to do ample justice to all interests affected.

So much has been written about the operations of the American navy during the late war with Spain that the subject may be considered pretty thoroughly exhausted; but the reflections of those upon whom rested the responsibility for the successful termination of the struggle still possess great value, and as a matter of record their views upon the practicability of the innovations that were made may determine others in accepting or rejecting them. The experience of the American fleet under Admiral Sampson before Santiago was exceptional in that so much dependence was placed upon the searchlights to maintain the blockade. Within a week of his arrival at Santiago the American commander had thoroughly established this service, and then he felt that should Cervera attempt to leave the harbor the American sentries would have ample warning. In his interesting article in the Century for April, Admiral Sampson says:

Every night when the ship came up to her position and turned the light on, and I saw the harbor illuminated, I felt entirely secure. I looked at it many times during the night, always with the same feeling; and there it was night after night, with no variation. After we arrived we had the friendly aid of a brilliant moon, and as the moon waned we became very anxious; but after we had the searchlight we reviled the moon, because really we could not see as well with the moon as without it.

It is a matter of considerable interest that the Spanish squadron had only one searchlight, and that that had never been prepared for service.

Concerning the cable-cutting expeditions under his direction, Admiral Sampson explains the presence of so many cables and the absence of land lines in Cuba:

A curious cable system had grown up in Cuba, owing to the insecurity of the land lines. The Spaniards had learned from experience that only a submarine telegraph was secure against destruction by the Cubans. The poor insurgents had not the means of reaching the submarine cables, for the Spaniards occupied the towns and cities where the ends of the cables were landed; but the land lines on the south side were always at their mercy.

From Batabano on the west to Guantanamo on the east the towns were connected by submarine cables, and in some cases more than one cable was employed. To destroy all connection with the outside world was difficult. There were four cables from Santiago de Cuba to Jamaica, and one from Guantanamo to Santo Domingo; then there was the Key West cable to Havana, over which frequent, if not constant, communication was held during the whole war.

The government found itself without means of cutting this network of cables, and the Western Union Telegraph company, which had consented to the proposed cutting of the Havana-Key West line, furnished the grapneling apparatus required for the work in other parts of the island. Concerning the conditions that the American forces encountered, Admiral Sampson says:

As the water off the ports where the telegraph cables were to be destroyed was very deep, varying from a few hundred fathoms to several thousand, it was necessary that the grapneling outfit should be strong enough to lift a thousand fathoms of cable, or, if working in shoaler water, the cutting ship must work close under the shore and be exposed to fire. As all the cables are on the south side of the island, where we were not at the time prepared to blockade or to defend the grapneling ship, it was necessary to send a sufficient force to fight wherever it might be necessary. For this reason Captain Taylor of the Indiana was put in charge of the duty, with a considerable force.

In spite of these difficulties the Americans succeeded in cutting half a dozen important cables, and a few local lines, like that connecting Cienfuegos and Manzanillo, and while this did not bring about the original purpose to isolate the island from the outside world, it had the effect of crippling the service and was considered a valuable accomplishment.

The most comprehensive, complete and orderly narrative of recent developments in the field of "wireless telegraphy" that has yet been published is the paper before the Institution of Electrical Engineers at London, which is presented elsewhere in this issue. Marconi relates the nature and extent of his experimental work and the results obtained, and while much that is contained in the paper has been published in fragmentary form, it has never before been arranged in an orderly manner, so as to enable the student to make a critical examination of the work and clearly ascertain the relative importance of the discoveries there recorded as well as the bearing of each upon the art and its importance in advancing the investigation to a successful termination. The interest manifested in this work has been stimulated by the experiments that have been successfully conducted since that time in transmitting messages between France and England. The English electrical journals say that the enthusiasm displayed was greater than any former demonstration in the history of the society, even surpassing that which greeted Nikola Tesla's exhibition of high-frequency phenomena at the Royal Institution. Interest in this subject is not confined to the work

Wireless Telegraphy.

[Continued from page 199.]

attempted to signal any greater distance than about two miles with reflectors, but I am of opinion that across clear space it will be quite possible to obtain satisfactory results at far greater distances, especially if the reflectors are accurately made any larger than those I have used. By means of the same apparatus exhibited here I have succeeded in signaling over a distance of $2\frac{1}{2}$ miles without, of course, the use of any real "base" lines, which were supposed to be essential for any distance greater than a few feet. It was by means of reflectors I obtained the results over $1\frac{3}{4}$ miles, mentioned by Mr. Preece at the British Association meeting of 1896. I have, however, dedicated more time to the other system, i. e., the vertical-wire system.

A station at Alum Bay, Isle of Wight, and another at Bournemouth, the distance between them being $14\frac{1}{2}$ miles, were erected at the beginning of last year, in order to test the practicability of the system under all conditions of weather, and also to afford an opportunity of proving that "wireless telegraphy" was not a myth but a working reality. I believe some details of the special conditions of these stations would be of interest. The installation at Alum Bay is in the Needles Hotel, and the Bournemouth station (which has lately been transferred to the Haven Hotel, Poole, thereby increasing the distance to 18 miles) was at Madeira House, South Cliff. At each station a pole 120 feet high was used, which supported the aerial conductor, usually a stranded conductor of 7-20 copper wire insulated with rubber and tape. A 10-inch induction coil is used at each station, worked by a battery of 100 Obach cells, "M" size, the current taken by the coil being at 14 volts from six to nine amperes. The spark discharge takes place between two small spheres about one inch in diameter, this form of transmitter having been found more simple and more effective than the Righi oscillator I had previously used. The length of spark is adjusted to about one centimeter; this, being a much shorter spark than the coil can give, allows a good margin over any irregularity that might be caused by the break. No care is ever taken to polish the spheres, as the place where the spark occurs, as the results seem decidedly better with dull spheres than with polished ones. The first tests were made between the Isle of Wight and a steamer, the height of the mast on the boat being about 60 feet. Readable signals were obtained up to a distance of 18 miles from Alum Bay. During the course of these experiments I had the pleasure of the company and assistance of Captain Kennedy, R. E., who was good enough to draw a map showing the course of the steamer. It has apparently been thought that weather or varying conditions of atmospheric electricity may interfere with or stop the signals transmitted by this system, but experience of over 14 months of continual everyday work has brought me to the conclusion that there is no kind of weather which can stop or seriously interfere with the working of such an installation. We have given demonstrations to several eminent scientists, who came down and wanted a show, often when we did not expect them, but on no occasion have they found any difficulty in the work of transmitting and receiving messages between the two stations.

In September of last year, in consequence of the expiration of our lease at Madeira House, Bournemouth, we transferred that station, as I have said, to the Haven Hotel, Poole, thereby increasing the distance to 18 miles. Experiments and tests are carried out daily between the two stations, the improvement in apparatus having allowed us to reduce the height to 80 feet at each end. An average of fully 1,600 words is daily transmitted through the ether each way. In the spring of last year Lord Kelvin inspected our station at Alum Bay, and he was kind enough to express himself as highly pleased with what he saw. He sent several telegrams to his friends, including Mr. Preece and Sir George Stokes, and insisted on paying one shilling royalty on each message, wishing in this way to show his appreciation of what was done, and to illustrate its fitness at that time for commercial use. We are now working at experiments directed toward still further reducing the height necessary for a given distance, and also a good deal on syntonic systems. In May of last year Lloyds desired to have an illustration of the possibility of signaling between Ballycastle and Rathlin Island, in the north of Ireland. My assistants, Mr. Kemp and the late Mr. Glanville, installed the instruments at Ballycastle and at Rathlin Island. The distance between the two positions is $7\frac{1}{2}$ miles, of which about four are overland and the remainder across the sea, a high cliff also intervening between the two positions. At Ballycastle a pole 70 feet high was used to support the wire, and at Rathlin a vertical conductor was supported by the lighthouse, 80 feet high. Signaling was found quite possible between the two points, but it was thought desirable to bring the height of the pole at Ballycastle to 100 feet, as the proximity of the lighthouse to the wire at Rathlin seemed to diminish the effectiveness of that station. At Rathlin we found that the lighthouse-keepers were not long in learning how to work the instruments, and, after the sad accident which happened to poor Mr. Glanville, that installation was worked by them alone, there being no expert on the island at the time. Following this, in July, we were requested by a Dublin paper, the Daily Express, to report from the high seas the results and incidents

of the Kingstown regatta. In order to do this we erected a land station, by the kind permission of the harbor-master at Kingstown, in his grounds, where a pole 110 feet high was placed. A steamer, the Flying Huntress, was chartered to follow the racing yachts, the instruments being placed in the cabin. The height of the vertical wire was fixed by the mast was 75 feet. A telephone was annexed from our land station at Kingstown to the Express office in Dublin, and as the messages came from the ship they were telephoned to Dublin, and published in succeeding editions of the evening papers. The relative positions of the various yachts were thus wirelessly signaled while the races were in progress, sometimes over a distance of 10 miles, and were published long before the yachts had returned to harbor. During the several days the system was in use between the tug and the land station over 700 messages were sent and received, none requiring to be repeated. On trying longer distances it was found that with a height of 80 feet on the ship and the same height as already stated on land, it was possible to communicate up to a distance of 25 miles, and it is worthy of note in this case that the curvature of the earth intervened very considerably at such a distance between the two positions. On one occasion, on a regatta day, I had the pleasure of the company of Professor G. F. Fitzgerald of Trinity College, Dublin, on the ship, who, as would be expected, took a very great interest in the proceedings.

Immediately after finishing at Kingstown I had the honor of being asked to install wireless-telegraph communication between the royal yacht Osborne and Osborne House, Isle of Wight, in order that her majesty might communicate with H. R. H. the Prince of Wales, from Osborne House to the royal yacht in Cowes Bay and during the trips his royal highness frequently took. The working of this installation was a very pleasant experience for me, and it afforded, also, an opportunity of more thoroughly studying the effect of intervening hills. In this installation induction coils capable of giving a 10-inch spark were used at both stations. The height of the pole supporting the vertical conductor was 100 feet at Osborne House. On the royal yacht Osborne the top of our conductor was suspended to the main mast at a height of 83 feet from the deck, the conductor being very near one of the funnels, and in the proximity of a great number of wire stays. The vertical conductor consisted of a 7-20 stranded wire at each station. The royal yacht was moored in Cowes Bay at a distance of $1\frac{3}{4}$ miles from Osborne House, the two positions not being in sight of each other, the hills behind East Cowes intervening. This circumstance would have rendered direct signaling between the two positions impossible by means of any flag, semaphore or heliograph system. Constant and uninterrupted communication was maintained between the royal yacht and Osborne House during the 16 days the system was in use, no hitch whatever occurring. One hundred and fifty messages were sent, being chiefly private communications between the queen and the prince. Many of these messages contained over 150 words, and the average speed of transmission was about 15 words per minute. By kind permission of the Prince of Wales I will now read to you some of the telegrams which passed between the royal yacht and Osborne House:

August 4th, from Dr. Fripp to Sir James Reid:
H. R. H. the Prince of Wales has passed another excellent night and is in very good spirits and health. The knee is most satisfactory.

August 5th, from Dr. Fripp to Sir James Reid:
H. R. H. the Prince of Wales has passed another excellent night, and the knees in good condition.

The following telegram was sent during a cruise, and while the royal yacht was under way, as you will see from the context:

August 10th, from H. R. H. the Prince of Wales to Duke of Connaught:
Will be very pleased to see you on board any time this afternoon when the Osborne returns.

This telegram was sent when the yacht was off Bembridge, at a distance of about seven or eight miles from Osborne. On August 12th the Osborne steamed to the Needles, and communication was kept up with Osborne House until off Newton Bay, a distance of seven miles, the two positions being completely screened from each other (even to the tops of the masts) by the hills lying between. At the same position we found it quite possible to speak with our station at Alum Bay, although Headon Hill. Golden Hill and over five miles of land lay directly between. The positions were $8\frac{1}{2}$ miles apart. Headon Hill was 45 feet higher than the top of our conductor at Alum Bay station and 314 feet higher than the vertical wire on the Osborne. The yacht on the same trip proceeded till about three miles past the Needles, communication having been maintained during the whole trip. Another day, when I did not happen to be on board, the yacht went on a cruise round Bembridge and Sandown, communication being maintained with Osborne House, although more than eight miles of land lay between the two positions. The Prince of Wales and other members of the royal family, especially the Duke of York, made much use of the system, and expressed themselves as highly satisfied with its practicability. I consider these results rather interesting, as doubts have been expressed by some as to whether it would be possible by this system to telegraph over long stretches of land. Results across hills were also obtained near Spezia by officers of the Italian navy, using my system.

In December of last year my company thought it desirable to demonstrate that the system was quite

practical and available for enabling telegraphic communication to be established and maintained between lightships and the shore. This, as you are probably aware, is a matter of much importance, as all other systems tried so far have failed, and the cables, of which some three or four ships are sometimes connected, are exceedingly expensive, and require special moorings and fittings, which are troublesome to maintain and liable to break in a storm.

The officials of Trinity House offered us the opportunity of demonstrating to them the utility of the system between the South Foreland lighthouse and one of the following light-vessels, viz., the Gull, the South Goodwin and the East Goodwin. We naturally chose the one furthest away—the East Goodwin—which is just 12 miles from the South Foreland lighthouse. The apparatus was taken on board in an open boat and rigged up in one afternoon. The installation started working from the very first without the slightest difficulty. The system has continued to work admirably through all the storms, which during this year have been remarkable for their continuance and severity. On one occasion, during a big gale in January, a very heavy sea struck the ship, carrying part of her bulwarks away. The report of this mishap was promptly telegraphed to the superintendent of Trinity House, with all details of the damage sustained. The height of the wire on board the ship is 80 feet, the mast being for 60 feet of its length of iron and the remainder of wood. The aerial wire is let down among a great number of metal stays and chains, which do not appear to have any detrimental effect on the strength of the signals. The instruments are placed in the aft-cabin, and the aerial wire comes through the framework of a skylight, from which it is insulated by means of a rubber pipe. As usual, a 10-inch coil is used, worked by a battery of dry cells, the current taken being about six to eight amperes at 14 volts. Various members of the crew learned in two days how to send and receive, and, in fact, how to run the station; and, owing to the assistant on board not being as good a sailor as the instruments have proved to be, nearly all the messages during very bad weather are sent and received by these men, who, previous to our visit to the ship, had probably scarcely heard of wireless telegraphy, and were certainly unacquainted with even the rudiments of electricity. It is remarkable that wireless telegraphy, which had been considered by some as rather uncertain, or that might work one day and not the next, has proven in this case to be more reliable, even under such unfavorable conditions, than the ordinary land wires, very many of which were broken down in the storms of last month. The instruments at the South Foreland lighthouse are similar to those used on the ship, but as we contemplate making some long-distance tests from the South Foreland to the coast of France, the height of the pole is much greater than would be necessary for the lightship installation. We found that 80 feet of height is quite sufficient for speaking to the ship, but I am of opinion that the height available on the ship and on shore would be ample even if the distance to which messages had to be sent were more than double what it is at present. Service messages are constantly passing between the ship and the lighthouse, and the officials of Trinity House have been good enough to give expression of their entire satisfaction with the result of this installation. The men on board send numerous messages almost daily on their own private affairs; and this naturally tends to make their isolated life less irksome.

My company has been anxious for some time to establish wireless communication between England and France, across the channel, in order that our French neighbors might also have an opportunity of testing for themselves the practicability of the system, but the promised official consent of the French government has only been received this evening. Otherwise this communication would have been established long ago. The positions for the stations chosen were situated at Folkestone and Boulogne, the distance between them being 32 miles. I prefer these positions to Calais and Dover, as the latter are only separated by a distance of about 20 miles, which is only slightly more than we are doing every day at Poole and Alum Bay, and as we find that distance so easy, we would naturally prefer further tests to be made at much greater distances. We did ask for permission to erect a station at Cherbourg, the corresponding station to be at the Isle of Wight, but the French authorities stated that they would prefer us to have our station in that country in some other position on the north coast.

My system has been in use in the Italian navy for more than a year, but I am not at liberty to give many details of what is done there. Various installations have been erected and are working along the coast, two of these being in Spezia. Distances of 10 miles have been bridged over in communicating with war vessels, although 10 miles has been found quite sufficient for the ordinary fleet requirements. Other installations are now contemplated in this country for commercial and military purposes, and I am confident that in a few months many more wireless-telegraph stations will be established, both here and abroad.

The city of Tarboro, N. C., will hold an election on April 15th to determine the issuance of the \$300,000 of bonds for the construction of the water works and sewerage system and \$10,000 of bonds for the erection of an electric-light plant.

DEVELOPMENT OF THE TELEPHONE FIELD.

Independent Telephone "Trust."

Mr. P. C. Burns of Chicago, who went East on March 25th for the purpose of incorporating the American Independent Telephone company, which was intended to control the anti-Bell field, has returned to Chicago without having accomplished his mission. Mr. Burns refused to discuss the plans of the promoters of the scheme or give any explanation of their failure to close up the deal according to the original programme. In fact, he displayed a good deal of irritation when pressed for a statement and declared that "too much had already been published" about the project.

It is now admitted by those who are favorably disposed toward the movement that the announcement concerning the organization of the "trust" and the companies that were to be included in it was unfortunate from their view, and at least premature in the case of six large concerns, which promptly repudiated the claims of the promoters regarding their relations toward the project.

It has transpired that the options held by Mr. Blaine and his associates will expire on May 1st, and that thus far nothing has been done toward acquiring possession of the property involved. In order to take advantage of the options that have been secured it will be necessary to perfect the organization and elect officers of the new company, procure the funds with which to pay "spot cash" for the factories and business taken over, and arrange the details of management of the new concern. Much time will necessarily be consumed in the details of a transaction of such magnitude, and for this reason, no doubt, surprise was manifested at the delay in putting the plans into immediate execution.

Independent manufacturers who are not in the deal do not appear concerned over the reports that the trust will force them to the wall. The fact that they have successfully withstood the pressure brought to bear by the Bell company for years has given them assurance and confidence in their own strength.

The Detroit News, commenting on the "reported \$7,000,000 trust of independent manufacturers said to be in process of organization in Chicago," quotes A. A. McLeod, the secretary and treasurer of the Detroit Switchboard and Telephone Construction company, who said: "We have manufactured and put in over 9,000 telephones in Michigan and are now building a plant complete of 4,000 instruments in New Orleans, and we are figuring on two large eastern cities. I guess the trust will not make very much headway with the big companies." Mr. McLeod declared that the Detroit company would not join the combination.

The Pittsburg Dispatch makes the distinction that many of the companies enumerated in the list given out by the promoters of the "trust" cannot be classed as manufacturers, but should rather be termed "assemblers" or dealers who buy parts and put them together for the market. The same paper declares that it has reason to believe that the movement is in the interest of the Bell company, and that the ultimate aim of the combination is to give the Bell control once more of the entire field.

NEW COMPANIES.

A telephone company has been formed at Billings, Mont., to construct and operate a line to Musselshell, Mont.

J. F. Boydston, H. H. Boydston, Holland Boydston and others have incorporated the Platte Purchase Telephone company, with a capital stock of \$15,000, at Edgerton, Mo.

Among recently reported Illinois incorporations was that of the Macon County Telephone company of Decatur, with capital stock of \$20,000, by H. M. Whitner, C. S. Hankins and W. P. Shade.

The Green River Telephone company at Henderson, Ky., has completed its organization, with J. H. Hickman, Owensboro, president; O. W. Rash, Henderson, vice-president, and H. K. Cole, general manager.

The Harrison Telephone Toll Line company of Owensboro, Ky., has been incorporated, with a capital stock of \$3,000, by J. W. Carter of Owensboro, I. C. Adair of Fordsville and John J. McHenry of Louisville.

The Wytheville, Va., Telephone company has re-organized, with Julius A. Brown, president; Frank Owens, vice-president, and L. D. Calfee, secretary, for the purpose of rebuilding, extending and equipping the Wytheville exchange and lines.

The Home Telephone company of Dayton, O., was incorporated March 27th by H. C. Kiefaber, W. P. Sunderland, Samuel R. Harshman, F. G. Mithoff and Albert Emanuel, to operate a telephone system in Dayton and Montgomery County on \$100,000 capital.

The Wyoming County Telephone company of Castle has been incorporated to operate a telephone line connecting Castle, Silver Spring, Gainesville, Rock Gen. Warsaw, Pike, Portageville and Perry, Wyoming county, New York, and Mt. Morris, Nunda and De-ton, Livingston County. The capital is placed at

\$2,000, and the directors for the first year are Miles A. Hopkins, D. E. Van Arsdale, S. B. Windsor, C. M. Johnson, S. J. Seward Chapman of Castle and E. T. Dudley and Newbern H. Louis of Silver Springs.

The Southern Electric Telephone company of Minneapolis has been incorporated. Its capital stock is \$30,000. The incorporators are D. N. Tallman of Willmar, Charles Webster and A. C. Webster of Waucoma, Ia., David C. Jones of Minneapolis and Andrew Larsen of Willmar.

Edward J. Hall and Charles D. M. Cole of Morristown, N. J., and Edward P. Meany of Newark, N. J., have applied for a charter for the American Telephone company, which will have a capital stock of \$25,000, to construct long-distance telephone system from New York to southern points.

Articles incorporating the Frederick County Telephone and Telegraph company, Maryland, were filed in the Circuit Court at Baltimore on March 29th, and a charter was issued by Chief Judge McSherry. The incorporators and stockholders are D. C. Winebrener, James E. Walker, Frank D. Stoner, Charles B. Trail, Dr. P. D. Fahrney, Dr. F. B. Smith, Daniel T. Ordeman, William P. Maulsby, Jr., John J. Murray and Edwin Devilbiss. The capital stock of the company is \$25,000, and the duration of the charter is for 40 years. It is understood that the company has bought the plant of the Interstate Telephone and Telegraph company of Frederick City, which was established in the fall of 1895, mostly by outside capital, with L. A. Carr of Durham, N. C., president. The company has 350 telephones in use, and its lines reach nearly every town in Frederick County.

EXTENSIONS AND IMPROVEMENTS.

The Erie company is putting in long-distance telephones at Youngstown, O.

The Warren County Telephone company of Mason, O., will build a 10-mile extension.

The Indiana, Pa., Telephone company, M. C. Watson, president, will build a 20-mile extension.

The North Ohio Telephone company of New London, O., will build an exchange at West Liberty.

Announcement is made at Houston, Tex., that A. L. Waterbury & Co. will establish a telephone system.

The Lineville, Ia., Telephone company contemplates extending its wires to connect with the Clinton and Warren line.

The Home Telephone company of Plain City, O., contemplates a 30-mile extension to its present system. A. L. Seely is president.

The Ticonderoga, N. Y., Telephone company, of which W. W. D. Jeffers is president, will shortly extend to Hague and to Sabbath Days Point, N. Y.

Telephone service will be inaugurated at Greenwood, near Victoria, B. C., before July. H. W. Kent, manager of the Vernon and Nelson Telephone company, will install the system.

Charles F. Solomon and E. T. Ijams will put in a telephone system at Clifton, Arizona, and Morenci. They will include all the exchanges down the valley, connecting with Solomonville and other points.

The Diamond State Telephone company has completed its line to Harrington, Pa. The line now reaches Millford, Georgetown, Lewes, Laurel, Bridgeville, Frederic, Magnolia, Bowers' Beach, Felton and several other towns.

The Jerome, Ariz., Reporter says that the telephone line to connect Jerome and Prescott will be completed at once. Messrs. Treadwell have bought the interest of G. W. Hull in the enterprise. The management expects to put in 50 instruments in Jerome, in addition to connecting with Winningham, Cliff and other outlying places.

W. A. Feenaughty of Addison has become president of the Canisteo Telephone company of Steuben County, N. Y. The line will run from Hegeville to Cameron Mills and Rathbone, and thence to Addison, connecting with the Cameron, the Tolbert Creek, the Woodhull, the Jasper, and the Canisteo and Hornellsville lines.

The Farm and City Telephone company of Farmer City, Ill., has purchased the interest in the Citizens' telephone lines throughout DeWitt, Logan and McLean counties, J. P. Shinneman retiring from the company, and R. C. Smith taking his place as secretary and treasurer. B. F. Wasson was elected president and superintendent. The company will erect 100 miles of metallic lines this spring, in addition to the present system of 300 miles of lines.

The Home Telephone company of Lewisburg, Pa., incorporated in 1895 with a capital of \$10,000, is operating 250 telephones and has 1,000 miles of wire. It contemplates extension to Williamsport, Bell-form, Daniel and Bloomsburg, and has exchanges in Lewisburg and Milton. The officers of the company are: J. T. Baker, president; C. F. Shaffer,

treasurer, and John P. Ruhl, secretary and general manager.

The Wayne Telephone and Telegraph company, with principal officers at Clyde, N. Y., will build, this summer, a 30-mile extension. At Lyons a company has been incorporated as the Lyons Telephone company, to be operated under the same management as the Wayne. It will connect Auburn with villages in Cayuga, Wayne and Seneca counties. The capital is \$500, and directors are S. E. Bishop and A. B. Bishop of Clyde, E. G. Bishop of Rhinebeck, and C. H. Towleron, Calvin Hotchkiss, James Bashford and Clyde W. Knapp of Lyons.

The United States Telephone company of Cleveland has contracted for 2,000 miles of main long-distance telephone lines to connect with the lines of companies in the Ohio Telephone association. One line will go through Medina, Wayne, Holmes, Knox, Franklin and Delaware counties. Another will pass through Columbiana, Portage and Stark counties, while a third will go through Huron, Lorain, Sandusky, Ottawa, Wood, Lucas, Fulton and Williams, and a fourth will pass through Lake and Ashtabula counties. The main Ohio lines will start from Cleveland. Arrangements have been made for connections at the Indiana line with long-distance telephone lines of that state.

Independent Telephony in Illinois.

An account of the progress made by the Citizens' Telephone company of Woodstock, Ill., is furnished by a correspondent at that point, which has been the scene of a bitter contest between the Bell interests and the local independent enterprise:

"Four years ago the Chicago Telephone company had no opposition throughout its territory in Northern Illinois, and its rates for private telephones were so exorbitant that no business man in the small towns and cities could afford one. As a natural consequence the field remained undeveloped, but with the expiration of the Bell patents the people of at least one county in the Chicago company's territory decided to oppose the monopoly which had given them only poor service and had demanded impossible rates. This county was McHenry, and Woodstock, the county seat, grew rapidly from an exchange of 25 to one of 110, while the Bell company lost two of the five telephones which it had at one time. In Harvard, a city of 3,000 inhabitants, a score of business men organized a home company which is to-day operating 200 telephones, paying a large dividend and improving an already admirable service by devoting its surplus to the application and development of every new and valuable improvement. Marengo has had a similar experience, the local company operating about a hundred and forty telephones. In both Marengo and Harvard the Bell company is confined to the toll-stations. With the growth of exchanges furnishing service at a third of the old Bell rates came the demand for toll-lines, and this demand has been thoroughly supplied by the Citizens' Telephone company, a development of the partnership firm of Wager & Joslyn. This company has built more than 100 miles of metallic-circuit lines, connecting 22 towns and cities in McHenry County, and is building exchanges in all the larger places. It has recently begun the development of farmers' lines, for which there is a great demand in all quarters. Each farmer is made a member of the nearest exchange at the rate of \$15 a year. Though an agricultural county with no large city, McHenry will boast of a thousand independent telephones this summer. Until recently the Bell company has fought in vain for a foothold. At last, however, in one corner of the county, by the expenditure of large sums of money and putting in many free telephones, it has succeeded in establishing an exchange and inducing those who had not experienced the extortions of the old days of the Bell's undivided power to lend it a paying patronage. In the village of McHenry the Bell company and the home company have each about 50 telephones. The home company has persistently refused to cut rates, though the Bell company has put in more than 20 free telephones. The home company is gaining a steady and patriotic support from the business men who believe in trading at home and do not desire something for nothing. With this exception the Bell company has been completely vanquished by local industry, coupled with a courteous treatment of a long-suffering public. Throughout the whole Northwest the same result is being rapidly attained, but nowhere has it been more rapid and pronounced than in McHenry County, Illinois."

ANNUAL MEETINGS.

At the annual meeting of the National Telephone and Telegraph company of Fort Wayne, Ind., the following-named officers were chosen: President, George W. Beers of Fort Wayne; vice-president, C. H. Cory; secretary, D. J. Cable, and treasurer, W. H. Duffield of Lima, Ohio.

The Capital Telephone company of Sacramento, Cal., held its annual election March 21st and elected the following-named directors: President, Frederick Cox; vice-president and general manager, M. J.

Dillman; treasurer, W. E. Gerber; secretary, M. R. Beard; A. Heilbron, Frank Ruhstaller, Sr., Herman H. Grau, George B. Katzenstein, George W. Locke and A. A. Van Voorhies.

New England Telephone Notes.

[From the Boston correspondent of the Western Electrician.]

An adverse report on the bill providing for regulation of telephone charges, also on the one for supervision of telephone companies, came from the committee, but five members thereof dissent, and a warm debate is due this week on the matter in the Legislature.

The Bell telephone instrument output statement for the month of March again breaks the company's record, in both the gross and net number. It is stated that, notwithstanding the fact that the Bell company's manufacturing department is increasing its plant and employing a larger working force than ever before, the company was unable to fill its March orders for instruments within 10,000. That is to say, had the company installed all the instruments wanted the total gross would have been about 77,000 and net more than 63,000. The figures follow:

	1899.	1898.	1897.	1896.
Gross output.....	67,033	28,909	19,192	19,283
Returned.....	13,530	15,737	6,495	7,331
Net output.....	53,503	13,172	12,697	11,952
Since Dec. 20:				
Gross output.....	162,844	86,667	53,309	54,993
Returned.....	41,725	38,568	20,911	22,132
Net output.....	121,119	42,099	32,398	32,861
Total outstanding.....	1,246,365	961,220	806,247	709,397

The city of Somerville, after a protracted debate on the subject, has decided to grant permission to the New England Telephone and Telegraph company to place its wires in underground conduits.

The stock of the Michigan Telephone company was listed March 27th on the Boston stock exchange.

MISCELLANEOUS.

The Bell Telephone company of Philadelphia, which has issued common stock to the amount of \$2,616,750, without bonds or preferred stock, and is paying two per cent. quarterly dividends, has been listed at the Stock Exchange in that city.

In the recorder's office at Keokuk, Iowa, an amendment has been filed to the articles of incorporation of the J. C. Hubinger Brothers' company, by which the capital stock of the company is changed to \$1,000,000, divided into 10,000 shares of \$100 each. Of this \$600,000 is to be preferred stock.

A meeting of the Council lamp and electricity committee of Rochester, N. Y., has agreed upon a form of telephone franchise. The highest rate that can be charged per year for a telephone is \$48, and the city is to have instruments free in all its offices. The franchise shall not be transferred without consent of the council, and the council may cancel it whenever it deems proper.

TELEPHONE LITIGATION.

The Southwestern Telegraph and Telephone company, on March 25th, instituted suit against County Collector Paul Meerscheidt and the members of the County Commissioners' Court, at San Antonio, Tex., for an injunction restraining the collector from levying on its property to collect a franchise tax, and to restrain the court from assessing the franchise of the company.

Justice Cox, at Washington, March 23d, signed an order directing the taking of testimony in Richmond and Norfolk in the case of James F. Manning & Co. against the Chesapeake and Potomac Telephone company. The suit was the first one brought in equity against the telephone company, and was taken under consideration to test the act of Congress which fixed the maximum rate for telephone service in the District of Columbia at \$50 per year.

TELEPHONY ABROAD.

A heavy snowstorm prevailed at Brussels, March 28th, and in that vicinity, resulting in the complete disorganization of the telephone system. The damage done to the wires is so extensive that it is not likely that the repairs necessary to the restoration of the service can be made within a month.

The establishment of telephone service between Berlin and Paris is taken as an indication of better feeling between Germany and France than existed formerly. It is announced that two lines will be established. One of these is to pass by way of Frankfurt, the very city where the treaty of 1871 was signed. The German government has even decided to send delegates to Paris to arrange the final details.

The London correspondent of the Chicago Record under date of April 4th says: "The story reaches here that during the recent violent storm, the telephone wires between Brussels and the suburb of Ixelles being broken and communication interrupted, it was suggested that telephoning without wires be attempted. This was tried with satisfactory results, and since then the inhabitants of Ixelles have been telephoning to Brussels with the greatest ease. Electric experts here more than doubt the story so seriously set forth. Telephoning demands conditions so different from those requisite for telegraphing that they declare telephony without wires is practically impossible."

COMMUNICATION.

Brundage Telephone Bill.

To the Editor of the Western Electrician:

In your issue of March 25th I was very sorry to see an adverse criticism on the telephone bill of Representative Brundage. I happen to know Mr. Brundage very well, and went before the committee on municipal corporations, to whom this bill was referred, and heard the discussions relative to the various bills before them, at that time three in number.

There were two bills for the reduction of telephone rates besides Mr. Brundage's bill. One of these bills were introduced by the rift-raff, evidently with a view of sandbagging the telephone company; the other, I have good reason to believe, was introduced for the sole purpose of defeating the Brundage bill, and was advocated by friends of the Chicago Telephone company.

They have neatly led everybody into a trap by an article which they had published in the Chicago Tribune. If you will notice, the only item which they took up in that article was the one relating to the amount to be charged for service. The sole reason that this amount is low is because Mr. Brundage was compelled to cut it down in order to kill the other two bills. The telephone company had its emissaries on the ground at the time of the introduction of the bill, and used every endeavor to get the charge as low as possible—so low as to make the bill a failure—and when I suggested to the committee that they leave out all rates, making no mention of charges whatever, they were the first to object and insisted that the low rate be kept in the bill. The inspired article to which I refer made a great show and bluster about the rates being too low, but entirely avoided any mention of the principal item in the bill, and the one of which they are most afraid—the privilege of intercommunicating.

This is the only solution of the telephone problem. Railroad, express and telegraph companies are obliged to receive freight, express and messages and transmit them to competing companies in order that they shall ultimately reach their destination. They have no trouble in adjusting the compensation of the several companies through whose hands the business is done. Why could not telephone companies do the same?

This would at once stop all propositions tending to sandbagging or selling out, for if any company should start an exchange, as soon as it had a half dozen telephones, or less, it could begin doing business to the full extent of the needs of its subscribers, and there would be no incentive for the Bell company to buy it out, for the reason that every new subscriber of the competing company would at once add to the business of the Bell company. The Bell company would be compelled to do business on the merits of its system. If the new company had better telephones, or gave quicker service, or charged less for it, the Bell company would be compelled to do the same. This arrangement at once disposes of the threadbare and somewhat doubtful claim of the Bell company, viz., that "an increase in the number of telephones increases the expense of switching in a greater proportion," from the fact that the new company would be subject to exactly the same conditions as the old company. If the old company has 16,000 instruments and the new company 1,000, they must both prepare switching facilities to take care of a business on an exchange of 17,000 instruments, which is certainly an equitable and just position to put them in. They have in the city of Chicago 16,000 telephones. If, we will say, the Illinois Telephone company started into business, the moment they placed a telephone, that subscriber would have the use of 16,000 telephones of the Bell company. At first thought this would seem to be an injustice to the Bell company, but as they are paid for every message sent over their lines, and as they also pay the other man for every message which they transmit to him, the proportion of payments would be as 1 is to 16,000 on one side, and as 16,000 is to 1 on the other side, so that each one is paying in exact proportion to the business he is doing.

No one deplors the price inserted by the Bell people any more than Mr. Brundage, but it was absolutely necessary to get that bill out of the hands of the House committee. By submitting temporarily to that reduction in price he got the bill through the House and before the Senate. The Senate is composed of a more conservative class, who are endeavoring to serve the interests of the people. If they get reasonable encouragement from the electrical profession and the users of telephones, they will report the bill to a conference committee, which will be composed of men like themselves. Living rates will be allowed, or all mention of rates will be omitted, and the bill will become a law in that shape, providing the legislators are properly advised by the press and the people.

The clause about common carriers cuts no figure whatever. The matter is before the Supreme Court, and if it decides that the Legislature has a right to declare certain companies common carriers it will save another enactment two years hence. But if it decides that the Legislature has not this power, it will not invalidate this bill in the least.

For these reasons, and for the fact that this bill will be invaluable to the users of telephones because it will stimulate at once a healthy and honest competition and will shut off all of those companies which are organizing for the purpose of selling out,

and because a law compelling telephone companies to interchange messages is equitable and just, I sincerely hope that the Western Electrician and all users of telephones will use their influence in every way possible to advance this bill and have it become a law. Once we have competition, the telephone rates will take a decided drop, and, above all, we shall get service—a thing which we do not get now.

CHARLES G. ARMSTRONG

European Telephone Service.

A parliamentary paper has just been issued, showing the result of an investigation conducted by the English government, through its consular department, relative to the telephone service in the countries of Europe, with the view of instituting comparison with the English system. Statistics upon the New York telephone system are also printed, but no other American city is represented. The ground covered embraces all the industrial countries of the continent, and furnishes detailed information as to the chief cities of Austria-Hungary, Bavaria, Germany, Italy, the Netherlands, Belgium, Sweden and Norway, and of Switzerland. Of the French telephone service no useful particulars were obtainable; and from Russia only one example is furnished, that of Helsingfors.

Information was sought upon 23 points, which may be summarized as follows: Those relating to population and size of area; nature of concession, whether private, state or municipal; powers and rights-of-way leaves; numbers of subscribers; tariffs and hours of service; wages of workmen and operators, with their hours of attendance. To these were added questions as to the composition of the wires, the character of the circuits, and where the plant, including apparatus, was manufactured. It was also desired that copies of accounts should be obtained, with details of capital expended and profits or dividends earned; but answers on these points are either not forthcoming, or, in the majority of cases, too ambiguous to be of any value. The same may be said of answers to a question on "Quality of service, and whether the subscribers are generally satisfied?" Replies respecting the wires used are uniformly silicium or phosphor-bronze; single, as a rule, for overhead, double and of copper for underground. The plant and appliances appear to have been obtained mostly from Stockholm and Germany.

It is remarked that Italy is the principal country at all resembling New York, judging from the reports on the service in the cities of Rome and Florence. Both places are served by private companies, which are the survivors of other companies, now defunct or amalgamated, and which hold concessions from the Italian government for 25 years, commencing on January 1, 1893. These concessions are, however, subject to cancellation after 12 years on payment, as compensation, of a sum equal to the average net profit of the three preceding years, multiplied by the number of years which each concession has still to run. If undisturbed for the full 25 years, the plant, lines and offices become the property of the state. A tax of 10 per cent. is imposed on the gross profits of each concession, free communication with postal and telegraph offices, and a reduction of 50 per cent. in favor of all government, provincial or municipal offices. In Rome and vicinity the concession covers an area including a population of about 500,000. The subscription is 168 lire (\$30) annually, with an extra charge for distances exceeding three kilometers. The service is continuous, night and day. Subscribers number 2,102. About 50 women are employed at the central bureau, working seven to eight hours a day, with wages of \$6 to \$10 per month. Workmen's wages are set down at 40 to 55 cents a day, working 10 hours. The dividends of the company, which were formerly three per cent., are now, under the more secure conditions, six per cent. In Florence the same rate of wages prevails, and there is the same continuous service all night and all Sundays. A two-weeks' leave of absence is granted annually to the operators, and a holiday on each alternate Sunday. The subscription ranges from \$30, within one kilo, to \$45, within three kilos. There are about 900 subscribers in a population of 250,000. Although the law requires double wires, it has not yet been generally enforced, and single wires are the rule.

Helsingfors, in Russia, is the only other instance reported where the telephone service is in the exclusive control of a private company. The same story comes from there as from Italy, several competing companies, ending in amalgamation and a joint concession. In the case of Helsingfors, with only 80,000 inhabitants, the company obtained its privileges from the municipality on very easy terms, paying only one mark for every wire in the town; but nothing for its 16 trunk wires along the roads. It has 2,800 subscribers. The subscription is from \$25 to \$28 per annum, if the instrument and line are hired, and \$19 if they are bought. Workmen and women receive on an average 75 cents for a day of 10 hours.

Of municipal telephony the only examples presented are from the Netherlands, Amsterdam and Rotterdam having taken over in 1806 the systems previously worked by private companies, and extending in both places to a radius of 3 1/2 English miles. The concession to the municipalities is granted by the state for a period of 25 years, with option of purchase at any earlier period. The system is double wired, and is a combination of overhead and underground. Amsterdam has a population of 500,-

oo, with subscribers numbering 1,925; Rotterdam, a population of 295,000, and 1,320 subscribers. In Amsterdam each subscriber pays \$11 entrance fee, and \$38 per annum. In Rotterdam the entrance fee is rather less, and for private (not business) subscribers the rate is \$28. The service is continuous night and day. No royalty is paid to the state, the only consideration imposed being the obligation to provide all cable wires for connecting subscribers with telegraph offices and trunk lines—both in the hands of the state. The capital outlay is estimated for each connection at \$170 in Amsterdam and \$225 in Rotterdam. For the first-named place the receipts and expenditure in 1897 have been published. The surplus in that year was about \$20,000, expenditure being over \$50,000, against receipts of \$72,000. A surplus of over \$20,000 was estimated for 1898. In Rotterdam the estimate for that year is given as \$28,000—interest and redemption of the capital outlay of \$325,000 to be defrayed from that amount. The wages in Amsterdam appear to be lower than in Rotterdam. Pension for old age or when injured during service and compensation to relatives if killed are fixed by the Rotterdam Municipal Council, according to years of service and rate of wages.

Partly governmental and partly private enterprise afford the much talked-of systems of Sweden and Norway. Beginning with private associations connecting small towns and villages, merely for mutual convenience, telephony had a good start in the country districts before the dividend-paying concerns were developed in such places as Stockholm, and still more of the government system, which did not come into operation until 1891. In that city the Bell company started in 1880, the Allmänna company three years later. The competition of the government, commenced in 1891, resulted in the two systems being connected and the double wire being adopted throughout Stockholm. With a population of 271,638, the Stockholm subscribers number 19,369, of which 12,899 belong to the Allmänna company, 4,506 to the state service, and 1,964 to the Bell company. It is not clear, however, whether these figures represent separate subscribers, or whether any of them subscribe to more than one system. The tariff of the state telephone department only is quoted; but it is presumed that the three competitors' charges are alike, viz., an entrance fee of \$13, and a similar amount per annum for ordinary business purposes, but \$22.50 per annum if with the right of an unlimited number of calls. Some reduction is made for limited service, and a private telephone may be had for \$10 a year, with an entrance fee of \$3. The state appears to be earning no profit itself, but is threatening with reduced dividends its competitors, one of which (the Allmänna) used to pay eight per cent. to its shareholders.

According to the account received of the Christiania Telephone company, wages paid in that city are very low. Rates of subscription for single lines, not exceeding 1,500 meters, connected with the central station, \$22.50 per year. Extra charges are made for calls in excess of 6,000 a year, and guarantees are required for at least three years' subscription if a new line is required 500 meters from the nearest central station. Christiania has a population of 200,000, of whom 6,475 are subscribers to the company's system. Last year's dividend was 5 1/2 per cent.

From Bergen, a town of 65,000 to 70,000 inhabitants, there is a similar report of the Joint Stock company's operations, with 1,800 subscribers, and earning apparently the same amount of dividend on capital outlay. It should be noted, lastly, that for these undertakings in Sweden and Norway no royalties have to be paid to either the state or the municipality, the latter only claiming special rates for its own service.

There remain to be considered only the purely state telephone systems. Of these, the German and Bavarian have been in government hands from the first; the Swiss also, except for a private venture at Zurich, which was speedily absorbed into the federal system. In Austria-Hungary, as well as in Belgium, the acquisition of the telephones was postponed until 1897 or thereabouts, the local undertakings until then being in private hands, although the trunk wires as well as the telegraphs were in most instances owned by the state.

The Vienna system extends over an area of 69 square miles, 70 per cent. of the wires being double, the remaining 30 per cent. single. The population numbers 1,400,000. At the time of the transfer there were 7,700 subscribers, which in 1897 had increased to 10,573. Within a radius of 1 1/2 miles from the central exchanges the subscription is \$42 per annum. At these central exchanges the service is continuous throughout the day and night. The female attendants are paid about \$15 a month; laborers 50 cents a day. Trieste, with 163,979 inhabitants, has 1,020 subscribers. The general circumstances are the same as in Vienna. Prague has a population of 320,805, the subscribers to telephone exchanges numbering 2,200. Wages are about the same as in Vienna. In the Prague report mention is made of telegrams destined for subscribers on the exchange are telephoned to them; also that subscribers may telephone their telegrams to the postoffice for transmission by telegraph.

In Belgium the concessions to private companies expired in 1893, when the telephone systems came under government control. Ghent, with its surrounding districts, has a population of 200,000. The

subscribers number 900, but whether this is in Ghent proper is not quite clear.

In Switzerland the telephone system has been worked by the federal government since 1881, and is considered very popular. Berne, with a population of 53,000, has 2,025 subscribers; Zurich has 157,000 inhabitants, with 4,400 subscribers; Geneva has 3,264 subscribers out of a population numbering 58,700. The underground cables are of double wire throughout; the overhead, as a rule, single wire. The tariff rates are the same all over Switzerland, namely, \$20 and \$14 for the first two years respectively, and \$8 for succeeding years, a charge of one cent being made for each communication, "thus proportioning the expense to the use made of the telephone." The following table gives some particulars of the service in

HOME MEDICAL BATTERY.

1896, extracted from the Swiss government trade returns:

Total length of lines, in miles.....	6,524
Total length of wires, in miles.....	45,969
Number of nets.....	252
Number of stations.....	23,198
Number of subscribers.....	25,090
Number of local conversations.....	13,436,198
Number of interurban conversations.....	2,729,570

From Bavaria reports have been received relating to Munich, Stuttgart and Wurtemberg; also from Frankfurt, Cologne, Hamburg, Leipsic and Berlin, all of which are, of course, under the Imperial German Telegraph Administration. The conditions resemble those in the city of Berlin, and need not be particularized. It is worth noting, however, that mention is made in the Munich report that the female operators are required to be of good education, and able to "transcribe and translate without serious mistakes at French or English dictation." Probably this rule applies to all Germany and to other countries—Switzerland, for example—as well.

The area of Berlin and suburbs, including Potsdam, has a population of 2,314,451, of whom 28,785 are subscribers to the telephone service. It has nine

FIGS. 1 AND 2. WALL SWITCH RHEOSTATS.

principal exchanges, each arranged for 5,000 to 6,000 subscribers, and 35 public stations, besides 95 at stock exchanges. By means of its trunk wires the capital is in communication with about 350 large towns, both within and without the boundaries of the empire. The system is described as single-wire throughout, each connection averaging 1.9 kilometers. The chief features of the tariff are:

(a) For each telephone instrument erected within the district of the city telephone system, and not more than five kilometers (as the crow flies) from the central exchange, an annual rent of 150 marks.

(b) For each telephone beyond the above limit, the distance within which connection is possible being decided by the imperial postoffice, for every 100 meters of additional wire, or part of that length, beyond the five kilometer limit, an additional annual payment of three marks.

For messages accepted to be transmitted by tele-

graph a general charge of 10 pfennigs is made, and one pfennig for each word. Exchanges are open from 7 a. m. to 10 p. m. Night service between two subscribers can be arranged for by an extra charge. Female telephone clerks are employed at the telephone bureaus, and have the position of officials. The girls have to be of good education and able to pass an examination. The Berlin report concludes with the following remark, which is applicable to the whole of the German imperial telephone service:

"No statistics can be given relative to the financial position, as in consequence of the union of the postal, telegraph and telephone systems under one administration, the revenue and expenditure are reckoned under one head, and separate data do not exist. The introduction of a different system of charges is in contemplation, but it is not known if the tariff will be lowered in consequence."

Frankfort-on-Main, with a population of 229,279, has 3,909 subscribers; Leipsic (398,448) has 4,294 subscribers; Cologne (321,564) has 3,784 subscribers; Hamburg city proper has 625,552 inhabitants, of whom 12,064 subscribe to the local telephone system. The service is installed for one year certain, with three months' notice after the end of the first year.

Wall Switch Rheostats.

The wall switch rheostats, herewith illustrated are especially made by the Western Electric company of Chicago for use with ceiling fan motors which have but one speed and for ceiling and desk motors running in series on 220 and 550-volt circuits. By the use of one of these wall switch rheostats three speeds can be given to a single motor or to a group of motors connected in series. A wall switch rheostat can be placed in any convenient location either near to or remote from the motor or group of motors to which it is connected. It will be found of great convenience in controlling the speeds of motors placed in restaurants and stores where it is not advisable for attendants to have access to motors while in operation, or when fans are so placed that access to them is inconvenient. Fig. 1 shows the size made for the Arctic ceiling fan on 110-volt circuit. All other sizes are made in the style shown in Fig. 2.

Home Medical Battery.

J. H. Bunnell & Co. write: "At a special term of the Supreme Court, Part Second, held in New York on March 30th, Justice Francis M. Scott granted a permanent injunction in the case of J. H. Bunnell & Co. against the Manhattan Electrical Supply company, restraining the latter from manufacturing or selling medical batteries similar in appearance or design to the well-known No. 4 D. D. Home medical battery. An accounting for damages was ordered, and on March 31st judgment therefor was entered against the Manhattan company."

Bunnell & Co. originated this battery outfit, a cut

of which is shown, several years ago, and as it was an entirely new departure, in form and otherwise, from anything hitherto produced, its introduction to the trade and medical fraternity as well as to the public was expensive. However, the manufacturers, having faith in the merits of this battery, persisted and in time were beginning to reap their reward, when, it is claimed, various concerns, seeing the demand that had been created, commenced making and selling imitations of the battery. Finally it was determined to commence suit against all infringers, beginning with the Manhattan company, which was considered the most responsible of the aggressors.

The decision just rendered in favor of J. H. Bunnell & Co. is said to mean a vigorous prosecution of all offenders, and it is understood that the attorneys for Bunnell & Co. have been instructed to immediately proceed against several other manufacturers

and dealers who are handling imitations of this battery.

It is stated, also, that the Manhattan company has applied for and received a license from Bunnell & Co., giving it the right to make and sell the battery in question under royalty.

Electric Railroads in Germany.

Germany is making rapid strides in the construction of electric street railroads, according to the report of Ernest L. Harris, the United States consular agent at Eisenstock. In Meissen, Weimar and Eisenleben roads are being built; the following-named cities are planning the immediate construction of electric plants and electric street railroads: Pforzheim, Trier, Ratisbon, Colmar, Jena, Kaiserslautern and Worms. The population of the cities mentioned runs from 15,000 to 50,000 each. There are still a number of cities of this size in Germany which have no street railways of any kind. A number of towns in Saxony—mere villages a few years ago—have grown through the rapid development of industries into important centers. In many cases a single long, narrow street runs through the middle of them.

Mr. Harris suggests that concessions be sought in German cities and that American electrical manufacturers compete for the equipment of roads now contemplated.

Becken's Non-magnetic Watch.

As electricians are well aware, watchmakers have exercised great skill in adjusting watches to all influences save those of magnetism, which frequently impairs the finest regulation, and with it much of the value of a timepiece. In these days of widely distributed and powerful electro-magnetic apparatus, no ordinary watch is safe. The balance and hair spring of a watch are influenced, and these susceptible parts become disarranged. However, Carl A. Paillard, a celebrated adjuster of Geneva, Switzerland, has, after 14 years of scientific experimenting, invented a palladium hair spring and a compensation balance that

BECKEN'S NON-MAGNETIC WATCH.

are said to entirely overcome the difficulties heretofore encountered. These movements have been put to the severest tests. They can be brought into actual contact with dynamos or electric magnets, and are not affected, it is said, in action. They are entirely insensible to heat if placed on a stove. The hair spring will not rust if placed in salt water. Watches with these movements, therefore, are especially valuable to travelers, artisans, professional men, navigators, railroad and telegraph men, engineers, electricians and all residents of cities.

The Paillard non-magnetic watches are made by A. C. Becken, Chicago, in all grades and sizes. The movement is shown in the cut. Every watch is warranted to give perfect satisfaction. They are claimed to be unsurpassed for durability, workmanship and accuracy. They are made by skilled workmen; the jewels are carefully selected, the cases are exceptionally strong and of highest attainable finish, and each watch is thoroughly tested.

Electric Railways in Breslau.

The city of Breslau is about to grant a charter to the street-railroad company for a term of 24 years, with privilege of substituting electric power for horses. The following particulars are furnished by C. W. Erdman, the United States consul at Breslau: The reconstruction of the roads must be completed within two years after the contract has been approved. Overhead and underground systems are to be used. The company agrees to take from the city the necessary current for lighting and operating the cars, and the city binds itself to furnish sufficient power for this purpose, but provides that it shall not be liable for any damages in case of a breakdown at the power house. The fare is to be 10 pfennigs (2.38 cents), with transfer over any of the lines. The city is to receive from the company for the privilege and the use of the streets—after the expenses for power, engineering, keeping tracks, cars and wire in repair are deducted—33 1/3 per cent. of the receipts. After December 31, 1907, the city and company will share equally in the net profits. At the expiration of this contract the city has the right to take charge of the property of the company.

The receipts of the horse street-railway company of Breslau, during the year ended December 31, 1898, were \$367,560, or \$18,790 more than in 1897. The system has a total length of 50.018 meters (31 miles), and employs 510 horses, of which each does an average daily work of 22.69 kilometers (14 miles) in single and 25.40 kilometers (15.84 miles) in double harness. Ninety-eight closed and 40 open cars are

in use. In the course of last year 14,470,811 persons were conveyed. The salaries paid to the 472 employes amounted to \$114,440.28. The net profit was \$60,493.57, which allowed a dividend of 12 1/2 per cent.

SPACE TELEGRAPHY.

It is said that Marconi will visit the United States this fall.

Marconi is a native of Italy, and it is said that he is but 26 years of age.

In England someone has proposed the name "etherphone" for space telegraphy.

It is said that the next test by Marconi will be between New Haven and Dieppe—a distance of 64 miles.

In the recent experiments in telegraphing without wires across the English channel by the Marconi system the speed was from 15 to 17 words a minute.

Lord Kelvin is reported to have said: "I am not at all surprised at the results attained by Marconi. I believe wireless telegraphy has already become a practical success, and its future is immense. For oversea communication it has many advantages which will make it invaluable."

The Washington correspondent of the Chicago Record says that now that the Signal Corps of the army has been partially relieved of its duties and responsibilities caused by the war, Col. Allen and Lieut. Squier have resumed their experiments in wireless telegraphy, and hope for important results.

One great objection to Marconi's system is the fact that it seems impossible to guard the secrecy of the messages absolutely; another is the slowness at which messages have thus far been transmitted, and a third is the doubt whether the new method is available for great distances. However, there seems a great and undoubted field of usefulness in making possible communications between vessels at sea, one with another, and also with points on shore. Fog, wind and rain seem to make no difference in the working. The value of a practicable system of space telegraphy in a storm along the coast is very obvious.

Marconi says that the French government has given him more encouragement than any other. He contends that the cost of the new method of transmission is small compared with cabling. The whole installation by which the English channel demonstrations are carried out cost only about \$1,250. With a multiplication of appliances the expenditures would be greatly reduced. Asked if wireless communication across the Atlantic was practicable, the inventor said: "Speaking broadly, I believe so, but I have not yet made calculations with that view. I expect it would require a tower on the coasts of West Ireland and the United States from 1,000 to 1,500 feet high, with certain lengths of wire netting to catch the current and make the circuit. I don't positively affirm this demonstration is possible, as there are many difficulties, but when seriously tackled no doubt they could be overcome."

Professor Zickler of Brunn, Moravia, has perfected a method of signalling through space with ultra-violet rays of vibration. At the sending station he uses an arc light, as the electric arc is particularly rich in ultra-violet rays. The light from the lamp is concentrated by means of a concave mirror, as in the case of a searchlight, and is projected in a slender beam. A lens used in the front of the lamp to assist in the work of concentration is made of a specially selected material, a kind of quartz, which will not filter out of the light the invisible ultra-violet rays. Immediately ahead of the lens is placed a movable screen of glass, that has also been chosen carefully because it will obstruct these ultra-violet rays, although it will not interfere with the visible radiance from the arc. The letters of the Morse code or any other are signalled simply by removing the glass screen from in front of the lamp and then restoring it. The interruptions of the invisible radiance effected in this way are of such lengths and are so spaced as to fall into an intelligible scheme. Instead of opening and closing a "key," as in ordinary telegraphy, the operator uses a convenient device for altering the position of the glass screen in front of his arc light. At the receiving station a bit of apparatus is used, in which a suitable lens catches the pencil of parallel rays and focuses them. Just inside the box in whose front this lens is set there are two terminals of an electric circuit brought near to each other, but without touching. One of the terminals is a small globe coated with platinum foil. The other is a round, flat plate, having a polished surface, so as to serve as a reflector as well as an electrode. It not only helps to complete a circuit for the flow of a current through wires in the station, but it also catches the focused incoming ultra-violet rays, so that they fall in a tiny spot on the center of the disk. The disk is set at such an angle that the rays are reflected onto the globular terminal. Both, then, feel the influence of the ultra-violet rays, and are enabled to develop a stream of sparks that would not otherwise flow. This phenomenon was discovered and announced by Hertz and his followers, and upon it the Zickler system is based. The flow of the current thus promoted may be made to affect other instruments in

the circuit, such as a "sounder" or telephone or a bell. And when, by the interposition of the obstructing screen at the sending station, the arrival of ultra-violet rays at the receiving end is stopped the flow of the local current ceases. The system is a costly one, and the inventor has thus far signalled through a space of one mile only.

CORRESPONDENCE.

New York Notes.

New York, April 3.—The application of the owners of the Metropolitan Street Railway company to the Board of Rapid Transit Commissioners for permission to construct and operate the tunnel-and-viaduct railway system planned by the board for the boroughs of Manhattan and the Bronx holds a large share of public attention. The commissioners have applied to the Legislature to have the amended rapid-transit act now pending in that body further amended to give them statutory power to consider the Metropolitan proposition. In their memorial the commissioners state that the proposition is substantially as follows:

First—The routes and plan of construction prescribed by the board and approved by the municipal authorities, and Appellate Division to be adopted, subject only to modifications in detail. The plan includes tunnel construction, except at the extreme upper part of the road.

Second—Construction to begin at once on the section of the road running from the city hall through Elm street, Fourth avenue, Forty-second street, Broadway and the Boulevard to a point above St. George, and that section to be completed within three years.

Third—The remainder of the road upon the routes prescribed by the board to be built within two years after the grantee shall earn 5 per cent. upon the actual cost of the first section.

Fourth—Passengers to be carried the entire length of the road for a single fare of five cents, and to have the right to a transfer from or to any part of the Metropolitan system for an additional fare of three cents. The fare upon express trains running at a rate of not less than 20 miles an hour, and for at least two miles below Forty-second street at not less than 30 miles an hour, to be 10 cents, with right of transfer from or to any part of the Metropolitan system without additional charge.

Fifth—The grant to be in perpetuity.

Sixth—The grantee to be entitled to use side galleries and other spaces in the tunnel not necessary for railroad purposes for any wires, tubes or conductors authorized by law, and to receive rentals therefor.

Seventh—Rental to the city to be five per cent. of gross receipts, provided that the grantee shall first receive five per cent. net upon the cost of construction, such cost to be subject to proper scrutiny by the board. The grantee to be exempted from taxation until it shall have earned five per cent. on cost, as proposed to the bill submitted to your honorable bodies with the memorial of the board.

The bill embracing the final amendments suggested by the board is now pending in the Legislature.

Some of the provisions of the Metropolitan offer have aroused lively opposition. Particular objection is taken to the grant of a perpetual franchise. This is considered a "theft of the people's rights," to use the words of one speaker, and the Sun says that it is illegal anyway. Another provision regarded with much suspicion is that given under the sixth head quoted above. This clause is thought to insure the owners of the franchise a practical monopoly of the electrical distribution of the city. Such a monopoly, with the electrical utilities existing and in view, would be of incalculable value. There are many, too, who still say that the city should build the system and that a constitutional amendment will obviate the municipal debt-limit objection. Others have objected to the ten-cent fare on express trains. The compensation clause, too, has been criticized, and it is suggested that shrewd financing might not leave much for the city after the grantee had had "five per cent. net upon the cost of construction."

On the other hand, Mr. Whitney asserts that the offer made by the owners of the Metropolitan company is the best that could be made, and he says that if the support of the public is not heartily given the proposal will be withdrawn. "The Metropolitan company," he maintains, "is not going into this matter as a speculative matter. The men who are interested financially only seek a fair return for the money involved and the risks they are called upon to assume. Under the terms as set down we have figured that a fair return will be made for the outlay of \$50,000,000 on this work. Any change in the conditions which would tend to lessen the revenue would upset all calculations. All these questions have been carefully considered by our experts. The formal proposal was drafted after every point was covered."

There was a good attendance at the lecture of Prof. Elihu Thomson on "Electricity at High Pressures," before the New York Electrical society on last Wednesday evening. Prof. Thomson handled the subject with his usual clearness and exhibited interesting apparatus and experiments.

The Brooklyn Gas and Electric Light company (capital stock, \$1,500,000) was incorporated in New Jersey on March 28th. The men asking for the incorporation papers were H. S. Tourny, Maurice Landauer and Frank M. Weizman, all of New York.

It was announced last week that over 07 per cent. of the additional stock of \$18,000,000 of the Manhattan Railway company had been taken by the stockholders. The rest will be subscribed for by the underwriting syndicate.

The Metropolitan company will begin the operation of the new cross-town cars on the Twenty-eighth and Twenty-ninth street lines about the middle of the month. Compressed air is used at the motive power on these cars. H. H. Vreeland, president of the Metropolitan company, is reported to have said:

"The new system is out of the experimental stage, and I am confident of its complete success. All that hinders our opening the route is the construction of the compressor. This will be finished and ready for operation in about two weeks. The new power house is practically completed, and the new cars need only the power equipment."

Backed by R. P. Flower and his financial associates, the Brooklyn Rapid Transit company is rapidly extending its field of operations. The latest acquisition is the Brooklyn elevated railroad, which was turned over to Mr. Flower's company by the receiver on March 25th. The new owners will operate the cars by electric power and put on open cars in summer. Electric elevators at the stations are also promised. Power for the electric system will probably be taken from the existing power houses of the Brooklyn Rapid Transit company. It is believed that the Flower syndicate will ultimately secure all the railroads on Long Island. Announcement was made on Saturday to the stockholders of the Brooklyn Rapid Transit company that they will have the privilege of subscribing at par to additional stock, probably about \$3,000,000 in amount, the proceeds to go toward purchasing and electrically equipping the Brooklyn and Brighton Beach railroad and electrically equipping the Prospect Park and Coney Island railroad, and "for such additions and improvements to the properties owned or controlled by the Brooklyn Rapid Transit system as may be deemed desirable." M. S.

PERSONAL.

C. G. Luthy, general manager of the Royal Electric company of Peoria, visited Chicago Wednesday.

H. K. Gilman, general manager of the Western Electrical Supply company, St. Louis, was a Chicago visitor early in the week.

Mr. Francis Raymond has opened an office in St. Louis for the Martin J. Insull company and will sell electrical appliances and machinery.

Dr. Nicholson, professor of mechanical engineering at McGill University, Montreal, has resigned to become the head of the mechanical and electrical engineering departments at the municipal technical school now being established at Manchester, England. In his new field Dr. Nicholson will be called upon to devote himself largely to developing new lines of research in practical engineering, with special reference to industrial experiments. This will be an attempt to rival the German technical schools, which have played so great a part in the industrial development of that country.

Two presentations were recently made to Mr. C. L. Oechsner on the occasion of his leaving the General Electric company for a better position with the British Thomson-Houston company in London. The first of these consisted of a fine gold chain and traveling case by Mr. J. G. Barry, on behalf of Mr. Oechsner's colleagues in the Schenectady works. The second was made by the grand high priest of the St. George Chapter (Schenectady) Royal Arch Masons, in which body Mr. Oechsner has been a high priest. This consisted of a beautiful ruby and diamond Knight Templar's jewel. Mr. Oechsner joined the Thomson-Houston company 11 years ago, and was for some years assistant to the late Charles J. Van Depoele. After the Thomson-Houston company was absorbed in the General Electric company, he became drafting inspector in the engineering department of the latter company, and has since filled that position. He has many friends in Schenectady, both in and out of the works, who wish him luck in his promotion.

James W. Plaisted of Portland, Me., celebrated his 65th birthday and the 50th anniversary of his connection with telegraphy on March 31st. The double event was commemorated by a reception and a banquet. Mr. Plaisted in the course of his reply to the congratulations of his friends said: "There have been many changes in the business during my connection with it. There are now 31 wires between Portland and Boston, and I intend to run two more copper wires between these points during the coming summer. Fifty years ago there were no telegraph lines east of Portland, but one was built the year after I entered the employ of F. O. J. Smith between this city and Bangor. I have constructed the telegraph lines on every railroad in the state of Maine. Another thing which I am quite proud of is the fact that I ran the first telephone line in the United States from the place of business of Charles F. Williams on Sudbury street, Boston, to his residence in Somerville. I also ran the first telephone lines in Portland, Lynn, Lawrence and Bangor. I am not so young as I used to be, but I guess I will build quite a number of lines yet."

ELECTRIC LIGHTING.

Avondale, Ala., is considering a bond issue for water works and an electric-light plant.

The new Langhans filament for electric lamps, which is being introduced by an English syndicate, is said to be composed of silicon and carbon. It is not yet known whether these elements unite to form a carbide, or are merely in intimate mechanical contact. The efficiency of the Langhans filament is said to be somewhat below that of the Nernst

lamp, but it may be that improvements will bring it up to a higher point.

The Wilcox Lighting, Plumbing and Ice company will establish an electric-light plant in Wilcox, Ariz. The direct-current, low-tension, three-wire system will be used. All machinery has been ordered, and it is expected that the plant will be in operation by June 1st.

An adverse report from the committee to which was referred the proposition that Massachusetts towns and cities be empowered to absorb local gas and electric-light plants was rejected by the Legislature, and the bill favoring such authorization has been placed on the calendar.

The electric-light plant and water power at Petersburg, Va., has been purchased from the Upper Appomattox company by John L. Williams of Richmond, Middendorf, Oliver & Co. of Baltimore, Md., and associates. It is the purpose of the purchasers to furnish light and power.

The San Francisco Chronicle says that Claus Spreckels has decided to establish in that city an electric plant that will be without a rival in the world, and which will furnish to the people of San Francisco light, heat and power almost at cost. In accordance with his plans articles of incorporation of the Independent Electric Light and Power company, with a capital of \$10,000,000, have been filed with the county clerk. The directors for the first year are Claus Spreckels, John S. Spreckels, Adolph B. Spreckels, Charles E. Hume and W. K. Gibson. It is understood that Claus Spreckels will be chosen president of the company, and that it will also enter the telephone business.

ELECTRIC RAILWAYS.

T. W. Pratt of Huntsville, Ala., is interested in a project to build about five miles of electric railway in that town.

The City Council of San Diego, Cal., has passed the ordinance authorizing the San Diego, Pacific Beach and La Jolla Railway company to use electricity as a motive power in propelling cars on its road.

The Kansas City-Leavenworth Railway company (capital \$1,000,000) has been chartered under the laws of Kansas to build an electric line from Kansas City, Kan., to Leavenworth, Kan., a distance of 26 miles.

An ordinance has been adopted authorizing the San Diego (Cal.), Old Town and Pacific Beach Railroad company to use electricity as a motive power for propelling cars on its railroad in the city of San Diego.

The Dallas (Texas) Consolidated Electric Street Railway company has announced the sale of the property to a syndicate of Des Moines capitalists, the principal members being G. Van Ginkel, I. M. Earle and P. H. Bousquet. The sale was consummated on a basis of \$900,000.

A certificate by the Auburn Interurban Electric Railroad company has been filed for an extension of 16.2-3 miles from the present end of the line in the village of Skaneateles, N. Y., through the towns of Onondaga, Geddes, Camillus, Marcellus and Skaneateles, all in the county of Onondaga, to connect with lines to Syracuse.

The Cedar Falls and Normal Railway company has been incorporated in Iowa, with a capital stock of \$25,000, to build about 25 miles of electric railroad in the city of Cedar Falls and in the counties of Black Hawk, Grundy and other adjacent counties. The incorporators are C. W. McElyea, Sarah McElyea and Jennie E. Beyer, all of Nevada, Storey County, Ia.

For years the Alley "L" road in Chicago was unable to pay operating expenses and fixed charges. But electrical operation and connection with the Union Loop have put another aspect on its affairs, and the South Side Elevated Railroad company, which owns it, has declared its first dividend at the rate of three per cent. per annum. The dividend will be paid for the first four months of the year on May 1st.

By the consolidation of the various street railroads in Charleston, S. C., under the Charleston Consolidated Railway, Gas and Electric company, it is planned to use only one power house. Either the Sullivan Island power house of the Charleston and Seashore railroad or the power house of the City Railway company will be enlarged to supply sufficient power for the whole system, or a new plant will be built.

A Chicago paper chronicles this curious accident: A Division street electric-car hurled a load of hay against a city fire-alarm box at Grand avenue and Halsted street, and set off the apparatus inside. When the engines came the firemen extricated Christian Thiele, a much surprised farmer from Proviso, from his load. The wagon was righted, and Thiele, both of whose wrists had been broken, was taken to the home of friends.

The North Jersey Street Railway company, which recently obtained control of all the electric lines in Northern New Jersey except the North Hudson County railway, has completed arrangements for leasing that company's lines. The terms will not be made known for a few days. The North Hudson company operates all the lines in Hoboken, West

Hoboken, Union Hill and the townships in the northern part of the county.

It is said that contracts for building and equipping the New Orleans and Jefferson railroad have been let to the International Traction company of Detroit. The work calls for an expenditure of nearly \$225,000. The road will be 8½ miles long and will connect at Atlantic avenue with the New Orleans and Carrollton lines. A double track will be built on Napoleon avenue to the city limits, and single track to Lake City. The time for completing the road was recently extended by the City Council.

State Treasurer E. P. Shaw, who is interested to a large extent in street-railway companies, was the purchaser, for his syndicate, of the Newburyport and Amesbury Railroad company's system, which was sold out at auction on March 28th, by order of the United States Court. The price paid was \$100,000. There were several bidders, among them being the Haverhill and Lawrence Street Railway company, the Lynn and Boston and the Quincy and Boston companies. The road was bonded for more than \$270,000.

The Waupaca (Wis.) Electric Light and Railway company will build five miles of electric railroad between the city of Waupaca and the Wisconsin Veterans' Home and Chain o' Lakes. Grading is nearly completed. The proposed equipment for this road is two open motor cars and two open trailer cars, and one closed baggage car, for which bids will probably be asked May 1st. The president of the company is Irving P. Lord of Waupaca. Electricity for operating this road is to be secured by water power.

J. C. Short of New York and associates have secured a franchise from the Board of Supervisors of Chesterfield County for the construction and operation of an electric-railway line from Richmond to Petersburg, Va. The line will be built on the roadway of the old Petersburg turnpike, will be 22 miles in length, and will be for passenger and freight business. Work is to begin in 30 days and be completed in one year. The property-owners from Richmond to Petersburg united in asking that the privilege be granted, and the board's action was unanimous.

The Boston Elevated Railway company has purchased the valuable property on the water-front in Boston known as Lincoln's wharf. It is on Commercial street, near the point at which the proposed tunnel to East Boston will begin to decline to run under the harbor. The property comprises upward of 100,000 square feet of area, part solid ground and part pile structure above the water. The buildings thereon are of small value, being old and mainly of wood, but the estate is valued at nearly \$300,000. The railway company will demolish the old structures and erect a fine power house in their place, very much like the present large one on Albany street. There will be a fuel depot here also, the wharf facilities enabling the company to receive its coal by water at this point. Plans are not completed yet for the new station, but will soon be ready, with specifications for construction and equipment.

ELECTRIC VEHICLES.

The General Electric Automobile company, having its head offices in Philadelphia, Pa., makes the following announcement: This company, controlling basic patents covering the application of electrical power to independently operate vehicles of all descriptions, is now receiving orders for the prompt delivery of "horseless" conveyances of the latest and most approved types. Its specialty is the lightness of its apparatus, with storage battery one-half the weight of other makes and of greater efficiency.

It is announced that the officers of the New England Electric Vehicle Transportation company, recently incorporated in New Jersey, with the intention of operating in Boston and other New England cities, as one of the sub-companies of the Electric Vehicle company of New York, have been decided upon as follows: President, George von L. Meyer, "ex-speaker of the Massachusetts House of Representatives; vice-president, Charles L. Edgar, of the Edison Electric Illuminating company; treasurer, Thomas K. Cummins, Jr., of the Old Colony Trust company. Of the \$25,000,000 capital stock authorized, \$15,000,000 has been offered at private subscription and taken. Five per cent. was payable March 31st, and five per cent. more will be payable June 15th. The cabs, it is estimated, will cost about \$3,000 each, and 100 have been ordered for Boston and 100 for Newport.

The Chicago Electric Vehicle company was incorporated under the laws of Illinois on April 4th, with a capital of \$2,000,000. The incorporators are Edward L. Brewster, Samuel Insull and William G. Beale. "It is our purpose to run a line of electric cabs in Chicago," said Mr. Brewster recently. "Mr. Insull and I are associated in the Chicago Edison company, and we for some time have thought a line of electric cabs would be a good venture here. So we have got up this company. Our plans are not reduced to working details yet, but we probably shall put out after awhile about 100 cabs. They will be high vehicles, splendidly built, and will be on the type of a sample cab made by the Fischer Equipment company of Chicago, and that has been in service in our streets recently. I cannot say just now who will

be in the company with us, but although our papers of incorporation have just been filed, we have had applications for purchases of stock already. The cab service here is not what it should be. The type of vehicles we expect to put out already is in successful operation in Paris, and we expect to succeed well here."

INDUSTRIAL COMBINATIONS.

Articles of incorporation were filed at Trenton, N. J., on March 27th of the Consolidated Street Car company, with a capital of \$18,000,000, the incorporators being William P. Chapman, Jr., New York; A. G. Ridley, Brooklyn, and Francis D. Pollak, Jersey City. The objects of the company are stated to be to engage in and carry on the business of manufacturing street-railway cars, automobiles, omnibuses and other vehicles for conveyance of passengers, freight or express railroad rolling stock and its equipments. The New York Tribune states that this company is a consolidation of a number of the most important street-car manufacturing companies of the country. The capital consists of \$8,000,000 of seven per cent. cumulative stock and \$10,000,000 common stock.

Negotiations for the consolidation of all the street-railway and electric-light companies of Washington, except the Capitol Traction company, have been consummated, according to press reports, and the stocks of the various properties are now being transferred to the syndicate. The Baltimore Trust and Guarantee company and the United States Mortgage and Trust company of New York conducted the negotiations, and are largely interested in the purchasing syndicate. The details of the deal have not been made public, though it is understood that an issue of five per cent. bonds, amounting to \$11,000,000, will shortly be offered for public subscription. There will also be an issue of stock. The total issue of bonds will be \$20,000,000, though there will be a sufficient amount reserved in the treasury to protect underlying liens and for betterments.

An official circular, signed by W. K. Bixby, president of the American Car and Foundry company, states that the constituent companies are the Michigan-Penninsular Car company, Detroit, Mich.; Jackson & Woodin Manufacturing company, Berwick, Pa.; Missouri Car and Foundry company, St. Louis, Mo.; Ohio Falls Car Manufacturing company, Jeffersonville, Ind.; Union Car company, Buffalo, N. Y.; St. Charles Car company, St. Charles, Mo.; the Wells & French company, Chicago, Ill.; Terre Haute Car and Manufacturing company, Terre Haute, Ind.; Buffalo Car Manufacturing company, Buffalo, N. Y.; Niagara Car Wheel company, Buffalo, N. Y.; Ensign Manufacturing company, Huntington, W. Va.; Murray, Dougal & Co., Milton, Pa.; Minerva Car company, Minerva, O. The total annual capacity of the American Car and Foundry company is said to be: Passenger, 500 cars; freight, 90,000 cars; wheels, 900,000; pipe, 300,000 tons; bar iron and axles, 90,000 tons, and castings, 130,000 tons.

ELECTRICAL SECURITIES.

The Mexican Telegraph company has declared a dividend of 2½ per cent., and the Central South American Telegraph company has declared a dividend of 1½ per cent. for the first three months of the year. These companies, as is well known, are closely identified with American exporters engaged in Central and South American trade, and they have proved valuable adjuncts to this business, as well as good investments.

TECHNICAL SCHOOLS.

The annual catalogue of the Massachusetts Institute of Technology of Boston for the school year of 1898-1899 may be had on application to H. W. Tyler, 491 Boylston street, Boston. The number of students now in the institution is 1,171 and the number of graduates is 1,961. The catalogue is a volume of 347 pages, and gives very full information about the school.

The second annual dinner of the Civil Engineering Society of the Massachusetts Institute of Technology was held on March 31st at the United States Hotel in Boston, over 70 members being present. President Herbert H. Starr, '99, presided, and the guests included Professors G. F. Swain, Dwight Porter, C. Frank Allen, A. E. Burton, A. G. Robbins and P. McKibben, Bernard Herman, '99, was toastmaster.

Mr. W. N. Gray, electrical engineer and contractor of Minneapolis, lectured to the students of the College of Engineering of the University of Minnesota March 14th upon "Gasoline Engines for Small Electric-light Plants." His experience leads him to prefer the "hit-and-miss" type rather than those that take an explosion at every stroke. The engine is still capable of being improved, the main journals being generally too small to carry the weight of the large balance wheels without risk of sudden and serious "hot boxes." The best field for gasoline engines is in remote places, where transportation is so expensive that gasoline can easily compete with more bulky and heavy fuels. The control of the gasoline market by a trust is the principal source of uncertainty in the use of such fuel. Mr. Channing T. Gage of the American Steel and Wire company lectured on March 23d upon "The Manufacture of

Copper Wire," describing the interesting process of mining and reducing the ore, following the copper through the ingot to the rod and the wire. Professor Morgan Brooks of the University of Nebraska lectured on March 30th upon "Finance and Engineering," showing how the reduced rates of interest now current are affecting the engineering industries. He said that the lower cost of money enables works to be undertaken that promise only a comparatively low but sure return. Mr. J. T. Fanning, hydraulic and consulting engineer of Minneapolis, will soon lecture upon the "History and Development of Water Power." On April 28th Mr. Walter E. Snow of the Sturtevant Blower company, Boston, will lecture upon the "Influence of Mechanical Draft upon the Ultimate Efficiency of Steam Boilers."

MISCELLANEOUS.

A dispatch from Zurich, Switzerland, states that the first stretch-car on the continent to be propelled by means of liquid air was tested in Zurich on April 2d. If the reports of the experts are satisfactory, it is said that the city will remodel the entire municipal traction system so as to employ the new motive force.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals, until April 11th, for furnishing the New York navy yard with a quantity of insulating tape and electric lamps. Intending bidders can obtain specifications upon application to the Navy Pay Office at New York, or to the bureau at Washington.

Among the exports declared from foreign countries to the United States for the quarter ended December 31, 1898, were the following items: Vienna, Austria, carbons, \$4,732.12; Palmerston, Canada, telephone poles, \$126.95; Cologne, Germany, detonators, \$1,938.13; Nuremberg, Germany, carbons for arc lamps, \$14,986.96; Rome, Italy, electric instruments, \$739.05.

The City Wastes Disposal company, which is organized for the purpose of constructing and maintaining works for the disposal of waste material and the building of docks, piers, canals, reservoirs, tunnels, bridges and gas, electric-light and water plants, has been incorporated. The capital stock is \$150,000, of which \$2,500 is paid in. William Lee Church, Frederick W. Garvin and Oscar L. Lefferts are the incorporators. The principal office in New Jersey will be in East Orange.

The Treasury Department is inviting sealed proposals until April 15th for manufacturing and placing in position in complete working order in the United States public buildings at Akron, Ohio, and St. Albans, Vt., combination gas and electric-light fixtures. Bids will also be received until April 12th for similar work in the public building at Pottsville, Pa. Drawings, specifications and blank forms of proposal can be obtained upon application to H. A. Taylor, assistant secretary of the treasury, Washington, D. C.

"The latest invention is a pipe line made of glass," says the Bradford Era. "The glass manufacturing firm whose plant is located at Port Allegany, near Bradford, Pa., is preparing to make glass tubes that can be used for sending oil or gas across the country, for carrying off sewage, supplying cities with water, etc. The glass pipe does not corrode, it is impervious to electrolysis in underground conduits, and, it is claimed, is less likely to leak than iron pipe. An Ohio company is now putting in such a pipe line, and a practical test of the system will soon be possible for a distance of one hundred miles."

The small magnetic pavilion set up in Greenwich Park, at a distance of 300 or 400 yards from the Greenwich Observatory, near London, is now complete. This little scientific outpost was found necessary in consequence of the disturbing effect upon the instruments of the large amount of iron which enters into the composition of the new observatory building, which is now also complete. The observatory officials have also placed in the park a declination magnet, a dip instrument for the inclination of the needle and a deflection instrument, besides thermometers, which the new buildings had shut in rather too closely.

TRADE NEWS.

Owing to great increase in business, the Cutler-Hammer Manufacturing company of Chicago has been obliged to increase its capital stock from \$50,000 to \$100,000.

All central stations have a greater or less demand for fixtures. The Western Electric company has a suitable assortment of reasonable-priced electric portables, brackets and fixtures to meet this demand.

The plant, business and patents of the Armorie Interior Conduit company of Pittsburg have been sold to the Safety Conduit company of Rankin, Pa., and the capital of the latter concern will be increased to \$250,000. The output of the plant at Rankin will be largely increased, and is expected to reach 50,000 feet of conduit a day.

The Swett & Lewis company, 11 Bronfield street, Boston, has purchased the business and good-will of the American Roentgen Ray company of Boston. It is prepared to furnish immediately anything in

the line of (1) tube machine parts and (2) X-ray tubes, fluoroscopes, spark gap tube tards, etc., as well as everything in the line of electrical apparatus.

The factory of the Haydenville company at Haydenville, Mass., for the production of brass and iron goods, for steam, water, gas and electricity, has passed into the hands of Cyster K. Sanborn of Brooklyn, N. Y., C. J. and A. S. Hill of Springfield, Mass., will be associated with Mr. Sanborn, and will remain at the factory, while Mr. Sanborn manages the New York end of the business.

W. M. Smith, the secretary and treasurer of the Chicago Insulated Wire company, has just returned from a trip through the Southwest in the interests of his company. Mr. Smith is more than pleased with his trip, as it resulted in adding a fine batch of orders to the company's already large list. The Chicago Insulated Wire company is doing a large business in its special line, and is well pleased with the outlook.

At a meeting of the board of directors of the Pratt & Whitney company, held at Hartford, Conn., March 24th the following-named officers were elected: President, Amos Whitney; vice-president, Rowland Swift, secretary, Roswell F. Blodgett, and treasurer, J. C. Stirling. The office of the second vice-president, lately held by George W. M. Reed, was not filled. The treasurer's report showed that the sales for the past year amounted to \$1,315,603.10, a net profit for the year of \$82,940.71. T. J. Nicholl of Rochester is the new managing director, taking the place of Gen. H. J. Morse of New York.

The Phoenix Battery Manufacturing company, recently incorporated in St. Louis, with a capital stock of \$250,000, one-half paid, is the successor of the Phoenix Carbon Manufacturing company. The latter company some time ago sold to the National Carbon company the department which manufactured carbon for electric lighting. It retained its battery manufacturing and other departments, and it was decided to reorganize the company and incorporate under a new name. The stockholders in the company are S. M. Dodd, J. C. Van Blarcom, James Campbell, Allen T. West, Albert Blair, S. B. Pike, S. G. Pooser and J. C. Van Blarcom, trustee.

The following description of the junction boxes manufactured by Johnson & Morton, Utica, N. Y., may be of interest to the trade: The tablet board containing all the switches and connections of the box is removable and can be placed in the box after all wiring is installed and after the interior finishing in the building is complete, thus preventing any possibility of damage to the finish of the visible parts of the box. As the junction box is the only part of a concealed-wiring installation which shows, this point is a great advantage. The concealed-wiring pocket allows the wires to be brought in through the back, top, bottom or sides of the box, as may be most convenient, making the boxes standard, independent of location of outlets. All branch circuits are supplied with detachable fuse-holders, consisting of an insulating bar with heavy copper ends which make sliding contact in substantial jaws. The use of this fuse-holder enables fuses to be replaced while current is on the box without danger of short circuits. Boxes are made standard width, regardless of the number of circuits, and are so designed that they will fit between the uprights in ordinary wooden buildings without any cutting. All copper work is highly polished and lacquered, the slate is enameled, baked and polished after all drilling is completed, and the woodwork is highly finished by hand. The boxes are easily installed and connected up, and have received the approval of the National Board of Underwriters.

BUSINESS.

The Thermo-electric company of New York reports a large call for Harrison primary cells, for which it has closed contracts for several thousand in California and the West.

The Western Electric company, Chicago, carries in stock alternating-current Stanley motors for any voltage and any frequency from one-quarter horse power up to horse power, and transformers from too-light capacity up to 300-light capacity.

The F. & L. flush push switch, which has been on the market for several years in the single-pole type, has been very successful. It is gratifying, therefore, to the Electric Appliance company, which is placing this specially on the market, to be able to announce that the double-pole and three-way styles are now ready, and that they possess the same merits of successful operation which have done so much to make the single-pole switch popular.

The Montauk Multiphase Cable company of New York is just in receipt of a large additional order from Melbourne, Australia, for its fire-detecting cable. A remarkable feature in connection with this cable is that at this long distance from the point of manufacture, subject to rough usage in transportation, it at once proved its superiority in all ways for the purposes designed. It was subjected to practical tests, calling out the fire brigade in ample time for the suppression of fire, receiving the indorsement of Chief Stein, and subsequently receiv-

ing the approval of the builders and architects of Melbourne.

Charles M. Eddy, secretary and treasurer of the Dearborn Drug and Chemical Works, Chicago, manufacturers of the well-known Dearborn compounds, reports a flourishing business. The products of the Dearborn company are well known all over the country, and are said to be in great demand. The success of the Dearborn company is due, in no small measure, to the energy displayed by President W. H. Edgar and Mr. Eddy.

The Chicago Fuse Wire and Manufacturing company announces a steady and increasing demand for its trade-mark line of tested fuse wire and links and says that its new method of packing in tin boxes has become very popular, alike with the dealer and

consumer, as it keeps the wire practically air-tight and insures against any possible danger in handling the stock. Conforming to the National Underwriters' rules, this company is placing its trade-mark on each fuse-link terminal, and it states that in this branch of the business it has also made great improvements, enhancing the appearance and accuracy of the goods. By a special improved process the company is able to reduce the cost of making and thus offset the recent advanced cost of material.

The new "99" model Emerson alternating-current fan motor promises to be very favorably received by the public this season, as it has in the past. In accordance with the policy of the maker of this motor, it is being rapidly improved in every conceivable manner, as time and usage suggest, to keep it in

the front rank. One of the novel and important improvements, among the many new features of the "99" model, is the new design of the blade, which is entirely different from anything heretofore presented in the fan-motor industry. The blade of the Emerson fan is so designed that while the speed and breeze thrown out are in no manner diminished, as is claimed, the noise of the blade cutting the air is decreased to such an extent as to be hardly noticeable. The Emerson alternating fan is being extensively handled this season by the Western Electrical Supply company of St. Louis, Mo., which, as usual, is keeping pace with the times and supplying the trade with an article of unusual merit. The Western Electrical Supply company is also meeting with large sales on the Paragon direct-current desk and ceiling fan motors, which it handled so successfully last season.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued March 28, 1899.

621,778. Electric-lighting Gas-burner. John M. Anck, Philadelphia, Pa. Application filed March 24, 1898.

An electric-lighting gas burner consists of a body with a fixed electrode thereon, an electrode lever mounted on the burner, a member secured to the lever, insulation between the member and lever, an electrode secured to the member, a secondary lever pivotally supported and normally out of contact with the electrode member, but adapted to contact therewith when the circuit is closed and means provided for retaining the secondary lever out of contact with the electrode member.

621,807. Insulating Compound. Bruce Ford, Johnstown, Pa. Application filed January 12, 1898.

An insulating compound permanently liquid at normal temperatures is composed of a mixture of a solid asphaltic substance and an oil and having a specific gravity greater than that of water.

621,827. System of Electrical Distribution. Walter H. Knight, New York, N. Y. Application filed March 18, 1898.

This method of changing the phase of an alternating current consists in rectifying and delivering it to a storage battery and deriving from the storage battery a number of simultaneous impulses corresponding to the phase desired, the impulses varying successively and alternately.

621,848. Electric Railway. Harry C. Reagan, Jr., Philadelphia, Pa. Application filed January 8, 1896.

It is proposed to utilize a transformer, a rectifier, a direct-current motor, an alternating-current motor operating to propel the car, a battery, conductors leading from the transformer to the rectifier, conductors connecting the rectifier with the direct-current motor, conductors leading from the transformer to the alternating-current motor, conductors leading from the rectifier to the battery and devices for controlling the conductors.

621,854. Electric Hose Signal System. Howard Sargent, Cambridge, Mass. Application filed January 21, 1898.

The last claim is given: In an electric-hose signal system a line of hose having a nozzle, couplings and circuit wires along its length, and a terminal coupling, each line coupling adapted to connect the circuit wires as the hose sections are joined, and the terminal coupling comprising a body portion or shell attached to and carried by the hose, an inner insulated ring carried by said body or shell, said shell and the insulated ring constituting the terminals of the electric circuit, a double screw-threaded coupling ring of insulating material fitted to the shell and adapted to fit a nipple on the engine, a source of current and a signal connected through the shell and ring to the circuit-wires, and a suitable circuit-closer.

621,855. Electric Arc Lamp. Ruper Schefbauer, Jersey City, N. J. Application filed March 11, 1898.

In an electric arc lamp there is described the combination with the uprights of a lamp frame, a cross-piece mounted to move up and down on the uprights, a neck on the under side of the cross-piece, a socket formed on the upper side of the cross-piece, a packing washer in the socket, through which packing washer the upper carbon passes, springs for pressing the cross-piece downward, a socket at the bottom of the lamp frame, a washer in the socket, a glass globe located between the uprights of the frame, and having its lower open end resting on the washer in the bottom socket, the upper end of the globe being within the neck, on the under side of the movable cross-piece on the uprights.

621,863. Printing Telegraph. Sylvester J. Small, Seattle, Wash. Application filed November 13, 1897.

A system of telegraphing comprising a transmitter, constructed and arranged to transmit electrical impulses varying in length with each different letter, but always the same length for the same letter, a cutting mechanism whose operation corresponds with the impulses so transmitted and a printing mechanism operating at intervals corresponding with the impulses of the transmitter and the operations of the cutting device.

621,876. Electric Arc Lamp. Ernest P. Warner, Chicago, Ill. Application filed December 31, 1897.

Magnetic bodies surround the arc at such distances that the disturbing effect upon the arc of each magnetic body will be neutralized by the effects of the remaining magnetic bodies, whereby substantially symmetrical burning away of the ends of the carbons is secured.

621,907. Electrolytic Cell. Herbert H. Dow, Midland, Mich. Application filed March 5, 1897.

In electrolytic apparatus it is proposed to use an outer receptacle containing a liquid divided into two electrically insulated portions, and an inner cell covered by the liquid and having one electrode passing through each portion of the liquid.

621,968. Porous Diaphragm for Electrolytic Cells and Method of Producing Same. Herbert H. Dow, Midland, Mich. Application filed September 19, 1898.

An improved method of forming the porous diaphragm in electrolytic cells consists in slowly precipitating by

drates capable of readily combining with halogens, by the action of soluble alkali (as the latter is formed in the cell) by electrolysis on a soluble alkaline earth salt, and the subsequent precipitation of another metallic hydrate substantially inert to halogens, by part of the alkaline-earth hydrate first precipitated, the method being carried out with solutions of such composition that a coherent diaphragm is formed in place.

621,924. Means for Speed Reduction of Asynchronous Alternating Motors. Karl E. F. Knauth, Charlottenburg, Germany. Application filed January 6, 1896.

The method described of changing the speed of alternating-current motors consists in changing the character of the currents in the induced windings from pluriphase to single-phase to cause the motor to rotate at near half-synchronous speed.

NO. 621,908.

621,963. Electric Action for Musical Instruments. William B. Fleming, Detroit, Mich. Application filed December 30, 1897.

A music sheet is provided with two series of perforations to regulate the travel of the sheet, one perforation of each pair being elongated; electric contacts are arranged to be closed through the perforations, and an electric contact may be closed through the elongated perforations in advance of an electric contact being made through the other corresponding perforations.

621,976. Overload Safety Device for Electric Circuits. Lewis G. Rowand, Camden, N. J. Application filed December 24, 1897.

An overload safety device for an electric circuit consisting essentially of an electric device in series with the circuit, having a movable member, the electric device being normally inactive, an electric device in shunt with the circuit, having a movable member, a switch upon the main circuit controlled in whole or in part by the movable member of the shunt electric device, the shunt electric device being controlled by the movable member of the series electrical device and adapted to become active when the series electric device becomes active.

NO. 622,087.

621,984. Trolley-catcher. Oliver W. Whitehead, Dayton, Ohio. Application filed July 18, 1898.

In a trolley catcher there is the combination with a spool upon which the trolley rope is wound of a spring controlling the spool to keep the trolley rope taut, and a spring of greater strength to control the spool to draw down the trolley when the latter leaves the wire, mechanism for placing the spool under the control of the stronger spring, and an enlargement on the trolley rope adapted to actuate the mechanism when the trolley rope is drawn from the spool by the trolley when the latter leaves the wire.

622,075. Protective Fuse. Emil B. W. Reichel, Berlin, Germany. Application filed September 29, 1898.

The fuse is connected between terminals, a base supporting the terminals, a slide engaging the fuse, a cover for protecting the fuse parts, a spring carried by the cover adapted when the cover is in place to engage the slide and exert thereon pressure, and an inclosing receptacle carried

by the cover containing a portion of the spring, another portion of the spring extending through the receptacle and engaging the slide.

622,078. Means for Generating Electricity from Machinery of Locomotives. Harry F. Roach, St. Louis, Mo. Application filed January 23, 1899.

The mechanism described for rotating the armature of a dynamo mounted on the main framing of a locomotive, comprises the following elements in combination: A dynamo, a crank shaft for driving the armature of the dynamo, a link connected to the crank shaft, a bracket mounted on the main framing of the locomotive and formed with guideways, a cross-head mounted in the guideways to which the link is connected, a rock shaft mounted in the bracket and provided with a rock arm, links connecting the rock arm and the cross-head, a main rock arm mounted on the end of the rock shaft, the cross-head proper of the locomotive, and a link connection between the cross-head and rock arm.

622,087. Filament for Incandescence Electric Lamps. Charles H. Stearn, London, England. Application filed August 11, 1898.

The process of treating a solution of cellulose known as "viscose" for the manufacture of filaments for incandescent electric lamps and similar bodies consists in first agitating and filtering the solution, and then projecting it from an orifice of suitable shape into a precipitating solution.

622,116. Electric Switch. Max H. Caspari, New York, N. Y. Application filed February 25, 1898.

An electric switch comprising a horizontally disposed casing, a line terminal passing through the lower part of the casing, a second insulated terminal entering the casing at a higher elevation than the first one, and an extension of the casing hinged thereto and adapted to be raised above or also below the main casing, the two being connected through the hinge and being partially filled with a conducting liquid.

622,124. Secondary Battery. Walter A. Crowder, Chicago, Ill. Application filed June 8, 1898.

A supporting plate or grid with its complementary active material, a flexible porous envelope arranged in a thin sheet and surrounding the plate, and a perforated separator composed of a sheet of porous material arranged to fill the space between the elements and hold the flexible envelope in contact with the plate, are combined.

622,144. Electric Propulsion of Railroad Tramway, or Other Similar Vehicles. Jean J. Heilmann, Paris, France. Application filed September 21, 1898.

In an electric locomotive there is the combination with an axle and its axle boxes of a truck frame having pedestals to receive the boxes and provided with perforated lugs notched in their under sides, springs resting on the boxes, hangers attached to the springs and passing through the lugs, and collars on the hangers having ribs to enter the notches in the lugs.

622,151. Electric Incandescent Lamp. Charles Howard, London, England. Application filed May 7, 1898.

This lamp has an elongated neck, projections on the neck, a cap having notches or gaps to receive the projections, a wire extending around the lower edge of the cap below such projections, and turned-up corners on such edge to engage the wire.

622,177. Electrical Knob. Cornelius M. Brown, Newark, N. J., assignor of one-half to George Watts, Plainfield, N. J. Application filed February 26, 1898.

The improved knob for doors has a chambered body with a front and a side opening, a sliding front-plate receptacle recessed and perforated, an electric push-button with its forward end projecting through the perforation and resting against the rear side of a front transparent plate, the transparent plate and electrical devices acted on by the push-button, the plate or plates adapted to be removed or interchanged and be pressed backward and drawn outward at the side opening of the chamber.

622,186. Railway Advertising Apparatus. Charles J. Feder, Paterson, N. J. Application filed December 28, 1898.

The advertising apparatus is carried by the car and consists of a revoluble sign, an adjustably mounted electromagnet or magnets, an electric circuit including the magnets, and a revolving member of the running gear of the car, the member constituting a circuit-making-and-breaking device, an armature lever, an armature adjustably mounted on the armature lever and controlled by the magnets, and operative connecting means between the armature lever and the sign.

622,188. Keyless Switch-socket for Incandescent Lamps. Max Meyberg, Los Angeles, Cal. Application filed November 14, 1898.

In a lamp socket there is the combination with a plate of a cap-piece thereon, the lower edge of which is turned outward, a sleeve over the cap-piece, the upper edge of which is turned inward, and screws through the cap-piece into the plate above the edge of the sleeve.

Western Electrician

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, APRIL 15, 1899.

No. 15

Patton Automobile Truck.

The automobile truck illustrated on this and the next page is interesting from its large size, and from the fact that it is electrically operated and yet self-contained, generating its own power. It was built for the Patton Motor company by the Fischer Equipment company, and has seen considerable service on Chicago streets. It illustrates the Patton electric-motor system, which W. H. Patton of Chicago has been exploiting, more particularly for railway operation, for the last nine years. Mr. Patton's idea is to use a combination of gas or gasoline engine, electric generator, electric motors and storage battery on each motor-car or other transportation unit. This naturally seems a cumbersome and un-

and under all conditions, and also to reinforce such engine with the necessary flexibility of power."

As shown by the pictures, the truck is very substantially built for heavy work. It is 12 feet long, 5½ feet wide and weighs, with machinery but without load, about 3½ tons. It carries loads of two or three tons without difficulty. The wheels turn on ball bearings and have iron tires ¾ inches wide, although solid rubber tires are to be substituted. Frame, springs and all parts of the wagon are of exceptional strength and solidity.

Power is obtained from a three-cylinder gasoline engine, made by the American Motor company, direct-connected to an eight-kilowatt, 125-volt, six-pole Crocker-Wheeler dynamo. This set, placed

partly from the wagon body, drive the rear wheels (one for each wheel) through double-reduction gearing. Two band brakes are supplied, one for each motor shaft. These brakes are actuated by foot pressure exerted at the driver's seat and are of sufficient power to control the movement of the wagon with perfect safety. The storage battery consists of 55 Willard cells of 120 ampere-hours' capacity each. It is placed in a box built under the wagon, between the front and rear axles and behind the engine. The steering gear is clearly shown in Fig. 2. It consists of a large hand-wheel mounted on a shaft having a pinion engaging in a rack attached by steering knuckles to the hubs of the front wheels.

The controller for the motors is upright and iron-

FIG. 1. PATTON AUTOMOBILE TRUCK.

necessary method of transmitting power, but Mr. Patton says that he unites the economy of the gas engine at steady average load with the flexibility of the electric system, and that the combination shows a satisfactory efficiency with all the advantages of self-contained units. Mr. Patton argues as follows: "The gas engine of itself has not the necessary flexibility of power, and would not work under such conditions with any degree of economy, for it is a well-known fact that these engines must work at about normal load to give good results, and that any great overload is refused by their stopping; and it is also a well-known fact that in overcoming train inertia nearly twice the power is demanded over that required to maintain ordinary momentum, as it is also a well-known fact that on varying grades and conditions the power demanded of the engine often runs far below its normal capacity. Knowing these facts by actual experience with gas engines, the Patton electric-motor system was designed with the purpose of balancing up the load for the engine so that it might have a constant load factor at all times

lengthwise of the wagon, is installed well forward in the truck and under the level of the wagon seat. It is partly above and partly below the floor of the wagon box. The dynamo is attached to one end of the engine shaft and a moderate-sized flywheel to the other. The engine and dynamo turn at 500 revolutions per minute. The cylinders are upright. The generating unit is shown clearly in Fig. 2 on the next page, the front panel of the wagon box being lifted up for the purpose. Electric ignition is used, the coil being actuated by current from the storage cells. The water tank for the gasoline engine is under the engine and directly in front of the battery tray, shown depending from the middle of the wagon in Fig. 1. A small pump connected with the engine circulates the water through the tank and many feet of brass piping on the outside of the sideboards above the wagon box and the foot-board of the driver, by which means the water is cooled. The gasoline tank, with a capacity of 15 gallons, is under the seat.

Two four-pole motors, said to be of 7½ horse power each, suspended partly on the rear axle and

clad, like the controller of an electric-railway car. It is placed in front of the driver's seat, as shown in the pictures. It is arranged for three speeds—three, six and eight miles an hour. Back of the controller, on the seat, is the reversing switch. A starting box is placed under the seat on one side. This is used in starting the gasoline engine, when the dynamo is run as a motor by the battery current until the engine runs by its own power, and the speed becomes sufficient to reverse the conditions.

The controller, dynamo and batteries are connected in multiple, so that the dynamo is driven at a nearly constant load, the current being taken by motors or batteries as the demand of the load varies. When the load is light the surplus goes into the batteries, and when there is a heavy demand for power the battery adds to the capacity of the dynamo.

Some tests of the performance of this truck have been made, but they are not available for publication. It is said that the engines take about 1¼ gallons of gasoline an hour, but exact data of speed and load vary greatly according to the pavement and have not been tabulated.

Detroit Street-railway Ownership.

[Correspondence of the Western Electrician.]

Detroit, April 10.—The enormous street-car sale in Detroit presents some unusual phases, in that it marks the termination of a long series of defeats, on part of Governor Pingree, in his former attempts to bring about the municipal ownership of street railways. But, at last, he is on the very edge of succeeding. The story is a most interesting one.

A commission of three—Governor Pingree, Carl Schmidt, a millionaire tanner, and Elliott G. Stevenson, a silver-democratic lawyer—has absolute power, under the McLeod bill, recently signed by the governor, to buy the 180 miles of street railway in Detroit, now owned by R. T. Wilson of New York and by Tom Johnson of Cleveland. The principal provisions of the bill are as follows:

A commission of three, to be appointed for terms of two, four and six terms each, and their successors for six years each, with power to buy the street-railway system for the people; aldermen are ineligible; each commissioner to be under \$250,000 bonds; the city treasurer to be the custodian of all moneys of the street railway and for the purchase and operation of the system; power expressly granted for the commission to acquire, at its discretion, by lease, purchase or otherwise, the 180 miles of street railway in Detroit, also all suburban lines that may be deemed necessary to operate these roads, as a private business, in behalf of the people; debts for possible shortages are not to be charged to the people, but to the street-railway properties; universal transfers and the lowest possible fares, after all expenses are paid. If the properties, several years hence, revert to the present owners, the city having made a trial and abandoned the experiment, it is expressly stipulated that the commission is to have no power to extend the franchises before handing them back. The last clause is deemed most important, for had franchises of the Johnson-Wilson company a long time to run, there is small doubt that the roads would ever have been offered to the city. As it is, the franchises average only 10 years. When the Johnson-Wilson roads were bought, some four years ago, an effort was made to have the expiring franchises extended 30 years, but this was impossible, on account of the three-cent fare agitation of Mayor Pingree. The three-cent road built under the franchises he gave ran successfully for a time, but was suddenly, without adequate explanation, sold to the Johnson-Wilson people, who now control in the whole city 180 miles of electric system. It has always been given out that the reason for the transfer was that the three-cent roads did not pay; but, as the books of the company were never produced, the people have always questioned the statements, referring to them as an invention of the street-railway people to prevent the further spread of the three-cent-fare heresy.

The passage of the McLeod bill raised a storm of protest from many Detroiters, who see in it too much eagerness on the part of Pingree to take over the roads at enormous cost to the taxpayers. At present all is awaiting the reports of the special appraisers, and, in the meantime, various experts are giving their estimates of the probable cost of the transfer, the sums varying from \$5,000,000 to \$12,000,000. General opinion seems to be that the entire 180 miles of electric system and equipment could be duplicated for less than \$4,000,000. Among the appraisers for the people will be Professor Beaman, electrical expert from Kansas University, and Professor M. E. Cooley, engineering and electrical expert, University of Michigan. The railway company has not yet given up its books, but attests its willingness to do so when the three commissioners are ready to act.

Tom Johnson refuses to talk on municipal ownership. He has four sumptuous rooms at the Russell House and travels with his valet, S. B. Clark, a keen lawyer from New York, is with him. Mr. Clark is said to know more about the legal phases of street-railway franchises than any other man in this country. He was a former partner of Elihu Root. It is supposed that he will draft the papers when the street-railway commission takes charge for the people.

Governor Pingree expresses himself as well pleased. He says the first thing he will do, after control, is to shut off all free-pass books, now in the hands of city officials and the press, which, he declares, represent a loss to the company of \$233,000 a year. "With no watered stock to be cared for, and only legitimate expense, there can be no possible doubt," he says, "of the coming for good of three-cent fares. Rates will gradually be reduced till they are at the lowest possible notch, less the actual cost of running the road. Will they reach a straight three-cent fare? I am sure of it. A civil-service examination will be made to keep the road out of politics. There will be no change in the method of operation for the present."

As soon as the appraisers appointed by the commission file their reports, the commission will go ahead and buy the road, at whatever figure it thinks just and fair. Not a straw is in the way of closing the deal. Under the McLeod act, the commission has full power to act.

N. C. Goodwin, a street-railway manager of 23 years' experience, says that, in his opinion, the Detroit electric railway system is worth \$6,500,000, and that it is bonded for \$11,000,000; and that if the city buys the road, it will have to pay the bonds.

Tom Johnson has thus far refused to be inter-

viewed. When asked what, in his opinion, the road is worth, he deftly turns the conversation.

The McLeod bill will doubtless be fully carried out within the next two or three weeks, and the great experiment of municipal ownership on a brilliant scale will have its first practical test in the 180 miles of electric street-car lines of Detroit.

The appointment of the McLeod commission is considered a great personal victory for Governor Pingree, who raised the question of municipal ownership in 1889, and who has been hammering away at it, in season and out, for the last 10 years. When a three-cent road was started in Detroit, in 1895-96, Johnson tried to get an extension of his five-cent franchises, but Pingree refused, unless a three-cent fare was attached. The three-cent road was somewhat mysteriously absorbed by the Johnson-Wilson syndicate about a year and a half ago, and Wilson and Johnson immediately set to work to make a three-cent rate very unpopular. This succeeded well, until it was found that the average life of the five-cent franchises was only about 10 years. This made

Expansion of Electric-vehicle Interests in Chicago.

For some time Mr. Samuel Insull, president of the Chicago Edison company and prominently identified with electrical manufacturing interests, has been investigating the merits of and probable demand for electrically propelled vehicles. Satisfied that the field is one of much importance, Mr. Insull, with the co-operation of Frederic Nicholls of the Canadian General Electric company of Toronto and other business men of that city and Chicago, has secured the incorporation of the Woods Moto-vehicle company of Chicago, which will absorb the already successful business of the Fischer Equipment company of this city and greatly extend the business, building self-propelled vehicles for business and pleasure under the patents of C. E. Woods.

The certificate of incorporation of the new company was filed in the secretary of state's office at Trenton, N. J., on April 10th. The authorized capi-

FIG. 2. PATTON AUTOMOBILE TRUCK

it impossible to bond the road, and in turn Johnson and Wilson decided to sell out to Pingree. Pingree, seeing a chance for his three-cent ideas again, was only too happy to have the necessary legislation passed. By many Detroiters the whole enterprise is looked upon as but another wheel in another gigantic Pingree political machine. G.

Street-railway Situation in Indianapolis.

The franchise contract between the city of Indianapolis and the Indianapolis Street Railway company has been signed and ratified. By it the company secures a grant for 34 years and agrees to pay the city within that period \$1,160,000 and grant a four-cent fare where tickets are purchased in lots of 25 or more. The people of the city, with slight exceptions, are greatly aroused over the grant. Much talk of "crooked work" is afloat. The popular demand was for a shorter franchise and three-cent fare. C. F. Smith, D. M. Parry and Frank A. Maus, said to be three men of financial standing, had proposed to take a 30-year franchise with a three-cent fare and at the same time pay into the city treasury more than the successful company pays.

tal is \$10,000,000, of which \$2,500,000 is to be preferred stock and the remainder common stock. Beside Messrs. Insull, Nicholls and Woods, the gentlemen interested include George A. Cox, A. E. Ames and H. P. Dwight of Toronto and S. M. Fischer of Chicago. Mr. Insull will be president of the company, Mr. Nicholls vice-president and Mr. Woods secretary and managing director. The headquarters of the company will be in Chicago, and the existing factory in this city will be retained and extended or a new one procured. It is said that factories will also be erected in Cincinnati, Philadelphia and Toronto.

While the Woods Moto-vehicle company will do a general manufacturing business in the automobile line, extending its operations over the whole country, it will be closely affiliated with the Chicago Electric Vehicle company, the incorporation of which was noted in the Western Electrician last week. This company, formed by Mr. Insull, Edward L. Brewster and W. G. Beale, all of whom are likewise interested in the Chicago Edison company, will operate electric cabs on the streets of Chicago and will undoubtedly use Woods equipments.

Methods and Tools in the Electrical Repair Shop.

By B. F. FELLO.

Among the leading causes of defective service in a dynamo or motor are rough and improperly adjusted commutators. We have had commutators brought to the shop in the condition shown in Fig. 1. Here the scarred and ridged condition is plainly seen. It is well known to electrical machinists that when a commutator is found so badly cut as that shown in the sketch the armature should be removed and the commutator turned off. But some neglect to do this. It can be done very easily by simply centering the commutator in the lathe. Only a small shaving should be taken off, just enough to true the surface. In case the commutator is but lightly scored, a fine file can be used for dressing, finishing with sandpaper.

In order to make sure that the commutator is true, it should be tested in its own bearing and with the brushes on. The cylinder may be turned slowly by hand and the least roughness or irregularity detected by the action or the rise and fall of the brushes. Fig. 2 shows the same commutator when turned down. The brushes and their setting are also indicated. In Fig. 1 the brushes are marked B. B.

As is known, when the brushes are adjusted too far out the safety fuse is likely to blow, and the dynamo will fail to make a satisfactory output. As it is practically impossible to get a perfect adjustment of the brushes if the conditions are as shown in Fig. 1, the necessity of keeping these parts in good order is obvious. Sometimes the brushes have been worn to a condition corresponding to that of the commutator, while at other times the connections are at fault.

A commutator which has become gummed with oily substances will cause a poor contact. Loose brush-holder screws are sometimes found; many brushes loosen and tip out of level, so that the contact is defective. Again, the tension springs may fail to serve their purpose. Usually the trouble is due to the springs losing their temper. New springs should be put in. Clogging of bearings is a common imperfection and the direct cause of much trouble. If a loose bearing gathers dust and gum, the foreign matter packs on one side, throwing the shaft out of line to a slight degree, enough to disturb the alignment and produce endless difficulties. The best way to prevent this difficulty is to make sure that all the journals are thoroughly cleaned of foreign matter previous to any alterations in the setting.

Some dynamo tenders prefer a very glossy finish on the commutator; others aim at perfect smoothness to the touch, but no gloss.

ARMATURE-COIL SHORT-CIRCUITS.

The short-circuiting of armature coils is frequently due to simple defects, such as the accumulation of copper dust back of the commutator, the presence of pieces of metal between pole-pieces and armatures, oil-and-dirt balls, etc. Injuries to the insulation of the wire must, of course, be avoided. A careful inspection and test should be made at intervals with a view of locating and ejecting foreign deposits. A knife blade is a good tool with which to scrape the mica insulation between the segments with the view of cleaning it. If the short-circuit is due to a defect in the insulation of the wires of the armature, each wire should be lifted and wound with silk tape. In replacing the wires, care should be taken to get the strand back into its original position, using a mallet or soft-metal hammer for the purpose. Then put a coat of shellac on the portion repaired.

BEARINGS.

When overhauling a commutator, all bearings should be looked over for worn and loose places. Chattering of the brushes and consequent sparking and cutting will be avoided by keeping the bearings tight. Rebabbiting may be resorted to if the parts are worn. In some cases new sleeves can be put in.

TOOLS.

There is much chipping of metals to be done in all railway repair shops, and hammers of proper weight and proportions should be provided. Fig. 3 is a 1 1/4-pound head, Fig. 4 a one-pound head and Fig. 5 is a light head for chipping on soft metals. The first two can be purchased of dealers. The last is provided with a head made with lead hardened with tin and put into the channel, as shown. The weight of this head is 12 ounces. Stiff blows may be struck the cold chisel with this hammer, and the elasticity of the hardened lead will soften the stroke.

The pattern of chisel with which the best work may be done is a perfectly straight one. Curved chipping chisels are not a success. The first bevels of the chisel should be alike on both sides and the second or ground bevels should also be alike. With a chisel of this form, well tempered and ground, and either of the hammers described, a good job of chipping may be done.

REPAIRING STEEL ROLLS.

Steel rolls and shaft frequently require new bearings. If the old bearing end is broken off, or so badly worn as to require a new end, I chip out a hollow in the base and set up the shaft in a dry-sand mold C, Fig. 6. The dry sand is provided with a tap at F, and the soft metal finds an outlet there and falls to the receptacle G. The clearance in the flask B should be rammed with sand. The outline

of the lower part of the shaft is indicated, and this section can be accommodated in a pit dug in the ground. Surplus metal can be run off through the channel E.

After casting on the new end, I turn the piece down in a lathe and get it as true as possible. In setting up, the utmost care must be taken to get the steel rolls level. The spindles should be plumb, and this ought to be accomplished without resorting to the use of paper under the bolster flanges. The bolster should be a close fit, and no adjustment ought to be necessary. This means correct workmanship. It is often necessary to tip the spindles to bring them concentric with the center of the ring. This is wrong, as it many times throws the spindles out of plumb. There should be no occasion for this expedient.

Electric Traction on Highways.

By JAMES ASHER.

In the system which I propose there are two trolley wires over the road. There are two of Siemens' bow trolleys extending from the motor wagon to the wires; one trolley presses against the lower surface of one wire, and the other trolley presses against the other wire. Each of these bows corresponds to the trolley wheel which is used on American railways. It will now be understood that the current from the distant dynamo arrives at one bow trolley by one of the overhead wires, then it descends to the motor on the wagon and ascends along the other trolley, enters the other trolley wire and returns to the dynamo at the power station. This method of leading the current of electricity to and from the electric motor allows great lateral deviation on the part of the motor wagon and renders feasible a simple overhead construction at corners. The trolley wires may be several feet apart.

Figs. 1 and 2.

Figs. 3, 4 and 5.

METHODS AND TOOLS IN THE ELECTRICAL REPAIR SHOP.

One loaded wagon, bearing an electric motor, can draw several other loaded wagons. Thus some of the advantages of an electric railway may be secured without the great expense of ties and rails. Much steeper grades can be ascended than is the case with electric railways. A motor wagon can draw a dozen wagons bearing heavy loads. The motor wagon may be of 25 horse power. Several neighbors might frequently unite in the formation of a train of wagons to convey grain or other produce to market to a distance of 30 miles. Only one person would be needed to manage the whole train.

This system would possess not only the cheapness of the trolley system, but also the ability to draw enormously greater loads.

In winter, when the ground is covered with snow, the motor wagon can draw goods and passengers on a train of sleighs.

Light carriages bearing electric motors and trolleys may be electrically driven. Horseless carriages having storage batteries may have these batteries recharged by making a connection with the overhead wires. Thus, on common roads, the work usually done by horses can be electrically performed with facility, speed and low outlay.

Philadelphia Exposition.

Dr. Edmund Cobbe of Philadelphia is in Chicago in the interest of the Philadelphia Exposition, which is to be held in September, October and November under the auspices of the Philadelphia Commercial Museum and the Franklin Institute. This exhibition will be devoted entirely to the display of American manufactures especially suited for export trade, and an opportunity will be afforded to compare American products with articles made in foreign countries. Agents of the exposition abroad have been purchasing samples of articles with which Americans compete in foreign markets. No foreign exhibitors will be given space in the exposition, as the exhibition is intended to promote American industries. The plan of bringing foreign merchants to this country to inspect the factories and products of the United States, which resulted so satisfactorily in June, 1897, will be adopted this year, when the Second International Commercial Congress will be held. Dr. Cobbe says that the electrical section will be representative of the advancement that has been made and that several large houses have already made

application for space. One prominent manufacturer asked for 6,000 square feet, but this was not allowed, as only 20,000 square feet will be assigned to the electrical exhibits. An effort will be made to avoid duplication of exhibits, and each manufacturer will be asked to make his exhibit as compact as possible.

Commercial Field for Liquid Air.

[Special correspondence of the Western Electrician.]

Detroit, April 8.—In an interview on the probable application of liquid air to the street railway and electrical business, Professor Freer, the leading authority on chemistry at the University of Michigan, says: "It will have a great effect on electricity, although no man can yet figure out the result. It may entirely change our system of electrical conductors. You know, at a certain point of low temperature, one conductor is as good as another; lead is as good as iron, steel as good as copper; the intense cold makes all metals of equal value as conductors. Now, heretofore our chemistry of low temperatures has been developed on a basis of only 70 degrees below zero; but liquid air is at least 312 degrees below."

"Do you think," he was asked, "that liquid air will supplant electricity?"

"It is extremely unlikely," he replied, "because liquid air cannot be made commercially efficient unless we burn coal to produce it. I think its use commercially is restricted to free, natural sources of power, as water power, where it can be made cheaply. I do not take any stock in Tripler's exaggerations as to the whole world being run in the near future with liquid air."

"What about Tripler's statement that three gallons of air can produce to gallons of liquid air, and so on, continually?"

"It's like trying to pull yourself up with your boot-

Fig. 6.

straps. It is absurd. It is a physical impossibility. It is the old dream of perpetual motion in a new, pleasing form. If three would produce 10 we might go on forever and eventually liquify all the air about the earth. There is nothing in the theory."

Samuel Insull's Manufacturing Interests.

Samuel Insull is once more to be identified with important electrical manufacturing interests, this time under his direct control and ownership, and those who are familiar with his aggressive business policy realize that he will take a commanding position in this field at once. Mr. Insull enjoys the advantage of extended acquaintance with this branch of the industry, and his invariable success inspires confidence in his new undertaking. He has been in New York during the last week closing up the negotiations for the acquisition of several important lines which he will hereafter control. Mr. Insull stated positively that he would remain in Chicago at the head of the Edison and the Commonwealth companies, and he dismissed as an idle compliment the rumor that he was to take charge of the central-station work in New York under the Whitney syndicate. He also denied most emphatically the reported negotiations for the sale of the Chicago Edison property to the Chicago gas interests.

Mr. Insull admitted, however, that he was preparing to engage in the manufacturing business on a large scale. He confirmed the report of his acquisition of the electric-vehicle interests in Chicago, noted elsewhere in this issue, and his purchase of the greater portion of Mr. Sigmund Bergmann's interest in the General Incandescent Arc Light company, in which he formerly had only a minority interest. He has also acquired the whole of the capital stock of the New York Electrical Equipment company, which will virtually be owned by the General Incandescent company and operated under the same management, doing a construction business as heretofore, but reaching out now in its operations as far west at least as Buffalo and Pittsburg. The General Incandescent Arc Light company will go on manufacturing the same line of goods it has made heretofore, which involves no interference with the work of the larger manufacturers. There is an immense domain of smaller specialties to be filled up, and it is this branch that the company will develop. Small sizes

of dynamos and motors will be made, but particular attention will be given the minor articles of all kinds needed by illuminating companies and their customers. The officers of the General Incandescent Arc Light company are: Samuel Insull, president; S. Bergmann, first vice-president; Martin J. Insull, second vice-president, and P. H. Klein, secretary and treasurer. Mr. Insull also stated that the Paragon motor interests had been bought and would be pushed in both the fan and small power fields. The Wright discount meter is owned by him and is to be manufactured in the General Incandescent Arc Light company's factory in New York city. A "G. I." incandescent lamp has just been put on the market, but Mr. Insull was reticent as to the details of its production.

The plans for placing goods on the market are similar to those which Mr. Insull inaugurated when building up the Edison General Electric company, and which have since been followed closely by the General Electric company. The General Incandescent Arc Light company will control its own distributing agencies as far as possible, and in the West the organization of the Martin J. Insull company to take over a large business already running in Chicago afforded further facilities. There will be representatives in Minneapolis and St. Paul, Milwaukee, St. Louis and other large cities. Influential affiliations have been offered everywhere.

In New York the parent company has its familiar down-town distributing agency in Cortlandt street. Mr. J. B. Cowan, who has been in the service of the Chicago Edison company, and who once was traveling representative for one of the big Scotch thread houses, has been appointed manager of the export department and of the New York sales office. Agencies will soon be opened in the larger eastern cities, and it is quite likely that a London branch will be established.

South African Trade.

[From the Washington correspondent of the Western Electrician.]

Our electrical trade with South Africa is increasing rapidly, and now that a line of steamers running at regular intervals is connecting the two countries, it can be safely predicted that there will be a still more marked increase in this trade in the future. The competition for the electrical supply of South Africa is, as might be expected, very keen. The demand, too, is large and rapidly expanding. It is evident, therefore, that our electrical manufacturers who are striving for the trade of this rapidly growing country should carefully study the situation and see that they are not outstripped by the country's vigorous growth.

The fact has been brought to light that Germany is America's greatest competitor for South African trade, and the aggressive tactics employed by German manufacturers may be studied with profit by the American exporter who desires to keep his finger on the pulse of the world's commerce. There was a time when German importations in many branches of trade practically held the South African field against all comers. The prejudice of that country was all in favor of things "made in Germany." But within the last year or two there has been a wonderful change with regard to importations from that country. It would appear that colonial merchants will not purchase German goods if they are able to procure them from the United States or England at the same price. Consequently, German trade has been materially checked, to the advantage of American shippers.

A glance at the shipping freight rates shows the great advantage American exporters have over those in England and Germany. The freight rates from the United States to Cape Town are as follows: First class, fine goods, \$8.50 per ton; second class, fine goods, \$6; third class, rough goods, \$5.46; fourth class, rough goods, \$4.25. The rates from Germany to Delagoa Bay are: First class, \$12.15; second class, \$9.72; third class, \$9.11; fourth class, \$8.50. The freight from England is: First class, \$13.36; second class, \$10.12; third class, \$8.50, and fourth class, \$7.78.

American manufacturers can obtain a larger share of the trade of South Africa by "hustling for it," as that expressive colloquialism is understood in the United States. A. F. T.

Southwestern Convention to Be Held in May.

E. L. Wells, Jr., the secretary of the Southwestern Gas, Electric and Street Railway association, announces that the date of the annual convention of the association, to be held in Austin, Texas, has been changed from April 19th to May 17th. The postponement was deemed advisable by the directory on account of the prevalence of smallpox in the Southwest, and especially in the republic of Mexico, and also on account of the inability of the Commercial Club of Austin to complete the convention and exposition building as soon as was expected.

Electrician, Spare That Tree!

Appropos of the old controversy over the effect of electric wires on the foliage and branches of shade trees, the New Orleans Times-Democrat gives publicity to a good story told by a man connected with an electrical company in that city. "Some time ago," he says, "a prominent citizen came raging into

our office and declared that a wire of ours had killed a pet tree on his premises. 'That tree has been standing there for twenty years,' he said, 'and we regarded it as one of the family. My children played under it when they were babies, and it's associated with some of the pleasantest memories of my life. When it began to die we all mourned, and we couldn't imagine what ailed it until yesterday, when I noticed that infernal wire lying right across a branch. My poor tree has been electrocuted, sir, and, by heavens, I feel as if murder had been done at my house.' I went out to view the scene of the assassination and found the tree still alive, but feeble. When I came to trace the wire I discovered one end nailed to the roof of an old barn and the other twisted around a discarded pole. It had been cut off for at least two years and forgotten. So I made the following report: 'Tree alive, wire dead. Wire evidently killed by tree. Bill inclosed.'"

Professor Bell Believes in "Wireless Telephony."

[Special correspondence of the Western Electrician.]

Detroit, April 10.—Professor A. G. Bell of telephone fame was at the Cadillac Hotel, this city, to-day, on his way to visit the school for the deaf and dumb at Lansing, Mich. When interviewed for the Western Electrician, Professor Bell said:

"I am very much interested in the experiments in wireless telegraphy recently made with success between Calais and Dover. The principle now seems established that the ratio of the distance the current will successfully operate is not in proportion to the height of the stub wires, on poles, but to the square of the height. Thus, if with poles 100 feet high you can send a current four miles, with 200-foot poles the current would go 16 miles.

"Do I believe in wireless telephony? Why not? I haven't any doubt but it will come, in the near future. And what a saving that would be! Our com-

Electrically Operated Paint Factory.

By ORRIN E. DUNLAP.

Among the manufacturing plants at Niagara Falls, that are using electric power for the operation of machinery is the Francis-Frost company, which manufactures weather and waterproof paint. The plant is in the northern part of the city, and to the people of Niagara Falls it affords an example of the efficiency of transmitted electrical power, and an indication to factory-site seekers that it is unnecessary to locate near either of the great power stations in order that they may operate successfully.

This is a feature encouraging to the future growth of the city in all directions, and many times it is found that these smaller factories employ more hands in proportion to the power used than many of the great electro-chemical plants now becoming so numerous in the Niagara locality. In fact, at Niagara Falls a Business Men's Commercial association has recently been organized to advance the interests of such plants and add to their number by offering special inducements to them.

In the Francis-Frost works several things are found which prove the convenience and safety of electrical power in a plant where there is inflammable material on all sides. The building occupied by this company was originally designed as a gas-house. It is built of brick, and in form is octagonal. It is located close to the river bank, over the Whirlpool Rapids, where both up and down the river the view is most delightful. While its exterior appearances belie the statement, the factory has five stories, three of which are above and two below the ground level. The mixing floor, a view of which is presented in Fig. 1, is at the top of the building, and there three mixers, each having a capacity of 100 gallons, are located. The next floor down is the mill floor (Fig. 2), where a 25 horse power electric motor, two 36-inch burr mills, one 30-inch burr mill and five steel mills are operated. Next below is the tank and stock floor (Fig. 3), where there is one 550-gallon

FIG. 2. ELECTRICALLY OPERATED PAINT FACTORY.—MILL FLOOR, SHOWING 25 HORSE POWER MOTOR DRIVING SHAFTING FOR PLANT.

pany already has enough wire out to reach 42½ times around the earth, and more is being strung every day. The telephone business will continue to increase until no man knows its limits.

"As to the future of electricity, I could not say. The science is not yet really developed. The latter end of the nineteenth century especially will be known as the age of electric marvels."

Professor Bell is at present very much interested, he says, in the X-ray. Asked if it had any bearing on the telephone, he said: "Not that I know of, at present; but experimenters are working all over the country, and there is no telling what they may bring forth."

Asked what he thought of the value of patents, as protection for inventors, Professor Bell said:

"No invention can really be made useful to mankind unless it is patented, for the simple reason that no capitalist will invest his money to bring out the invention, unless he has some security for his loan; and he will never make an advance unless he has a share in a patent. In this sense, at least, the government patent office does well in stimulating creative genius. I do not believe that any invention can really be made serviceable to mankind unless patented. I hold this view in spite of the fact that many eminent inventors in this country profess to distrust the security offered by a patent, declaring that they would prefer to keep their methods secret, or else sell out before competition filled the market." J. H. G.

tank and six 150-gallon tanks. The large tank is located about the center of the floor, and from it, over the other tanks, there runs a three-inch pipe, with valves leading into each of the smaller tanks. The two floors below this main floor are used as stock rooms, one for lead, zinc and oxides, and the other for oils, turpentine and dryers. The power for the operation of the plant is supplied by the Niagara Falls Hydraulic Power and Manufacturing company. The plant is lighted by incandescent lights and has an electric lift connecting all floors.

In the manufacture of the paint the raw materials are mixed on the top floor and run down through a pipe to the mills on the floor below, where the ingredients are ground. From this floor they pass into the 550-gallon tank on the ground floor, where they are mixed and thinned. From this they pass into the 150-gallon tanks, where they are shaded up, and then run into the cans and barrels for shipment. The company's output is about 1,000 gallons a day, and this is put up in packages holding from a half-pint to a barrel.

J. C. Frost is president of the company and T. J. Wilcox is secretary-treasurer. The superintendent is George Chittenden.

The Big Creek (Cal.) Power company has placed an order with the Westinghouse Electric and Manufacturing company for a complete outfit for the generating of 225 additional horse power at Big Creek.

Wehnelt's Interrupter Anticipated.

No sooner had the discovery of A. Wehnelt been given to the world than the announcement was made that it had been anticipated. Starting from the well-known fact that a current passing through a liquid between two electrodes of very unequal area is capable of producing luminosity on the smaller electrode, and that these luminous effects show signs of intermittence, Wehnelt sought to determine whether there was a true interruption of the current, or only a variation between a maximum and a minimum value. The accompanying diagram illustrates the method employed. On inserting a lead plate, b, and a platinum electrode, c, in a beaker, a, filled with dilute sulphuric acid, taking care to conduct the current to the wire through a tube, d, filled with mercury, to prevent spluttering, it was found that such a cell, with the wire as anode, acted as a very perfect interrupter of frequency about 1,000 per second, giving sparks over 40 centimeters long with six amperes and 12 volts. A condenser is superfluous, and there is no need to eliminate self-induction. The interruptions occur with remarkable regularity, as may be judged by the constant pitch of the tone emitted. One of the special applications in which the discovery is expected to be very useful is for purposes of wireless telegraphy.

J. Strachan calls attention in the London Electrical Review to the following extract from Gore's "Art of Electro-metallurgy," entitled "Electrolytic Vibration and Sounds."

As long ago as the year 1801 Gerlon observed that mercury exhibited peculiar movements whilst acting as an electrode in electrolysis, and this phenomenon has been since investigated by Sir J. Herschel, Sir H. Davy and others. According to G. Lippmann, the contraction of a globule of mercury (whilst acting as a cathode in dilute sulphuric acid), on the passage of the current, is due to a change in the capillary constant. (Journal of the Chemical Society, vol. xi. p. 1,094.) It was whilst investigating these peculiar movements and searching for thermic changes in electrolysis, by passing an electric current through a solution of double cyanide of mercury and potassium with mercury electrodes, that I first heard a faint sound, and then observed the surface of the mercury covered with waves; and by further research was led to the discovery of electrolytic sounds; the dancing motion and musical sound being due to the alternate formation and destruction of films upon the mercury by electrolytic action. A paper on the subject in the proceedings of the Royal Society, 1862, contains a full account of the phenomenon and the influence of various circumstances on it.

The best liquid for producing the sounds consists of ten grains of cyanide of mercury and 100 of pure hydrate of potash, dissolved in 2½ ounces of aqueous hydrocyanic acid, containing 5 per cent. of the anhydrous acid ("Scheele's strength"); the liquid should be filtered. The phenomena usually occur only at the negative electrode, and out of a large number of solutions examined, the only ones in which the phonetic vibrations occurred were those alkaline cyanides containing dissolved mercury. The quicksilver may be contained in two very small watch glasses submerged in the solution, and the current from either two Grove's or five Smees' cells, conveyed to the electrodes by platinum wires, protected, except at the ends, from contact with the liquid by means of tubes of glass or india-rubber. During the occurrence of the sounds the current itself is rendered imperfectly intermittent, and the arrangement may to a certain extent be employed for similar uses to those of a break-hammer.

Death of Prof. G. H. Wiedemann.

The death of Dr. Gustav Heinrich Wiedemann, professor of physics at the University of Leipzig, is reported. Professor Wiedemann was a scientist of eminence, and his name was known all over the world as the editor of the Annalen der Physik und Chemie, generally known as Wiedemann's Annalen. He was in his 73d year, and his scientific researches

Fig. 1. Mixing Floor.

Fig. 3. Tank and Stock Floor.

ELECTRICALLY OPERATED PAINT FACTORY.

began as far back as 1845, when he was a youth at Berlin University. He devoted his attention to physics and chemistry, and his electrical investigations and experiments were far-reaching and useful, as is shown by his writings. His most pretentious electrical work was "Die Lehre von der Elektrizität," published in five volumes in 1885. Since 1871 Dr. Wiedemann had held a professorship at the University of Leipzig.

Tammany and Municipal Ownership.

[From the New York Sun.]

The Tammany Hall general committee has obligingly passed a resolution imploring the Legislature to give the city the right to build and operate a gas plant for the purpose of lighting and heating itself. Municipal ownership of public franchises and declamations against corporations are a part of the official Tammany programme. The edifying attitude of Tammany in regard to corporations and franchises

has been impressed upon the community in the last few weeks. Corporations from which Tammany is excluded are necessarily evils to be abated. On the other hand, corporations which are leavened by Tammany are necessarily free from those evils and do not need to be interfered with.

Municipal ownership, with Tammany to do the managing and multiply the offices, would undoubtedly be a dream and a delight. Expensive, but who will grudge expense when the money goes to an appreciative concern like Tammany? Municipal ownership may be expensive, but Tammany believes it to be good.

There is a beautiful business-like simplicity in this project, as in most other of Tammany's projects. It is ingenious, but it is great.

Electrical Machinery in England.

[London correspondence of American Trade.]

It is a pity that the Bureau of Statistics of the United States Treasury Department does not give more details of the export trade in American electrical manufactures, machinery, etc., instead of

WEHNELT'S ELECTROLYTIC INTERRUPTER.

merely lumping the various articles under the generic title of "instruments and apparatus for scientific purposes, including telegraph, telephone and other electric supplies;" while under another heading we simply have the particulars of electrical machinery shipped abroad under one total, it thus being impossible to tell how the trade is growing.

Apart, however, from official sources, there is every evidence that American electric-light plant and machinery is doing well in England. The sale of your electrical appliances in this country has risen in value from \$393,270 in 1896 to \$465,412 in 1897, and to \$692,500 in 1898; while the total value of your shipments of electrical machinery during the last six months of 1897 was \$661,581, and during the whole of 1898 \$2,512,920. It is certain that the trade is rapidly extending, particularly in Great Britain.

There can be but little doubt that the American manufacturer of electrical appliances stands pre-eminent to-day. This is particularly the case in the production of railway plants. While the continental makers have been content to theorize, the American electrical engineers have been busy in the domains of practical experiment and work. The demand for electric transportation has been much greater for suburban travel in the United States than in England, and this has furnished another incentive for practical rather than theoretical work by American manufacturers.

In addition to the transportation interests there

electric underground railroad, including rolling stock, power houses and electrical elevators, has been placed in the United States. The total amount of the contract comes to nearly \$12,000,000, although this will not all be for electrical equipment.

The development of this trade has aroused the attention of the technical journals here. The Electrical Review, in commenting on the fact that these contracts are being placed in the United States, says that the German and American manufacturers are quick to appreciate the wants of a community and will supply just what is wanted without inquiring whether it is a reasonable or foolish demand, and adds that English engineers should study the reason of the successes of the Americans. That seems rather tardy advice, considering the millions of dollars' worth of electrical plant now on order in the United States of America on British request. The Engineer, another leading London paper, says: "We are becoming more and more dependent upon American toolmakers. Within the last few months we have gone to the United States of America to get elevators for the Central railroad of London, and now we are forced to go to the American side of the Atlantic for electric motors with which to equip them. Until our manufacturers take the trouble to teach their hands how to provide new machinery we must continue to witness the humiliating spectacle of seeing our contracts awarded to Americans." It is hardly to be wondered at when English tenders for steel rails range from \$2.50 to \$7.50 per ton more than American and German bids.

There is a decided boom on just now in the matter of providing better and quicker transit in London and the principal British towns, and electric railroads are being constructed in the metropolis, Leeds, St. Helens, etc. I think it would be well for American manufacturers in this business wishing to compete to write to the city engineers, care of the local board, in each city. The leading industrial and trade cities are the centers which should be addressed first. The Central Underground Railroad company has just received some of the numerous electric locomotives ordered from United States makers.

Nor is it only in Britain that American railroad electric supplies find a ready sale; Germany has made great strides of late years in the manufacture of railroad material, but American apparatus finds a ready sale there; while in France, for example, nearly one-half of the 24 roads operating electrically are now using Thomson-Houston equipments.

As regards the future, experts here think that after a time Europe will possess equally efficient machinery with America, and it will then be only a question of raw material, and you have nothing to fear from Europe in this respect, your copper mines being inexhaustible, your iron, steel and coal almost limitless.

Mine Defense of Santiago.

The mine defense of Santiago harbor is the subject of an article prepared by Lieut. Capehart of the navy, who investigated the mine fields through which the Merrimac passed. He says that had proper care been taken of the electrical apparatus no fleet could have ever passed into the harbor. All mines examined were found clogged with marine growth to such an extent as to render them in many instances almost useless. Lieut. Capehart draws the following conclusions:

"Contact mines of the type encountered at Santiago and Caimanera are liable because of the growth of barnacles to become very much impaired as regards the operation of their different parts. This growth forms so rapidly in the warm water of the tropics that in a very short space of time it is sufficient to prevent the arms from driving the plungers in far enough to break the vial containing the sulphuric acid. They, therefore, require constant attention, and from observation it seems that to make them effective they should be raised and cleaned about every two weeks. The examples of the Texas and Marblehead in picking up on their screws mines of this description are sufficient to illustrate the harmless condition to which they may revert, no matter how good they may be when planted. The moral effect of a mined harbor is tremendous, and the question of risking valuable ships is of vital importance. What would have happened to a ship attempting to run the mine fields is problematical, but the chances are that she would have been sunk, for notwithstanding the number of bad mines encountered enough good ones were left to have destroyed her. The electrical mine was perfect in type and design, and had it been properly planted and cared for the protection given by it to the entrance would have been absolute. The lesson to be learned is evident: Mines cannot be planted hurriedly and carelessly allowed to remain without attention and then be expected to give theoretical results.

"It does not require much of an argument to convince us all that practical education in this particular branch of our profession is what the service needs. The details, at times so seemingly insignificant and unimportant, are just the trifles which make success or dismal failure. In a mine defense one cannot admit for an instant that there is a chance of a failure, for it must be so perfectly installed that it may be counted upon with perfect confidence. This is feasible and possible, and a course of training would, in a short time, make the members of our service masters of the important details, without which knowledge no assured success can be expected in either mine defense or countermine."

are three distinct lines of export: First, mining appliances, which include pumps, locomotives, hoists, blowers, etc.; second, appliances for the transmission of power; third, telephone and electric-light appliances. We have seen that your sales here of electrical appliances have doubled within three years, while the shipments under the other two heads must have been equally satisfactory.

The street railroad at Bradford is equipped with an American plant, the important Middlesborough and Stockton line is American throughout, the new railroad at Cork is to use American machinery, while the extension of the Leeds railways will be made with American materials. There is also an extensive lighting plant for the Metropolitan Supply company coming from an American house. I learn that one United States firm alone has a total of 262 electric-railway motors and generators now under construction for England, which is the best evidence that the American manufacturers are steadily gaining favor in Europe.

Mr. Asher's plan for operating wagon trains by electricity, outlined on another page, suggests many applications of electric power, but it is hardly possible that in the form proposed the scheme will ever be put in practice.

might be found in this scheme if the necessary permission could be obtained for stringing overhead trolley wires in roadways, and operating motor wagons along certain lines in a systematic manner.

Statistics have been prepared by the government showing that American exports of manufactured goods now average \$1,000,000 a day. There were 204 working days during the first eight months of the current fiscal year, and during that time the total exports were \$207,000,000.

An examination of the latest official utterances upon the Paris Exposition of 1900 discloses the fact that thus far no steps have been taken to amend the patent regulations so as to protect foreign exhibitors.

In Wiedemann's Annalen A. Sommerfeld has presented the results of interesting experiments upon the propagation of Hertzian waves along a wire and the particulars of his investigations in this interesting field.

The statement which was cabled from London last week and published in the Western Electrician, regarding the alleged telephoning without wires between Brussels and a suburban point, was probably the product of a fertile imagination, but it has served to direct attention to the possibilities in this field.

772,989 miles of wire, while the extra-territorial and toll lines now aggregate 385,911 miles and the long-distance system 123,275.05. It would be difficult to make a fairly correct estimate of the wire mileage of the numerous independent exchange and toll-line systems and private lines that have developed so rapidly since the expiration of the Bell patents.

In the meantime Marconi continues to improve his apparatus and show constant advancement in the art of telegraphing through space. It is now announced that he will attempt to establish communication, through his system, between Nice and Corsica, 110 miles apart.

American manufacturers of electrical apparatus receive encouraging reports from abroad concerning their products, especially from Great Britain, where it is being accepted in spite of the natural prejudice that exists there against everything made outside of the British possessions.

An analysis of the electrical exports from the United States shows a rapidly increasing trade with the British colonies, especially Canada, the Australasian colonies and South Africa, markets which the British manufacturer has hitherto held.

The United States consuls in Japan furnish highly complimentary reports upon the reception accorded American electrical machinery, and they also testify to the appreciation of the methods employed in this country.

Conflicting views are entertained in many states upon many points that have been raised in litigation over the duties, responsibilities and liabilities of telegraph companies. In many parts of the country it has become customary to send messages over the telephone to telegraph offices, where they are taken down by a representative of the telegraph company and transmitted as telegrams to more distant points.

Under such circumstances, therefore, the telegraph company is liable for a mistake on the part of the agent in the name of the person for whom the dispatch is intended, which prevents it from ever reaching him. Where an error of this kind led to the miscarriage of a telegram designed to inform the plaintiff of the death of his father, a verdict of \$200 against the Western Union Telegraph company was upheld on appeal.

Death of M. K. Bowen.

M. K. Bowen, president of the Chicago City Railway company, succumbed to an attack of appendicitis on Sunday evening, April 9th, after less than 48 hours' illness. Mr. Bowen had attended to his official duties to the last, and had left his office Friday evening after disposing of such business matters as required immediate attention, with the intention of taking a holiday. He had secured transportation to Colorado Springs, where he expected to recuperate his health, which had not been rugged for several years, and he appeared greatly relieved by the release from the exacting duties of his position, looking forward with the liveliest interest to his western trip. During Friday evening, however, he complained of severe pains, which he attributed to indigestion, and he applied some simple remedy, but without obtaining relief. During the night his suffering was so great that medical assistance was summoned. The physician recognized unmistakable symptoms of appendicitis in an advanced stage, and a consultation was held at midnight, when it was determined to remove the patient to the Chicago Hospital and perform an operation. Mr. Bowen readily consented, and the operation was performed Saturday morning at an early hour. It was then found that the disease had progressed too far to be checked, and although Mr. Bowen rallied after the operation and made a hard struggle, the physicians in attendance held out no encouragement.

Mr. Bowen's family were summoned to his bedside an hour before his death, when it was apparent that the end was fast approaching. Death relieved him of his sufferings at about nine o'clock on Sunday evening. Mr. Bowen's wife and two children, Allen B., aged 12 years, and Marian, aged four years, survive him. The funeral was held Wednesday and the remains were taken to Jackson, Tenn. The directors of the Chicago City Railway company met Monday afternoon at five o'clock and passed resolutions of condolence with Mr. Bowen's family.

Menard Kenner Bowen had won recognition and had gained the prominence he enjoyed in street-railway circles by ability, earnestness and well-directed effort. He was only 41 years of age at the time of his death and he had been head of the South Side system for several years, although he was elected to the presidency only in January, 1898. One year before, however, he had been made general manager, a position created for him by the board of directors as a reward for his valuable services as superintendent. He had been identified with the company five years at that time, and had been superintendent four years.

Mr. Bowen's early experience fitted him for the position he finally secured. He was born in Jefferson Barracks, Mo., the army post on the Mississippi River, 10 miles below St. Louis, in 1858. He was the son of General John S. Bowen, who was a graduate of West Point, and a grandson of Pierre Menard, the first lieutenant-governor of Illinois. He received his early education at the St. Louis University and later took a course in engineering at the Washington University in St. Louis. At the age of 19 Mr. Bowen went into the service of the United States government as assistant engineer on a triangulation survey of the Mississippi River. Later he was made assistant engineer of the jetty work in the harbor of New Orleans and the pass. In 1880 he became identified with the St. Louis and San Francisco railway and was given charge of the topographical survey from Fort Smith, Ark., through to California. He was engaged in this and similar work for several years, and then entered the street-railway field.

His career as a street-railway man began at the time the cable system was occupying public attention. His first important undertaking in this line was at Kansas City, where he became chief engineer and superintendent of construction of the Kansas City Railway company, which was then building its cable lines. He was so successful in this enterprise that when the road was completed he was retained as general superintendent of the system. The field proved too limited, and Mr. Bowen was induced to go to New York as the representative of the Short Electric Railway company. After a year's experience he decided to return to the operating branch of the business, and secured a position with the Chicago City Railway company as the assistant of Charles B. Holmes, then president and superintendent of the company. Mr. Bowen soon relieved Mr. Holmes of all responsibility in the operating department, and at the end of the first year he was given the title of superintendent. From that time he was an important factor in the management of the South Side system, and it may be said that he was absolutely in control of the operating department, and the extensions and improvements that were undertaken and completed during that time were of his planning and execution. He showed marked executive ability and a capacity for organization rarely combined in one individual. Under his direction methods of conducting the business of the company were revised, new lines were constructed, old roads extended and rebuilt, and the motive power changed from horse to electricity on all but the trunk lines, which were operated by cable. At the time Mr. Bowen assumed the duties of his position as superintendent there were no electric lines operated by the company. To-day all but the State street and Cottage Grove avenue lines are electrically operated.

In addition to his duties as superintendent Mr. Bowen introduced many improvements in the service which required entirely new apparatus, and made

extensive experiments which resulted in marked advancement in the construction department. He introduced the accepted methods of steam railroading as far as possible, and during his administration the shops of the company were greatly enlarged and improved and their efficiency raised. One of his first experiments was in cast-welding joints, and the early experience proved so satisfactory that the entire system has since been reconstructed along these lines. Another innovation in street-railway practice introduced by Mr. Bowen was the use of a dynagraph car, which is an ordinary car equipped for the purpose of determining and showing the condition of the track over which it passes. The result of this test enables the management to determine just how much money will be required to reconstruct the track and put it in first-class shape. Mr. Bowen described this device and the method of operation, and related the results which he had obtained through its use, in his paper on "Track and Track Joints," which he read before the American Street Railway association at the St. Louis meeting. This paper, which was printed in the Western Electrician, November 7, 1896, is still regarded as his most notable contribution to the literature of street-railway construction and operation. It attracted attention abroad as well as in this country, and provoked considerable discussion. Another subject which had long proved a problem in street-railway management was the proper heating of cars. Mr. Bowen designed the Columbia heater, which has been very extensively adopted for this class of work with satisfactory results.

A feature of Mr. Bowen's management was the establishment of departments for which the head was held responsible with corresponding recognition

MENARD KENNER BOWEN.

for whatever was accomplished. The men in charge of the several departments assemble every week for conference with the superintendent upon matters pertaining to the operation of the road. This plan has proved very satisfactory, and is now recognized as an established feature of the South Side system.

These are only a few of the many innovations introduced by Mr. Bowen. As a matter of fact, a complete record would require a detailed history of the period of his connection with the company, for he was ever studying the problem and constantly working to improve the system.

At the annual meeting of the directors of the company in January, 1897, Mr. Bowen's work was recognized and rewarded by promotion to the position of general manager, which had been created especially for him. His duties had been gradually increasing and his responsibilities growing, but as he proved competent in every emergency it was determined to give him a title that would be in keeping with the nature of his duties. As general manager he had absolute control of the company's business under the president and board of directors, and at the expiration of the first year he was elected president. He continued to hold this office to the time of his death.

Mr. Bowen was in many respects a remarkable man. He was resourceful and self-reliant, and he had the faculty of inspiring confidence in his ability among his associates and winning the most loyal service of his subordinates. He understood every detail of the system of which he was the head and he could run a car, direct the work in the blacksmith shop or the power house. His valuable experience in engineering work gave him an advantage and his familiarity with manufacturing enterprises also aided him greatly in his work. This extensive knowledge and practical experience likewise made him appreciate the work of those engaged in the operation of the system.

Mr. Bowen was a member of the Union League Club of Chicago and the Masonic fraternity. He was also greatly interested in the American Street Railway association, and was chairman of the general committee having in charge the arrangements for the meeting and exhibition to be held in this city in October.

Cost of Public Lighting.

(Special correspondence of the Western Electrician.)

Detroit, April 5.—Commissioner Ingram of the Detroit Public Lighting Commission read a sensational report last night, at a session of the Board of Control, asking that the working staff be cut down 30 per cent. and that other radical changes in management be made. In part, Mr. Ingram said:

We are spending too much money, and in order to make a good showing in operating expense we are charging to investment account what properly belong to expense account. We must curtail our expenses. Our investment on our track is now \$99,000. Does anyone imagine we have \$200,000 worth of property to show for it? Our fixed charge, per lamp, is now \$12 and is increasing rapidly. During the past few years we added to our investment account the sum of \$160,000. On a basis of average equivalent, this adds to the cost of an arc lamp \$4.10 per year. At this rate our fixed charges will soon equal our operating expenses, and in two and a half years our investment upon which we must pay interest, etc., will be \$1,000,000.

Mr. Ingram's comparisons of the cost of arc lighting showed that Detroit's account was higher than that of any city in the country, whose reports were accessible, except Chicago. He said:

Our lights are costing vastly more than appears from the printed report. It is our practice to charge up the cost of excessive maintenance to the cost of maintenance that has wrought the mischief. By thus reducing the pro rata fixed charge per light, the actual cost has been made to appear low in the eyes of the public.

Mr. Ingram also claimed that purchases had not been made in a business-like way. For instance, he said, the executive officers had recommended that three Westinghouse engines and dynamos be thrown aside and new ones of another make installed, costing three or four times as much, on the plea that the new machines would occupy less room, when, as a matter of fact, they would not effect any saving whatever. The net gain from the change would be but 1,200 incandescent lights, which, he declared, at present the city does not need, as the old machines have a capacity of 3,600, and the heaviest load this year has been only 1,800, one-half the actual capacity.

Commenting on some of the investments of public money, the commissioner said:

For the six months ended December 31, 1898, we received as rental for our poles only \$86.89. Our investment for conduits alone is \$34,000. We have authority to compel private companies to use them and pay us for it. Our investment in poles, pipes and towers is \$227,000. We have 394 miles of wire strung on lines and towers; 5,210 of these belong to us, 923 to the police and fire department and the balance to private companies. There are 5,756 contacts with our poles by outside parties, and for all this we receive a beggarly rental of \$86.89, less the rental received for the \$34,000 invested in conduits. Our excessive maintenance and repair cost is caused by a superfluity of bosses, superintendents and assistants; I therefore recommend that the force be cut down 30 per cent.

Continuing, Mr. Ingram showed that the actual cost of the city's arc lights is now \$109.50 each per year. The report created a stir in electric-light circles. It was filed for action next Tuesday night. As the other commissioners are hostile to Mr. Ingram's charges, sensational results are looked for in the management of the Detroit electric-light plant.

The estimates submitted by the commissioners of the public lighting plant for the ensuing year amount to \$163,455. They have not yet been allowed.

Dawson's Telegraph System.

Upon authority of the United States consul at Clifton, Ont., it is announced that the Canadian government has decided to construct a telegraph line to connect the Yukon territory with British Columbia, and that a party of engineers has already been sent north to commence the work without delay.

The plan of the minister of public works is to construct the line of telegraphs between Lake Bennett and Dawson City at once. At the same time surveyors will examine the country northward from Quesnelle, British Columbia, which is the terminus of the present government system, known as the old Cariboo line, in order to connect with the line to Dawson.

The ministers have decided that the franchise for the telegraph line to Dawson is too valuable and too important from the standpoint of the national safety to be entrusted in other than government hands, and, accordingly, the enterprise will be conducted and controlled entirely by the Dominion government.

Electrical Machinery in Japan.

The United States consul at Osaka says that the manufacturers of electrical apparatus in the United States control the Japanese market.

"Electrical engines are imported from the United States, and they are giving general satisfaction. Telegraphic machinery was imported into Japan during 1897 as follows:

United States.....	\$2,301
Great Britain.....	1,102
Germany.....	691

"But little came from any other country. The Japanese government owns both the telegraph and telephone service.

"It is said that considerable delay has frequently occurred in the execution of orders from Japan for electrical machinery in Europe, and that, in consequence, the American market has been given the preference, with the result that the superiority of such machinery has been fully established. The more direct communication between the United States and Japan, together with the lowering of overland freights, should stimulate manufacturers of machinery to increased effort for this market."

DEVELOPMENT OF THE TELEPHONE FIELD.

Old-time Telephoning.

By AN OLD-TIMER.

Twenty years ago telephony was far different in every respect from the art to-day. A solicitor in those days had almost to go on his knees to make his arguments, and was told 99 times in 100, "Why, I can jump into my buggy and drive to the person I want to talk to and back before I could get him by telephone," which was too often true, for there was no multiple switchboard then, and the American district telegraph system was one in which the call was made over an American district telegraph instrument, a ticket was made, and in due time (often too long due) the call got through and the persons got together. But in the meantime the person calling, tired of waiting, had called again and again, all the tickets for which were consecutively answered, with the result of an unpleasant remark, such as "Oh! quit bothering me. I had 379 long ago and got through with him. Don't call me up again, please," with much emphasis on the last word, which gave the listener a choice of meanings between polite and profane.

The first exchange in Chicago opened with only 11 stations, from most if not all of which there was very little income, save a prospective one which might accrue from the advertising. These 11 "patrons" were bankers, I think, every one of them, and it was suggested that some plan of grouping all subscribers of one class together might relieve the pressure on the exchange which almost immediately developed when the system commenced to grow. This was an idea of General Stager, and in reply to a complaint of one of the patrons when the exchange had grown to a list of 500 or 600 subscribers, he said: "We have a solution of the trouble at last. We are going to group all the banks, the railroads, the different kinds of merchants together and so"—

"That's just what we don't want," came back the impatient answer. "I want everybody else but those in the same business I am in;" and the general's doll lost its sawdust.

There was a universal complaint by mail, by messenger, by telephone, of being "cut off," and these correspondents were not always more polite than prolific, while their remarks were often seasoned with verbal dressings and other condiments which are inadmissible in print. The matter became so serious that instructions were given to the electrician of the system to "sit down behind the switchboard and watch until the guilty party is detected, if it takes a month."

He watched and caught the mischief-maker in one short session. It was the plugs used for connecting lines on the board. These were made up in pairs on flexible cords. The handle of the plug was screwed onto the metal tip. When these were inserted in the board a twist was given to insure a firm contact. The switchmen used either hand indiscriminately, and the insertion of a left-handed plug almost invariably unscrewed the handle from the contact-plug. This broke the circuit, cut off the subscriber and left him to the indulgence of peppery remarks, which were not heard by the operator to whom they alluded. The connections were made solid before dark that day, and the mails for several days brought congratulations in abundance to the management, quite often accompanied by the request that now that the young devil was caught he would be made an example of, or words to that effect.

The exchange grew, and with it the difficulties increased in a rapid progression. With 500 lines it was seen that the addition of one subscriber meant a possibility of 500 more calls, and the next line increased this possibility by 501, so that what in ordinary business would naturally result in cheaper rates meant in telephony that wholesaling was more expensive than retailing.

It soon became evident that one board would not have room to permit of the necessary number of operators to do the work. So a second board, a duplicate of the first, was set up, into which dummy plugs were to be placed and removed as numbers were called or rung off. This plan was a failure. Plugs did not always get into the dummy, and were often allowed to remain after connections were broken.

Electricians all over the country, not only practical but theoretical scientists, pronounced the idea of connecting a number of duplicated boards together, so that operators could work independently without interference with any line which might have a connection on any other board—a mechanical and electrical impossibility.

The difficulty was solved by an invention in which the wire of any subscriber was carried to board one, two, three, etc., and then turned back through a brass contact piece at each board, ending where it commenced. This addition of the loop permitted any operator to "try" a line without breaking in on a subscriber, and thus knowing whether the line was engaged. This invention, for which a joint patent was issued to C. C. Haskins and C. H. Wilson, solved the difficulty, and was at once invaded by several parties. The patent held, however, and ran its course, having become the property virtually of the Bell company.

The Bell company (which was the competitor of the American District Telegraph company and owns it to-day) and the American District Telegraph com-

pany each covered so much ground that in order to have perfect communication by telephone it was convenient, if not necessary, that the large business houses should be patrons of both systems. As one of these systems did its calling by magnets and the other by battery and key, it became a problem how to call up both parties simultaneously. Finally a key was devised having a long, sweeping contact with the magneto-circuit, ending with a battery contact as the key came down. This answered the purpose and did good service.

Competition was close and earnest. It was the policy of a solicitor to ask a promise that, "If you don't take our system now, you won't take the other without letting me know first." Sometimes it was given thus: "Well, if the opposition cannot give me a line by a certain hour I'll take yours."

On one occasion a promise of that kind was made, and the prospective patron rushed to the opposition office, followed slyly by the solicitor, and told his story. "If you can put a line into my office by 6 o'clock, I'll sign an application for a line; otherwise the other party gets the application." The time was short, but the superintendent of construction was equal to the task. He was called up and asked if he could accomplish the feat. "Wait a minute," was his answer, and almost immediately came back, "Yes, sir, by 5 o'clock." The contract was signed; the line was in by 4:30, but the party next door complained next morning that his telephone wouldn't work. It was not to be wondered at, for the new man was using his wire, and the second line was run for the old subscriber!

A thoroughly disheartened subscriber came into the American district telegraph office one day, and said regretfully that it was no use, he must give up the telephone, as folks could not make him hear anything they said to him. The representative of the company called up his office, and asked him to try the line, at the same time noting that he held the receiver in his right hand. Turning to a messenger boy the electrician said: "Go to Ed Kelly and tell him I want a left-handed telephone," and as the boy hesitated, he hurried him with a gentle push, and silenced any remark he might be tempted to make. Kelly, who had rare capacity for appreciating a joke, poked leisurely over a pile of receivers, crooning a little song, and finally picked out one, which he handed the boy with, "Tell him we are nearly out of left-hand receivers, and there is only one left after this."

The ruse worked. The receivers were exchanged, the patron heard well with his left ear, and was astonished when he learned that he was deaf on one side.

A receiver in the office of a German gentleman, who had been hardly convinced of his need of a telephone, worked quite unsatisfactorily for some cause, and an expert was sent for to "either make the instrument work satisfactorily or take the thing out." The trouble was found, but it was deemed best to charge the receiver with the fault. The inspector examined the receiver carefully, and muttered some words about someone having disobeyed instructions, sending an instrument not intended for German use, which would have to be changed, all of which was accidentally overheard by the patron. It took 24 hours to get a German telephone from Milwaukee. This worked admirably, and the gentleman laughs to this day over the little trick which won him over.

A different experience was that of a well-known and well-educated Hebrew gentleman, who subscribed for an instrument in the store and one in his residence on the South Side. When the lines were completed an inspector, as they are called now, went over to instruct the subscriber how to use the telephone. The wife had been fully instructed in the meantime. When the connections had been made, the old gentleman opened the conversation in German. Then he tried Hebrew. French followed, and finally English. When all this had been accomplished satisfactorily, he rose from his seat, shook hands with the expert, and said: "It is most astonishing. It speaks all languages perfectly. Send around your bill," and the bill was paid on presentation without any intimation that "a little off would be appreciated."

Michigan Bell Activity.

[From the Detroit correspondent of the Western Electrician.]

The Michigan Bell Telephone company made a net gain of 1,326 subscribers in Michigan for the month of March.

Manager Land of the Michigan Bell Telephone company has opened a sub-station at 170 Griswold street. A handsome gilded sign on the window shows the 772 points in the state of Michigan which can be reached by the company's lines.

P. G. Reynolds, superintendent of construction of the Michigan Bell Telephone company, has established a linemen's hotel at 198 Lafayette avenue. It is really a boarding-house for the linemen of the company. Accommodations are provided for 25 linemen, including good board and clean cots, practically the same kind of life as is accorded them in camp. Mr. Reynolds thinks this is a more economical plan for the men than to have them hunt their own boarding-houses.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The telephone line between Audubon, Ia., and Kimballton is being extended to Harlan, Ia.

The Merchants' telephone company is being formed at Melrose, Minn., with a view to putting in a local exchange and building a toll-line to Meire Grove. Other lines will be built as rapidly as possible.

The officials of Polk County, Ia., at Des Moines, have concluded to assess the telephone and telegraph companies doing business there, under a recent ruling of the county attorney. They have not paid county and city taxes heretofore except on real estate. The Iowa Telephone company's property is placed at about \$80,000. The Mutual Telephone company will probably amount to the same. The latter will decline to pay the tax, holding the tax collected by the state treasurer is sufficient.

A bill to regulate telephone charges, and another to permit telephone companies to use public highways for poles and wires, so long as they do not interfere with safety and travel, have been introduced in the Minnesota Legislature. The former makes \$3 a maximum rate for single instruments and \$2.50 for party lines. The second bill prohibits companies from maintaining poles in a city, village or town until they have a franchise.

The Knoxville Telephone company of Knoxville, Ia., is planning a toll-line to Pella, Ia. It will probably strike Flagler, Durham, Harvey and Tracy, and will eventually reach Oskaloosa.

The Northeastern Telephone company of Rush City, Minn., proposes to extend its toll lines from Mora, Minn., to Aitkin this summer. Herman Moorik has been granted a franchise for a local exchange in Aitkin also.

Well-deserved promotions have been made in the cases of C. P. Wainman and J. W. Christie of the Northwestern Telephone Exchange company. The former has been general superintendent of Minnesota, North and South Dakota and becomes general manager, succeeding J. P. McKinstry, promoted to vice-presidency. Mr. Wainman is succeeded by Mr. Christie, heretofore superintendent of the Minneapolis system.

The Mississippi Valley Telephone company is preparing to install a few instruments in Minneapolis soon, in answer to the demand of a number of patrons in the Guaranty building. The system will hardly be in shape for operation for several months yet.

The Duluth Telephone company of Duluth, Minn., is offering one-way service at \$1 per month.

A local telephone company was voted a franchise at Northwood, Ia., at the late election. The Iowa Telephone company has a system there, but the new organization will start with 100 subscribers.

A number of farmers in Mamre Township, near Kerkhoven, Minn., have formed a telephone company and will put up a line between Kerkhoven, Minn., and East Salem in the spring.

The Rocky Mountain Bell Telephone company will probably erect a modern building for its exchange at Missoula, Mont., this summer.

The Minnesota Central Telephone company is working to extend its wires to Morris, Minn., and thence to Sauk Center. The company is also preparing to change its entire system to a metallic circuit.

C. F. Greening of Grand Meadow, Minn., proposes to make a number of changes and improvements to the exchange there. A toll line will be built to Racine.

Farmers on the Illinois side of the river between Eliza and Muscatine, Ia., are building a telephone to connect with Muscatine.

The Fort Dodge (Ia.) Telephone company is an applicant for a franchise at Humboldt, Ia. The Iowa Telephone company will renew its request also.

The Iowa County Mutual Telephone company is about to construct a line from Marengo, Ia., to Ladora, thence to Genoa Bluffs, about 18 miles.

R. H. Evans has begun work on the new telephone system at Duluth, Minn., in accordance with the terms of the franchise. The new company proposes to put all wires in the business districts underground at the start. The Duluth Telephone company is manifesting considerable activity. It is claimed that it is putting in extensions under the guise of substituting copper-metallic for iron circuits.

The Oshkosh Northwestern Telephone company of Oshkosh, Wis., contemplates moving its exchange to new quarters, where it will have more room, by June 1st.

The Northwestern Telephone Exchange company is experimenting with a telegraph auxiliary in North Dakota. If a long-distance wire is busy, the station wanted by a newcomer will be called by telegraph and much time saved, as the new connection can be made instantly and the person wanted be at hand when the first talker is through. Winnipeg (Man.) business men have been consulting with the company in Grand Forks, N. D., with a view to having the system extended to Winnipeg.

The Otumwa Long Distance Telephone company has been granted a franchise in Otumwa, Ia. The company has its system in operation, but had never been formally authorized by the people to do business.

The Mutual Telephone company of Des Moines, Ia., has been granted a franchise for an exchange at Pella, Ia., and will proceed to install it as soon as possible. The company has also been granted a franchise at Monroe, Ia. Valley Junction will vote on granting the company a franchise April 27th.

The Citizens' Telephone company of Mankato, Minn., has let the contract to Jones & Winters of St. Paul to put in 430 feet of lead cable.

The American Telephone and Telegraph company will open an office in Superior, Wis., and begin work on a toll line to the Twin Cities at once. It is expected to have connection with the larger cities of the country by May 15th.

The Wisconsin Telephone company at Neenah, Wis., is changing the system from a ground-wire to copper-metallic return-circuit system.

The Northwestern Telephone Exchange company has been granted franchises in McIntosh and Red Lake Falls, Minn.

The Blue Earth Valley Telephone company offers to establish an exchange in Amboy, Minn., if sufficient subscribers can be secured.

The Sterling-Amboy Telephone company has been formed at Sterling Center, Minn., to build a line to Amboy.

The Northwestern Telephone Exchange company is considering erecting numerous suburban circuits from local exchanges into the country, extending a distance of 10 miles or less in different directions, for the benefit of the farmers.

The Wisconsin Valley Telephone company is preparing to establish a local exchange at Mondovi, Wis., at once. It will also extend toll lines to La Crosse and Minneapolis.

The Sauk Center (Minn.) Telephone company has secured about 100 subscribers for the new exchange.

A number of improvements and additions are being made to the telephone exchange in Wadena, Minn.

Cloid H. Smith has been granted a franchise for a local telephone system at Odebolt, Ia. He offers all-night service if he secures 75 subscribers.

C. E. Odel of Reinbeck, Ia., has gone to Iowa Falls, Ia., where he proposes to establish a telephone exchange.

A deal is under way for the purchase of the telephone exchange at Clear Lake, Ia., where a number of improvements are projected.

The Minnesota Mutual Telephone company has completed arrangements to extend its wires to Sandstone, Minn.

E. Hewett and Hans Swanson contemplate putting in a local telephone exchange at Warren, Minn.

The Southwestern Minnesota Telephone company is reconstructing its system in Pipestone, Minn. A 150-drop switchboard is being put in, and other improvements are under way.

An ordinance granting a franchise to the American Telephone and Telegraph company has been introduced in the Board of Aldermen of St. Paul. Business men are urging the council to pass it in order that the city may have long-distance connections.

An expert has reported on the condition of the police telephone system in St. Paul. He finds that it is simply worn out. It has been in use 13 years, and the parts are all worn so that it is unreliable.

The Western Stearns County Telephone company has been formed in New Paynesville, Minn., to connect that village with the smaller towns of the county. Dr. P. C. Pilon is the prime mover of the enterprise.

The Fairmont (Minn.) Telephone company will extend wires to Armstrong, Ia., as soon as weather will permit.

The Perry Telephone company has been granted a franchise for an exchange at Adair, Ia.

The Minnesota Mutual Telephone company will extend its wires to Herman, Minn., and probably to Breckenridge.

A local telephone exchange is projected at Brodhead, Wis.

MANUFACTURERS AND DEALERS.

Perhaps no concern engaged in the manufacture of woodwork for telephone and electrical purposes has a better reputation than that of E. J. Noblett of Chicago. Mr. Noblett has for years done business with the largest telephone companies in the country, among them the Chicago Telephone company and the Central Union Telephone company. Mr. Noblett has a reputation for making only first-class articles, and those in need of reliable woodwork may find it advantageous to communicate with him.

The Western Telephone Construction company of Chicago has just placed an order with the American Hardwood Manufacturing company of Grottoes, Va., for 12 carloads of telephone boxes, each car containing more than 1,000 complete sets of backboards, battery and magneto boxes. In addition to this order it has contracted with the Grottoes company for a large quantity of special telephone desk cabinets, switchboard cabinets and other woodwork. The American Hardwood Manufacturing company has been making a specialty of telephone woodwork for four or five years, supplying the largest manufacturers of telephones in the country with woodwork.

A telephone system is being organized at Waynesville, N. C.

Canadian Telephone Service.

At the annual meeting of the Canadian Bell Telephone company in Montreal some interesting statistics were presented in the directors' report, from which the following items are selected:

During the year 1,637 subscribers were added, the total number of sets of instruments now earning rental being 32,082. The company now owns and operates 343 exchanges and 340 agencies. The company added 666 miles of wire to the long-distance system in 1898; 326 miles are in the Ontario department and 340 miles in the eastern department. The long-distance lines now owned and operated by the company comprise 17,233 miles of wire on 6,096 miles of poles. The receipts for 1898 were \$1,302,994.04, made up as follows: Exchanges, \$935,703.52; long-distance lines, \$264,455.49; private lines, \$12,743.32; miscellaneous, \$90,041.71. The expenses were \$971,792.30, divided as below: Operating, \$897,138.73; legal, \$9,582.22; insurance, \$13,740.20; bond interest, \$47,042.16; miscellaneous, \$4,288.99. The net revenue was \$331,151.74.

John L. Bittinger, the United States consul-general at Montreal, has prepared a report on "Telephone Service in Canada," dated March 15th, which contains the following information:

The Bell Telephone company, Limited, covers the provinces of Ontario, Quebec and Manitoba, in the Dominion of Canada. The cost for telephone service in the city of Montreal is \$30 for private residences and \$50 for business houses per year. There is no cost for installation and rent. The cost at pay-stations in the city is 10 cents for five minutes.

The telephone is first located by the company where the subscriber directs; if afterward the instrument is required to be moved, the change is made by the company at the expense of the subscriber.

The Bell Telephone company has a long-distance service in the provinces of Ontario and Quebec, covering hundreds of stations. The charges for this service for written messages of 20 words or under are as follows: Up to 15 miles, 15 cents; 15 to 25 miles, 25 cents; 25 to 225 miles, 50 cents. Charge for delivery is extra, and for each additional twenty words, or fraction thereof, one-half the tariff is asked.

The province of Nova Scotia is covered by the Nova Scotia Telephone company; New Brunswick, by the New Brunswick Telephone company; Prince Edward Island, by the Prince Edward Island company; Newfoundland, by the Anglo-American Telegraph company. The city of Vancouver, British Columbia, is covered by the New Westminster and Burrard Inlet Telephone company. Victoria is covered by the Victoria and Esquimalt Telephone company.

Independent Toll-line System.

The negotiations entered into a few weeks ago between the United States Telephone company of Ohio and the National Telephone and Telegraph company of Indiana have been completed. The National company controls long-distance wires all over Northern Indiana and Ohio and Southern Michigan, and the United States company is rapidly extending its lines throughout Ohio.

The following-named officers were elected at the annual meeting of the National company last month: President, George W. Beers of Fort Wayne; vice-president, C. H. Cory of Lima, Ohio; secretary, D. J. Cable of Lima, Ohio; treasurer, W. H. Duffield of Lima, Ohio; directors, C. H. Cory, D. J. Cable, W. H. Duffield, W. L. Parmenter, F. W. Holmes of Lima, and G. W. Beers, Henry C. Paul and Samuel M. Foster of Fort Wayne.

The president's report showed that the mileage of the lines had been increased 20 per cent. during the year. The number of telephones in use at exchanges is 15 per cent. greater, the number of towns or toll stations connected with the system is 40 per cent. greater, and the net earnings of the company exceed those of last year by a little more than 100 per cent.

The question of uniting with the United States Telephone company of Ohio was taken up. The Ohio people were represented by James B. Hogue, secretary, and H. D. Critchfield, general counsel, of Cleveland. The deal commenced for a union of lines was concluded. By this agreement the whole of the Ohio company's lines are opened to the patrons of the National company. The connection with the Michigan lines will be made at Sturgis, and within 60 days a junction will be formed in the new exchange now building at Anderson, in which President Beers holds a controlling interest, with the lines of the New Long-distance company at Indianapolis, thus making the lines of the National company the connecting line for all the independent telephone users in Indiana, Michigan and Ohio.

EXTENSIONS AND IMPROVEMENTS.

Word comes from Tucson, Ariz., that "Edwin Treadwell is about to complete a telephone line from Prescott to Jerome, Ariz., a distance of 26 miles. The backer of the enterprise is his father, the professor."

"We challenge the world to beat it," is the proud boast of Otto Wettstein, Jr., of the La Porte City, Ia., telephone exchange. Mr. Wettstein's challenge was received on a directory of his new exchange. It contained the names and addresses of 120 "paying subscribers" in a town of 1,400—certainly an excellent showing.

TELEPHONY ABROAD.

The Dover Council is inviting other English boroughs to co-operate in securing a reduction of the limit of towns to which telephone licenses may be granted to below 50,000 population.

The Telephone and Switchboard Syndicate, Limited, London, was registered on March 17th, with a capital of £10,000 in £10 shares, to carry on business as financiers, company promoters, underwriters, concessionaires, contractors for public and other works, capitalists or merchants.

By direction of the postoffice authorities in Berlin, automatic telephones are to be placed in all their offices, railway stations and many other places. They will be on the penny-in-the-slot principle, and for the small sum of a penny the necessary number of minutes allowed for a brief conversation may be obtained.

The International Telephone Manufacturing company, Limited, was registered at London on March 1st, with a capital of £200,000 in £1 shares, to manufacture telephones and telephone appliances, to establish, work, manage, control and regulate telephone exchanges and electric-light works and to carry on the business of a telephone, telegraph and electric-light, heat and power company.

In the House of Commons recently the question was asked the secretary of the treasury whether the government received 10 per cent. commission from the National Telephone company, or from any other private telephone company, and whether it was on account of this arrangement that the government refused to take over and make the telephone a public service. Mr. Hanbury replied that the present licenses paid—as future licensees would pay—a royalty of 10 per cent. The answer to the second paragraph was in the negative.

At the Court of Common Council, London, when the Guildhall resolutions were brought forward, it was stated that the decision of the government as announced by Mr. Hanbury would largely affect these resolutions. Mr. Morton said that the thanks of the people of London, indeed of the United Kingdom, were due to the government for the steps it was to take. The Bristol Stock Exchange, however, is protesting against the government telephone measure as explained by Mr. Hanbury. It regards the proposals as an unwarranted attack upon the interests of capital.

The Bristol Chamber of Commerce has passed a resolution regarding the government telephone proposals to the effect that they are unsatisfactory upon the following grounds: "(1) That the proposals do not meet the requirements of commerce, and are calculated to prove highly detrimental thereto; (2) that they would result in a multiplicity of systems organized by local authorities, which probably would be found afterward difficult to unite; (3) that the working in detail of the telephones would be vexatious; and (4) that the council of this chamber regrets that apparently no weight was attached to the recommendations made to the government by numerous public bodies to the effect that one central authority was necessary for the satisfactory working of the telephones of the country."

The London Standard believes that it is probable that the provision in the telephone bill which only allows boroughs of 50,000 and upward to set up their own telephone systems will be dropped, as the general feeling is that any borough which is able to fulfill the necessary conditions should be allowed to establish a telephone exchange within its own boundaries. At Tunbridge Wells the corporation telephone committee considers that this, if adopted, will work against a proper development of the telephone system throughout the country, and it believes that it would be best that any town council, even if representing less than 50,000 residents, should have the same local telephone chances as the larger cities. Therefore, the committee advises the council to apply forthwith for a license to work a municipal system of telephones within the area now served by the National Telephone company, including Tunbridge Wells, Tonbridge and Southborough.

The committee appointed by the council of the Institution of Electrical Engineers of England to consider and report on the future of electrical engineering in the branch of telephony has made a careful investigation of the conditions, and, as a result, it is announced that the council has adopted the following report, submitted by the committee: "That, in the opinion of this committee, it is undesirable, from the point of view of the progress of electrical engineering, for the purely local telephone industry throughout the country to be held as a monopoly, or that legislation on the future of telephony in these kingdoms should discourage the undertaking of exchange systems within telephone areas by independent enterprise. The committee is therefore of opinion that the council should strongly urge on the government that such legislation may have the further effect of removing existing disabilities to the carrying out of the recommendation." It is also announced that copy of this report has been forwarded to the government.

Irving Hale's Career.

Brig.-Gen. Irving Hale, United States Volunteers, whose name has been so honorably mentioned of late as the commander of one of General MacArthur's victorious brigades, is a soldier of thorough and scientific training. He was born in the state of New York, and when a child went with his parents to Colorado. When about 18 young Hale secured an appointment as cadet at the United States Military Academy, and reported at West Point in June, 1880. He aspired to the distinction of establishing a record in class-standing, and in June, 1884, when the class was graduated, Hale's intention to be number one had been fulfilled, as had also his desire to reach the highest standing ever made in the history of the academy. He had gathered to himself class rank number one in all branches but two, and in these had pushed his sole competitor so hard that there was only the fraction of one per cent. between them.

With the academy officers he was respected and trusted, and was in turn corporal, first sergeant and captain in the cadet battalion.

The academy class graduated in June, 1884, furnished the almost unprecedented number of seven second-lieutenants to the Corps of Engineers, at the head of which number was Hale. He was assigned to station at Willets Point for the course in the torpedo school, and while there he became acquainted with a daughter of the commandant of the school, General King, whom he afterward married. He was later detailed as instructor in the department of engineering at the military academy and served for some time in this capacity.

A few years after graduation Hale resigned from the army and settled in Denver, where he became identified with the General Electric company. In Denver he became interested in the Colorado National Guard. He was able to give the organization the benefit of his military knowledge and scientific training, and was rewarded by rapid advancement. When the war with Spain began he was the brigadier-general of the state forces, and in supplying Colorado's quota of volunteers Hale was commissioned colonel, the highest place within the appointing power of the governor.

General Hale's part in the Manila campaign is well known. He was promoted brigadier-general of volunteers for gallant and meritorious services in the short campaign which resulted in the capture of Manila. In operations since that time he has been frequently mentioned for his energy and activity, and in the fighting of the last two weeks he has been conspicuously in the thick of it.

New Device for Igniting Welsbach Lights in Series.

The reduction in price of Welsbach lights has greatly increased the demand by those limited to gas as an illuminating agent, not only on account of the greater economy in consumption over the old style of burners, but in the vastly increased candle power per foot of gas. The difficulty of igniting

Fig. 1.
NEW DEVICE FOR IGNITING WELSBACH LIGHTS IN SERIES.

Fig. 2.

these lamps in elevated fixtures limited their use until the old forms of electric gas-lighting apparatus were modified so as to be applicable.

In lighting a number of these lamps in series, by coil or frictional machine, the peculiar enclosed form of the light, the chimney and delicate mantle presented conditions of considerable embarrassment in the attachment of the spark electrodes, as not only had ample insulation to be provided in a narrow and contracted space in the lamp parts, as turned out by the manufacturers, but, at the same time, the mantle must not be endangered.

The A. L. Bogart company of 123 Liberty street, New York, which has for a long time made a specialty of electric-igniting attachments for this class of lamps, has lately put on the market the simple and convenient device for series spark-lighting illustrated in Fig. 1, which is particularly adapted for use with Welsbachs with mica chimneys. The two electrodes are rigidly attached to a porcelain holder,

provided with a slot in its base, which embraces the top of the mica chimney, as shown in Fig. 1. Fig. 2 shows electrode holder or clip on an enlarged scale. A porcelain pillar is also supplied, which insulates the metal-work of the entire lamp. With this device no alteration of the lamp is necessary. The electrode spark points are below the level of the top on the chimney, so that drafts of air cannot divert the stream of gas from the spark.

Safety Third-rail System.

Much interest is displayed by the general public in systems of distributing current to street-railroad motors so as to avoid the use of exposed conductors.

A system of this character is being exploited by the Safety Third Rail company of New York. It is the invention of Captain J. McL. Murphy, and it has been embodied into a road now in operation at Manhattan Beach. The road equipped is the Marine railway, connecting Brighton Beach and Manhattan Beach, and it is 1,951 feet in length. The track is of standard railroad construction, with 56-pound, 4 1/4-inch T-rails and stone ballast, and differs from a trolley track only in the absence of the overhead

FIG. 1. SAFETY THIRD-RAIL SYSTEM.

system and in the use of the third rail, which is laid in sections or lengths on the ties in the center of the track. A standard 500-volt current, taken from a special dynamo located in the lighting station of the Manhattan Beach Hotel, is used.

The Murphy system accomplishes its object in the following manner: Referring to Fig. 1, a series of third rails is provided, as plainly shown, each of which is usually one-half a car or train length. By means of the automatic switch, Fig. 2, the sections are connected to the main supply wire or feeder at such times as the car is directly over the sections and making contact therewith. At all other times the sections are cut out or "dead."

The sectional third rails are so spaced that the car is taking current from one section before it leaves the one preceding, and thus the current supply is continuous as the car proceeds. The only live sections are those immediately under the car, and hence there are none exposed to do damage.

The Murphy system belongs to the electro-magnetic class; that is, the special feeding switches (Fig. 2) are operated, each by its electro-magnet, receiving currents from the car as it passes over the particular section to which the switch is allotted.

In a word, there is a switch to each section of rail. The switches are grouped as desired in a set of, say, two alongside the track, as in Fig. 3, or "bunched" and placed, say, in a weatherproof box or vault, as are the nine switches shown in Fig. 4.

The car is operated by a motor-dynamo (Fig. 5), which takes current from a few cells of storage battery and transforms it to the full line potential, rendering the car independent of the power-house current and able to pick up its switches anywhere. This little machine has sufficient capacity to handle two switches and supply the lights in the car.

Assume the car to be over a rail and ready to start. The switch being open there is no connection between the feeder and the car. The motorman operates the controller and connects the motor-dynamo to the third rail and to the ground, and current passes

through the fine wire of the switch and causes it to operate. In response to this current the plunger rises and first makes contact between the main feeder and the rail and then breaks the current of the fine-wire winding which first lifted it. The controller is now open, and current comes from the feeder through the coarse-wire winding of the switch to the third rail and from thence through the car motor to ground, causing the car motor to revolve and the car to move. The switch is held shut because of this main current in the coarse-wire winding. In this closed condition the switch will remain as long as the car is taking current from the section to which the switch is connected. When the car leaves the section, there is no longer any current passing through the switch feeding it, and it fall open, first, making another break in the circuit between the feeder and the sectional rail, and, second, restoring the circuit from the sectional rail through the fine wire to earth. The switch is then ready for the next car. The car being thus started, the motor-dynamo is no longer needed to operate the switches, because the car is provided with two sets of shoes which are connected together and placed sufficiently far apart to span the distance from section to section. The forward shoe, as it impinges on a section, subjects it to the full line potential, drawing its source of current from the rail preceding, for the main feeder has already been connected thereto in the manner just described. Once started, therefore, the car becomes independent of the motor-dynamo, for it uses the power-house current to operate the switches.

It will be noted that the switch remains closed until the car ceases to take current from the section it controls. It will then fall open from lack of current to hold it up and there is then no current to break, and hence no arc at the switch jaws, and it is therefore a non-arcing switch, and this is considered by many engineers as one of the most important features of the operation of the Murphy system.

CORRESPONDENCE.

New York Notes.

New York, April 10.—The rapid-transit situation is still troubled and indeterminate. A late development is the official announcement that a traffic agreement, to take effect not later than May 1st, has been entered into by the Manhattan Railway company and the Third Avenue Railroad company. This is an offset to the offer of the owners of the Metropolitan Street Railway company to take up the tunnel scheme. The agreement at present only contemplates transfer arrangements between the elevated

FIG. 3. SAFETY THIRD-RAIL SYSTEM.

lines and the crosstown and other connecting lines of the Third Avenue system, but it may lead to a closer union. The transfers are given for three cents additional fare, for both express and local trains. They will practically extend the facilities of the elevated system to Yonkers and New Rochelle, as well as giving the crosstown connections. Another aspect of the alliance lies in the fact that both systems contemplate electrical operation on a vast scale. A joint power house or system of power houses is therefore practicable and probable. The president of the Third Avenue company says: "With the installation of electricity upon the elevated and the lines of the Third Avenue railroad, the capacity of the combined railroads will be immediately increased more than twofold, and with the improvements and betterments already planned for prompt undertaking there will be provided for the traveling public through the united efforts of these two great railway systems a scheme for supplying rapid transit

broad enough to cover the possibilities of the need for many years to come." The agreement has had a good effect on the stock of both companies.

As to the Metropolitan offer for the proposed underground road, that is still pending, of course, as the amended rapid-transit act has not been finally disposed of by the Legislature. Governor Roosevelt says that it is the most important subject now before the state lawmakers. The offer of the Metropolitan people is being carefully scrutinized. Controller Coler states his conviction that the subway privileges will prove a greater source of profit than the working of the railroad itself. "They will give the Metropolitan people a monopoly in heat, light, power, telegraph and telephone wires," he says. "No one will be able to compete with them as a carrier of pipes and wires. If this franchise is to be granted in perpetuity, it is our duty to look ahead and see that the city is to get something commensurate with the privileges it is giving away." It is believed that in any event the franchise will not go to the Metropolitan people without modification.

his project contemplates the construction of an esplanade along the Boston embankment of Charles River, which flows between Boston and Cambridge. Under the esplanade the subway would be built, connecting Harvard bridge with the present subway, via a tunnel under Beacon Hill to Scollay square. The improvement of the embankment has been contemplated for three or four years; but the subway is a new idea. That it would assist materially in simplifying the transit problem is apparent to everybody in Boston and the southwestern suburbs. Cars coming in from Cambridge, Brighton, Newton, Watertown and Arlington, with their service for an aggregate population of more than 200,000 people, which now goes through the existing subway to a large extent, could be diverted, without inconvenience to passengers, into the proposed channel of traffic under the hill. Estimates show the cost of the subway alone to be \$2,502,500. The committee has taken the matter under advisement and will consider it in connection with the pending proposition from the mayor for a subway to connect with

Yetman, T. J. Killian, H. C. White and E. A. Smith. Historic Lexington and Concord are to have new electric railways this year, and it will be possible in future for patriotic folk to go over Paul Revere's famous route on the 19th of April in a trolley car. The line will connect at Arlington with the Boston Elevated Line under the name of the Lexington and Boston Street Railway company, and the Waltham, Ayer and Pepperell company will run through Concord and Lexington on its way from Waltham to Pepperell. Both these companies contemplate getting under way with their projects as soon as the weather is favorable for construction work.

The Northampton and Amherst Street Railway company has been organized with the following-named officers: President, F. S. Coolidge of Fitchburg; vice-president, B. E. Cook, Jr., of Northampton; clerk and treasurer, C. W. Wyman of Brattleboro, Vt.

In the annual report of the Massachusetts Board of Railroad Commissioners considerable space is devoted to the excellent results that have been ob-

Fig. 2

Fig. 4.

Fig. 5.

SAFETY THIRD-RAIL SYSTEM.

Another offer to construct the system has been received by the commissioners. It is from the Metropolitan Contract company, and the terms are thought to be more favorable to the city than those of Mr. Whitney and his associates. Frederic B. Esler, who is the president of the Metropolitan Contract company, offers to construct the tunnel for the sum of \$33,000,000, and will agree to pay to the city the interest on the bonds issued by the city for construction, and also create a sinking fund with which to pay off the interest of all the bonds before their maturity, so that the road and tunnel will become the property of the city at the end of the period prescribed by the act without the expenditure of any money whatever and absolutely clear of incumbrance.

Tammany has caught the municipal-ownership fever, and as a first step has declared in favor of city ownership of the gas plants. M. S.

New England News.

Boston, April 8.—Mayor Josiah Quincy of this city is continually making suggestions that surprise the average citizen, but at the same time impress people with their importance. His latest move is in the direction of another subway, and he appeared before the legislative committee on metropolitan affairs at the capitol last month with maps, plans and designs bearing on the subject. Briefly stated,

the Southern station via Washington street and other thoroughfares, submitted earlier in the session.

One of the most important jobs of construction work in connection with the new Southern station in this city is now under way at Fort Point channel, so called, where an immense drawbridge for six tracks is to span the water. It is to be of the style known as the rolling lift, and into its construction will enter upward of 3,000,000 pounds of steel. The Pennsylvania Steel company has the contract, and the operating power will be electricity supplied to Westinghouse motors from the power plant at the station. Counter-weights will be a feature of the structure, their weight being planned at about 1,700,000 pounds. On the north side of the channel the weight of metal in girders and other essential parts of the bridge will be 4,600,000 pounds.

A committee of 25 from the Electrical club of Boston has been appointed to make arrangements for the entertainment of the Telegraphers' association, which will hold its annual convention in September of this year in Boston. This club is composed of men well known in the various branches of electrical business. The officers, elected at the annual dinner in February, are as follows: President, H. J. Pettengill; vice-presidents, Charles E. Bagley, Frank Stevens, W. E. Durgin and Thomas W. Flood; secretary, M. C. Harrington; treasurer, Charles H. Haddock; governing committee, G. H.

tained, in the opinion of the commission, from the Boston subway since it was opened to the public for travel. Estimates of the gain in accommodations by the building of the subway are submitted, showing that the underground route is accommodating 50 per cent. more cars and more than twice as many passengers, compared with the number accommodated on Tremont street before the subway under that thoroughfare was constructed. It is shown that the entire cost of the subway, originally estimated at \$5,000,000, will probably be less than \$4,250,000, exclusive of the alterations that will be necessary to adapt it to the use of the elevated railway. The commissioners' statistics show that 330,000,000 passengers were carried during the year by the street railroads of the state, a gain of more than 22,000,000 for the year. The total capital investment advanced during the 12 months to \$68,758,800. This includes capital stock and net debt. The gain is upward of \$5,500,000 for the year. The ratio of surplus to capital stock stood higher at the end of the last year (4.41 per cent.) than in any previous year since 1800. Cash dividends declared aggregated \$2,076,233, being an increase of \$10,000 over the 1807 dividend record. Total income for all the companies amounted to \$18,247,235.81, while total expenditures, including dividends, were \$17,789,466.70, the balance of \$457,769.02 being carried to surplus. There were 54 companies that paid no dividends and 49 that paid

amounts ranging from $2\frac{1}{4}$ per cent. for the lowest up to 8 per cent. preferred and 7 per cent. common, distributed by the Boston system. The companies that passed dividends, however, represented only about one-tenth of the capitalization of the entire list. The number of passengers carried by the street railways exceeded the number carried by the steam railroads of the state by 228,948,907. The total length of track operated on is about 1,623 miles. The additions for 1898 amounted to about 128 miles. Only $7\frac{1}{2}$ miles of this remain unequipped with electricity, and a petition has been submitted this month in Boston for the substitution of electricity for horse power on the quaint old-fashioned little line on exclusive Marlboro street in the Back Bay section, where the residents hitherto have almost unanimously clung to the ancient style of travel.

The Boston Light, Heat and Power company, which has been reaching out for a number of prosperous small plants in New England cities and towns, has recently made an offer for the Willimantic (Conn.) Electric Light company and Citizens' Gas-light company, also for the gas and electric concern in Spencer, Mass., owned by the men who control the Willimantic plants.

The legislative committee that has been hearing testimony on the need of replacing the tracks of the street railway on Tremont street, ordered up when the Boston subway was constructed, has presented a report favoring the restoration of the tracks in that thoroughfare.

W. Clifford of Pittsburg, agent for the Cappell electric fan, has been awarded the contract for installing a ventilating fan at the main shaft of the Hoosac tunnel. The fan will be 16 feet in diameter, with a capacity of 600,000 cubic feet of air per minute. It will be driven by power from the North Adams Electric company.

An adverse report has been given by the committee on street railways in the Massachusetts Legislature on the petition for vestibules for the front platforms of cars in Boston in the winter months. It was argued strenuously before the committee at hearings given on the subject that the safety of the public would be lessened by the adoption of this protection for motormen, and remonstrants against the idea said that there would be danger in crowded cities of collisions in case the view of the motorman on a car should be obstructed.

Two companies are bidding for the privilege of doing a motor-carriage business in Boston. The matter came before the Board of Aldermen, and petitioners representing what is known as the Boston Transit company were given a hearing. Representatives of the other company which desires to secure a franchise for similar purposes were present, not in opposition, but to ask for a continuance. It was stated that this company was incorporated in New Jersey as the New England Electric Vehicle and Transportation company, and had secured the New York city privilege, being in successful operation there. The Boston company is incorporated under the laws of Massachusetts, and has a number of Boston capitalists back of it. B.

PERSONAL.

Dr. J. J. Deshler of Glidden, Iowa, was in Chicago early this week.

Captain W. L. Candee of the Okonite company of New York was a Chicago visitor early in the week.

H. W. Hill, president of the Hill Clutch company of Cleveland, Ohio, is spending a few days in Chicago.

Mr. Jay Holmes, at 39 Cortlandt street, New York, has assumed the general agency for the Onondaga Dynamo company of Syracuse for New York city and the territory contiguous thereto.

Mrs. J. B. Keller, mother of E. E. Keller, general manager of the Westinghouse Machine company of Pittsburg, died at her home in Rochester, on April 10th, aged 63 years. Mrs. Keller was for 40 years a resident of Rochester and was highly esteemed.

Clinton L. Rossiter, president of the Brooklyn Rapid Transit company, is in Chicago, where he is inspecting the elevated electric-railway systems. Electricity will be introduced on the lines of the Brooklyn Elevated company, recently leased to the Rapid Transit system. Mr. Rossiter may use the Sprague multiple-unit system of control now in use on the South Side system and has promised that when this is done he will run cars on the Brooklyn elevated line at two-minute intervals throughout nearly all of the 24 hours, instead of the long intervals now in vogue. As President Rossiter's health has been affected by the work incidental to the acquisition of the big properties recently secured by the Brooklyn Rapid Transit company, he is making his visit one of pleasure as well as business.

ELECTRIC LIGHTING.

The Redwood City (Cal.) trustees will call an election for May 20th to vote \$4,125 for a new electric-light plant and \$8,000 bond, for new water mains.

The city of Vincennes, Ind., will receive proposals for lighting the city with electricity and with gas on May 22d. The contract will extend for 10 years and will carry with it a franchise for private light-

ing. Bryan & Humphrey, St. Louis, Mo., are consulting engineers for the city.

It is reported that Stewart Lyons is making arrangements for the erection of an electric-light plant for municipal and domestic purposes in Coquille, Ore.

The Fisher's Island Electric Light, Heat and Power company has been incorporated to do a general electric-lighting business at Fisher's Island, N. Y. The capital stock is \$10,000.

Residents of Tucson, Ariz., think that an electric-light plant is badly needed in that town. Judge C. W. Wright, in a recent address, said that a \$50,000 plant should be erected.

Fire broke out recently in the electric-lighting plant at Union, Ore., and the plant was so badly damaged that an entirely new plant will be necessary. The owners will rebuild at once.

The city of Fulton, Mo., has voted \$4,000 for improvements and enlargements in its municipal lighting plant, and has placed the work in the hands of Bryan & Humphrey, consulting engineers, St. Louis, Mo.

The issue of \$50,000 worth of bonds voted about a year ago for a municipal light plant and a water system in Healdsburg, Cal., and over which there was some trouble, has been declared legal, and Healdsburg can now erect its own electric-light plant.

A new gas and electric-light plant is to be established at Santa Monica, Cal., by the Santa Monica Electric and Power company, which now furnishes light to the city. The new electric plant will include a 500 horse power steam engine, one electric generator of 500 kilowatts capacity and two smaller generators of 600 kilowatts each.

On March 28th a meeting of the new Twin City Electric company was held at Grand Rapids, Wis., and it was decided to build at once a new and up-to-date plant. It is the intention of the company to furnish light for the cities of Grand Rapids and Centralia, as well as power for several factories and milling companies. The capital stock of the incorporation is \$20,000.

Sag Harbor, Long Island, famous as a whaling port in days gone by, is going to get abreast of the times, for the Board of Village Trustees has granted to Robert K. Story of New York permission to establish an electric-light plant there. Mr. Story says that he will erect electric lights throughout Sag Harbor and furnish better lights than that given at present, at a rate cheaper than the cost of now lighting the streets.

PUBLICATIONS.

The Western Electric company, Chicago and New York, has issued Bulletin 19 F, which describes the Arctic ceiling fan and accessories. This is the fourth of a series of bulletins describing the various fan motors manufactured by the Western Electric company.

The enterprising Pelton Water Wheel company of San Francisco and New York has issued a handsomely printed and illustrated catalogue of 90 pages entirely in Spanish. It relates to the "Rueda Hidraulica Pelton," and all tables and dimensions are given in the metric system. This is a very practical and sensible way to assist American trade extension in Mexico, Central and South America. As there is an immense field for the introduction of water-power transmitting machinery in the Spanish-American countries, the new catalogue should amply repay the care and money expended on it.

The "Universal Electrical Directory" (J. A. Berly's), published by H. Alabaster, Gatehouse & Co. of London, is out for 1899. This is the well-known red-covered electrical directory, and the publishers' price is six shillings. It contains the names of the members of the electrical and kindred industries throughout the world. The British alphabetical section now comprises about 9,845 names, the Continental section 8,195 names, the American 5,304 and the Colonial 2,120, a total of 25,464, approximately 1,670 names of individuals and firms more than were contained in the book for 1898. For simplicity and facility of reference the book is divided into four groups, British, Continental, American and Colonial, which are again subdivided into alphabetical and classified sections. In addition to the new names incorporated in the present issue, much financial information is given, the telegraphic addresses and local telephone numbers are given, and the total of pages added to the work is 64, as compared with that of 1898, making in all about 1,182 pages entirely of directory matter.

ELECTRIC RAILWAYS.

Tom L. Johnson, the widely known street-car manager, in an interview in Cleveland, is quoted as saying: "The time is going to come when the people will ride free upon the street cars run and operated by a municipality, the same as they now get their letters delivered to them by the postal system. Municipal control is as easily handled as governmental control. Politics would not be able to cut any fig-

ure. In every separate organization, where the servants of the company, government or municipality are subject to examination by public sentiment, where free access to the inner workings is made possible, no corruption is found. It is only in the hidden byways that political chicanery can be possible."

The City Council of Gothenburg, Sweden, has decided to purchase the concession and stock of the Gothenburg Tramway company, paying therefor £70,000. It is as yet undecided whether the municipality will build and operate electric tramways or will lease the right to do so to an operating company.

The owners of the Wellington Extension mine at Oyster Bay, B. C., have let a contract to the firm of George C. Hinton & Co. for the placing of a complete tramway and electric-light system, the first cost of which will be about \$60,000. It is expected that the plant will be in position by the middle of summer. The electric tramway line will be about five miles long and operated by two 150 horse power generators.

The Batte (Mont.) Inter Mountain says that W. A. Clark and W. L. Hog, constituting the Silver Bow Railway company, have purchased the Columbia gardens, about four miles east of the city, and will construct a new electric line to that resort. The new corporation agrees to construct a new double track from the junction to the gardens, a distance of two miles, the road to be operated by electrical power.

The Northeast electric railway of Kansas City is being rebuilt. This line consists of five miles of double-track extending from Fifth and Walnut streets, on Fifth street to Independence avenue and thence out the latter thoroughfare to Budd Park. The new rails weigh 103 pounds to the yard, and steel poles support the suspension wires for the overhead conductors. The Electric Installation company of Chicago has the contract for the overhead construction work.

Negotiations are said to be in progress by which Henry Everett, the Cleveland street-car magnate, and his associates will likely secure possession of the plant of the Akron (O.) Street Railway and Illuminating company. It is understood that the Everett people have made a cash offer amounting to \$1,250,000 for the property, and the offer will probably be accepted. The street railway has just secured a 25-year extension franchise, and in return will carry passengers for a four-cent fare.

The Grand Rapids, Grand Haven and Muskegon Railway company was incorporated last month, with a capital stock of \$100,000, to build 40 miles of electric railroad between the Michigan towns named in the title. The company is preparing to make surveys and complete preliminary work for the road and for three draw and pile bridges. When this is finished contracts will be let. The officers of the company are: President, Thomas F. Carroll; vice-president, David A. Crow, Grand Rapids; secretary, C. W. Taylor, Detroit, and treasurer, Joseph Kirwin.

It is admitted by stockholders of the Tarrytown, White Plains and Mamaroneck electric railroad that the road has been sold to the Union Railroad company. The price is said to be about \$550,000. The company owns 20 miles of franchises in Westchester County, New York. A line is in operation from Tarrytown on the Hudson to Mamaroneck on the sound, passing through White Plains. A short time ago the town authorities of East Chester and Scarsdale gave a franchise from Mount Vernon to White Plains, enabling the road to make a connection with the Union railroad in Mount Vernon. The Union Railroad company now has all the surface lines in Westchester County except two small local roads, one in Larchmont and the other in Port Chester. The company, since it has become allied through the Third Avenue company with the Manhattan Elevated of New York city, is promising the people of Westchester County and the Bronx rapid transit to Manhattan. It proposes to double-track its lines wherever possible and connect with the elevated road at One-hundred-and-seventy-seventh street. A fare of five cents will be charged from all parts of Westchester County to One-hundred-and-seventy-seventh street.

ELECTRICAL SECURITIES.

The directors of the Edison Electric Illuminating company of Boston offer to stockholders of record on April 6th 1,702 shares of the capital stock of the company at \$120 per share, at the rate of one new share for every 22 old shares now held. This distribution leaves in treasury of company 58 shares, which, with any of the above issue not subscribed for, will be sold by public auction at such time as the directors may order. Rights to subscribe will expire at the close of business on May 13th.

ELECTRIC VEHICLES.

The Electric Process company (capital, \$125,000) has been incorporated at Newark, N. J., to run cars in Pennsylvania cities by leasing franchises.

The Lewis Motor Vehicle company has been incorporated at Trenton, N. J. The capital stock is \$5,000,000. Thomas W. Synnott and Harry A. Berwind are incorporators.

TELEGRAPH.

Gen. A. W. Greely, chief of the Signal Service, is now in Cuba, to confer with Col. Dunwoody about the operation of the telegraph lines in that island. At present volunteers operate the telegraph lines. As they are to be mustered out a new arrangement must be made to operate the lines by civilians or by the enlistment of the Volunteer Signal Corps. It is this condition that Gen. Greely hopes to arrange.

The overland telegraph lines connecting Havana with Santiago have been completed by the Signal Corps. They place the commanding general in Cuba in communication with every command and all the important towns of the island. The corps has constructed 200 miles of line in sixty days. The trunk line extends from Pinar del Rio through the center of Cuba to Baracoa, the extreme eastern port. Nine lines north and south cross the trunk line.

INDUSTRIAL COMBINATIONS.

It is said that the new Consolidated Street-car company will take over the street-car business of Pullman's Palace Car company of Chicago and absorb the following-named concerns: J. G. Brill company, Philadelphia; St. Louis Car company, St. Louis; American Car company, St. Louis; John Stephenson company, New York; J. M. Jones' Sons, West Troy, N. Y.; Kuhlman company, Cleveland, O.; McGuire Manufacturing company, Chicago, and Peckham Truck company, New York.

MISCELLANEOUS.

It is stated that the French government is so pleased with the success of Marconi's wireless-telegraph experiments across the English Channel that it proposes to have him conduct experiments between the South Foreland lighthouse, the present experimental station in England, and the Eiffel Tower in Paris, a distance of 230 miles.

A crank wrote to Mayor Ashbridge of Philadelphia the other day to suggest that electric-light wires be placed in the reservoirs and in the bed of the Schuylkill River, and that at stated periods every day heavy alternating currents of electricity be transmitted through them. By this method, the writer argued, all fever microbes and germs would be killed or rendered harmless.

The public printer is inviting sealed proposals, until May 4th, for furnishing the Government Printing Office electrical supplies during the fiscal year ending June 30, 1900. Detailed schedules of the articles required, accompanied by blank proposals, and giving the regulations with which bidders must comply, will be furnished upon application to F. W. Palmer, public printer, Washington, D. C.

The lower house of the Missouri Legislature has passed the bill introduced by Mr. Fitzgerald to tax franchises. It names almost every class of business, including incorporated banks, railroads, street railways, telegraph, bridge, ferry, telephone, sleep-ing-car, gas, water, electric-light and power companies, and provides that they shall pay the same tax on their franchises as is paid on other kinds of property. It is estimated that this will add many millions to the values for the purpose of assessment, particularly in St. Louis and Kansas City. An emergency clause was passed, so that if the bill becomes a law it can take effect in time for this year's assessment.

TRADE NEWS.

On March 27th the office and factory of the Shawmut Fuse Wire company at 93 Federal street, Boston, were destroyed by fire. The company has secured permanent quarters at 161 High street, where it will be pleased to receive its customers and friends.

The Weston Electrical Instrument company is making contracts for its new factory at Waverly, N. J., a suburb of Newark. A railway switch is now being constructed to the spot, and ground will be broken in a few days for the erection of what will be one of the most complete manufacturing establishments in the United States.

The Smith & Hemenway company of New York, which recently purchased the entire hardware business of the Maltby-Henley company and the Bindley Automatic Wrench company, has been forced by reason of the absorption of these companies to seek larger quarters, and after May 1st will be pleased to see its numerous friends and customers at the new address, 296 Broadway.

The Commercial Electrical Supply company of St. Louis has passed out of the hands of Joseph

Franklin, D. H. MacAdam and Joseph Franklin, Jr. Funds to meet all indebtedness of the company are now in treasury of the newly organized company, and all claims will be met as they fall due. The company has passed into the control of Mr. William F. Nolker, sons and associates, who have ample means to make the company one of the foremost supply houses of the West. The capital stock will soon be increased, and it is probable that the management and arrangement as to agencies will continue about the same as in the past.

The Gate City Electric Supply and Construction company of 74 North Broad street, Atlanta, Ga., has been organized to do a general electrical supply and construction business throughout the South. The officers of the new company are: President, W. H. Turner; vice-president, J. D. Turner; secretary, Dr. J. P. Kennedy; treasurer and general manager, Oscar C. Turner; superintendent, D. A. Jett. Mr. Oscar C. Turner, the general manager, has been identified with the electrical business of Atlanta for the last seven years, and was with the Georgia Electric Light company as purchasing agent before he went into business for himself. The company will carry a large stock and will endeavor to sell and do "everything electrical."

The many friends in the electrical trade of W. F. Hanks, until the late consolidation of electrical journals with the Electrical Engineer, and of E. L. Powers, "the American Directory man," formerly of Chicago, will be interested to know of the organization of the E. L. Powers company and its purchase of "Johnston's Electrical and Street Railway Directory," formerly published by the W. J. Johnston company. The new company will have E. L. Powers as president, E. L. Blanchard as vice-president and W. F. Hanks as secretary and business manager, and quarterly "American" directories will be issued, covering every branch of the electrical industry. The combination of the efforts of three such experienced men as Messrs. Hanks, Blanchard and Powers, possessing, as they do, also, the confidence of the trade both East and West, cannot fail greatly to strengthen publications which are already well appreciated.

The Pelton Water Wheel company has recently installed two wheels in the Ophir mine on the Comstock under such extraordinary conditions as to head as to be worthy of note. One of these is a 32-inch wheel, direct-connected to a dynamo used for lighting the mine, and the other a 36-inch wheel, direct-connected to a blower for the purpose of ventilating the various shafts, drifts and stopes. Both of these wheels are located at the Sutro tunnel level and run under a vertical head of 2,020 feet. This is believed to be the highest head under which any water wheels have ever been operated, except a similar wheel furnished an adjacent mine some years ago, which runs under a 2,100-foot head. Upward of 30 Pelton wheels are running the various Comstock mines, under heads varying from 1,200 to 2,100 feet, operating dynamos, blowers, hoists, etc., many of which have been running several years with practically no expense in the way of repairs. From these references it will be seen that there is hardly any limit to the pressure under which these wheels can be safely and efficiently operated.

BUSINESS.

The Western Electric company has recently distributed a number of its catalogues on Petite arc lamps. Any reader of the Western Electrician desiring a copy may secure one by writing to the company for it.

The officers of the Fort Wayne Electric corporation report a good business in spite of recent difficulties. The Chicago office has just sold three 125-volt multipolar dynamos of 130 kilowatts each to the Plankinton estate at Milwaukee. These machines will be direct-connected to three engines. This order makes a total of six Fort Wayne dynamos sold to the Plankinton estate.

The L. P. & D. Transmitter company of Montpelier, Vt., says that it is getting considerable business from owners of isolated plants, as well as from central stations, that want to increase their capacity but are short of room for any additional machinery. Belted apparatus can be bought cheaper than direct-connected, and often it gives results that are just as good.

Users of copper wire who have scrap copper wire on hand will be enabled to realize on it by communicating with the Swarts Metal Refining company, 20 North Desplaines street, Chicago, which makes a specialty of buying up old wire of this kind. The Swarts company is perhaps the largest concern of

the kind in the country, and is well known among the electrical fraternity.

The Turner Engineering company of Bucyrus, O., is furnishing the Turner water-tube boiler (250 horse power) for the Findlay, O., street railway; two of 200 horse power each for the Central Traction company; three of 225 horse power each for the Indianapolis Ice and Cold Storage company. Large boilers of this type recently put into service are showing excellent results.

The Safety socket hook (see that "snap"!) is an original specialty of the Electric Appliance company. The special feature is a spring which holds the socket hook firmly in place on the screw-eye which is used in connection with it, thus preventing the lamp from being broken by being jarred or knocked from its position. The safety socket hook seems to be a marked improvement over the regular style.

In the Truitt regulating lamp the Central Electric company, Chicago, is placing on the market a desirable addition to electric-lighting appliances. A positive deficiency is one of the strong recommendations, for it lacks resistance and inductive features in its operation. Starting with lamp without current, simply turning it in the socket produces one, eight, 16 or 24 candle power illumination, as may be desired. This is secured by a simple departure from the ordinary socket mechanism, and by dividing the lamp base into three segments, these segments being connected to the two lamp filaments. Through series and multiple current application, together with the current given individually to the two filaments, the variation in candle power is obtained with remarkable freedom from complication. Any lamp of proper voltage operates equally as well on direct or alternating current. The Truitt regulating lamp has been tested eight months, it is said, with best results.

On the subject of fan-motor prices, the Emerson Electric Manufacturing company of St. Louis writes: "While we do not desire to change the prices that have been named by us at the beginning of a season, the conditions surrounding the price of raw material are so unusual that we are certain that we shall be forced to make an advance in the price of fan motors and ceiling fans within a very short time. We write you of the facts in the case so that you may understand that we are not attempting to take advantage of you by advancing our prices without again notifying you, and we will say that if you are in a position to place a definite order for any quantity of fan motors and ceiling fans prior to April 15th we shall accept the order on or before that date at the prices named in the schedule which was sent with fan-motor catalogue [of March 1st]. Any motors which you order from us prior to April 15th may be ordered shipped forward at any time prior to August 1st next, but when the number of motors on that order are shipped we can only accept further orders from you at the prices which may be ruling on the date order is received by us."

On Thursday morning, April 6th, a party of gentlemen visited Coney Island, under the guidance of Captain J. McL. Murphy, inventor of the safety third-rail system, on a trip of inspection over the Manhattan Beach safety third-rail road. The party included Henry L. Doherty, New York; Captain E. W. Brady, Washington; Irvin Butterworth, Columbus, O.; E. V. Baillard, New York; Arthur J. Wood, New York; J. S. Campbell, Gravesend, L. I.; M. J. Mandelbaum, Cleveland, O.; Will Christy, Akron, O.; Louis Steckler, New York; B. Mahler, Cleveland; J. McLeod Murphy, New York; W. M. McBillesby, New York. Without going into details, it should be stated that the point which would first strike many electrical engineers as being most valuable relates to the non-arc nature of the switches employed by Captain Murphy. Each of these switches, which serve to keep "alive" only the portion of supply rail beneath the car, is of such construction that it operates to make the circuit, and not to break it. Those who have watched the progress of the Safety Third-rail company will be interested to know that the day before this trip was made two gentlemen from Holland, Messrs. A. de Ritter, Jr., and Henry J. Spyster, both of Amsterdam, inspected the Manhattan Beach road in operation. Doubtless no higher compliment has been paid this system than the remarks made at that time by Mr. Spyster to Electrical Engineer E. V. Baillard of the Safety Third-rail company. Mr. Spyster said: "I am not afraid to say that I recommend this system. I will cable my opinion to my people." These two men represent the city authorities of Amsterdam. The party was most royally entertained in Minden's Hotel at luncheon by the Third-rail company.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 4, 1899.

622,207. Driving Mechanism. Herman B. Collins, Fulton, N. Y. Application filed April 10, 1896. Renewed September 6, 1898.

The actuating wheels for communicating motion from one of the parts to the other are revolvable on axes arranged at an angle with the axes of the revolvable head and the driver, an electric motor having its armature connected to the driver, and a fan actuated by the motor and arranged in proximity thereto for preventing heating of the motor.

622,210. Apparatus for Illustrating the Phenomena of Thunder and Lightning. West Dodd and Alvin D. Struthers, Des Moines, Ia. Application filed June 13, 1898.

A case is employed having one side hinged at its bottom to extend horizontally to serve as a door, with a frame fixed to the inside face of the door, a cross piece at the center of the frame to produce two compartments, a cover fixed on top of the frame and cross-piece to serve as a platform, an electric accumulator fixed in each compart-

ment, means for storing electricity in the accumulators, and means for discharging electricity to objects placed on the cover and platform.

622,214. Trolley Wheel. Silas W. Fletcher, Lowell, Mass. Application filed July 25, 1898.

The combination of a core, side plates arranged on opposite sides of the core, a series of concentric tread-washers, surrounding the core between the side plates, and bolts passing through the side plates and through holes formed partly in the core and partly in the washers.

622,225. Water Guard for Trolley Ropes or Poles. Thomas Hawken, Rockland, Me. Application filed October 31, 1898.

A guard for a trolley rope or pole consists of a block comprising sections adapted to be secured together and having a hole through it, the block adapted to embrace the rope or pole and be adjusted to any point thereof for the purpose of shedding water at that point.

622,230. Controlling Switch for Electric Motors. Reese Hutchison, Mobile, Ala. Application filed December 9, 1898.

There is an automatic lock for the switch and an electromagnetic device to control the lock, the electromagnetic device being connected with the motor circuit and so adjusted that upon the establishment of a predetermined strength of current the switch is released.

622,268. Telephone-switchboard System and Annunciator. George B. Rodgers, Knoxville, Tenn. Application filed April 27, 1898.

An annunciator having a pair of lines and a pair of restoring-magnet coils, the coils being alternately arranged so that a plane passed through the longitudinal axes of the line coils would intersect a plane passed through the longitudinal axes of the restoring coils, an armature normally over one pair of coils pivoted to swing from one pair of coils to the other, and arms on opposite sides of the armature extending toward one pair of magnet coils when the armature rests over the other pair, and stops limiting the swing of the armature.

No. 622,645.

mans, Evanston, and Norman Whichello, Chicago, Ill. Application filed January 29, 1898.

The equipment includes a hoisting motor, circuits therefor, main and reversing switch contacts arranged in the circuit, of a motor-magnet, including an armature and shaft, a main switch arm and a reversing switch arm mounted on the shaft of the motor-magnet armature and co-operating with the contacts, and means for controlling the motor-magnet.

622,450. Insulating Material. Julius De Long, New York, N. Y. Application filed July 20, 1898.

This material consists of a mixture of cattle hair, ground corncob, ground cornstalk pith, jute waste and mineral wool.

622,452. Magneto-electric Motor-dynamo. Fred H. Donaldson, Garvanza, Cal. Application filed April 16, 1898.

A field composed of a series of permanent magnets suitably arranged and supported at substantially equal distances apart, and an armature comprising a shaft and a series of electromagnets extending at right angles from diametrically opposite sides thereof in the same longitudinal plane and arranged to alternate with the permanent or field magnets are the principal features of the invention.

622,466. Electric Railway or Tramway. Jean J. Heilmann, Paris, France. Application filed November 9, 1898.

An electric-railway system in which the alimentary current for the train motors is furnished by a generator in a fixed station, the generator being excited by a special dynamo, the field circuit of which is controlled from the train by means of an auxiliary wire or conductor.

622,472. Typewriting Machine. William T. Hoofnagle, Baltimore, Md. Application filed October 22, 1897.

A feature of this machine is a pivoted armature and one or more magnets movable toward and from the pivot point of the armature, and connections between the armature and type wheels whereby the latter will rotate in unison when the armature is moved.

622,481. Means for Securing Electrical Unity of Systems of Metallic Pipes or Mains. Dugald C. Jackson, Madison, Wis. Application filed October 12, 1898.

A length or section of fluid-conducting pipe or main having an enlarged portion formed thereon is adapted to be connected with an electrical conductor, whereby an effective electrical joint may be obtained between the section or length and an adjoining section or sections, and the main is preserved from deterioration.

622,596. Apparatus for Holding and Connecting Guard Wires of Electric Cables or Other Wires. Ralph Bostock and Frank A. Cheetham, Brighthelm, England. Application filed November 29, 1898.

Hooks are pivoted at opposite points of a block; weighted crank levers are pivoted in the block, and connections are made between the block and the hooks, so that wires in tension attached to the hooks will be held until the tension is relaxed, when the weighted lever will release the hook from same.

622,606. Contact for Controllers. George H. Condict, New York, N. Y. Application filed February 7, 1899.

The controller cylinder and raised contact bars thereon, with a stationary bracket and an insulating support therefor parallel with the controller, a detachable spring-pressed hinged contact finger adapted to engage the contact strips of the cylinder, a stop adapted to be engaged by a portion of the finger to limit its downward movement and an independent electrical connection between the outer portion of the contact finger and the circuit to be connected.

No. 622,628.

622,607. Electrical Advertising Machine. Harry W. Cox, Nottingham, England. Application filed July 15, 1898.

Removable plates are carried by frames and made with raised portions which represent the advertisement to be reproduced; brushes make contact with the lamps to be lighted; ratchet mechanism rotates the drum and limits its motion.

622,608. Electrical Advertising Machine. Harry W. Cox, Nottingham, England. Application filed September 15, 1898.

A group of lamps is employed with spring contacts or brushes arranged in rows, a cylinder for each of such rows, selecting fingers carried by the cylinders and making direct electrical connection with the lamps through the spring contacts or brushes, a rod for such fingers to turn upon, a second rod for limiting the motion of the fingers, and a third rod for holding the fingers in their selected position.

622,609. Carbon Brush-holder. Renwick E. Crockett, Michigan City, Ind. Application filed November 29, 1898.

A carbon brush-holder comprises a body arranged for attachment to the brush-holder support, a brush casing arranged to slide in the body, a tension device connected

with the brush casing and acting in the direction in which the casing is adapted to slide, and means for holding the tension device in position.

622,618. System for Overhead Electric Wires. William Glasgow, Chicago, Ill. Application filed January 30, 1896.

The line wire is divided into separate divisions of a continuous and unbroken nature, independently supplied with the electric current, a series of intermediate hangers supporting each division of the line wire, switches supported by the hangers, switch-operating arms connected to the switches and to the line wire, and adapted to operate the switches upon the breakage or undue sagging of the line wire, these switches having branch connections with the line wire and with a suitable return conductor.

622,627. Resistance and Contact Apparatus for Electric Currents. Henry Lyon, Glasgow, Scotland. Application filed July 6, 1898.

Two liquid-containing jars are employed, in the bottom of each of which is a metal cup having electrical connections; there are also a metal cone, suspension cords and pulleys for the cones, flexible coils of wire connecting the cones to separate conductors, and handles to operate the pulleys.

622,628. Resistance and Contact Apparatus for Electric Currents. Henry Lyon, Glasgow, Scotland. Application filed July 6, 1898.

Resistance and contact apparatus for main and shunt electric currents having liquid-containing jars comprise a metal cup in each jar, metal cones in the jars, a pulley to which the cones are secured, so as to cause certain cones to make contact and others to break contact upon the operation of the pulley, in combination with hinged contact pieces and means carried by the pulley for operating the contact pieces.

No. 622,230.

622,629. Multiple Telegraph. Ernest J. P. Mercadier and Henri R. J. Pierquin, Paris, France. Application filed January 3, 1896.

In a system of multiplex telegraphy produced by the employment of alternate or undulatory vibrating currents, there is in combination with the vibrators or tuning forks an equal number of induction converters, the two joint induction coils whose primary wires are in circuit of the secondary wires of the converters, the graduated condensers shunting the secondary wires of the coils, and the telephonic translator having its wires connected with the secondary wires of the joint induction coils.

622,636. System of Multiplex Telegraphy. Henry A. Rowland, Baltimore, Md. Application filed April 27, 1896.

This method of transmitting intelligence consists in dividing the waves of an alternating electric current into groups, modifying one or more of such groups by suppressing one or more waves therein and transmitting the modified current over a line.

622,639. Electric Meter. Gustave A. Scheffer, Peoria, Ill. Application filed January 20, 1899.

The motor armature described consists of a metallic disk or plate provided with radial saw cuts or slits extending nearly to the periphery of the disk, in combination with a suitable commutator device for supplying current to the individual segments or portions of the armature.

622,645. Electro-harmonic Signaling Apparatus for Telephone Systems. Fred H. Brown, Chicago, Ill. Application filed May 3, 1897.

The apparatus described includes an induction coil, a line wire included in circuit with the secondary of the induction coil, a battery having one of its poles connected to one terminal of the primary of the coil, a switch lever connected to the other terminal of the battery, contacts arranged to be respectively engaged by the lever, a circuit including one of the contacts and connected to the other terminal of the primary of the coil, an electromagnetic interrupter arranged in the circuit, an auxiliary circuit including the other of the contacts, a local transmitter arranged in the auxiliary circuit, means for normally holding the lever in position to open the interrupter circuit, and to close said auxiliary circuits, in combination with a distant receiver arranged in the line circuit whereby when the lever is moved to close the interrupter circuit the diaphragm of the distant receiver vibrates harmonically and synchronously with the interruptions in the interrupter circuit.

622,646. Electric Signaling Apparatus for Telephone Systems. Fred H. Brown, Chicago, Ill. Application filed May 3, 1897.

The first claim is given: In a signaling apparatus for telephone systems an induction coil, a battery having one of its terminals connected to one terminal of the primary of said induction coil, a circuit connection leading from the other terminal of said battery, a switch lever arranged in said circuit, a pair of contacts so relatively arranged with respect to said switch lever that when said lever is contacting with one of said contacts it is out of contact with the other, a circuit connection from one of said contacts to the other terminal of the primary of said induction coil, an electromagnetic interrupter arranged in said circuit connection, an auxiliary circuit connection leading from the other of said contacts, a local transmitter arranged in said auxiliary circuit connection, means for normally holding said switch lever in position to close said auxiliary circuit to the battery, and to open the electromagnetic interrupter circuit, a line wire included in circuit with the secondary of said induction coil and a distant signaling device arranged in said line circuit.

622,328. Magneto Ear-Phone. Frank H. Collins, Everett, Mass. Application filed February 21, 1898.

A transmitter is connected with the battery, and is adapted to be secured to the apparel of the user, a receiver also connected with the battery and coil, the receiver consisting of a suitable casing in which is contained an electromagnet, a deflected tube secured to the end of the casing and a diaphragm secured between the casing and tube.

622,355. Electric Elevator. Thaddeus W. Heermans, Evanston, and Norman Whichello, Chicago, Ill. Application filed January 29, 1898.

In a controlling device for electric motors, a controller arm, a rotatable shaft, a plurality of arms having crank or eccentric connections with the shaft arranged to engage the arms for actuating the same and means for rotating the shaft are described.

622,369. Controlling Switch for Electric Motors. Reese Hutchison, Mobile, Ala. Application filed November 26, 1898.

The combination is described of an electric motor, a motor circuit therefor, means for varying the effective strength of current in the circuit, including a multiple contact switch, an automatic electromagnetic locking device for locking or holding the switch in any contact position, and means for mechanically disengaging the locking device.

622,392. Method of and Means for Operating Electric Motors. Charles J. Reed, Philadelphia, Pa. Application filed August 17, 1898.

The method of operating electric motors from a divided source of electrical energy consists in supplying the fields from a fixed number of the divisions of the source of energy at a constant electromotive force and supplying the armature from a variable number of the divisions of the source of energy at a variable electromotive force and in rotating the connections at frequent intervals in a fixed order of sequence.

622,398. Electric Steering Apparatus for Vessels. Gaston Sautter, Paris, France. Application filed November 17, 1898.

A transmitting apparatus, a series of commutators provided with magnetic relays or their equivalents controlled by the transmitting apparatus, an auxiliary motor, the circuit whereof is adapted to be opened and closed and its current reversed by the commutators and relays, a differential train of gearing controlled by the auxiliary motor, a rheostat and commutator controlled by the train of gearing and a principal motor controlled by the rheostat and commutator and directly controlling the rudder are described.

622,412. Telephone Cabinet and Support. Paul W. Bossart, Marietta, Pa. Application filed February 11, 1898.

A transmitter-supporting arm having its lower end recessed at one side and normally closed by a part of a fixed device to which it is attached is in combination with a spring contained within the recess and operating to lift the arm, a transmitter mouth-piece and a pivotal joint connecting the mouth-piece to the arm and allowing horizontal motion.

622,413. Granular Electrode and Process of Treating Same. Paul W. Bossart, Marietta, Pa. Application filed June 6, 1898.

A telephonic instrument has in circuit a body of non-metallic metal-coated granular electrodes which have projecting on a sides of their surfaces

Western Electrician.

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, APRIL 22, 1899.

No. 16

D. G. Hamilton, President Chicago City Railway Company.

The directors of the Chicago City Railway company have elected Mr. David Gilbert Hamilton president of that corporation to fill the vacancy caused by the death of the late M. K. Bowen. Mr. Hamilton was second vice-president of the company and a practical street-railway manager. He was familiar with the company's affairs and policy and had a large financial interest in the enterprise. For these reasons he was selected to succeed Mr. Bowen, and, as he was the only member of the board who was thus equipped, he consented to act, although his personal interests demand his attention.

Mr. Hamilton is a lawyer by profession, but he has been identified with street-railway interests so long that he is more widely known as a successful manager of transportation properties than through his legal connections. This may be due partly to the fact that he abandoned general practice early in his career and has since made a specialty of trusts, real estate and probate matters, in all of which he is a recognized authority. His advice in matters pertaining to investments is considered especially valuable by capitalists and his experience in organizing and conducting financial transactions of magnitude, as well as in the management of quasi-public enterprises, has gained for him the confidence of investors in this class of properties.

Mr. Hamilton was born in Chicago in 1842 and he completed his education in this city. He also entered upon the practice of his profession here and he has always been closely identified with the leading enterprises of the community. At times he has controlled large interests elsewhere, but he has always lived in Chicago and he has made this city the headquarters of all business interests that have been under his management. He has seen the city constantly changing, growing and extending its influence, and he has great faith in its future.

Mr. Hamilton's family occupied a position of prominence and influence, and the young man had many advantages for those days. His father was a successful contractor, and gave him an excellent education as a foundation for his business career. The young man was first placed in a private school, then passed through the high school of the city and entered Asbury University, now De Pauw, at Greencastle, Ind., where he completed his course in 1865. He rounded out his studies by a special course at the law school of the old Chicago University, from which he was graduated in 1867. He at once established himself in Chicago, where he devoted himself to the practice of the law. He abandoned general practice after a year, and from that time made a specialty of trusts, real estate and probate practice.

During the last 15 years he has been actively engaged in the management and operation of street-railway properties, and he has had valuable experience in the building and equipment of some of the most important street-railway enterprises in the country.

When he became actively interested in the Chicago City Railway company, 15 years ago, that property was comparatively insignificant; the cable had not been introduced and electricity was still an unknown factor. The old horse lines were restricted, and the development of the industry seemed to have come to a standstill. But improved methods of operation were introduced—first the cable and then the electric motor—and with mechanical propulsion assured street-railway interests assumed an importance in the financial world that had not been dreamed of by the most enthusiastic advocate of the new order.

For five years Mr. Hamilton devoted considerable attention to the affairs of the South Side system. He was a director during that important period in the company's history and gained valuable experience in the management of street-railway properties during that time.

Ten years ago, in company with other Chicago

capitalists, Mr. Hamilton formed the National Railway company of St. Louis, which has since proved such an important factor in the transportation affairs of that community. The object of this organization was to acquire and operate street-railway properties. Mr. Hamilton was elected director at the time of organization, and at the next meeting he was chosen president. He continued at the head of the company until January 25th of the present year, when he relinquished control of the property. For 10 years the "Hamilton syndicate," as the company was called, engaged in the development of street-railway business in St. Louis. It absorbed the Citizens' Railway company, Cass Avenue and Fair Grounds Railway company, with which the Northern Central Railway company and the Union Railroad company were consolidated, the St. Louis Railroad company, the Southwestern Railway company and the Baden and St. Louis Railroad company. Mr. Hamilton was president of each of

D. G. HAMILTON.

these companies, as well as the National company, but he continued to reside in Chicago, and the offices of the corporations were in this city.

The system controlled by the Hamilton syndicate in St. Louis was extended and completely rebuilt during Mr. Hamilton's administration, and the value of the property increased every year. It was considered one of the best street-railway investments in the country, which was of itself a high compliment to Mr. Hamilton's management and administrative ability.

Recently Mr. Hamilton was induced to return to the directory of the Chicago City Railway company and he had been elected second vice-president at the January meeting. His familiarity with the affairs of the company and his experience in the management of this class of properties make his services very valuable at this juncture.

Aside from his professional work and his street-railway interests, Mr. Hamilton has many important financial connections, and he is engaged in other enterprises that occupy much of his time. He is resident director of the Union Mutual Life Insurance company of Maine, director of the Title and Trust company of Chicago, director of the National Bank of Texas and is interested in other enterprises. He has always encouraged educational institutions and has devoted much of his time to

this work, especially the University of Chicago and the De Pauw University at Greencastle, Ind., in both of which organizations he is a member of the board of trustees.

Mr. Hamilton is a member of the Chicago club, the Union League club and the Washington Park club, as well as many purely social organizations, but he gives very little time to club matters and has never taken an active part in their management or direction. Mr. Hamilton resides at 2929 Michigan avenue.

Talk of Street-railway Consolidations.

Within the last few weeks the talk of consolidating the principal surface street-railway systems of Chicago has been revived to some extent. It is said that Mr. Yerkes is willing to merge the North and West Side companies into the combination, but that the stockholders of the Chicago City Railway company on the South Side are unwilling to surrender their property, even though a price of 400 be fixed on the stock, compared with 300 for North Chicago and 125 for West Chicago. Representatives of the Whitney-Widener-Elkins group of capitalists were in Chicago last week, and the newspapers had much to say about the possible consolidation of the street-railway interests of Chicago at their hands. However, it is more likely that the visitors came to further the interests of the new Illinois Electric Vehicle company exclusively; and the suggestion that the street railways may be absorbed to avoid conflict with the proposed system of electric vehicles seems exceedingly far-fetched. On the whole, the combination of the three principal surface street-railway systems of Chicago seems remote. It is possible, however, that the Yerkes companies may be united into one by eastern capitalists and that Mr. Yerkes may retire from the street-railway field in Chicago.

This is a Philadelphia dispatch, dated April 15th, to the New York Sun: "Capitalists of this city are engaged in forming a combination for the control of all the electric traction companies in Pennsylvania outside of Philadelphia. The concern is to be called the Electric Traction company of America, and it is to be capitalized at \$25,000,000. The par value of the stock is to be \$50 a share, \$5 of which is to be paid in at once. Among those said to be prominently identified with the movement are John Lowber Welsh, Silas W. Pettit, W. H. Shelmerdine and former Mayor Warwick. The head office of the company is to be in Philadelphia. The scheme is entirely local in so far as those interested are concerned, but the presidency of the company will go to A. A. McLeod, formerly president of the Philadelphia and Reading railroad. The various trolley companies throughout the state have been carefully looked into and data prepared showing the capitalization of each, with prospects for extensions and increased earnings. It was said authoritatively this afternoon that Mr. McLeod had consented to accept the presidency of the company."

Canadian Niagara Project.

[From the Ottawa correspondent of the Western Electrician.]

The Ontario government and the Canadian Niagara Power company have come to an agreement by which the company has decided to relinquish its monopoly before November 1st next. The agreement provides that the company may continue to do business, but the monopoly clause will be stricken out. A second company is negotiating with the government, and has about arrived at a definite agreement, the details alone not being arranged, but when they are it will commence work at once.

At a public meeting held in Nephi, Utah, recently, it was decided that the town should have an electric-lighting system.

Repairing Electrical Machinery.

By B. F. FELLOs.

Recently the bearings of one side of a dynamo shaft indicated by a rattling sound that something had given out. The bearing is presented in section in Fig. 1. It carries the cylinder connection A. The cup encircles shaft B, and attached to this cup are the studs H H, which are bored out for the shaft G and spiral spring I. The bearing is of the three-point description, and is designed so that all three points of the contact D D on the cone E, and on the cups, present a free rolling surface. The difficulty is that the end pressure from the center of the shaft at C, against the balls and points of contact F F, results in a partial sliding motion at times, and this produces friction. In this particular case the cone was found to be broken at J, over the key K. It was fixed by turning of a shoulder, as at L, Fig. 2, and upon this was shrunk a steel collar M, Fig. 3. This collar or ring made the cone perfectly tight. To have a cone made to replace a broken one, draw out the shape. This will give the makers a general idea of what is wanted. If it is desired to send measurements in detail, obtain a proper length from base to point. This is obtained by measuring the length in the pinion which is to be driven by it. It is important that both shall correspond in length. After the cones are reduced to their proper length, the pitch line is found.

There is a factor connected with the use of cone bearings of electrical machinery which should be considered, and that is the coefficient of friction. Now a coefficient is simply a quotient, and in this case is simply a number that is determined upon by experiment; it shows the relation the surfaces bear to the weight pressed upon them. Thus, if a block of iron were laid on the table it would require a certain amount of force to drag it along the table, but if the table were oiled and the same block put on it would require less force to start it. The proportion that this force bore to the weight would be called the coefficient of friction. If it took a force of 25 pounds to move a block of 50 pounds' weight on a certain surface, the coefficient would be .50, and if it took but a force of 10 pounds to move it the coefficient would be .20, and multiplying the weight by the coefficient will give the force to overcome the friction. The lower the coefficient of friction is, then the easier it will be to drag an object and the less the friction. Friction depends on pressure, not extent of surface, and the block may be set up edgewise, but its weight being the same, the friction will not change. The force with which one surface presses upon another surface varies with the weight or pressure of the pressing surface, and the friction will be this pressure or weight, multiplied by the coefficient of friction.

ANGLE OF CONES INCORRECT.

Some of the lighter designs of electrical machines are supplied with ball bearing of the pattern shown in Fig. 4. The trouble with these types of bearings is that the thrust contact, combined with the roller contact, cannot work well with any oil when the cone is shaped to an angle of only about 28 degrees to the angle of the force acting upon it. This is sketched in Fig. 4, in which the shaft center is A, and the lines of contact of the balls C to B. The pressure often causes the set-screw to cut a groove around the shaft as at D, Fig. 5. It will not do to remedy this with a sharp-pointed set-screw, like Fig. 6, for this will cut the shaft still more, nor will a flat point, like Fig. 7, do, for this will not grip well and will slip. The medium between the two may be used, as in Fig. 8. Such a point can be screwed firmly to its seat on the shaft and usually hold permanently. On the old style of motor driving we often had difficulty with the gearing in getting a good mesh, and in getting the requisite firmness. Much skill was required in setting, if there ever was occasion to make alterations and repairs. Oftentimes a new set of gearing has been put on and permanently good results have been looked for; but the operator has been sometimes disappointed in finding the gear worn out in a few months. Of course, this was due to improper fitting. I always found it a job that required thoroughness and patience and considerable skill, withal, to fit the gearing and shafting and bearings, so that each one supported the other. A common difficulty is encountered in endeavoring to make the driving gear run perfectly true on the shaft. If the gear were the least bit out on the shaft it would wobble a good deal when one came to try out to the rim. And when it is considered that the pinion is on the side of the rim, and not on the outer edge of it, it is realized that the defect is a serious one. A pinion cannot run in an elliptic. It must be concentric with the source of movement at all points in its revolution. Any deviation from its course, from whatever cause, by which the source of power is placed at a variable distance during its revolution, will produce an unsteady movement in the pinion, which occasions undue strain. The ring being tipped out of level, or being level and not concentric with the shaft, are conditions that need close attention. In such states a periodical changing of the pinion is not a commendable a practice as its removal. Ping sometimes are not concentric with the shaft, owing to the pin on the top of the lifting ring being broken off. This pin keeps the rail steady and in its proper place. Its absence will permit the rings to get out of their normal position. Attendants should be instructed to keep a lookout for this accident, as it is liable to occur unnoticed.

ants should be instructed to keep a lookout for this accident, as it is liable to occur unnoticed.

STRAIGHT BEARING.

In Fig. 9 is a pattern of so-called "straight" bearing which the writer has noticed on some electrical machine shafts. The pressure of the balls and cups is about evenly distributed from K K to L, so that the forces do not contribute to any irregularity in the weight. The balls touch the sides of the cone flanges evenly, and there is opportunity for the oils to work. In one case which came to my notice the end of the shaft was gauged with a set-screw at A. The work was not perfectly performed and the pointed screw was heated, the temper drawn, and then a ball-cup end was formed for the steel ball C, Fig. 10. The end of the cone shaft was then cupped to receive the ball, resulting in a ball-socket union at B.

MAKING A CYLINDER TRUE.

If the cylinder is of the common style which screws onto a straight shaft, the work of turning down the rim can be easily accomplished by putting the cylinder and shaft in the lathe together.

REPAIRING ELECTRICAL MACHINERY.

When the cylinder is held in the lathe it can be turned off on both sides without removing and can be accurately trued as far as side lines are concerned before the turning is started. A few blows with a rawhide mallet will cause the cylinder gear to run true, no matter how badly out of true its rim was before putting in the lathe. The lathe cutting-tool will then take off equal quantities of metal from all points around the rim.

ROUND DRIVING STRAPS.

Round driving straps of dynamos and motors are subject to strain, and often wear out rapidly, even when the most improved devices are used. These straps are generally made of leather, but even when the best leather is used their life is short, and they are a source of loss by causing stoppage of the machine while replacing broken with new ones. Numerous substitutes for leather have been placed on the market of late years, one of the best of which is made of canvas, saturated with cement, and folded until the proper thickness is reached. This blank is then pressed into nearly a U-shape, except that the sides near the ends are nearer together than they are at the bottom. Both sides are parallel, the variation in the distance apart being effected by bending the sides inward, so as to form a jog near the middle. The object of this shape is to allow the

looped part to have a curved thickened interior, so as to better resist the wear.

MOTOR CONNECTIONS.

Broken connections about the motor, safety fuses blown, fractured joints, etc., are among the principal causes of a motor failing to start after the current has been turned on. If the connections are found to be loose it is a simple matter to tighten them. In case of wear or breakage, some repair work will be necessary. It would be out of place to give directions as to how bearing rolls should be covered, as electricians often differ as to how and with what they should be covered. Whatever it is, have it well done. See that there are no ridges at the edge of the covering and that the laps are made straight and even. Also see that they are put on so that they will not run against the lap when they are in the frame. It is also important that they be kept clean. Keep all the driving bands tight. All the hands should be composed of two strands, the first strand to be twisted separately, in order that when the strands are doubled, and the second, or cable-laid twist, is put in, the band will form a loop at one end, and be long enough at the other to allow

one of the strands to be unwound a little, put through the loop, when both ends are tied in a square knot. A knot of this description is no larger in bulk than the diameter of the band, and when put on and tied in good shape the knot will last as long and wear as well as the rest of the band.

REPAIRING A BROKEN FRAME JOINT.

I recently repaired a fractured motor-frame joint on the plans shown in Figs. 11 and 12. Fig. 11 shows the character of the break. Fig. 12 shows the method of repair, which consists in putting in a cast piece C set-screwed at D and riveted at E E. By properly proportioning rivet and plate area, a joint may be made to have 85 per cent. of strength of the solid piece.

Circumferential seams should be double riveted, not so much as a measure of strength to resist pressure, but to better resist the strains and shocks received by motors in service. Every rivet should be driven by power. It is becoming possible to thus drive a greater proportion owing to the improvement in machinery for the purpose, the latest style riveters having a greater reach and scope. There are several of the smaller portable machines for special parts. One of these is especially recommended for closing the rivets in the ring. By using such an appliance a rivet longer than could be closed by hand

may be driven and will leave no larger head, the extra length having been forced into the long hole, completely filling it. The head is also changed in shape by the holding-in die, which forces part of the metal from the head into the hole, making both ends equally to be relied on for tightness.

BROKEN PULLEY.

In one shop they could not get good work from a motor, owing to the condition of a driving pulley, which was broken, as in Fig. 13. A piece was broken out at F. Fig. 14 shows how this was repaired by putting a patch G on the inside and fastening with rivets.

Patches may be divided into two principal kinds; that is, hard patches and soft. There is no difference in the material which is put on in either of these

FIG. 2. THE BALANCING OF ARMATURES.

kinds; the only difference is in the method of applying. Both the hard and soft patches, therefore, may be made of iron or steel, as is most convenient. The hard patch is put on and riveted. The soft patch is put on with bolts, which are tapped; passing through and screwing up all the bolts is what holds the patch in place, in place of the rivets used for the hard patch. It is better to drill the holes than to punch them, although some men use a portable screw punch for this purpose, also for punching the holes.

CARE OF UNUSED MACHINES.

Electrical machinery is often kept in damp places and frequently stands idle for months. Probably as good a way as any is to wipe exposed metal parts with vaseline and cover with a cloth to keep off dust. The parts should be thoroughly cleaned before using, as oil and lubricant will gum. In some classes of metal work it is the custom to cover exposed surfaces with a species of paint as a protection. This is made by dissolving a wax candle in spirits of turpentine and painting the iron or steel. Such an application to a motor or dynamo would be cleaner than vaseline, and would be likely to work well. When electrical machinery is to stand idle for a considerable time, and it is not advisable to cover the bright parts with white lead or other rust-proof paint, protection might be given by boxing up the machinery as closely as possible.

RUBBER INSULATION.

For greasy insulation that is old and will not stick a mixture of 1½ pounds of resin, two pounds of oil of turpentine, two pounds of india-rubber cut into small pieces, six pounds of fish oil and two pounds of tallow is recommended as an adhesive agent. The pieces of rubber are placed in an iron pot and warmed

FIG. 1. THE BALANCING OF ARMATURES.

to a temperature of 122 degrees. When the rubber is dissolved add the resin, and when this is dissolved, the wax. Fish oil and tallow are melted in a separate vessel, and after slightly warming both portions they are mixed with diligent stirring, which is continued until the mass is cold, when it may be used.

CUTTING INSIDE THREADS.

The inner threading of a compound barrel joint was in bad condition, as shown in Fig. 15, and it was necessary to either put in a new case or recut the threads in the old one. Several repairmen were approached, but could do nothing until a new case was secured. It seems that none was available, and a machinist added to his reputation by recutting the threads in the old case with a cutting tool B, Fig. 16, holding the case in the chuck plate on the lathe by use of the arrangement C. This indicates what one may do if he only has the tools and machinery to work with. The cutting tool is pro-

vided with a V-shaped tip, which should be well hardened and close ground.

GLUING RUBBER INSULATION.

The following receipts for gluing rubber are of service: First—Equal parts of gelatin and isinglass are for 10 hours steeped in water and then boiled with tannin to the consistency of dough. The surface to be glued must be carefully cleaned before applying the warm glue. Second—One pound gutta-percha, cut into small pieces, is (in a water bath) heated in 10 pounds of benzol until completely dissolved. Linseed-oil varnish, up to two pounds, is added next.

Philadelphia Exposition.

The promoters of the Philadelphia Exposition, which will open on September 14th and continue until November 30th, are encouraged by the interest displayed by leading manufacturers of all lines of machinery and articles for export trade in the exhibition. It is the purpose to exhibit every line of manufactured products of the United States especially suitable for export. These exhibits will form the principal department of the exposition, and will comprise everything which is, can or might be exported, from locomotives and heavy machinery to the smallest novelties.

No foreign manufacturers will be permitted to exhibit, but arrangements have been made for a department of foreign manufactures, which will consist of collections of samples of goods made in the commercial countries of Europe and successfully sold in all foreign markets in competition with American goods, and in foreign markets in which American trade has not yet been developed. These samples will be exhibited side by side with American products of the same class, and will show manufacturers just what competition they must meet abroad, as well as the peculiarities in the demands of foreign markets. The samples of goods of foreign manufacture are being selected and purchased abroad by representatives of the exposition, aided by the entire consular service of the United States.

A third department will show how American goods

PHILADELPHIA EXPOSITION.—MAIN BUILDING.

must be packed, labeled and shipped in order to meet the requirements of foreign trade, which vary according to the degree of development or civilization in each country of the world.

As has already been announced, the exposition will be under the joint auspices of the Philadelphia Commercial Museum and the Franklin Institute. The board of directors of the Philadelphia Exposition association includes a number of the most prominent and energetic business men of Philadelphia.

Congress appropriated \$350,000 to aid it. The city of Philadelphia has given \$200,000 and the state of Pennsylvania \$50,000, and \$100,000 is being raised in Philadelphia by individual subscriptions. A bill now pending in the Legislature of Pennsylvania appropriates \$200,000 more, making a total exposition fund of about \$900,000.

The main buildings, which are now under construction, cover eight acres of ground, and the available exhibition space will be at least 200,000 square feet. Outside of the space occupied by the erection of detached structures for special exhibits within the exposition grounds, which comprise a tract of 56 acres of land on the bank of the Schuylkill River, within 15 minutes' ride of the city hall. There will be a large area for amusement features, which promise to be as unique and interesting as the exposition is practical.

Assumption of Risk in Passing Rope Under Wires.

In a personal injury case it appeared that the plaintiff, while in the employment of the defendant company as a lineman in placing wires, was injured by an electric shock, caused by coming in contact with wires heavily charged with electricity. At the time he was under the control of a foreman who was in charge of the work in which they were engaged; and in his petition he alleged that he was commanded by the foreman to pass the rope he was then using with which to handle the wires under two primary electric-light wires, and in doing so, while exercising due care, he received the shock from which the injuries resulted.

The trial judge directed a verdict for the defendant company. He instructed the jury that there were two reasons why the plaintiff could not recover damages upon the facts which he had testified to be true: First, because it clearly appeared from the

testimony that the act of passing the rope and wires under the electric wire, which he was instructed to do, was not necessarily dangerous, but only so if the person passing them under should come in contact with the wires, which he would be supposed to avoid in the exercise of due care. Hence, there was no negligence in directing this to be done, or, if there was, it was not the proximate cause of injury to the plaintiff; the proximate cause of injury being the act of the plaintiff in accidentally or negligently coming in contact with the wire. Second, it appeared from the plaintiff's testimony that he understood the probable danger of coming in contact with the wires; and if there was necessarily danger of coming in contact with them involved in passing the rope and wire he held under the electric wires, he must be held to have assumed the risk, and he could not excuse his thus going into known danger because instructed so to do by the agent of the defendant company.

The case having been taken up to the Court of Civil Appeals of Texas, the latter expresses the opinion that the judge took the correct view of the evidence, and it holds (Newnom against Southwestern Telegraph and Telephone company, November, 1898) that, such being the case, it was proper for the judge to instruct the jury to return a verdict in favor of the defendant.

The Balancing of Armatures.¹

BY CLAUDE W. HILL.

In these days of drum armatures with turned cores, accurately planed or milled slots, and symmetrically formed windings, the amount of balance obtained in the ordinary course of manufacture is quite sufficient for the moderate speeds of revolution generally in use. Occasionally, however, we have to construct machines to run at unusually high speeds, and then it becomes necessary to test the balance of the armatures and attach counterweights if required.

The usual method of testing the balance of an armature is to place it upon level parallel straight edges, when the heavy side is supposed to sink

to the bottom, and counterweights are then attached to the opposite side of the armature until it will remain at rest in any position on the rails. In practice the writer has found this method unreliable and unsatisfactory, and the following figures will show the reason:

Fig. 1 represents an armature 16½ inches diameter, weighing 10 hundredweight, and intended to run at 750 revolutions per minute. We will assume that it is out of balance to an amount equal to a weight of two pounds at the periphery on one side. When this weight is at the position A, it will tend to sink to the position B, and in doing so will exert a diminishing horizontal tractive force tending to roll the armature along the straight edges. The amount of the tractive force exerted at each point from B to A is shown on the curve, Fig. 2. The force necessary to produce movement of the armature is shown by the horizontal line drawn on the curve, and we see that this line cuts the curve at 53°. Laying this out on Fig. 1, we see then that within the arcs C and D the weight of two pounds is insufficient to produce any movement of the armature, while within the arcs E and F the movement will be comparatively feeble and uncertain, especially if the armature has been running in the machine and the shaft has become slightly magnetized. By this method of testing this armature would therefore appear to be in sufficiently good balance. Upon being placed in the machine and run, however, the centrifugal force due to the unbalanced weight would be 26½ pounds, which would be sufficient to cause considerable vibration, and possibly sparking and breakage of commutator connections.

A more sensitive way of testing is to place the armature on anti-friction wheels, themselves running on ball bearings. The heavy side of the armature would then fall much nearer to the zero position, although there would still be sufficient friction to prevent it getting quite there.

The best plan is to test with that force which it is our object to compensate; that is to say, the centrifugal force itself. To do this the armature should be mounted in bearings which are free to move, then while the armature is running the heavy side can be found with a piece of chalk and counterweights adjusted on the opposite side until the cessation of movement of the bearings shows that the center of gravity coincides with the axis of the shaft.

1. From the London Electrical Review.

Electrically Driven Temperley Transporter.

The Temperley transporter was first introduced in 1893, when the portable beam type was tried with marked success by the British admiralty for coaling men-of-war during the naval maneuvers of that year. Since then these transporters have been much used for this purpose by the British government, and they have been applied in a variety of new forms for use on shore, where they are found to offer many advantages, especially when a long overreach is necessary and goods have to be conveyed to a considerable distance from the lifting point.

The special feature of the Temperley transporter is a pulley carriage or traveler of novel design, working on an elevated track, and provided with a simple automatic device by which the traveler is arrested and held stationary while a load is being lifted or lowered, and which sustains the load while the traveler is moving.

The operations of lifting, transporting and lowering the load are effected by the simple action of hauling in and paying out a single rope, and any ordinary form of winch may therefore be used for working the transporter.

The travelers are made in several sizes and patterns and are adapted to work on beams and other forms of track, either inclined or horizontal. Hitherto the transporters have been steam driven, but electricity has found its way into favor for this purpose. The first electrically driven tower transporter has been supplied to the London Lead Smelting company at Millwall. The accompanying illustrations of this installation are reproduced from the Iron and Coal Trades Review of London. In the background (Fig. 1) are two horizontal warehouse transporters, one with the arm over the river hinged up vertically, and the other with the arm in a horizontal position overhanging the water. It will be observed that the

FIG. 1. ELECTRICALLY DRIVEN TEMPERLEY TRANSPORTER.—GENERAL VIEW.

transporter in the foreground consists of a traveling tower, which can be moved along the rails and placed in front of any vessel or lighter lying at the quay, and is provided with a transporter beam 68 feet long. The projecting arms of the transporter overhang the water for 30 feet and the quay 30 feet, the gauge of the rails and the width of the tower being eight feet. The arm over the water is made to hinge up when not in use.

The driving machinery has heretofore been somewhat cumbersome, consisting of a boiler and engine, but in the present case this apparatus is replaced by an electric motor, carried on the lower part of the traveling frame, which is covered in to form the house. An enlarged view of the machinery is given in Fig. 2, p. 227. The floor forms a platform from which the driver has a clear view into the lighter. The buckets, after being lifted from the lighter by the transporter, travel along the beam at a speed of 300 feet per minute. The buckets can be automatically dumped at any desired point without touching the ground, but as close to the ground or the heap of material as desired, so as to avoid the breakage of coal or other material. The motor is then reversed, and the empty bucket is returned to the lighter at an equal speed. The average capacity of the apparatus is 30 to 60 tons per hour, according to the load lifted. The transporter is principally used for unloading coal, coke, limestone and ore from lighters.

The electrical equipment consists of a motor, which is geared directly to the transporter winch. It is the C.B. 200 railway type, which is used for crane and hoist work. The nominal capacity of this particular motor is 12 horse power when running at 250 revolutions per minute, but it is capable of giving over double this capacity when necessary. It is series-wound and is supplied from a 220-volt circuit. The controller is the British Thomson-Houston standard P. 13, with magnetic blow-out, by means of which the deleterious effects from the burning of the contacts by the arc formed at the moment of opening the circuit are prevented. This controller is capable of regulating the motor so that different speeds can be obtained in either direction. There is only one handle, movement of

which in one direction gives "forward rotation" of the motor, and the other direction "reversed motion" of the motor.

The electric equipment is considered a great improvement over the original style of apparatus.

Electricity in South Africa.

[Prepared for the Western Electrician by the Philadelphia Commercial Museum.]

The attention being given to the development of the coal measures of South Africa implies a demand in the immediate future for mining apparatus, and electrical appliances should, in consequence, come into request. Electric-light installations have not yet been established outside of a few important centers, and the development of existing street-car lines and the construction of new roads are being considered. In Durban, the chief city and port of Natal, the question of the ownership of the street horse-car lines, for some time in dispute between the municipality and the operating company, only awaits settlement to bring about the adoption of electric power. On the Rand the authorities have been coquetting with the question of establishing electric-light and power stations for some time, but there is now promise of a more general use of the force in Johannesburg, Pretoria and elsewhere. A correspondent at Cape Town writes that there is a general disposition throughout the country (South Africa generally) to adopt the electric system of lighting.

American manufacturers of electric appliances have been represented in the South African field of late years, and particular attention has been given to the machinery market, but the proportion of the business which falls to the American houses is much smaller than might be expected, judging from the ability of American makers to fill the requirements. No separate classification is made

power Otto cycle gas engine, a drum dynamo, water tank, gas-bag, etc., all fitted on a single cast-iron base, ready to be set in working as soon as delivered. The dynamo has inverted pole-pieces, and is capable of lighting 15 16 candle power, or 30 eight candle power lamps, or of charging accumulators. It is fitted on slide rails, which allow of the belt being tightened while the dynamo is running. The engine has tube ignition, piston, detachable water-jacket, sensitive governor and is provided with two heavy flywheels. A supply of gas is secured at a cost of three-fourths of a penny (English) an hour.

A correspondent at Cape Town writes that a line of goods which would find a market is electrical apparatus—bells and lighting. Electrical pumps are largely used at Johannesburg, Transvaal, for pumping water from the dams to the mills. So far, the principal makers have been Gwynne, Easton & Anderson and Hayward Tyler, all English makers, the design being three-throw ram pumps, with helical gearing belts, driven from the motors, and capable of delivering 20,000 gallons per hour.

Correspondents of the Philadelphia Commercial Museum agree that the business prospects are better than they have been, and it is thought that a period of greater prosperity is dawning. The period of political and commercial unrest appears to be passing, and trade is undoubtedly improving. Adequate representation is essential to the development and successful issue of South African business. It should be noted, too, that the tendency of American manufacturers to sell direct to the wholesaler or retailer, rather than through a commission house, is reflected in the foreign market, where traders are exhibiting a desire to open up trade relations with manufacturers, to the exclusion of "middlemen."

Motor-carriage Exposition at Berlin.

An international competitive exhibition of motor-carriages will be held at Berlin in September, and as a general invitation to all manufacturers of this style of equipment has been issued, American makers of electric vehicles will doubtless be interested in the following particulars, which are summarized from a recent report of Frank H. Mason, consul-general at Berlin:

The exposition will be held in a covered building, known as the Exercier-Haus, 34 and 35 Karl strasse, and will be open daily from 10 a. m. to 6 p. m. The rent of exhibition space will be as follows: For the first 25 square meters of ground or wall space, \$2.38 per square meter; for the second 25 square meters, \$1.90 per square meter; for the third 25 square meters, \$1.42 per square meter, and for all additional space accorded to one exhibitor, 90 cents per square meter. The committee reserves the right to reject any article offered for exhibition, but the applicant will be immediately notified of its decision. Each exhibitor will be required to furnish for the catalogue, not later than August 1st, two photographs or photographic plates representing his exhibit. Possession of exhibition space will be given to exhibitors on the morning of September 1st, and articles for exhibition must be in place and ready for exhibition by ten o'clock on the morning of September 3d. During the hours of exhibition, the exhibits shall not be covered, but remain open for public inspection, and may not be withdrawn during the continuance of the exposition, except with the consent of the committee of management. All exhibits are to be withdrawn and taken possession of by the owner within 24 hours after the close of the exposition.

The price of admission to visitors is fixed at 47.6 cents on the opening day, and during other days from 11.9 to 23.8 cents; season tickets, \$1.19 each. Exhibitors, their employes and agents, will receive non-transferable tickets, good during the exposition, for the nominal price of 23.8 cents.

Exhibits will be classified as follows:

- (a) Motor carriages and devices of all kinds for the transport of persons.
- (b) Motor wagons for transport of freight.
- (c) Motor cycles and trailers.
- (d) Motors and accumulators for motor carriages.
- (e) Parts and wheels for motor carriages.
- (f) All articles relating to motor carriages and not otherwise classified.

Not more than two examples of the same class will be permitted to each exhibitor. A progressive series of tests, races, etc., is in contemplation, the programme for which will be announced by the committee of management at the opening of the exhibition. Neither prizes nor medals will be given. The advantage to exhibitors will be confined to the results of the competitive tests, which will be related in detail in the report of the committee.

Water Power in Ottawa Valley.

[Special correspondence of the Western Electrician.]

Mr. Andrew Holland of Ottawa has prepared an estimate of the various water powers in the Ottawa Valley. His calculation is as follows: Ottawa River, 664,000 horse power; Rideau River, 1,300 horse power; Mississippi River, 14,700 horse power; Madawaska River, 20,600 horse power; Bonnechere River, 3,400 horse power; Petit Nation, 2,000 horse power; Blanche River, 2,000 horse power; Lievres River, 98,450 horse power; Little Blanche, 300 horse power; Quyon River, 100 horse power; Coulonge River, 27,600 horse power; Black River, 2,000 horse power; Gatineau River, 31,675 horse power, making a total volume of estimated power of 890,225 horse power.

Detroit Street-railway Situation.

The Detroit correspondent of the Western Electrician says that the proposed purchase of the street railways of Detroit will be consummated in a few weeks, as soon as the appraisers bring in their reports. In the meantime Governor Pingree is holding open meetings in various parts of the city to educate the people on the importance of the transaction. Prominent speakers are in attendance to answer all questions put to them tending to clear the public mind.

Mayor George T. Marks of Port Arthur, Ont., the only city in this country, so far as known, enjoying municipal control of street railways, visited Detroit, and in an interview on the problem said, in part: "Eight-for-a-quarter tickets are sold, for use morning and evening, while during the day the rate is six-for-a-quarter. Despite the fact that we have a population of only about 7,000 to draw on, the roads pay the municipality 2½ per cent. profit. In connection with the road the city of Port Arthur owns its own electric-light plant, and a flat rate of 22½ cents per month per 16 candle power incandescent light is charged. Meter rates are eight cents per 1,000 watts. Our investment is \$130,000. The income is not sufficient to pay the interest on the bonds, but the people would not have the plant sold to a private concern for anything."

Another feature of the case is presented in a dispatch to the Chicago Record: "The most important matter under consideration with Governor Pingree's municipal-ownership commission is the securing of a security franchise. That franchise to secure a 30-year extension of the present ones is now in the hands of Judge Speed and will be sent to the council. Its terms provide for a universal transfer system and a six-for-a-quarter ticket rate of fare. Governor Pingree and other members of the commission have maintained from the first that it was the intention of the McLeod bill to purchase the roads only on the consideration that the earnings would pay all operating expenses and fixed charges and create a sinking fund of a sufficient sum to release all bonds at the end of the average life of the present franchises, which is about 15 years. Now, however, it is conceded that there is doubt that this can be done, and it is admitted by Judge Speed that the bonds will be for 30 years at four per cent. In other words, the commission contemplates an extension of credit of 15 years. This is vigorously opposed, and the council will undoubtedly reject it on the ground that if the purchase of the street railways is not made and this three-cent fare is not agreed upon it will result in the people paying over \$10,000,000 more for rides on street-cars during the coming 10 years."

Canadian Power Transmission Project.

[Ottawa, Ont., Correspondent of the Western Electrician.]

The Bedford Electric company of Halifax, N. S., proposes to install an electric plant at St. Margaret's Bay to transmit light and power to Halifax and other points in the vicinity and to furnish power for the operation of an extensive pulp mill to be erected. The transmission line will be 18 miles in length and the pipe line from the power house to the dam about 4,000 feet in length. It is also proposed to operate an electric tramway to Halifax.

The Canadian General Electric company has been awarded by the Department of Railways and Canals the contract for the erection of a power house and the complete equipment of the Soulanges Canal with electrical apparatus for operating the locks by means of electric motors. The entire canal, covering a distance of 14 miles, will be illuminated by arc lamps. Owing to the success met with in the operation of electricity at the canal at Sault Ste. Marie, Ont., as applied to the locks, the department decided to make a more extensive application of its use in the illumination and electrical operation of the locks of the Soulanges Canal.

Mr. J. R. Booth of Ottawa has closed a contract with the Canadian General Electric company, Toronto, by the fulfillment of which the machine shops and new car works of the Canada Atlantic railway in Ottawa will be supplied with electrical power generated from the Chaudiere Falls at the west end of the city. The electric company will install two three-phase generators, each of which will be of 200 horse power capacity. The power will be transmitted to the works, three and a half miles distant, by an overhead line. Besides furnishing power for the car works and the machine shops, this energy will operate the locomotive transfer tables, the traveling cranes and the entire lighting system of the different works and adjoining yards.

The Quebec Electric Railway company is busy making arrangements for applying electricity this spring to the whole 60 miles of its road. At present it employs electricity only in the city of Quebec. During the year it is to be applied also to the railway to La Bonne Ste. Anne. It has already sold a number of the old cars that were in use on that road, and new ones have been received from Ottawa to replace them. The right-of-way has also been acquired for the new road to be built and operated by the company from Quebec to the Falls of Montmorency, parallel with the turnpike road, through the village of Beauport. A good portion of the \$7,500,000 of new bonds issued by the company will be used in these works.

Wireless Telegraphy Anticipated.

[London correspondence of the New York Sun.]

Somebody has dug up from a copy of the Spectator 188 years old a curious bit of prophecy or prophetic imagination that gives the idea of wireless telegraphy in a guise which, while not scientific, does approach marvelously close to the present fact, when it is considered that in 1711 electricity and magnetism were practically unknown. This is the passage:

Strada in one of his Proleusions gives an account of a chimerical correspondence between two friends, by the help of a certain loadstone, which had such virtue in it that if it touched two several needles, when one of the needles so touched began to move, the other, though at never so great a distance, moved at the same time and in the same manner. He tells us that the two friends, being each of them possessed of one of these needles, made a kind of dial plate, inscribing it with the four-and-twenty letters in the same manner as the hours of the day are marked upon the ordinary dial plate. They then fixed one of the needles on each of these plates in such a manner that it could move round without impediment so as to touch any of the four-and-twenty letters. Upon their separating from one another into distant countries they agreed to withdraw themselves punctually into their closets at a certain hour of the day and to converse with one another by means of this, their invention. Accordingly, when they were some hundred miles asunder, each of them shut himself up in his closet at the time appointed and immediately cast his eye upon his dial plate. If he had a mind to write anything to his friend he directed his needle to every letter that formed the words which he had occasion for, making a little pause at the end of every word or sentence to avoid confusion. The friend, in the meanwhile, saw his own sympathetic needle moving of itself to every letter which that of his correspondent pointed at. By this means they talked together across a whole continent, and conveyed their thoughts to one another in an instant over cities or mountains, seas or deserts. * * * * * In the meanwhile, if ever this invention should be revived or put in practice, I would propose that upon the lover's dial plate there should be written, not only the four-and-twenty letters, but several entire words which have always a place in passionate epistles, as flames, darts, die, languish, absence, Cupid, heart, eyes.

An Electric Railroad with Steep Grades.

The double-track electric railroad between Butte and Centerville, Mont., is 13½ miles long, and overcomes an elevation of 416 feet, the grades ranging from six and 7½ per cent. in the steeper parts of the line. The road was built under the general direction of Francis W. Blackford, who described it in a paper read before the Montana Society of Engineers. The crossings of three steam railroads were made overhead by steel span or plate girders, the other crossings, four in number, were wooden bent trestles, planned to carry "Jumbo" cars of 15 tons weight, with a load of 180 persons, or a total weight of 30 tons. The elevation of the track on curves was computed for a speed of 12 miles an hour.

The power supplied to the cars is enough to enable them to ascend much steeper grades, the objection to the heavy grades being the difficulty in safely descending them. The safe descent is, indeed, the special feature of the operation of this line. Except on the paved streets of Butte, the road is laid throughout with 52-pound second-hand steel rail that had been in use on the Oregon Short Line railway. The rail was but little worn, and made an excellent track. The rails are bonded with the Atkinson horseshoe bond, cross-banded every 600 feet. The power is transmitted by an overhead wire, supported by cedar poles on each side. The feed wire, however, does not follow the turnings of the road, but runs straight up the hill and feeds at the crossings and at the end of the line.

The road is supplied with 16-foot single-truck cars with 30-inch wheels, each car having two 35 horse

FIG. 2. ELECTRICALLY DRIVEN TEMPERLEY TRANSPORTER.— MOTOR CONTROLLER AND HOISTING APPARATUS.

hang, down and the like. This would very much abridge the lover's pains in this way of writing a letter, as it would enable him to express the most useful and significant words with a single touch of the needle.

Rates of Fare to New York Convention.

The Trunk Line association has granted a rate of a fare and one-third, on the certificate plan, from all points in its territory and return for delegates and friends attending the twenty-second convention of the National Electric Light association, to be held in New York May 23d, 24th and 25th. It is expected that the same rate will be granted by the other railway associations at an early date.

Mr. W. Forman Collins has been appointed master of transportation for Chicago and vicinity.

COMMUNICATION.

Electrical Carbonization of Wood.

To the Editor of the Western Electrician:
Will you kindly make known to your readers whether the carbonization of wood has ever been attempted by the use of electricity on such a scale as would demonstrate the practical economy of producing charcoal for commercial purposes by an electric process?
G. E.

Chicago, April 13, 1899.

Advices from Joplin, Mo., last week stated that zinc ore broke all records, and jumped from \$47 to \$50 a ton, the highest price ever paid and double the price paid a year ago.

power motors. In addition to the usual chain brake, the cars have the General Electric brake, the latter being used as an emergency brake only. The trip from the corner of Park and Main streets, Butte, to the corner of Center and Main streets, Centerville, is made with ease in 15 minutes. Each car makes two round trips an hour. The line has been in successful operation since August 7, 1898, and no accidents or runaways have occurred. In only one instance has the emergency brake been applied.

Two Unusual Fires.

The focusing of the sun's rays by an electric-light bulb set fire to a curtain in the home of John M. Sager in New York last week. Mr. Sager's three-year-old daughter, Lily, was burned. Her condition is not dangerous. Her mother saved her and put out the fire as well. An investigation showed that the incandescent electric lamp had caused the fire in the manner indicated. Mrs. Sager had decorated the bulb with ribbons and crochet-work, and had hung it in the window.

A four-ton load of hay on a truck was ignited in Chicago a few days ago while passing through the Root street subway under the Rock Island tracks. It was completely destroyed. The driver when apprised of his danger jumped to the ground, unhitched the horses and sent in an alarm. When the Fire Department arrived the load of hay was a mass of flames. Water was turned on and the truck saved. The fire was attributed to one of the wires on the load of hay coming in contact with the overhead trolley wire, causing a spark which set fire to the hay.

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO. TELEPHONE, MAIN 1746.

Eastern Office: 148 Times Building, New York.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the entire contents of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, \$3.00 for a full year of 52 numbers; in clubs of four or more, \$2.50, with free extra copy for eight subscriptions; foreign countries, \$5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—the only general electrical paper published in the West—thoroughly covers a territory exclusively its own. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers desiring western trade will appreciate the UNEQUALLED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

be convincing. This will be "Japan's World's Fair of 1902." The government is anxious to convince the civilized world that it has become the equal of occidental nations in the way of industries and progressive commerce. All countries will be invited to send delegations and exhibits. While the proposed world's fair is intended nominally to give Japan a chance to show what she can do, it is apparent that she is anxious to study at close range the industrial achievements of other nations. For that reason it would be wise for American exhibitors to avail themselves of the new patent-right law of Japan which has just gone into effect.

The daily papers announce the invention of an instrument by a young experimenter in Alabama by which "two young men horn totally deaf were enabled to hear sounds." The same electrical principle is employed in a large apparatus by which an instructor can communicate speech to any number of pupils at one time without confusion. The inventor has put together a portable instrument by means of which a deaf mute was enabled to hear the playing of a piano at a distance of 60 feet and to distinguish a voice in ordinary conversation. The details of the experiment and a description of the machine will be awaited with general interest. A great deal of attention has been given this subject in Europe, and many interesting experiments conducted there have been described in the Western Electrician. It is to be hoped that some real advancement has been made by the young inventor in Alabama.

Many suggestions of interest and value, or otherwise, are offered for the consideration of Marconi and his associates who are engaged in developing the art of signaling through space. The London correspondent of the New York Sun steps forth with the following proposition:

The suggestion occurs to me just here, and I give it for what it may be worth, that the recent experiments in high kite flying at Blue Hill by means of wire cord might be made the means for testing practically the possibilities of wireless telegraphy over considerable distances. A kite flown from the top of Blue Hill, just outside Boston, might furnish means of communication with another kite-borne wire a thousand feet high near New York. If that proves successful Mr. Rotch has only to send one of his mile-high soarers to England, and the Sun's London correspondent will be glad to send the news of Europe to him at Blue Hill per ether waves with celerity and dispatch.

In view of the fact that the experiments already recorded include the transmission of messages over comparatively short distances, it is greatly to be feared that the newspapers will be compelled to continue paying tribute to the present telegraph companies in the form of cable tolls for a short time at least.

A damage case growing out of injuries alleged to have been sustained through the ignorance or carelessness of X-ray operators is now on trial in Chicago. The plaintiff in 1896 sustained an injury which affected his ankle, and he submitted the injured member to an examination under X-rays. The apparatus, he claims, was not properly handled, and a serious burn was inflicted which ultimately necessitated the amputation of his foot. Several operations had to be performed, and great physical pain as well as the loss of a foot are all charged to injuries sustained at the hands of the operators who made the sciagraph. Accordingly, claim is made for \$25,000 damages.

A somewhat similar case attracted considerable attention abroad recently. A prominent surgeon of Paris who was treating a young woman for an affection of the thigh joint attempted to secure a sciagraph of the seat of the trouble. The patient posed three times. The third exposure lasted over an hour, and it was subsequently noticed that stripes appeared on the skin, which was apparently burned. This burn resulted in a wound that caused long illness, and the patient sued the doctor for 5,000 francs damages. One of the witnesses, Dr. Bardet, secretary of the Société Thérapeutique, testified that burning would result in rare instances from the use of the Röntgen rays. Everything depended on the patient's physical condition. He maintained that if doctors were made responsible for such accidents they would be obliged to renounce the use of the rays.

In the case now under consideration in Chicago the defense declares that the injuries were not due

to burning by X-rays. Moreover, it is contended that at the time of the exposure practitioners had little reliable information concerning the action of the rays upon which to base their operations, and that it would be unjust, therefore, to judge their work at that time by the standard of efficiency that has since been established.

Development of electrical interests in Japan has created such a demand for copper that the industry is now enjoying the greatest boom ever known in that country. The Japan Times, commenting on this favorable condition, says: "Markedly increased as the output has recently become, so extraordinary is the demand for the metal that the prospective yields of the principal copper mines in Japan are already covered by contract; so that, for want of the commodity, further transactions are said to be practically suspended in Tokyo and Yokohama." The importation of copper has also increased during the last few years.

Statistics are quoted from the Chugai Shogyo showing the total consumption of copper in the empire to have increased from 5,936,000 pounds in 1892 to 12,355,000 in 1896. In 1892 the Japan mines furnished all but 76,000 pounds, and in the following year, although their output was reduced 20,000 pounds, the demand was so much less that only 7,000 pounds of copper was imported. In 1894 the output of the Japan mines was almost doubled and the imports increased to 51,000 pounds. There was a slight falling off in the home production in 1895, but the imports were largely increased, 156,000 pounds being admitted. The high-water mark for both home and imported copper was reached in 1896 (the latest statistics available), when 199,000 pounds had to be imported into the country to meet the requirements, although the output of the Japan mines amounted to 12,155,000 pounds.

Street-railway corporations which have contracts with the government for carrying mail will be interested in the litigation growing out of a labor controversy in which this matter played an important part. Judge John J. Jackson of the United States District Court for the District of West Virginia granted an injunction at the instance of the Wheeling Street Railway company, restraining certain striking motormen and conductors of that corporation from obstructing the operation of its cars or damaging the property of the complainants. The jurisdiction of the federal court was invoked on the ground that the railroad company is engaged in commerce between different states and in the transportation of the government mails. In the celebrated Debs case a similar injunction was maintained in a suit instituted by the direction of the attorney-general in the name of the United States, and the Supreme Court refused to interfere with the action of the Circuit Court in Illinois, adjudging the persons who had violated that injunction guilty of contempt and sentencing them to imprisonment. Labor organizations have frequently protested against the postoffice making contracts for this purpose, appreciating the advantage the companies would enjoy, but the government has refused to consider this feature of the question.

When the street-railway company at Wheeling attempted to run its cars last week the strikers' sympathizers interfered, and the men who had been secured to fill the places of strikers were roughly handled in many instances. On Tuesday Judge Jackson pronounced sentence upon five men who had been arrested by deputy marshals for various offenses which the court holds are violations of the blanket injunction issued by him the day after the strike began. The men under arrest were sentenced to pay fines of \$50 each and to go to jail for 30 days. After sentence had been pronounced Judge Jackson described labor unions as communistic clubs, and he denounced the people of the city who sympathized with the strikers. He said that the people had no right to conclude that the street-railway company should pay more wages than it felt willing to pay. The strikers had the right to quit, but had no right to use any means to prevent others from taking their places.

Judge Jackson's outburst has had the effect of intensifying the feeling against the street-railway company, and has really stimulated and secured accessions to the forces of the strikers.

In describing the equipment of a new manufacturing establishment in London recently a prominent trade journal made particular mention of the fact that "the shops are equipped with machines of the latest type, which have been obtained from America." This is certainly a substantial claim for recognition, but we are surprised that it has been so freely acknowledged.

If proof were needed to establish the fact that Japan is rapidly taking on European and American ways, the preparations that are now being made for an exposition in the mikado's realm would certainly

Marconi's Experiments.¹

By J. A. FLEMING

During the last few days I have been permitted to make a close examination of the apparatus and methods being employed by Signor Marconi in his remarkable telegraphic experiments between South Foreland and Boulogne, and at the South Foreland lighthouse have been allowed by the inventor to make experiments and transmit messages from the station there established both to France and to the lightship on the Goodwin Sands, which is equipped for sending and receiving ether-wave signals. Throughout the period of my visit messages, signals, congratulations and jokes were freely exchanged between the operators sitting on either side of the channel, and automatically printed down in telegraphic code signals on the ordinary paper slip at the rate of 12 to 18 words a minute. Not once was there the slightest difficulty or delay in obtaining an instant reply to a signal sent. No familiarity with the subject removes the feeling of vague wonder with which one sees a telegraphic instrument merely connected with a length of 150 feet of copper wire run up the side of a flagstaff begin to draw its message out of space and print down in dot and dash on the paper tape the intelligence ferried across 30 miles of water by the mysterious ether.

The public have already been placed in possession by the Times and other agencies of a general description of the apparatus employed by Signor Marconi, and there is no need, therefore, to enter into technical details. Within the last few days also various scientific men have been invited to give the public the guidance of their opinions on the novelty and utility of these demonstrations. These criticisms have for the most part not been of a very helpful character. The general public are not much concerned with questions of priority or with the claims or suggestions of rival experimentalists, but they are interested in ascertaining the serious possibilities of that which has been actually achieved. Signor Marconi has never hesitated to acknowledge that he has built upon the foundations laid by others, but a vast gulf separates laboratory experiments, however ingenious, from practical large-scale demonstrations conducted with all that regularity and freedom from failure which is the absolute condition of their public utility.

I cannot help thinking that the time has arrived for a little more generous appreciation by his scientific contemporaries of the fact that Signor Marconi has by minute attention to detail, and by the important addition of the long vertical air wire, translated one method of space telegraphy out of the region of uncertain delicate laboratory experiments and placed it on the same footing as regards certainty of action and ease of manipulation, so far as present results show, as any of the other methods of electric communication employing a continuous wire between the two places. This is no small achievement. The apparatus, moreover, is ridiculously simple and not costly. With the exception of the flagstaff and 150 feet of vertical wire at each end, he can place on a small kitchen table the appliances, costing not more than £100 in all, for communicating across 30 or even 100 miles of channel. With the same simple means he has placed a lightship on the Goodwins in instant communication, day and night, with the South Foreland lighthouse. A touch on a key on board the lightship suffices to ring an electric bell in the room at South Foreland, 12 miles away, with the same ease and certainty with which one can summon the servant to one's bedroom at a hotel. An attendant now sleeps hard by the instruments at South Foreland. If at any moment he is awakened by the bell rung from the lightship he is able to ring up in return the Ramsgate lifeboat, and, if need be, direct it to the spot where its service are required, within a few seconds of the arrival of the call for help. In the presence of the enormous practical importance of this feat alone, and of the certainty with which communication can now be established between ship and shore without costly cable or wire, the scientific criticisms which have been launched by other inventors against Signor Marconi's methods have failed altogether in their appreciation of the practical significance of the results he has brought about.

The public, however, are not in the least interested in learning the exact need of merit to be apportioned to various investigators in the upbuilding of this result. They do, however, want to know whether the new method of communication across the channel established by the expenditure of a few hundred pounds will take the place to any considerable extent of submarine cables which have cost many thousands of pounds to lay and equip. They do also desire to learn what reasons, if any, will prevent every lighthouse and lightship round our coasts from being forthwith furnished with the necessary apparatus for placing it in instantaneous and secure connection with the mainland. They also hope to hear that the methods can be applied to enable ships to be able in addition to communicate instantly in case of need with shore stations. To understand how far these things can be done, and to appreciate the necessary or present limitations of the method, it is requisite to explain that each vertical wire or rod connected to a Marconi receiving or sending apparatus has a certain "sphere of influence." Signor Marconi has proved by experiment up to

certain limits that the distance to which effective signaling extends varies as to the square of the height of the rod. A wire 20 feet high carries the effective signal one mile, 40 feet high four miles, 80 feet 16 miles, and so on. Up to the present time he has not yet discovered any method of shielding any particular rod so as to render it responsive only to signals coming from one station and not from all others within its sphere of influence. In spite, however, of what has been said, there is no inherent impossibility in attaining this desired result. At present all signals sent from the South Foreland to France affect the receiver on board the Goodwin lightship. But this offers no difficulty. In an ordinary electric-bell system in a hotel the servant recognizes the room from which the signal comes by means of a simple apparatus called an indicator, and a very similar arrangement can be applied to distinguish the origin of an ether-wave signal when several instruments are at work in a common region. Subsequent inventions, as also perhaps the promulgation of some necessary Board of Trade regulations for the use of the ether, will prevent official ether-wave receivers from being disturbed by vagrant electric waves sent out by unauthorized persons in their neighborhood. The practical upshot, however, of the matter is that at present if more than two stations are not established within certain regions these stations, pair and pair, can communicate with each other freely and regularly by means of ether-wave signals sent out and received by long vertical rods or wires. No state of the atmosphere, and neither darkness nor storm, interrupts, so far as yet found, the freedom of communication.

Up to the present time none of the other systems of wireless telegraphy employing electric or magnetic agencies has been able to accomplish the same results over equal distances. Without denying that much remains yet to be attained, or that the same may not be affected in other ways, it is impossible for anyone to witness the South Foreland and Boulogne experiments without coming to the conclusion that neither captious criticism nor official lethargy should stand in the way of additional opportunities being afforded for a further extension of practical experiments. Wireless telegraphy will not take the place of telegraphy with wires. Each has a special field of operations of its own, but the public have a right to ask that the fullest advantage shall be taken of that particular service which ether-wave telegraphy can now render in promoting the greater safety of those at sea, and that, in view of our enormous maritime interests, this country shall not permit itself to be outraced by others in the peaceful contest to apply the outcome of scientific investigations and discoveries in every possible direction to the service of those who are obliged to face the perils of the sea. If scientific research has forged a fresh weapon with which in turn to fight Nature, "red in tooth and claw," all other questions fade into insignificance in comparison with the inquiry how we can take the utmost advantage of this addition to our resources.

Street-railway Progress on the West Side.

In Chicago the reports of elevated and surface railway companies show that traffic is at present increasing more rapidly on the West Side than in any other part of the city. During March the average daily traffic on the Metropolitan elevated lines was 79,500, a gain of over 14 per cent. compared with the corresponding month of last year. In the same month the West Chicago Street Railroad company carried about 216,000 passengers a day, a gain of over five per cent. The Lake Street Elevated also shows a good increase, due largely to the new incline and surface extension to Austin and Oak Park.

Work is progressing steadily on the 4,500 horse power extension to the power generating plant of the Metropolitan company. Two units of 2,250 horse power capacity each are building in the enlarged power house, and they will be both available for use on the station load about September 15th. The station will then have a total capacity of between 11,000 and 12,000 horse power in six units. The Metropolitan company has rented headquarters in the Royal Insurance building, on Jackson street, to which it will move on May 1st. The West Side Construction company will then remodel the old terminal property on Franklin and Market streets and will probably sell it.

Limitations of "Wireless Telegraphy."

[From the London Electrician.]

Already one of the practical limits to wireless telegraphy, as at present practiced, is making itself manifest in the Marconi group of signal stations to the southeast of this island. "At present," writes Professor Fleming, "all signals sent from the South Foreland to France affect the receiver on board the Goodwin lightship." The professor thinks that this "offers no difficulty," and he suggests a means for discriminating between the signals. There is a difficulty left untouched, however, in the impossibility of sending messages simultaneously and independently to or from the lightship and France. An uninterrupted stream of messages between the stations on opposite sides of the channel would render com-

pletely useless the apparatus which is now used. Curiously enough, the first inventor of Wireless Telegraphy, that the apparatus created the same effect in the order took the form of hermetically sealed glass tubes between the two color stations, and was heard; indeed, the Wimeron station received the message, "We are going to pass Boulogne at five o'clock"—this having been sent from the light-ship to the light-ship.

This result, of course, had been foreseen, but the actual occurrence emphasizes the need for a means for confining a Marconi message strictly to its proper path. The sphere of influence of a wireless telegraph station has a fatal tendency to become too literally spherical. Messages scattered broadcast not only waste energy by traveling with functionless force toward celestial space; they do positive mischief by interrupting the everyday business of irrelevant stations in the vicinity. If the Marconi wave could confine themselves strictly to business, the prospects of wireless telegraphy would be enormously brighter than they now are. We are not without hope that ere long a satisfactory method of thus restricting their activity will be discovered.

Why Does Electricity Influence Plant Growth?

In a recent treatise on "Electro-horticulture," by Dr. George S. Hull, the author treats in successive chapters of the application of atmospheric electricity to the roots of plants and to the surrounding soil, of the similar application of currents from batteries, and of the effect of the electric light upon vegetation. That the general effect is beneficial he has no doubt. How does this action take place? Dr. Hull says:

"In considering the action of atmospheric electricity upon vegetation, we have to deal with a stimulus which exists in abundance. Plants grow most vigorously where it is most abundant and with greatest rapidity in the early morning, when the dew is most plentiful upon them, making them better conductors. Its most important action upon the stalks of plants is that of increasing their circulation of sap.

"Discharges of electricity in the air, especially during thunderstorms, cause some union between the oxygen and nitrogen in the vicinity of the discharges, forming oxides of nitrogen, which, being soluble in water, are carried to the roots of plants and absorbed by them directly.

"Electricity passed through the soil by earth batteries, the geomagnetifer, or other means, has some action upon its chemical constituents. . . . Currents of electricity may break up the more complex compounds in the soil into simpler ones, upon which the roots of plants may feed. . . . Others think that in some manner, under the electric influence, nitrogen from the air combines with some other substances in the soil, making compounds which are readily absorbed by roots of plants. A recent experimenter claims that the particles of electrified earth are set into molecular vibration, thus loosening the earth."

It is also probable that electricity has a stimulating influence on the bacteria that adhere to the roots of certain plants and convert the atmospheric nitrogen into soluble nitrates for them to feed upon. That electricity is especially stimulating to micro-organisms there is plenty of evidence to show. In conclusion, Dr. Hull gives what he calls a "glimpse of an electric farm of the future," in which the discoveries that he has described will be combined with results of investigations yet to come, for the benefit of scientific agriculture. The abstract quoted here was made by the Literary Digest.

Discovery of Acetylene.

[From the Ottawa, Ont., correspondent of the Western Electrician.]

The facts relating to the discovery of acetylene gas are interesting. It appears that some years ago Thomas L. Willson of St. Catharines, Ont., was smelting for metallurgical purposes. From time to time he used a good deal of rock salt in his furnace stock, and also limestone as a flux. Whenever these two materials were fused together the slag produced by the intense electrical heat included a dirty grayish substance wholly unlike anything else he had ever seen. For weeks he noticed this substance without giving more than passing attention to it, dumping it into the stream upon the bank of which he had built his furnace. One day a curious thing occurred and at a time when the pile of slag had become so large that its top rose above the surface of the water. A minute or two after dumping the slag as usual into the stream, some of it going under and part remaining above the water in a red-hot state, the sizzling and steaming was followed by a bright burst of flame. The next time Mr. Willson used rock salt and limestone the blaze again appeared over the slag after it had been cast into the river, and, it being at night, he was much struck by the brilliant white light produced. The next time that he had a batch of the queer grayish residue to dispose he did not waste it but saved it and poured over it some water for experiment. To his surprise there was no flame, but after pouring a while over this feature he held a lighted match over the pile, when instantly there was a white, glowing flame, and Willson knew he had found something worth while. His discovery was acetylene gas.

1. From the London Times.

DEVELOPMENT OF THE TELEPHONE FIELD.

Telephone Competition for Rochester.

[Special correspondence of the Western Electrician.]

Rochester, N. Y., is the latest large city to feel the effect of a war against the Bell Telephone company, and, recognizing the enterprise and reliability of a new organization, the Common Council of the city has granted the Home Telephone company a franchise by the vote of 17 to three. The wires of the company are to be laid in conduits, and the rate is to be \$18 a year for residence and business telephones alike. The company had already secured 1,500 subscribers when the franchise was granted. It is provided that work on the system shall begin within a month and be prosecuted diligently. Within two months the company must exhibit to the mayor 1,500 bona fide subscriptions for telephones on five-year contracts, and the system must be in actual operation with at least 2,000 telephones within 15 months from the time the franchise was granted. By way of compensation the Home company will give the city 40 free telephones, which, at the same rate as the city has been paying, means a saving to the taxpayers of \$4,000 a year, and for the period the city has been paying the Bell company for the same instruments \$100,000 would have been saved to the people. It is intimated that the Bell people will fight the franchise, but in Rochester, as throughout Western New York, the people are very anxious for independent telephone service, having tired of being bound to a monopoly.

The directors of the Home Telephone company are Hon. Frederick Cook, Thomas W. Finucane, George W. Archer, Albrecht Vogt, H. Wheeler Davis, Gustave Erbe, George R. Fuller, Jacob Gerling, J. Foster Warner, Edward W. Peck, Horace Brewster, Eugene H. Satterlee, Willard B. Spader, V. Moreau Smith, Ezra M. Higgins. A meeting was held last week for the purpose of completing plans for the immediate installation of a plant. The first business done was the drafting and adopting of a resolution authorizing Mr. Cook to execute a contract with the city under the franchise granted. The directors also appointed a number of committees to look after the several branches of the work to be done. The company has suffered a delay of eight months in the franchise matter, and during that time plans of construction were held in abeyance. It will take some time to complete and perfect them.

It has been suggested that the Bell company may apply for an injunction restraining the Home company from going on with the construction of the line, hoping thereby to delay the new company from proceeding until the time limit fixed in the franchise for the operation of an exchange shall have expired, thereby annulling the franchise. Even in such an event, the Home company does not believe that the Common Council would cut them off for an unavoidable delay.

The present movement has been bitterly contested by the Bell interests at every step, and its agents have been at work for months in Rochester. The controversy recalls the memorable struggle between the Bell company and the people of Rochester in 1886, when the city revoked the license of the company, the subscribers hung up their instruments and the service was stopped. It was the most remarkable controversy that has ever been waged against a powerful corporation, and as it resulted in a complete overthrow of the Bell forces, the appended historical sketch, prepared by M. W. Cooke, and published in the Rochester Municipal Manual, will be particularly interesting at this time:

In 1879 a few citizens of Buffalo associated themselves and organized the Bell Telephone company of Buffalo, under the laws of 1848, passed for the incorporation of telegraph companies. The capital stock when incorporated, was \$30,000, and the line extended from Buffalo to Rochester and through the intermediate counties. Its object was to introduce the use of the Bell telephone, the patents for which were controlled by the American Bell Telephone company, which company took 35 per cent. of the stock of the Buffalo company and held the right to name three of the directors; and the "parent company" received \$14 per annum for the use of each telephone, besides 35 per cent. of the profits, to which it was entitled by its stock, according to the representation of the general manager of the company. It was generally understood that the American Bell Telephone company acquired by purchase a sufficient number of shares of the stock, in addition to the 35 per cent., to control the management of the Buffalo company.

An exchange was established in Rochester and the operations of the company here were commenced and conducted by the use of wires carried, for the most part, over the lands and buildings of individuals. No legal proceedings for condemnation were instituted for the reason that agreements or licenses were obtained from a limited number for such occupation, and, in other cases, the use of private property was appropriated without license or contract.

In 1886 the company petitioned the Common Council for the right to erect poles and string wires upon and over the streets and property of the city, and the right was voted to the company, and it was provided that the wires of the fire-alarm-telegraph system should be carried upon the company's poles and standards, and that the poles to be erected should be "straight and slightly." This resolution was followed by like permission from the Executive Board of the city, providing in addition that the superintendent of the fire-alarm system should locate the poles and that the company should erect poles when needed for that system. The company now needed its business by making contracts with our citizens for the use of telephones at a "flat price" or at a fixed charge per annum for the use of each set of instruments. The price seemed reasonable and many citizens became patrons of the company's telephone subscribers. Subsequently a very large increase was made in the price for the service and the effect was to create great dissatisfaction. Many discontinued the use of the telephone, and no concerted resistance was made to the execution of the new price. It was claimed by the company, was a "benefit" to the comparatively small number of patrons of the telephone, and it was distinctly held out to the people of Rochester

that an increase in the number of subscribers would be accompanied by a corresponding reduction in the price. Alured by this representation, the people submitted, and continued and increased the patronage of the telephone until the number had reached very nearly 1,000, and the annual receipts from them conceded amounted to upwards of \$54,000. In 1883 the company claimed that it procured from the mayor the execution of a document under the seal of the city, purporting to secure to the said company the unlimited right to the use and occupation of the property and streets of the city without power of revocation, and conditioned only by the provision for the use of the poles by the wires of fire-alarm system, and by the provision that the poles be "straight and slightly." This alleged contract was not directed or authorized by the Common Council, and it could not legally authorize such a contract if it so desired. Under the said resolutions and alleged contract the company caused to be erected upon the south sides of East and West Main streets and on the east side of State street—the main thoroughfares and business streets of the city—large masses of pine about ninety feet high and placed in the ground without charter, and apparently without regard to their fate after a few years after the expiration of the Bell patents—it being a patent fact that pine poles so set will last but six or seven years in the ground. In October, 1886, the poles had been so placed and the wires of the company carried thereon; and, by the supposed contract with the city, the company assumed that it was rendered independent of the owners of private property for the transaction of its business so far as the continuation and construction of its plant were concerned. The business had become so established that the designing controllers of the company regarded the use of the telephone as a necessity to the citizens of Rochester, and so it then seemed to the people generally.

In October the company, through the press, heralded a change of the system of rearing telephones and the collection of its revenue in the city of Rochester, to wit, the flat price was to be abandoned November 1, 1886, and the "toll system," so called, introduced. It was proclaimed that the intended change was not designed or calculated to impose any additional burden upon the telephone subscribers, nor to increase the revenue of the company, but to protect it against the free use of the instruments by persons who were not subscribers. Not long afterwards the declaration came in definite form. It was an arbitrary schedule or tariff sheet made and issued without the sanction of the patrons to the telephone; and it initiated a radical change in the relation of the employers (the subscribers) and the servant (the company) supplying telephone service. It helied the proclamation heralding it; and instead of being a change for the benefit of the subscribers or the service, or one which would not impose additional burden upon them, it was, upon its face, an attempt to accomplish a very large increase in the revenue of the company for the same service, and a corresponding increase in the burdens upon the patrons, the company under the pretense of a necessitated change of system to guard the subscribers and the company against abuses. The company claimed that its necessities demanded an increase of 50 per cent. in the price if the toll system was not adopted. It was argued by the company that this system would enable each subscriber to collect from his neighbor, friend or customer, in addition to the increased charge he paid, a toll without limit. The general manager said the company did not desire to get more out of the subscribers, but to get the increased revenue out of the non-subscribers—the "outsiders," as he called them. He would make the "deadheads" living patrons by the aid and enforced service of the paying subscribers. This toll sheet provided for the sale of a large number of messages at two cents each, assuming that messages might be sold at wholesale; whereas it is apparent that the service of each message would be at the same cost to the company and each one interrupt the use of the line exactly the same as if it cost the sender ten cents. The device was clearly to get more money out of or through the aid of the subscribers.

Nay, it was more; it was an attempt to seize upon and occupy the stores, offices and residences of our citizens by this company for the transaction of its business without payment of rent. The toll price proclaimed was a flat price of \$50 for 500 messages to subscribers within a radius of one-half a mile, thus making each subscriber guarantee a revenue of \$50 or 10 cents per message, accompanied by a charge of six cents for every message after the 500 messages (less than two in a day) had been exhausted. To subscribers outside the half-mile an addition of \$20 per mile was made, making the first 500 messages cost 24 cents each, and six cents for all over that amount. Besides the imposition of the additional expense the change required the keeping of an account of messages and records, which had become a constant source of irritation and dispute. This system was objectionable upon other grounds, and they were so evident and fatal that the subscribers refused to discuss the propriety of the introduction of the system contained in said sheet, and preferred to dispense with the luxury entirely than be subjected to the expense, annoyance and trouble which would necessarily accompany the change dictated.

A decision of the Court of Appeals informed the company that the cords by which it was supposed the city was bound were ropes of sand and the gag a harmless device. The alleged contract was void and inoperative, as a contract, and all the city had to do was to assert its rights. Thereupon the Common Council, by resolution unanimously revoked all license, express or implied, to said company for the occupation of its streets or property.

The Executive Board did the same and the mayor reprimanded the company for deceiving him in 1883. The telephone subscribers flocked to the city hall, and in a deliberate and determined manner organized for resistance to any further legalized robbery of the city or its people, and resolved not to use, nor to allow to be used on their premises, said telephone until the company furnished such guarantees as the Common Council should demand to protect the city and the public from the abuse of the franchise from the city; that they would not, in any event, submit to the "toll system" as stated, and that such of them as were compelled by unexpired contracts with the company, to pay during the suspension must be treated equitably by the company upon such contracts.

Nearly every subscriber silenced his telephone November 20, 1886, at noon, and so they have remained and will remain until the offender brings forth "fruits meet for repentance."

In December, 1886, the telephone company erected a pole on the corner of Court and South Union streets, Seventh Ward, in the night or in the early hours of the morning, in defiance of the action of the city. The Executive Board directed the street superintendent to take down the pole unless the company did so within 24 hours. Upon notice of this action the company procured a temporary injunction and moved the Supreme Court to continue it at special term. After a hearing the court denied the motion with cost, and the decision was followed by a removal of the said pole by the company.

Subsequently an action was brought by the people of the state of New York in the name of the attorney-general against said company for purpose of removing the poles and structures in the streets as a public nuisance.

THE SETTLEMENT.

The People's association, after long negotiations, not being in position legally to make contract, referred the matter to the council, which effected the settlement; it was signed by the mayor and company May 10, 1888, and ratified by the People's association. The principal points follow: The rate will be a flat rate, for at least five years; the council's law committee can supervise the form of contract; the company's wires shall be strung along in the principal streets, one-half mile a year, until three miles are laid; the city has the free use of one two-wire duct in conduit. Telephone subscribers who ceased using their instruments in November, 1886, and who contract for service prior to June 1, 1888, shall receive credits for the amounts paid by them for service after November 20, 1886. All claims upon the contracts with subscribers existing November 20, 1886, for moneys which become payable hereafter, shall be collected. In litigation "cost" the Bell company shall pay reasonable counsel fees of the People's association.

Rights of Telephone Companies.

In the Circuit Court at Hagers Grove, Mo., last week a bill in equity was filed by the Shelby County Telephone company against A. L. Perry and others, asking the court for an injunction restraining defendants from running a telephone line into the city of Clarence, and also to prevent defendants from using or operating their line from Leonard to Clarence, so as to interfere with the operation of the line previously constructed between the two points by the Shelby County Telephone company.

It seems the Shelby County Telephone company has purchased a franchise from the city of Clarence for a telephone exchange in that place, in accordance with the Julian franchise law, enacted in 1893. This act has since been declared inoperative by the Supreme Court. The question now is as to the rights of telephone companies which erected telephone systems under the provisions and protection of this law before it was declared void. Do the merits of the law still apply and protect in any degree those who complied with its provisions when it was in force?

The other question involved refers to the rights of a pioneer or previous telephone line over a line built later. The Shelby County Telephone company states that it erected a line from Leonard to Clarence some years ago and later defendants erected a line parallel to it or along the same highway, and that the service of the Shelby County Telephone company's line has been impaired, the sound from one line reaching over to the other line and rendering conversation difficult.

At the trial several expert witnesses were examined, and the case attracted considerable attention. As this is the first case of the kind to be brought in Missouri, it will be closely watched. The case was transferred to the Macon Circuit Court, where the matter will be reopened and more testimony taken.

Difficulties of "Wireless Telegraphy."

[From the London Electrician.]

Wireless telegraphy an accomplished fact, wireless telephony obviously suggests itself to those seeking fresh fields and pastures new. Where Hertzian waves are made the vehicle, and the coherer is the means of receiving the transmitted energy, the difficulties of telephony are immensely greater than those of telegraphy. The high frequency of sound waves makes it impossible for any known form of coherer to respond to ether waves correspondingly frequent; while their irregularity, when speech is the sound to be transmitted, would render syntony impossible, even were transmission an accomplished fact. Rumor reaches us of successful wireless telephony in Belgium; but, from intimate acquaintance with the difficulties of the problem, we judge that the method adopted, if this rumor be true, was not one involving the use of the coherer. By leakage, or by magnetic or electrostatic induction, telephony without connecting wires is, of course, possible, and, within limits, commercially practicable. Its range of usefulness, however, is greatly restricted. Indeed, the immediate prospects of wireless telephony would appear to be decidedly inferior to those of the Marconi system of telegraphy.

Cook Invention Sustained.

In the Western Electrician of January 21st mention was made of a Patent Office decision in favor of Frank B. Cook, vice-president of the Sterling Electric company, in an interference suit brought by him against the Western Electric company, involving the broad principle of protection for telephone circuits. From that decision the Western Electric company appealed, and a decision is now rendered on the appeal, which not only sustains the former decision, but, it is claimed, gives a decision more favorable to Mr. Cook. The protector in dispute is largely used by Bell companies, and is the well-known combined terminal and protector manufactured by the Sterling Electric company of Chicago, which is being generally used by the independent companies in Indianapolis, St. Louis, Cleveland, Saginaw, Bay City, Lafayette, Wilkesbarre, Ashabula, Janesville, Mattoon, Danville, Oshkosh, Shreveport and other points.

Cheap and Poor.

Americans who advocate governmental control of telephone service will find that the cheap service of Germany would hardly be tolerated in this country. United States Consul Schumann writes from Mainz on this subject as follows: "The telephone service of this country is a public institution controlled and managed by the Department for Posts and Telegraphs. The rates are certainly very low, the charge for a local telephone being \$38.55 per annum, including the rental of the instrument. The service, however, is lacking in enterprise. I applied on February 20th to have a telephone placed in my residence and was told that the connection could not possibly be made before May or June, as they did not string wires in winter."

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Wisconsin Supreme Court has decided against the Wisconsin Telephone company in the case of the city of Marshfield against the Wisconsin Telephone company. The council offered the company a franchise, but it was not acceptable, and the council refused to make any other terms. The company then proceeded to erect poles in the city without permission. The city officials cut them down and secured an injunction to prevent the company erecting any others. The case then went to the Supreme Court, where the company has lost.

The Northwestern Telephone Exchange company has secured control of the telephone exchange at Larimore, N. D., which has not been in use for some time.

The Iowa Telephone company has begun using a new switchboard in Sioux City, Ia.

The Stoughton Telephone company is an applicant for a telephone franchise at Stoughton, Wis.

The Le Grand Farmers' Mutual Telephone company will construct a line between Le Grand, Ia., and Dunbar as soon as possible.

Otto Wettstein, Jr., proprietor of the exchange in La Porte, Ia., proposes to establish an exchange in Gladbrook, Ia.

Radeliffe, Ia., capitalists will form a company to build a line to McCallsburg.

The electric-light company at Humboldt, Ia., will ask for a franchise for a telephone exchange.

The owners of the local telephone exchange at Clear Lake, Ia., have formed a company.

A local mutual telephone exchange is projected at Avoca, Ia.

The Park Region Telephone company has been formed at Alexandria, Minn., to do a local and toll-line telephone business. The capital stock is \$10,000.

The city of Duluth has asked R. H. Evans to furnish a surety bond as a guaranty that his company will establish the telephone exchange as provided by the franchise. The city of Superior has granted him a franchise similar to the one granted by Duluth.

The American Telephone and Telegraph company has been granted a franchise in White Bear, Minn.

W. D. Spayth of Toledo, Ia., contemplates a telephone line from Toledo to connect with Garwin.

The Ottumwa (Ia.) Long Distance Telephone company is arranging to extend its wires to West Point, Ia., and intervening points.

The Northwestern Telephone Exchange company has been granted a franchise through Ulen, Minn.

The Wausau (Wis.) Telephone company has put in a new switchboard with 400 drops.

The Blue Earth Valley Telephone company has ordered a 200-drop switchboard for its Wells, Minn., office.

The telephone line between Glencoe, Minn., and Minneapolis will be rebuilt in the spring and a metallic circuit substituted for the present system. A more direct connection will be made.

The Fergus Telephone company of Fergus Falls, Minn., has let the contract to a Minneapolis concern to construct the toll line from Fergus Falls to Wadena, Minn., in the spring. Materials are being delivered for the work.

The Winona (Minn.) Telephone company will push work on an extension from Rollingstone to Oak Ridge. The company has been petitioned to continue the line on from Oak Ridge to Beaver and Minneiska.

F. E. Fee is an applicant for a telephone franchise at Hartley, Ia.

The Chicago and Lake Shore Telephone company will be formed soon to establish exchanges in eastern Wisconsin. Carl H. Wells of Appleton has been appointed state manager. Exchanges will be established in Kenosha, Racine, Fond du Lac and the Fox river valley towns.

The Dakota Central Telephone company has installed a system at Britton, S. D.

The Milbank (S. D.) Telephone company has been incorporated.

The Western Stearns County Telephone company has been formed at New Paynesville, Minn., to connect with the smaller towns of the county.

J. W. Kelly pleaded guilty to robbing the Iowa Telephone company at Waterloo, Ia., and was sentenced to four months in jail.

O. F. Blasier has bought the telephone exchange at Greene, Ia.

NEW COMPANIES.

The Madison (Ohio) Telephone company has elected the following-named officers: President, C. W. De Voe of Orwell; vice-president and treasurer, F. E. Howes of Mesopotamia; secretary and treasurer, E. J. Clapp of Thompson.

A charter was granted at Charleston, W. Va., April 14th, to the People's Telephone company of New York city. The capital subscribed is \$2,000, which may be increased to \$5,000,000. The shareholders are A. Wilford Hall, George Fruck, Oscar F. Shaw, Dunne P. Cobb and Frank W. Hubby, Jr., all of New York city.

Jacob Pepper, John Schoepflin, William Kroenenberg, N. C. Fish, H. D. Pierce, John A. Kloefer and Fayette Keely of Hamburg, Erie County, N. Y., are directors of the new Hamburg Telephone com-

pany, which will operate a line from Hamburg to Buffalo. The capital of the company is \$10,000. Other towns in Erie County will be connected.

The Mohawk River Telegraph and Telephone company has been incorporated under the laws of New York, with a capital of \$21,000, to operate a telephone and telegraph system from Syracuse to Albany by the way of Oneida, Rome, Utica, Little Falls, Fonda, Schenectady and other intermediate points, and to extend its lines to Northern New York and east through the New England states to the Atlantic seaboard, and south into New Jersey and Pennsylvania. The directors are Russell R. Stuart, Daniel O'Brien and John Holihan of Syracuse, William Mason of Binghamton, Harvey J. Donaldson of Ballston and James J. Dwyer and Thomas J. Dwyer of Utica.

The Zenith City Telephone company of Duluth, Minn., has completed its organization, and elected the following-named officers: President, R. H. Evans; vice-president, J. B. Stafford of Chicago; secretary, E. H. Stafford of Muskegon, Mich.; treasurer, A. M. Miller, Jr., of Duluth. The authorized capital of the company is \$200,000, and of this amount \$85,000 is already paid up. Messrs. Evans and Stafford have taken \$55,000 of the stock, and A. M. Miller, Jr., of Duluth has taken \$30,000. All the money necessary for the completion of the plant has been arranged for. Construction will actively begin as soon as the frost is out of the ground. The work preliminary to actual construction has been going on for some time. The plans and specifications are being drawn by the company's engineers, and will be ready very soon.

EXTENSIONS AND IMPROVEMENTS.

A proposition is being discussed to establish a telephone line between Idaho Falls and Jackson, Wyo.

The Citizens' Telephone company of Woodstock, Ill., is about to open an exchange in Crystal Lake with 25 subscribers.

Gladbrook, Ia., has granted a franchise to Otto Wettstein, Jr., of La Porte City, Ia., to put in a telephone exchange. Fifty subscribers have been secured to start with.

William M. Holmes of Ashland, Ore., has been granted permission to erect a telephone line along the county roads between Central Point and Eagle Point, to be completed in six months.

The Chicago Telephone company is building a seven-story brick building at 210 and 212 Washington street, to cost \$100,000. This adjoins the old telephone building and is an extension of it.

S. S. Creider of Sterling, Ill., who was in Chicago last week, reports favorable progress in his territory for independent interests. The Bell company thus far has made no impression upon the independent organization, although it is exerting all of its influences to regain control of the field.

The Crestline Telephone company has been recently reorganized with Edward R. Farr, president and general manager; P. J. Neff, vice-president; W. S. Johnson, secretary. The capital stock is \$10,000. The system has been changed from common-return to metallic circuits and a new switchboard of 200-drop capacity has been installed.

The Galena, Kan., Telephone company will soon have its toll line completed between Columbus, Galena and Weir City. The line will then be extended to connect with Fort Scott through Girard, Kan. This company also has a franchise to build an exchange in Columbus, Kan., and work will be commenced for a complete metallic system for 100 subscribers as soon as material arrives.

On April 4th the board of directors of the Wood County Telephone company decided to establish an exchange at the village of Nekoosta, Wis., to handle its increasing business. The new exchange will start with about 25 instruments connected and good prospects of increasing the number. President Fontaine and Manager Dougherty were instructed to make the exchange first-class in every respect.

The Elkhart, Ind., Telephone company has completed arrangements for toll-line connections with adjacent towns that will doubtless prove advantageous. Mr. E. C. Bieckel, the general manager of the company, says that Barber & Brailley, who own exchanges in 26 different towns and are now building in 10 others, have "made propositions that were acceptable, both for his services and for 13 per cent. of the stock in the Elkhart company. They made no suggestion or request for a change in policy or management, except to form a closer alliance with their other properties and other long-distance companies."

MANUFACTURERS AND DEALERS.

The Farr Telephone and Construction Supply company of Chicago has issued a card giving testimonials received from a few of its customers. It is needless to say that all these buyers speak in the highest terms of the Farr products. The Farr company has always taken special pride in filling the wants of its customers in a most satisfactory manner, and it now has on its list of patrons nearly

1,000 independent telephone companies besides many other customers.

Tammany and Telephone Rates.

In the examination of Richard Croker before the Mazet investigation committee of the New York Legislature, on April 15th, Mr. Moss hinted at several dark transactions which he may or may not be able to trace directly to the Tammany chieftain. For instance, he referred to the project of John Jacob Astor and others to form a new telephone company and reduce telephone rates. Having asked the witness if a representative of Mr. Astor had called to see him about this company, and having been told that such might have been the case, Mr. Moss asked if it was not a fact that Mr. Croker had refused to give his favor to the new telephone company because he had been "seen" by representatives of the New York Telephone company. Mr. Croker denied this, and then Mr. Moss wanted to know if the witness had not made an agreement with Charles F. Cutler, president of the New York Telephone company, to show a special favor to the latter company for a period of five years in consideration of a certain fixed sum of money to be paid to Croker annually. The witness denied this, but the asking of the question created something of a sensation in the courtroom.

Mr. Moss began the attack by asking Mr. Croker if his turning down of the new telephone company was because the New York Telephone company had, after they heard of the matter, also opened negotiations with him. Mr. Croker said it was not, but an idea of the unhappy position into which Mr. Moss led him is best obtained from the following verbatim report of Mr. Moss' questions and Mr. Croker's hating answers:

Q.—Didn't you have any conversation about that time with the representatives of the New York Telephone company? A.—No, not that I know of. When was this all?

Q.—Well, I am asking you when it was. You recall it, when was it? Mr. Croker, these people called? A.—I cannot tell what date; there was some talk, there is talk every day, about 50 kinds of telephones.

Q.—Well, I will say was it within five years? Say it was within five years, and probably you can figure it out closer. A.—I remember there was some talk about telephone three or four years ago.

Q.—And the New York Telephone people came to you? A.—I don't remember that.

Q.—Don't you remember that the New York Telephone people found out about the starting up of the proposed new corporation? A.—I don't remember it.

Q.—Wasn't the matter mentioned to you? A.—I don't remember it.

Q.—You never had any stock in the New York Telephone company? A.—I decline to answer that.

Q.—Did you have any conversation with Mr. Cutler about these matters? A.—I don't remember.

Q.—Do you know Mr. Cutler? A.—I have seen him.

Q.—Who is he? A.—He is Mr. Cutler. (Laughter.)

Q.—What is his business? A.—I believe he is at the head of the telephone business.

Q.—At the head of the New York Telephone business; you knew him and had a talk with him? A.—Nothing particular that I know of.

Q.—But this was some time ago? A.—I have not talked with him anything in particular.

Q.—Did you receive any money from Mr. Cutler at any time? A.—Never. I decline to answer that question.

Q.—You have answered it, and then you take your answer back and decline to answer. A.—I know what you mean; yes, I decline.

Q.—Did you make an agreement with Mr. Cutler for the payment to you of money? A.—I decline to answer that question.

Q.—Did you not make a five years' agreement with Mr. Cutler for the payment to you of a sum of money each year? A.—I decline to answer that question.

Q.—Do you deny it? A.—I decline to answer that question.

Q.—Will you deny it? A.—I decline to answer that question.

Q.—Will you deny or affirm it? A.—I decline to answer that question.

Q.—Mr. Croker, if you took money or made an agreement to take money or had a contract for money from these telephone people, would you consider that an honorable or dishonorable act? A.—Dishonorable.

Q.—Did you do it? A.—I decline to answer the question.

Bonds of People's Telephone Company of New Orleans.

An issue of \$200,000 20-year first-mortgage six per cent. gold bonds, maturing in 1918, of the People's Telephone company of New Orleans, La., is offered at 105 and interest. The company operates under an exceptionally favorable franchise from the city. The bonds are secured by a mortgage on the franchise, contracts, equipment and entire property of the company. The mortgage authorizes an issue of \$300,000 of bonds on a plant of 3,000 telephone instruments. William P. Curtis, the vice-president and general manager of the company, says that the People's Telephone company of New Orleans has 3,000 subscribers, giving it an annual contract income of \$130,000. Its annual expenses are \$55,000, with six per cent. interest on \$300,000 bonds, \$18,000, and sinking fund, \$15,000, making \$88,000 altogether, and leaving surplus profits of \$42,000. The number of subscribers is rapidly and steadily increasing, and, it is said, will easily reach 4,000 within a year. The company has the enthusiastic support of the people and the municipal authorities. Thomas F. Ahern, who is consulting engineer for the company, adds: "In my 20 years of telephone experience I have never known a better telephone situation than in New Orleans. The construction work and equipment of the People's Telephone company is of the highest possible character. The system used is pure metallic, and the wires in the business section are in underground cables. The cost of maintenance is covered in the figures given in Mr. Curtis' letter. I regard the earning power as conservative, and believe it will increase." A part of the bond issue has been placed abroad.

Gas-lighting Specialties.

The Advance Specialty company of Chicago presents the new hand lighter for lighting gas by electric spark, which is shown in Fig. 1. The principal advantage of this lighter is its simplicity, as it does not use an induction coil or magneto, nor does it re-

of an insulating bar with heavy copper ends which make sliding contact in substantial jaws. The use of this fuse-holder enables fuses to be replaced with current on the box without danger of short-circuits. The Johnson & Morton boxes are made of standard width, regardless of the number of cir-

FIGS. 1 AND 2. GAS-LIGHTING SPECIALTIES.

quire any wiring, as by inserting the battery into the handle all necessary connections are made. The battery is of the dry form and will run the lighter for a long time without recharge. The lighter is constructed in fine style and is nickel-plated.

Fig. 2 illustrates a modification of the Advance Specialty company's attachment for electric gas lighting, to be fastened to gas fixtures, thereby dispensing with wiring the house. The new design is called the Little Joker. It is neat in appearance, easy to attach and connect and cheap. It is fastened to the fixture by two small rings, which are hinged so as to clamp the fixture rod, and only require two screws.

Johnson & Morton Junction Boxes.

During the last few years the demand for well-made junction boxes has constantly increased, and with the view of meeting this demand Johnson & Morton, electrical engineers of Utica, N. Y., have placed on the market a line of boxes which is said to be giving very good satisfaction. A description of these junction boxes will prove of interest to prospective users, and the following details are given:

The tablet board containing the switches and connections of the boxes is removable and can be placed on the box after the interior finishing of the building and after all wiring is installed, thus preventing a possibility of damage to the finish of the visible parts of the box. As the junction box is the only part of a concealed-wiring installation which shows,

cuts, and are so designed that they will fit between the uprights in ordinary wooden buildings without any cutting. All copper work is highly polished and lacquered; the slate is enameled and polished after all drilling is completed, and the woodwork is highly finished by hand. They are, therefore, handsome in appearance, easily installed and connected up, and have received the approval of the National Board of Fire Underwriters.

Mayer Dynamos and Motors.

The cut shows the type of dynamos and motors manufactured by the Maxwell M. Mayer Electric

MAYER DYNAMOS AND MOTORS.

company, Second avenue and One-hundred-and-twenty-first street, New York. The machines are of the two-pole ironclad type, the whole magnetic frame being cast in one piece of open-hearth steel, which is bolted to a substantial iron base, which also

The armatures are of the slotted-drum type, finely laminated to avoid heating due to eddy currents. They are insulated with mica throughout, and the winding is such as to secure perfect electrical and mechanical balance. The carrying capacity of conductors is large, so that machines can stand considerable overload without injury. The commutators are tempered copper insulated with sheet mica. Carbon brushes are used in self-feeding brush-holders, and the tension on brushes can be changed at will. The mechanical construction is of the highest standard of excellence, all parts being heavy and the shafts running in self-oiling phosphor-bronze bearings. These machines are up-to-date, highly efficient, smooth running and noiseless, and will stand considerable overload without detriment. They are built in four sizes at present—one, two, three and five horse power. Every machine is provided with iron slide rails and underload automatic starting box for motors and field rheostats for dynamos.

The "S. J." Reflector.

A simple and neat reflector for incandescent lamps is shown in Fig. 1 of the accompanying illustrations. It is made by Schiff, Jordan & Co. of 232 and 234 Greenwich street, New York. The device, which is known as the "S. J." reflector, consists of an outer shade of silvered glass fitted with a base that screws into the lamp socket and an inner reflector of porcelain, that fits snugly over the lamp. The base of the lamp screws into a socket in the outer shade, this intermediate receptacle thus doing away with the necessity of a shade holder. Fig. 2 shows the lamp and the outer and inner portions of the reflector taken apart.

Victor Motors.

The Victor Electric company of 418 and 420 Dearborn street, Chicago, maker of the motors illustrated herewith, has been engaged in the manufacture of electrical specialties for about six years, during which time its business has grown steadily. The success of the company has been due to several causes. From the start the company has avoided the tendency to sacrifice quality to price. The aim has been, and is first to make the goods as perfect as possible, and next to sell them on as small a margin of profit as possible. The quality has been steadily maintained, and no misrepresentation of product has been tolerated. The company en-

FIGS. 1 AND 2. VICTOR MOTORS.

deavors to make its customers' interests its own, and gives prompt attention to all complaints. The Victor Electric company manufactures motors, batteries, rheostats, induction coils, electric dental engines, shunt boxes, electric air compressors, static machines, cataphoric obtunders, transformers, examination lamps, etc.

The shunt-wound motor shown in Fig 1 is of one-sixth horse power, and was especially designed for use where a high-grade machine for light power purposes is wanted. Danger of accidental damage is reduced to the minimum, as the motor is entirely encased in metal with the exception of the brushes, which are left exposed so that they may be readily adjusted and replaced. The most noteworthy feature is its noiselessness. When running at full speed it makes no perceptible noise. It is guaranteed absolutely for two years.

The Victor Electric company's fan motor (Fig. 2) embodies all the latest ideas in fan-motor construction. The company's aim has been to move a greater volume of air with less noise and a smaller current consumption than is done by the use of other fans, and, judging by the growth of the business and the commendations of customers, it has attained a high degree of success. The fan motors are artistic in design and finely finished; they are also substantially built and durable.

The War Department is inviting sealed proposals, until May 13th, for furnishing and installing electric-lighting plants at Fort Sumter and St. Helena Island, S. C. Prospective bidders can obtain full information upon application to the United States engineer at Charleston, S. C.

FIG. 1. JOHNSON & MORTON JUNCTION BOX.

Hatch Storage Battery.

The electrical trade in general and storage-battery buyers particularly will be interested to know that the Hatch Storage Battery company of Boston has just entered upon a most aggressive campaign in the exploitation of the Hatch cell.

For over a year this company has been husbanding its energies, so that its efforts and capital might not be wasted at an unfavorable period. But the great revival of trade in all lines during the last few months and the present outlook for the greatest prosperity, especially in the storage-battery field during the coming five to ten years, has brought the company's directory to the firm belief that the present is the time in which to let the public know the value of its product.

The Hatch Storage Battery company was organized

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

HATCH STORAGE BATTERY.

in May, 1897, and is at present officered by the following-named gentlemen: President, William S. Crosby; vice-president, Joseph Middleby, Jr.; secretary, Gorham H. Davis; treasurer and general manager, James P. Clare. The Hatch company is capitalized at \$500,000.

Relative to the technical features of the Hatch storage cell it should be explained that in its improved element there is no new chemical or electrical principle involved. The invention is of a purely mechanical nature, and relates to the construction of the element. The element is practically solid, and integral in all its parts, reducing the weight to the minimum amount of lead oxides necessary to do a given amount of work and for the mechanical support of light material, thus producing a storage battery of high efficiency, light weight, durability and compactness.

An examination of the construction of the Hatch cell will reveal how simply and effectually the oxides are locked up in their support, while they are also freely accessible throughout to the electrolyte of the cell.

The inventor had in mind the fact that the only materials in a storage battery which actually contribute to the storing of chemical energy are the metallic oxides and the electrolyte. To bring these two elements together, with a minimum of mechanical interference, was his thought and aim.

It is claimed by the Hatch company that the introduction of large masses of metal in the form of lead "grid" electrodes to serve as a mechanical support for the oxides introduces an element of danger,

internal resistance of the 100-ampere-hour cell is 0.0025 of an ohm, with other sizes in direct proportion, while the weight of the element to do a given amount of work is reduced fully one-third as compared with the grid type.

In constructing the Hatch element there is employed a porous plate of unglazed earthenware with square receptacles on its face side and grooves on its reverse side, as shown in Figs. 1 and 2. To the face side of each plate the lead oxide or active agent is applied, filling the mass one-eighth of an inch above the surface of the plates, so as to secure an agglomeration with the electrode during the forming process.

The plates thus loaded with the active agent are then placed together, back to back, with the grooves

crossed, as shown in Fig. 3. This forms one couple, positive and negative, of the element.

A series of these couples is then assembled, as shown in Fig. 4, to form the complete element, as many couples being associated as is necessary for the required capacity. The sides of this element thus assembled are flanked with a rigid support plate of glass, or similar material, and then encircled with heavy rubber bands, as shown in Fig. 4. The electrodes are then applied in any desired form, but ordinarily they are in the form of lead sheets, "interleaved" with the active material, as shown in Fig. 5.

Reference to Fig. 5 as a complete element will show how permanently the oxides are locked up, while the porosity of the entire mass is secured so that it will remain porous during the work, as the elasticity of the element allows for the expansion and contraction of the active material without closing the pores of its own mass.

Provision is also made for free circulation of the electrolyte between the plates, and, at the same time, allows a free escape of the gases formed by electrolysis.

As the first question asked by a prospective large investor in any particular storage battery would naturally be "Where have you a plant in operation, and how does it stand practical service?" the Braintree, Mass., plant of the Hatch Storage Battery company,

It is stated that the use of this storage-battery plant necessitates the employment of one less engine in the power station, equal to 1,250 horse power. The Braintree storage-battery installation is run at a cost estimated equal only to the interest on the cost of the battery. Such a plant speaks for itself.

The Boston Herald said of the plant illustrated. "From an economical standpoint it would appear that the results thus far obtained in the use of a storage battery by the Quincy and Boston Street Railway company have been highly satisfactory, and warrant its indefinite continuance. The company's first experiments led it to apply the battery to the entire Braintree system, which includes the Braintree, Holbrook and Randolph lines. The initial tests were watched with no little interest, as success meant a

big saving in operating expenses and a reserve supply of current that could be made available in case the power plant was temporarily crippled. Since the adoption of the battery the cars have been run at increased speed and at a saving of about 50 per cent. of the energy formerly employed."

In conclusion, as the question of infringement of patent rights in the storage-battery business has always been such a vital one, the Hatch company quotes from the legal opinion of Hon. Causten Browne as follows: "The question whether you (acting under the Hatch patents) can make and sell such batteries as are described in the Hatch patents without liability for infringement of the Brush patent is one to which I have given careful consideration, and I have come to the conclusion that the batteries described in the Hatch patents do not infringe the Brush patent. This Brush patent is the only one, so far as I know, in regard to which any question of infringement has been suggested. I therefore advise you that you may safely make and sell the batteries described in either of the Hatch patents, and practice the method described in the Hatch patent No. 585,472."

Electric Development in Brussels.

Something like American enterprise is suggested by the report of United States Consul Roosevelt

Fig. 5. Element Complete.

Fig. 6. Railway Station Plant at Quincy, Mass.

HATCH STORAGE BATTERY.

because of the traces of foreign metals in all lead, which, in the past, it is stated, have had much to do with the poor work of storage batteries and added unnecessary weight.

The electrical efficiency of a storage cell is determined primarily by its internal resistance, and this, in its turn, is governed by the freedom from interference with its chemical and electrical operation. Purity of material, with a minimum of the mechanical parts, and porosity of the active agent and its mechanical support, to admit of the free distribution of the electrolyte, are the essentials.

The construction of the Hatch element, the company feels, secures all these points perfectly, as the

shown in Fig. 6, installed for the Quincy and Boston Street Railway company, stands out pre-eminent as a sample of this company's work, although other installations of similar importance can be shown.

The Braintree plant consists of 200 cells of the Hatch battery, possessing 550 ampere-hours capacity. This equipment is used as an addition to aid a booster system supplying the Braintree street railway. This road gives service to about 20 cars in summer and about eight cars in winter, and it is 15 miles long. The booster is located at Quincy Point, seven miles from Braintree. This plant was started about May 1, 1898, and the Hatch company reports that it has been running since without the slightest hitch.

upon the development of the electrical interests at Brussels. Statistics show that in 1893 3,030 lamps met the requirements of consumers of electricity in the city of Brussels. At the present time there are 66,000 lamps. In consequence of the constantly increasing use of electricity, the city has been obliged to enlarge its plant, and it is now proposed to buy five new vertical machines of 1,000 horse power, to be placed in works already supplied with five horizontal machines of 500 horse power each. The city has another station in the basement of the railroad building, but, owing to the steadily increasing use of electricity, the production is insufficient to meet public demands.

Sale of Fort Wayne Property.

The Fort Wayne Electric corporation's plant and other property were purchased by the General Electric company at the receivers' sale on April 18th. The sale was held at Fort Wayne and occupied the entire day. Representatives of the General Electric company, the Siemens & Halske company of Chicago and of the Fort Wayne Emergency company were present. The General Electric company's representatives were Mr. Coffin, president and general manager; Mr. Parsons and Mr. Durstin, eastern legal representatives, and Attorney-general Taylor of Indianapolis. Mr. C. S. Knight of the Siemens & Halske company was present, and most of the Fort Wayne capitalists who had been interested in the effort to keep the ownership of the works in the city were also on hand.

The receivers' inventory divided the property into three classes; the first, including real estate, patents and equipment, was scheduled at \$207,261.89; the second, being merchandise, was placed at \$145,954.67; and the third, being real estate, furniture, machinery and tools, securities, etc., was estimated at \$181,245.18; total, \$534,461.74.

An attempt to dispose of the property as inventoried failed, and then it was decided to sell the entire property.

Mr. Coffin submitted the following proposition in writing, which was accepted, no other bids being presented:

"The General Electric company bids the sum of \$356,400 for the entire plant of the Fort Wayne Electric corporation, of which sum \$185,000 is to be paid for with \$185,000 at par value of the debenture bonds of the Fort Wayne Electric corporation, which bonds are owned by said bidder, and are the same bonds provided for in the decree of the United States District Court of the District of Indiana, in the order of sale of said property; the balance, amounting to \$171,400, to be paid according to the terms of the decree.

"This bid is conditioned that this purchaser shall receive all of the plant and property of every kind and description whatsoever of said Fort Wayne Electric corporation, ordered to be sold by said decree and order of sale, free and clear from any liens and claims of the receivers, and receivers' certificates, and also free from all other liens, encumbrances, claims of creditors and debts whatsoever."

From the sum realized from the sale, \$356,400, the following obligations must be met at once:

General Electric company.....	\$185,000
Receivers' costs	42,000
Charles A. Wilding, trustee.....	30,000
Court costs, etc. (approximately).....	20,000

Total

\$277,000
Subtracting this amount from the proceeds of the sale, leaves \$79,400, to which must be added collectable outstanding accounts aggregating approximately \$65,000 and \$8,000 in the hands of the receivers, a total of \$153,400, which amount will be disbursed to the unsecured creditors. The total unsecured indebtedness is \$900,000, so that the payment will aggregate about 16 per cent. of the total claims.

Representatives of the interests involved will bring the matter before Judge Baker of Indianapolis at once for approval.

Mr. Coffin encouraged the Fort Wayne people to hope for continuance of the plant in that city, it was said, and it was announced that the works would be reopened on Monday morning under the direction of J. J. Wood as superintendent and F. S. Hunting as purchasing agent.

Much disappointment was shown by the people of Fort Wayne with the result of the sale.

It is said that Henry C. Paul and Charles S. Bash will act as financial representatives of the General Electric company at Fort Wayne.

CORRESPONDENCE.

New York Notes.

New York, April 17.—Richard Croker, the Tammany leader, was subjected to a searching examination by the Mazet legislative investigating committee last week. He was asked many pointed questions about his relations with corporations doing business with the city or by municipal franchise, such as the Manhattan Railway company, the Metropolitan Street Railway company and the New York Telephone company. He refused to answer a large proportion of the questions, on the ground that he was not compelled to divulge his private affairs. He said that he had speculated in the stocks of various companies, but would not admit that in his position of dictator of the all-powerful Tammany organization he had tried to influence the market value of stocks to his own profit or that he had taken money from quasi-public corporations for furthering their interests. Nevertheless, Mr. Croker's answers to the questions put to him and his demeanor as a witness were so unsatisfactory and evasive, when not shamelessly explicit about the finances of the "organization," that the belief is general that there must be a large proportion of truth in the stupendous charges made against him.

Several hundred men—engineers, railroad men, electricians and others—witnessed a test of Captain J. McLeod Murphy's safety third-rail electric-railway system at Manhattan Beach on Wednesday

last. The test was made on 2,000 feet of track which connects the Manhattan Beach Hotel with the Oriental Hotel. It seemed to be the general opinion of those who witnessed the demonstration that the new system promised success.

A trial was made yesterday of one of the compressed-air motor cars to be used on the cross-town routes of the Metropolitan Street Railway company. After an examination of the mechanism at the compressor house at Twenty-third street and Eleventh avenue, one of the cars was run across town on Twenty-third street to the East River and back. In the car were several officers of the Metropolitan and American Air Power companies. Twenty of the new cars are now ready for use, and will be put into service on May 1st on the Twenty-eighth, Twenty-ninth and Thirty-fourth street lines.

In relation to the statement that William C. Whitney was interested, with the Auto-truck syndicate, in the acquisition of certain interests in Springfield, Ohio, Mr. Whitney said to a New York reporter: "The statements contained in the dispatch are not true. My name has, from time to time, been associated in the public press with a company known as the Auto-truck company. You may say that I neither have, nor have had, at any time, any interest in the company, nor do I know anything about its organization, property or affairs. The confusion arises from the circumstance that the Metropolitan Street railway owns a large interest in the American Air Power company—a corporation entirely distinct from the Auto-truck company—and has spent a large amount of money developing the system, as applied to surface railways. We believe the city of New York will soon realize the benefits to be derived from a new power on surface railways, in the use of which no tearing up of the streets is required. We have spent at least three years and the greater part of \$1,000,000 in experiment and development, which we now believe will prove entirely successful."

At the recent commencement exercises of the New York Trade School certificates of merit were awarded to 24 pupils in electrical work. This was out of a total of 310 certificates.

There seems to be little doubt that the "Whitney crowd" on the one hand and the affiliated Manhattan and Third avenue companies on the other are dicker with the owners of the United Electric Light and Power company for the purchase of it. If the Metropolitan people could get the United company, which is a Westinghouse company, they would, through the New York Gas and Electric Light, Heat and Power company, largely control the electric lighting of the city, having already taken over the Edison Electric Illuminating company. Their great rivals, the Manhattan-Third Avenue capitalists, are naturally opposed to this. Both parties are, therefore, in the field as purchasers of the United company, if a price can be agreed upon. The United Electric Light and Power company has a large plant at Twenty-ninth street and the East River and other stations. It distributes, at time of maximum load, about 10,000 horse power in electrical energy, using the alternating-current system.

After a meeting of the Board of Rapid Transit held to-day, at which the officers and counsel of the Metropolitan Street Railway company were present, it was practically decided that the proposed underground rapid-transit railway will not be built by that company. The meeting was hurriedly called, and followed upon a statement made by Governor Roosevelt, in Albany, that he earnestly hoped for the passage of the rapid-transit bill, but that he was opposed to granting franchises in perpetuity and for more than 50 years. William C. Whitney, Harry Payne Whitney, H. H. Vreeland, Thomas F. Ryan, Elihu Root, counsel, and Henry MacDonald, sub-counsel for the railway company, met the rapid-transit commissioners. At the direction of Mr. Whitney a letter was addressed to the commissioners, saying that in view of the objections raised the Metropolitan people "feel constrained to withdraw their proposition to build the underground rapid-transit railroad."

Speaking of the very recent acquisition of the Kings County elevated railroad by the Brooklyn Rapid Transit company, ex-Governor Flower made this statement a day or two ago: "This secures for the Brooklyn Rapid Transit company all the elevated roads in Brooklyn and all the trolley lines save one. The officers of the Rapid Transit company estimate that the saving in operating expenses alone through consolidation will be equal to four per cent. on the stock. Since April 1st the earnings of the entire system have shown an increase, on an average, of more than \$3,000 a day as compared with last year, and it is expected that with the summer traffic in full swing the increase will be more than \$5,000 a day, adding net earnings equal to one or two per cent. on the stock." A story has recently been circulated to the effect that an arrangement between the Rapid Transit company and the Manhattan Railway company, which owns the elevated railroads in Manhattan, is under consideration, whereby trains may be run from Harlem and the Bronx across the Brooklyn Bridge and clear to Coney Island and Manhattan Beach. In any event, it is reported that there will be a transfer agreement between the Brooklyn Rapid Transit and the Manhattan company similar to that which is to go into effect on May 1st between the Manhattan and the Third Avenue Railroad company. M. S.

Canadian Intelligence.

Ottawa, April 15.—Mr. Emerson has received from McGill University, Montreal, a report of the result of a test of his scheme for the manufacture of calcium carbide from sawdust. His method is acknowledged as the only means in existence by which sawdust can be converted properly into carbon. The scheme will be supported.

An important real-estate deal has been put through by the Shawinigan Water and Power company of Montreal, which will enable the company to go ahead with the development of the power at that place, which will only be exceeded in extent by the big plants at Niagara. Contracts for the work of developing the water power will soon be given out by the company.

The Ottawa Electric company has begun extensive improvements in its power at the Chaudiere Falls. New buildings and heavy machinery will be added. A new flume will also be built which will be 20 feet wide and will be closed in on one side by a cut of solid rock and on the other by an immense stone wall. It is expected that by the company's method of controlling the water flowing into the flume anchor ice will be avoided.

The Bronson & Weston company's lumber mills in Ottawa are about to be converted into an immense carbide factory. The factory will be operated by a 4,800 horse power electric plant.

The Dominion government has decided to construct a telegraph line to connect the Yukon with British Columbia. A party of engineers has left Ottawa for the Pacific coast with instructions from the government to commence at once the construction of the line from Skagway to Dawson City. The estimated cost of the line for the distance of 600 miles between the two points named is \$150,000, on a basis of \$250 a mile. It is expected that the line will be in operation by the 15th of November next, and when it is completed Dawson will be brought within six days' communication of Ottawa.

Captain G. H. Couvrette of Montreal, who has had 20 years' experience on grain-carrying ships between Duluth, Chicago, Buffalo and Kingston, has patented an electric grain shovel, to be worked in connection with the floating elevators now in use in Montreal harbor. By the use of the electric shovel, it is claimed that grain can be transhipped in less than half the time it has taken heretofore, and for at least one-third less than it costs to tranship grain at Ogdensburg, Prescott, Kingston or Buffalo.

The Metropolitan Electrical company of Ottawa, organized for the purpose of supplying electric lighting and motive power to Ottawa and the surrounding district, which includes many growing and prosperous towns, has just issued its prospectus to the public. The company has already been incorporated, and the authorized capital stock is placed at \$500,000, in shares of \$100 each. Thomas Lindsay of Ottawa is the president of the company. It is confidently believed that the new company will be successful from the outset, and as Ottawa, with its immense water-power advantages, is fast becoming a chief manufacturing center of the Dominion, the prospects for future development are exceptionally bright. The company will obtain its water power from the Deschene Rapids, near Britannia, about six miles from the city.

An invention has recently been perfected in Ottawa which, it is said, may take the place of the now much-used electric bell, and will also no doubt be extensively used as a fog signal at sea and along the shores where the fog signals are in use. The machine will be known as an electrical siren. The inventor of the new device is A. E. Trudeau of Ottawa. He has been working steadily for over two years on this invention, and has just completed a large fog horn, which will be tested on the great lakes as a fog signal. The machine is capable of producing a variety of sounds similar to those of a steam whistle, and can be heard at a great distance. The sound produced is very harsh and penetrating. It can be placed at a point inaccessible to an ordinary steam plant now used in fog signaling, and can be operated by wires connecting the power at almost any distance. It is also proposed to utilize it as a burglar alarm. The mechanism of the new machine is very simple and compact. It consists of a large copper horn, similar to that of a large base horn. The remainder is of iron. The sound is produced by the vibration of a diaphragm at the base of the horn, similar to that of a telephone, but on a much more extensive scale. The electric current as soon as turned on produces the sound. This new device, it is expected, will be adopted by the Dominion government to take the place of the rather cumbersome steam plant required for signaling stations. W.

PERSONAL.

Mr. Weare Parsons of Chicago has been appointed superintendent of the Southwest Electric Light and Power company at Joplin, Mo.

Mr. Shepherd A. Benson, for many years connected with the General Electric company in Denver, has been placed in charge of the Salt Lake office of that company.

Mr. I. C. Woodard, a well-known electrical man of San Francisco, was in Chicago last week. Mr. Woodard is returning to his home in California after an extended eastern trip.

ELECTRIC LIGHTING.

An electric-light plant, to be operated by water power, will be erected at Anstell, Ga.

The secretary of the treasury is inviting sealed proposals, until May 24, for installing an electric-light and power plant in the United States courthouse and postoffice building at Kansas City, Mo. Proposals from actual manufacturers only will be received. Specifications and plans can be obtained upon application to the Treasury Department, Washington, D. C., or of the superintendent of construction of the building at Kansas City, Mo.

ELECTRIC VEHICLES.

One of the principal features of next month's electrical show in Madison Square Garden, New York, will be the display of electric vehicles. The Pope Manufacturing company of Hartford, Conn., the Riker Electric Motor company of Brooklyn and the Woods Moto-vehicle company and the American Electric Vehicle company of Chicago have all secured choice exhibit spaces in the central part of the hall.

The London Standard says that the motor industry of Great Britain is active, and its future appears bright. There is a brisk call for motors. A traveler who recently arrived in Coventry from a continental trip brought back an order for one hundred, and he said that in France especially the demand for mechanically propelled vehicles is keen. Improvements are being made weekly, while remarkable speeds have already been recorded on long journeys. At present the cost is prohibitive to the great majority, but the possibilities of development for business purposes are not limited.

The Illinois Electric Vehicle company has been organized in New Jersey by a strong eastern syndicate, said to include William C. Whitney, Messrs. Elkius, Widener, Ryan, Rice and others interested in electric and transportation affairs. Substantially the same people own the electric-vehicle company in New York and in the New England states. The general plan is that the local companies operate electric cabs and other vehicles manufactured under patents controlled by the promoters. The same interests have lately acquired the Electric Storage Battery company of Philadelphia, and the chief owners of that company also own the Chicago Electric Traction company's storage-battery road in Englewood.

Consul-general Gowdy sends from Paris a synopsis of the regulations for the circulation of automobiles as follows: Every type of vehicle employed must offer complete conditions of security in its mechanism, its steering gear and its brakes. Each vehicle must bear the name of the constructor, the indication of the type of machine, the number of the vehicle in that type, and the name and domicile of its owner. No one may drive an automobile who is not the holder of a certificate delivered by the prefect of the department. In narrow or crowded thoroughfares the speed must be reduced to walking pace. In no case may the speed exceed 30 kilometers (18.6 miles) an hour in the open country, or 20 kilometers (12.4 miles) an hour when passing houses. The approach of an automobile must, if necessary, be signaled by means of a trumpet. Each automobile must be provided with two lamps—one white, the other green.

MISCELLANEOUS.

The Chicago offices and laboratory of the Electrical Bureau of the Board of Fire Underwriters have been removed to No. 67 East Twenty-first street, Chicago, to which location all future communications should be addressed.

TRADE NEWS.

Hollister Bros., 148 Monroe street, Chicago, printers and publishers, are installing a number of the Western Electric company's motors in their press-room.

The secretary of agriculture is inviting sealed proposals, until May 4th, for furnishing the department with telegraph supplies during the next fiscal year. Full information will be furnished upon application to the department, Washington, D. C.

The Advance Specialty company of Chicago reports large sales of its electric specialties. The company was pressed for room in its old quarters, and has removed to suite 42, No. 119-121 La Salle street, where it will be pleased to meet its friends and customers.

Sealed proposals are invited, until May 10th, for furnishing the office of public buildings and grounds in Washington with electric-battery supplies during the fiscal year ending June 30, 1900. Information can be obtained upon application to Colonel Theo. A. Bingham, Washington, D. C.

F. A. La Roche & Co., 652-660 Hudson street, New York, have purchased the plant and stock of

the Murphy Switchboard company, manufacturer of switchboards and panel boards, and the business will be hereafter operated in connection with the various other activities of La Roche & Co.

The W. H. Sills Mica company of Chicago reports a large business. The trade of the Sills company has enjoyed a phenomenal growth, and the concern is now receiving orders from all over the world. The Sills company handles only the best quality of mica, which may account for its constantly increasing output.

The Sioux City (Iowa) Brass Works have passed from the possession of a receiver to the Hawkeye Electric company, which does an electric power and lighting business. The name of the Sioux City Brass Works will be retained for the products of the brass foundry and machine shop, although the ownership has passed to the Hawkeye company.

Sargent & Lundy, the well-known electrical engineers of Chicago, will remove to 1140 Monadnock building, where the firm will enjoy much more commodious quarters. Sargent & Lundy have been identified with some of the largest electrical and mechanical installations in the West, and the firm is now working on a number of plants which require the best engineering skill.

Another evidence of the tendency of hardware dealers to go into the electrical supply trade is furnished by the announcement of the Smith & Egge Manufacturing company of Bridgeport, Conn., that it has added an electrical department to its business. This company has secured from the O. S. Platt Manufacturing company of Bridgeport the exclusive right to manufacture and sell the New England switches. The Smith & Egge company expects, also, to make a line of knife switches, and may add other specialties.

Correspondence instruction in technical subjects was instituted, it is claimed, by the International Correspondence Schools of Scranton, Pa., and its students and graduates, which are said to number more than 80,000, have ranked with students and graduates of other technical schools. The schools teach mechanical, electrical, steam and civil engineering, mechanical and architectural drawing, architecture, plumbing, English branches, bookkeeping, etc., having more than 50 courses. Students may study at home, devoting such time as they can spare, and the instructors are in constant communication with them through the mails.

Walter R. Weldon, an electrical man of Fort Wayne, Ind., has invented a new form of pipe covering that is said to be an insulator against electricity as well as against heat. This covering is cheap, and it is claimed to have all the advantages of usual steam-pipe coverings with the additional one of providing an easy method of insulating buried metal pipes from the escaping current of street railways. Mr. A. L. Hadley of the Fort Wayne Electric corporation writes: "I have tested a sample of pipe covering submitted by W. R. Weldon, submitting it to a pressure of 10,000 volts alternating current, with a maximum pressure of 14,000 volts. The sample tested is seven-eighths of an inch thick, and would require from 20,000 to 50,000 volts pressure to pierce the material of that thickness. The material is a very good insulator, and as long as it is kept dry, free from moisture, or with a coating of japauning material or asphaltum paint to make it waterproof, it would, without doubt, successfully protect iron or other pipes from street-railway currents."

BUSINESS.

The Electric Appliance company is distributing its 1899 fan-motor catalogue, which is a very satisfactory publication. The catalogue includes a full list of alternating and direct-current desk and ceiling fans, together with some other fan specialties. The company will be pleased to furnish copies to the trade and quotes especially attractive prices.

Lamp users desiring to realize on burned-out lamps should communicate with Goldsmith Bros., 63 Washington street, Chicago, who pay the highest market value for old lamp bases containing platinum. This firm also buys platinum scrap and places on the market an excellent line of platinum wire. The firm has been in this business for many years and is well known to the electrical fraternity, with which it is doing a large business.

The Western Electric company, in its manufacture of fan motors, not only has the armatures perfectly balanced, but also weighs the fan blades and inspects and balances the fans independently of the motors before assembling. This careful attention to details is one of the features which make the Western Electric fan motors so efficient. The 40-page fan-motor catalogue describing the various makes

of fans should be valuable to those who are interested.

The small, well-known Porter motors are made by Kendrick & Davis, Lebanon, N. H., successors to the Porter Standard Motor company. They are made to run on primary-battery circuits or, with suitable resistance, on 110-volt direct-current circuits. They are suitable for driving toys, advertising devices or fans. For amateurs the Ajax fan is supplied in parts, ready for assembling. A neat catalogue is sent by Kendrick & Davis on application.

The Charles E. Gregory company of Chicago, the well-known dealer in second-hand electrical apparatus, reports a large and increasing business. The Gregory company always carries a large assortment of every character of second-hand electrical apparatus, and there are few, if any, calls for apparatus made on the company that cannot be filled. Through the energetic efforts of General Manager A. Louis Kuchmstedt and his associates the company has built up an enviable reputation, and no dealer in second-hand apparatus is better known than this wide-awake concern.

An attractive souvenir is distributed to the electrical trade by the Becker Name Plate company of Boston in the form of an aluminum paper-cutter and envelope opener. Six cents* in postage stamps will bring this to anyone interested. Manager August Becker is a believer in novel advertising, and the practically free distribution of this souvenir is but one of the many ways he has of increasing a rapidly growing business. Mr. Becker has had 18 years' experience in the engraving and casting of bronze name-plates, and he now enjoys the patronage of a large number of the best concerns in the electrical field, both in the United States and Europe. Orders have recently been received, one for 5,000 plates, one for 2,000 plates, in the United States, and one for 1,000 from a large London house. Mr. Becker is now making a special effort to secure western trade, and his excellent work seems to entitle him to a large share.

W. N. Matthews, 312 Commercial building, St. Louis, is meeting with good luck in the sales of his large lot of second-hand machinery on hand in St. Louis. Mr. Matthews is also successful as a manufacturer's agent, and, as he recently expressed it, the way orders are coming in for Paiste specialties in the Southwest is a "sort of barometer of the times." Mr. Matthews was recently in New York, and since that time has made a trip to Kansas City, New Orleans, Memphis and Louisville, and had a good business all along the line. As a general agent for the Ritter soldering iron he has been most successful. From the gossip of electrical circles it may be assumed that Mr. Matthews will soon secure several valuable agencies from the East in addition to those he has. His reputation as one of the brightest young men in the supply trade of the Southwest seems to stand him in good stead.

Among other well-known goods which the Western Electrical Supply company of St. Louis, Mo., is offering to the trade are the telephone switchboards made by the Western Telephone Construction company. The Western Electrical Supply company has only recently taken the agency for this board, but has made an excellent start and anticipates a large demand, owing to the long-established and well-deserved reputation of this switchboard. The Western switchboard is at the present time in use in some of the largest independent telephone exchanges in the country. It is fully covered by broad patents controlled by the Western Telephone Construction company. Its numerous points of merit have met with universal favor throughout the country, judging from the number of boards in use. The Western Electrical Supply company will be pleased to furnish estimates on this switchboard to anyone anticipating the installation of a telephone exchange.

The American School of Correspondence of Boston has been most successful in imparting to engineers and mechanics a thorough knowledge of the theory and practice of their profession by means of a thoroughly up-to-date system of instruction by correspondence. The courses are limited strictly to steam, electrical and mechanical engineering, and, as these courses have been prepared by well-known educators and experts, the courses are complete, accurate and thoroughly abreast of the times. The courses all begin with the simplest mathematics, and the student is gradually advanced to the more difficult subjects, as designing boilers, engines, dynamos, electrical measurement, etc. The school is chartered by the commonwealth of Massachusetts, and, as its chief aim is to benefit the ambitious workman, the tuition is placed very low in order that every mechanic may secure the technical knowledge necessary for advancement in his profession. The school will gladly send a handbook to any address on request.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 11, 1899.

622,657. Circuit-breaker. Hjalmar E. Andersson, Stockholm, Sweden. Application filed February 14, 1899.

A circuit-breaker comprising two superposed tubes containing mercury, and an insulator consisting of a plate of

insulating material movable between the tubes to divide the body of mercury, in combination with a vessel containing an oleaginous liquid in which the proximate ends of the two tubes and the cut-off plate are immersed, and means for connecting the mercury at opposite sides of the cut-off plate respectively with opposite poles of an electric circuit.

622,660. Battery Cut-out for Electric Selector Systems. Thomas C. Drake, Malta, Ohio. Application filed February 17, 1898.

In this mechanism there is the combination of an electro-magnet to energize an armature lever, the armature

lever adapted to release and stop an impelled and retarded escape wheel, means to impel the escape wheel, a stop-catch carried by the armature lever to stop the escape wheel and make electrical connection therewith when the armature lever remains in normal position, a stop-catch electrically insulated from the first stop-catch and adapted to stop the escape wheel and break electrical connection therewith when the armature lever is in an energized position.

622,689. Process of Making Battery Electrodes. John C. Howell, London, England. Original application filed July 8, 1898. Divided and this application filed January 3, 1899.

The process of producing battery plates or electrodes which consists in first spirally cutting a metallic tube in the direction of its length and then securing the continuous ribbon so produced upon or to a core or frame.

622,690. Machine for Making Metallic Ribbon for Battery Electrodes. John C. Howell, London, England. Application filed January 3, 1899.

Apparatus is described for the manufacture of metallic ribbon comprising mechanism adapted to cut a metal tube of a mandrel having both a rotating and a receding motion with relation to the tube and adapted to collect and spirally wind the ribbon so produced.

622,736. Electric Overhead Railway. Jean B. Verroken, Antwerp, Belgium. Application filed May 24, 1898.

In an electric overhead railway there is the combination with suitable supports and cables and suspension rods of rails formed of a horizontal plate carrying an electric conductor by means of insulators, and furnished on the upper face with two vertical partitions between which are arranged the suspension rods furnished with a head at their lower ends to carry the rail.

622,747. Splicer for Trolley or Other Wires. Mont-traville M. Wood, Chicago, Ill. Application filed November 2, 1898.

A splicer for trolley or other wires comprising a tubular casing tapered in internal diameter and a splicer cap closed at one end arranged within the casing, the cap also tapering externally and adapted to receive in the open end thereof the end of the wire to be spliced, the end of the wire adapted to abut against the solid end wall of the cap.

NO. 622,977

622,748. Rheostat. William H. Woodman, San Francisco, Cal. Application filed November 17, 1898.

In an apparatus for affording electrical resistance an outer casing in combination with an inner frame having a movable member, a resistance supported by the frame so as to draw upon the movable member, springs bearing upon the movable member in opposition to the tension of the conductor, electrical connections and a switch for controlling the resistance.

622,759. Electric-arc-forming Device. Josef Czifowski, Vienna, Austria-Hungary. Application filed November 29, 1897.

This device consists of a body of metal readily fused or dissipated by the electric current, being suitably shaped to fit upon or conform to the opposing tips of two aligned carbon electrodes of an electric arc lamp and maintain them against lateral displacement while serving to establish the arc when the electrodes are connected in circuit.

622,785. Electric-light Radiator. Henry Stenz, Fair-vaux, Minn. Application filed March 26, 1898.

A globe for electric arc lamps comprising upper and lower frames of different size, and integral globe sections crimped or corrugated and secured between the frames, and having the end portion adjacent to the smaller frame contracted.

622,805. Apparatus for Line Distribution by Inductional Transformers or Secondary Generators for Electric Railway. Elias E. Ries, Baltimore, Md. Application filed December 30, 1887.

A system of electric propulsion comprising a series of spaced electric circuits extending along a railway, traveling motors fed from the working circuits, and inductional transformers charging the working circuits and charged from a main line.

622,866. System of Electrical Distribution. Charles F. Smith, Pittsburgh, Pa. Application filed November 4, 1898.

A system of alternating-current electrical distribution for single and polyphase transmitting devices comprising three or more conductors, a source of two-phase currents and

a transformer connecting one of the line conductors with the other two line conductors through the source of current and so proportioned as to equalize the line electro-motive forces and adjust the phase relation thereof.

622,885. Circuit-breaker. Harry P. Davis, Pittsburgh, Pa. Application filed November 4, 1898.

A circuit-breaker is described comprising two hinged-connected members, one of which has contact pieces, in combination with stationary circuit terminals, the heads of which are in position to be engaged by the contact pieces and with means for so supporting the circuit-breaker as to prevent downward or lateral displacement, but permitting ready removal when moved upwardly.

NO. 622,991.

622,893. Electric Igniter for Gas Engines. Ernest W. Graef, Baltimore, Md. Original application filed November 29, 1897. Divided and this application filed June 23, 1898.

An electrical contact device is located within the combustion chamber, an oscillating shaft projecting through the wall of the chamber for operating the same, the shaft and one pole of the contact device being connected to a source of electricity, the shaft upon the exterior of the chamber being provided with a crank, a pivoted lever connected to the crank by a joint having some lost motion, and a spring connected to and operating the second lever, means for actuating the spring lever to move it and its connections to make a contact and then to bend and release it, the spring by its recoil actuating the connecting parts to break the contact.

622,910. Electrically Illuminated Advertising Sign. William T. Bell, Nottingham, England. Application filed February 2, 1898.

An apparatus for operating electrically illuminated signs and the like comprises a switchboard provided with a series of depressible contact pins, one for each lamp, a jacquard pattern card having in it apertures which register with a part only of the contact pins, a carrier for the pattern card adapted to be moved toward and from the switchboard, the carrier having apertures registering with all of the contact pins, and means for moving the carrier and guiding it in its movements.

622,917. Electric Temperature Indicator. John H. Dorion, Springfield, Mass. Application filed May 31, 1898.

A temperature-indicating device has suitable metal posts forming the terminals of two electric circuits, each of which includes a source of electricity and an electric alarm bell; a movable metallic connection for closing the circuits, means for effecting the contact of the metallic connection with the posts, and two connections having different fusing points for normally holding the metallic connection out of contact with the post, whereby one of the circuits will be closed in advance of the other.

622,977. Electrical Steering Mechanism. Andrew L. Riker, New York, N. Y. Application filed May 23, 1898.

In an electric steering device a motor in operative connection with the rudder, a source of electrical energy included in a circuit with the motor, a reversing switch in the circuit and a second switch in the circuit, one member of which is mounted upon and moves with the rudder-head, whereby the movement of the rudder serves to automatically open the switch.

622,991. Trolley. Robert E. Carroll, Lima, Ohio. Application filed November 19, 1898.

The invention includes a trolley pole and a trolley wheel support on the upper end thereof, arms pivotally mounted on the opposite sides of the trolley wheel support below and in advance of the trolley wheel, and provided at their upper extremities with angularly arranged guide and concavo-conical guard disks arranged in front of the trolley wheel and operating to hold the latter to the line wire, and means for spreading the upper ends of the arms apart to disengage the disks from the line wire.

NO. 623,104.

623,006. Flexible Electrical Conductor. John W. Gottschalk, Philadelphia, Pa. Application filed February 8, 1899.

A braided conducting cord is made in continuous lengths, having enlargements at intervals formed by increasing the thickness of the covering.

623,009. Fire Alarm. Harlie E. Greene and John W. Haaly, Hot Springs, Ark. Application filed January 3, 1899.

The flanged and screw-threaded sleeve and nut clamp the wall of the inner case between and form an elongated passage way, the headed pin and a spring-actuated push-button bearing an inclined surface rest beneath the pin. The push-button has a range of movement at right angles to the pin.

623,022. Electric Catheter. Reason P. Johnson, Chicago, Ill. Application filed March 30, 1898.

In a catheter the combination with a flexible tube having a closed end or tip and lateral apertures of a helical wire coil within the tube, means for attaching such coil to a terminal of an electric circuit, and means for connecting the tube with a source of liquid supply.

623,033. Lightning Conductor. Gustav Raunacher, Vienna, Austria-Hungary. Application filed January 20, 1899.

In a lightning arrester a head having a central rounded surface and a plurality of points surrounding the same.

623,036. Carbon-sorting Machine. Charles T. Richmond and Mahlon M. Zellers, Cleveland, Ohio. Application filed March 26, 1898.

An important feature is a rotating chuck for holding a carbon, and is connected with one terminal of an electric circuit, and a contact plate in the described relation to a carbon in the grasp of the chuck, the plate being connected to the other terminal of the chuck, and means for adjusting the position of the plate relative to the axis of the chuck.

623,063. Apparatus for Measuring and Recording Electric Currents. Hermann Aron, Berlin, Germany. Application filed February 17, 1899.

Clockwork is employed to automatically change the rate during different periods of the day. Wheels are employed having a sliding motion on their axis, each wheel having in its nave a notch with an inclined face, a catch corresponding to the notch and a pointer to adjust the catch to a predetermined time, a spring to force the wheel nave toward the catch, a lever actuated by the wheel nave and mechanism to transmit the sliding motion of the wheels for the purpose of changing the rate of recording the current.

623,104. Electrode for Electric Accumulators. Henri Pieper, Fils, Liege, Belgium. Application filed December 28, 1897.

In an electrode for use in electric accumulators the combination of radially corrugated plates having the shape of hollow truncated cones open at the bottom and top, with plain plates of like description, the corrugated plates alternating with the plain plates and forming inclined open channels on both sides of the latter, and all of the plates being electrically connected to each other.

NO. 623,033.

623,117. Listening Key or Circuit-changer for Operators' Keyboards. Joseph Baxter, Fort Wayne, Ind. Application filed April 25, 1898.

In a ringing and listening key for operators' key boards a movable member is carried by a slide and provided with electrical conductors and electrical contact points are located in the line of movement of the member and connected with electrical conductors, the parts being so relatively arranged that in the movement of the slide one circuit is made and in the movement of the member carried by it another circuit is made.

623,118. Switching Apparatus. Jacob Cloos, Milwaukee, Wis. Application filed February 7, 1898.

The combination with a pivotally mounted switch lever of plugs flexibly connected with the lever upon one side of the pivot, and other plugs flexibly connected with the lever upon the other side of its pivot, contact thimbles normally connected with the feeders, electrically connected thimbles aligned respectively, the first with thimbles and others forming terminals of a loop or distribution circuit, the plugs upon the switch lever being adapted to connect aligned thimbles.

623,119. Switching Apparatus. Jacob Cloos, Milwaukee, Wis. Application filed February 7, 1898.

In a switch for controlling the series distribution of electricity the combination with feeder terminal sockets of loop-circuit terminal sockets, socketed contact portions and plugs adapted for insertion within the aligned sockets, the plates being each adapted through the medium of the connecting plugs to connect one feeder terminal with one loop-circuit terminal to include the loop circuit in series with the feeders, the portion being adapted for connection with the plates, and thereby with all of the feeder and loop-circuit terminals through the medium of plugs.

623,120. Switching Apparatus and Method of Counteracting Arcs. Jacob Cloos, Milwaukee, Wis. Application filed February 7, 1898.

In a device for extinguishing or preventing arcs between contact points the combination is claimed with a supply of insulating liquid of means for causing a vacuum or partial vacuum to effect a flow of the fluid between contact points.

CHICAGO, APRIL 29, 1899.

No. 17

Marconi System in Chicago.

The first public exhibition in Chicago of the Marconi system of signaling through space was given on Saturday, April 22d, by Professor Jerome J. Green of the University of Notre Dame. Professor Green's successful experiments at the Indiana institution had attracted a good deal of attention, and he was invited by the Chicago Tribune to come to this city and make a series of tests under widely varying conditions.

There was an impression in the public mind that the steel structures, the electrical circuits for lighting, street-railway, power, telephone and telegraph service, and the electrical apparatus of every description

building as the receiving end, a distance of three-fourths of a mile and in the heart of the business district. Probably no other part of the city contains as many large steel structures as that through which it was determined to make the initial experiment, and the fact that the first attempt failed was accepted by many skeptics as convincing proof in support of their theory regarding the impracticability of operation in large cities. The real cause of the failure of the first attempt remains a matter of conjecture, and is explained by the several witnesses in different ways. These features may be discussed later, and no doubt an attempt will be made to solve the problem or at least to establish com-

insulated wire to a ball on a flagstaff extending from the top of the Tribune building.

After repeated attempts had been made to establish communication between the Dearborn station and Tribune building the equipment was removed from the railroad office and tested in the Tribune building, where it was afterward set up. The receiving and sending apparatus were placed more than 100 feet apart, with several doors and a steel stairway intervening. No difficulty was experienced in this test, although the spheres were not used and only a couple of yards of insulated conductor was employed for vertical wires.

The next attempt was between the Tribune build-

MARCONI SYSTEM IN CHICAGO.—PROFESSOR GREEN RECEIVING SIGNALS AT TRIBUNE BUILDING.

that is to be found everywhere in large cities might interfere with the operation of the apparatus, if, indeed, it would not be absolutely impossible to establish communication where these conditions prevailed. The fact that Marconi's principal experiments and demonstrations were made on or near the sea or other body of water, and away from the "disturbing influences" of large cities, may have encouraged this view; at any rate, it was quite generally entertained, although electricians who have carefully studied the problem do not share in this opinion. Nothing but actual demonstration, however, could dispel the illusion of the public on this point, and it was partly for this reason that the exhibition of last week was arranged.

Professor Green arrived in Chicago on Saturday morning, and as the first test had been announced for noon, the preparations were hurriedly made. It was decided to make the first attempt between the Dearborn station as the sending point and the Tribune

munication between these points when improved apparatus has been secured.

The sending station in all the experiments was in charge of Professor Green's assistant, Albert Kachur. At the top of the Dearborn tower a spar had been thrust out with a polished zinc ball on one end of it. Attached to this sphere was an insulated wire, the other end of which was connected with the sending equipment. An eight-inch spark-coil was used, and current was secured from storage batteries. A ground was made through the steam piping, and later through the water system.

At the receiving station Professor Green, surrounded by local electricians who had been invited to witness the test, waited patiently for some manifestation of the waves sent out from Dearborn station. The equipment which he employed was constructed at the laboratory in Notre Dame, and was consequently crude. It was made after the pattern frequently described, and was connected by an in-

ing, as the sending station, and the Hartford building, across the street, for the receiving station. This, too, was successful, and the receiving apparatus was then removed to the Marquette building, two blocks away. In all of these tests the arrangements were exceedingly crude, and in the last one in particular little attention was given to details. A staff was extended from a window on the sixteenth floor of the Marquette building, and the vertical wire was suspended between that point and the eighth floor, where the receiving apparatus had been placed. After a few preliminary attempts had been made and the necessary adjustment completed, a sounder was attached to the receiving end and signals were received at regular intervals of five seconds. This completed the day's work in a very satisfactory manner.

Experiments more after the manner of those conducted by Marconi were undertaken on Sunday. The sending apparatus was set up at the life-saving station at the mouth of the Chicago River, and the receiving

equipment placed aboard the tug Protection, which had been secured for the purpose. An eight-inch zinc sphere was rigged up 35 feet above the ground at the life-saving station. The eight-inch spark-coil and the storage battery were placed on the lifeboat chute below and just outside the building. The zinc sphere was attached to a wooden spar and lashed to the lookout on the roof, and from this an insulated wire hung down and was connected with the coil. The receiving apparatus was located at the stern of the tug while it was still moored to the dock at the life-saving station. The zinc receiving sphere on board the tug was hung 27 feet above the deck and about 33 feet from the water. A four-inch wooden scantling was clamped to the after end of the deckhouse and strongly guyed with wire and ropes, and the zinc sphere was fastened at the end of a wooden arm about four feet from the top of the staff. The latter was 26 feet above the deck, and the arm slanted upward sufficiently to raise the ball another foot. From the sphere insulated wire hung to the receiving apparatus.

Albert Kachur, the assistant, was left in charge of the sending instrument at the life-saving station. To facilitate matters a code of whistle signals was agreed on. Three short blasts were to tell the people on shore the message had been received, and one and two short blasts of the whistle were to tell the operator to send a Morse dot and dash respectively. One prolonged blast was agreed on for a signal to stop sending. The lookout man on the life-saving station was to keep track of the signals by a marine glass after the tug got too far out for the sound to be distinguished. In fact, the tug had only gone a little way when it was found to be easier to detect the signals by means of the puffs of steam than to wait for the sound. In this way the Morse signals were received the instant the signals were made.

The first test was made while the Protection lay

although, taking into consideration the difficulties under which he was working, the exhibition must be regarded as highly successful. His idea of the failure of the Dearborn station test does not agree with the views of others. Local influences are the principal causes ascribed by Professor Green, who cites in support of this position the fact that the current from the spark-coil affected the lighting fixtures in the building, and in an office nearby each contact was noted by a flash

JEROME J. GREEN.

extending the entire length of the gas pipe supporting the lighting fixtures in the center of the room. This, however, was explained by Mr. Abbott as a sympathetic spark. He had observed similar demonstrations in his experiments.

It is believed that in the hasty preparation for the opening test the mechanical adjustment of the apparatus was not perfect and the proper spark was not secured. Mr. Abbott is confident that, with more time at his disposal and a better acquaintance with the surroundings, Professor Green will succeed in transmitting signals between Dearborn station and the Tribune building.

An incident of the opening experiment that attracted attention was the reception of signals at the Tribune office when it was known that no electric waves were being sent out from Dearborn station. This was supposed to be due to a spark from a trolley line or an elevated motor probably starting at Van Buren station on the Union Loop. It called attention most emphatically to a defect in the system, as applied to city service. With the multiplicity of trolley and elevated lines to disturb the normal electrical conditions, it was pointed out, the Marconi system, as at present employed, would be useless. This, however, could be remedied by the use of selective apparatus, but here again objection is

a long distance under the conditions which obtained.

Further experiments in long-distance signaling were, therefore, postponed.

The sketches herewith presented were made by Tribune artists.

Marconi's Experiments with French War Vessel.

Signor Marconi, says a cable dispatch dated April 24th, has successfully communicated from South Foreland, Kent, England, to the French armed dispatch vessel Ibis, while sailing in the English Channel. In conducting the experiment he was accompanied by a French naval officer. This feat marks also his first success in concentrating messages at one point to the exclusion of all others.

Copper Trust Said to Be Formed.

[From the Chicago Tribune.]

New York, April 24.—It was reported in Wall street to-day that the huge copper trust had become an accomplished fact.

It was claimed that the Daly-Haggin interest—that is to say, the great Anaconda mine—had entered the trust and that the formation of the combination would be announced next week.

The Standard Oil company's immense wealth is behind this trust. The capitalization probably will be \$500,000,000.

The Rothschilds several years ago purchased the Hearst interest, about one-third, in the Anaconda mine, and it is understood that they have been co-operating with Standard Oil men in securing a controlling interest in this and other valuable copper properties, with the object of combining them into a vast corporation, which shall dominate the copper market of the United States.

Butte and Boston, Boston and Montana, and other mines which are expected to figure in the consolidation made substantial advances yesterday in the Boston market.

Anaconda stock has recently shown marked activity on the local Stock Exchange, and to-day made the largest net gain of all issues on the list, touching 61% and closing at 60 1/4, a net advance for the day of 6 3/4.

The men active in the negotiations for bringing together all these copper companies are unwilling at present to discuss the prospect of the formation of the rumored company, but it is everywhere believed and nowhere denied that the details of the consolidation will soon be made public.

British Transpacific Cable.

A correspondent of the Chicago Record in Montreal gives details of the construction of the proposed all-British cable across the Pacific with great confidence. He telegraphed as follows on April 21st: "The British Pacific cable to the Antipodes, which is likely to be laid soon, will run from Victoria or Vancouver, B. C., to Fanning Island, thence to the Fiji Islands, and then to Norfolk Island, where the cable will branch, one line being laid to Auckland, New Zealand, and the other to Sidney, New South Wales. The distance from Vancouver to Sidney is

MARCONI SYSTEM IN CHICAGO.—SENDING SIGNALS FROM MONADNOCK BUILDING.

alongside the dock at the life-saving station. Then the Protection started for the open water of the lake, and the experiment began of seeing just how far out the apparatus would work and the extent of the apparent effect of the electric waves.

The water in the river became rougher as the Protection approached the mouth, and the coherer jolted somewhat on the uneven deck. The telegraph relay probably was influenced by the motion of the boat more than the rest of the apparatus, as the armature jolted visibly when the tug lurched on the rough swells. But the Morse dots and dashes were received on the tug with almost mathematical regularity.

When the tug reached the mouth of the Chicago River and steamed out into the open lake the wind was blowing from the northeast at a rate of about six miles an hour, which freshened later to nearly a 10-mile rate, in the direction best to "kick up" a sea off the Chicago shore. Half a mile out in the lake the boat began to pitch and roll on the swells, and the receiving apparatus was shifted to be parallel with the direction of the boat, which stopped some of the vibration.

The Protection was sent ahead at full speed, and about 1 1/2 miles from shore the boat stopped, but there was no visible difference. When the tug reached a point which Captain Fountain of the life-saving crew declared was two miles from the station the signals suddenly stopped.

The Protection kept on a little way and the apparatus was carefully gone over. No defect could be found in the connections, and it was evident the tug had gone too far from shore for the apparatus to work. There was no way of raising the zinc sphere any higher.

When the boat returned to a point within the range of influence of the electric waves, signals were again received, and before returning to shore the word "Marconi" was spelled out in Morse. This was deemed a fitting ending of the day's experiments.

Professor Green announced that he was not entirely satisfied with the results of these tests,

MARCONI SYSTEM IN CHICAGO.—SIGNALING BETWEEN SHIP AND SHORE; TRANSMITTING APPARATUS AT LIFE-SAVING STATION, RECEIVING EQUIPMENT ON TUG.

raised to introducing more complications into an already complicated system.

The closing test of the series was conducted on Tuesday afternoon, between the Monadnock building and the Tribune office. The apparatus worked perfectly and without the slightest interruption. An earlier attempt to transmit from Dearborn station failed, and Professor Green concluded that the apparatus at his disposal was not suitable for such

6,824 miles. Fanning Island, which will be the first place at which the cable will stop, is about 3,350 miles from Vancouver. This will be the longest stretch of cable ever laid. The line in its entirety will be under British control. The cable will cost about \$7,500,000. Of this Canada will supply about \$2,000,000, the imperial government a similar amount, and the remainder will be contributed by Australian colonies and New Zealand."

Wireless Telegraphy.¹

By RANKIN KENNEDY.

I would venture to make a simple explanation of the action of this transmitting of force from one vertical wire to another at a distance, believing, as I do, that it can be easily and clearly explained on the ordinary, well-established electrical and magnetic principles so well known to most people interested in electromagnetic work.

It is not necessary to go back to the Hertz theories. These have not yet been established, nor can they be until someone proves that the Hertzian

FIG. 1. WIRELESS TELEGRAPHY—PLAN.

waves vibrate at right angles to the line of their propagation, like light waves are supposed to do. Sound waves can be reflected, refracted and detected by means analogous to those used to reflect, refract and detect light or Hertzian waves, and we know that the sound waves don't vibrate in planes at right angles to their propagation lines.

It will be time enough to drag in the Hertzian theories when ordinary accepted theories fail to account for the effects.

There are only two electrical inductive effects known to electricians—electrostatic and electromagnetic—the latter represented by lines of force forming closed circuits. Both of them can act through air, non-conductors and conductors, hence it requires no wire to connect two places, from one of which we desire to act inductively on the other.

Theoretically, we should be able to induce an electric current in an instrument in New York by manipulating another primary current in London or Hongkong, without any wire connection or cable. Practically, there are some slight difficulties, such as the curvature of the earth and the length of the vertical wires requisite, and if we were telegraphing secret messages, they could be read by anyone with a vertical wire and an electric-bell outfit.

Attempts were made first to induce currents at a distance by what may be called the coil or loop method, and this is still under investigation by a very eminent professor, but it is a method doomed to failure at comparatively short distances for two simple reasons.

The science of vertical-wire telegraphy is the same as that of the common transformer or induction coil, and so is the science of the loop or coil telegraphy. In the latter case we set up a primary coil at A, and at B a secondary coil, where we wish to receive messages from A; the space between is the magnetic circuit, a bit longer than usual in transformers and a good deal larger in cross-sectional area than in iron-core transformers; a circuit about as long as Liverpool and as great in area has been used.

The simplest coil is a single turn or loop \mathcal{N} ; if we set up two coils $\mathcal{O}\mathcal{O}$ and generate alternating currents in one, an alternating current will be set up in the other, and if the magnetic circuit is of low resistance and the one loop equal to the

FIG. 2. WIRELESS TELEGRAPHY—ELEVATION.

other, the induced electromotive forces will be equal to the inducing electromotive force in the primary loop, always provided the whole of the induced magnetic flux passes through both loops.

Now the electromotive force generated in a coil of wire through which the induction varies is equal to the product of the number of turns multiplied by the rate of change of magnetic flux density. Expressed by Mr. Weeks as

$$E = 4.45 F r n 10^{-8}$$

F is the total flux, r the number of turns in the coil.

n the frequency of alternations, 10^{-8} to reduce to volts.

Now in a transformer with the primary a few miles from the secondary loop, the amount of the magnetic flux which reaches the secondary cannot be much more than a very small fraction of the whole, and the fraction which does reach it is not all effective, for it cuts both sides of the coil in the same direction, partially neutralizing each other.

4.45 is constant in value, F is naturally exceedingly small, r, for reason to be seen presently, cannot be more than one turn, or, better still, as Marconi has it, should be half a turn; the only factor left us to increase, to keep up the induction at a great distance, is n, the frequency. The higher the frequency, the greater the distance we can operate.

Now high frequency cannot be worked through loops and coils, for at quite limited frequency a loop or coil opposes enormous resistances against high frequency electromotive force, and the current passing is reduced to almost zero. And as F depends on current value, we soon reach a frequency at which any further increase is counteracted by the decrease in current, even in a single loop, vide Tesla's results.

For these reasons the loop or coil method is limited to low frequency, and consequently short distances.

Naturally one at once says: "But we must have a loop to procure a current; it must go in one end and out the other;" that is so, for continuous currents these must have an outgoing and return a complete circuit.

But alternating currents can be sent up and down a single wire with no metallic return. All we require is a capacity at the top of a vertical wire, and an alternating charging + and -, or + and 0 zero at the lower end; every charge at the lower end rushes up the wire as an electric current and charges the ball, or capacity at the top; when the charge at the lower end is discharged or reversed, a current rushes down from the capacity ball at the top. Here we have an alternating current produced in a single wire, and it is this current which induces, F, magnetic-force waves to act on the distant wire.

The reason why the wire must be long is that length takes the place of r in the formula; that is, instead of terms we would take d, the length in centimeters or feet.

Both electrostatic and electromagnetic induction takes place in setting up currents in a single wire. Fig. 1 is a plan of two wires vertical; Fig. 2 is an elevation of the same.

In Fig. 2 the electrostatic lines are curves proceeding from the capacity, C, to earth; hence the earth connection of the one pole of generator; the electromagnetic force travels in horizontal circles and cuts the distant conductor. In Fig. 1 the electrostatic lines are radial; they don't act inductively on the distant wire, but only act in producing the primary alternating current, a local effect concerned only in the alternating-current production in a single wire.

With high frequency the inductive effects near a single wire are startling and interesting.

The spark discharge has been looked upon as an essential in single vertical-wire telegraphy, but it is not so; it is used simply because it is at present the simplest and most effective method of producing very high-frequency charges and discharges; the induction magnetic flux from the spark itself is in the form of a thin disk, the axis of which is the spark; the spark acts for the instant of its duration as a current.

Other methods of producing high-frequency currents in a single wire will occur to many electricians. The sending and receiving wires are simply the primary and secondary of a transformer. The currents produced in the secondary are too minute and of too high a frequency to be received in any magnetic or electric instruments; but, luckily for vertical-wire telegraphy, Branly invented his coherer. This simple apparatus makes an excellent relay, and has been adopted in all the long-distance work—an impossibility without it.

There is no mystery about the long wire vertical; the mystery is, Why should anyone use a loop and low frequency?

The new Wehnelt interrupter and improved spark-producing apparatus may make great advances in the near future.

It seems to the writer very strange that nothing better than the rude, inefficient induction coil of 50 years ago should be the thing used for the high-frequency, current-generating apparatus.

They may be very simple, but they are costly and not durable machines in every-day, constant use.

If the wire is horizontal, there is little or no effect, probably because of the inductive effects of the earth, through which one-half of the magnetic flux would pass, the electrostatic induction would also be disturbed by the proximity of the earth to a horizontal wire.

The question is, What is the limit to be placed on the frequency of the current in the vertical wire, and what is its impedance to high frequencies?

No part of a single wire can be cut by its own magnetic flux. With a loop the flux from one side cuts across the wire on the other side, causing much impedance with high frequency.

F. McCormack will construct the electric-light plant at Pine City, Minn., as early as possible.

Operation of Electric Pumps.

A contributor sends to the Western Electrician some mechanical hints for the effective operation and quick repair, when necessary, of electric pumps and machinery of like character. He notes that, as in all other machines, the only way to get effective work from electrically driven pumps and other electrically driven apparatus is to properly connect the motors and to properly maintain the machines in working order. In one place where a slow-speed multipolar motor was directly connected to a pump plunger shaft, very poor work resulted as a result of defective adjustments. An examination showed that the brush-holder was broken at A (Fig. 1), due to the use of a set-screw of too large diameter. The tension on the brushes could not be adjusted correctly. The workmen condemned the whole outfit. But the cracked piece was finally repaired by cutting out two thin pieces like that in Fig. 2, and riveting them on each side. Thus supported, the tension could be properly controlled, and the pump was driven satisfactorily thereafter.

The direct-acting pump is of simple design, and for that reason is widely used for ordinary lifting or moving of liquids. Simple as its construction is, the writer has known of many cases in which the pumps have been rendered unserviceable through defective packing. Frequently the defect is attributed to the driving power of the pump. An electric motor or belt power from other sources cannot drive

OPERATION OF ELECTRIC PUMPS.

a pump when the flange D (Fig. 3) is forced so tight on the packing that the packing is caused to bind on the piston C. Yet men have been seen trying to overcome a leak at this point by screwing up the bolts to a snapping point. Worn-out piston rings, leaky valves, defective stuffing boxes, gummed parts, dry bearings, pump out of line and other defects should be looked for when a pump simply churns water, instead of blaming the electric motor or other source of power.

Usually the motor is geared to the plunger shaft of the pump, but in one case the machinist made the connection by means of a crank, as in Fig. 4, and this crank was held to the shaft by the set-screw F. This screw soon had a groove cut around the diameter of the shaft, and the lack of firmness of this weak connection caused the pump to lose power. Of course the fault was thought to be with the motor, until someone suggested that the crank be keyed to the shaft, as represented at G, showing a round key sunk into shaft and shoulder, resulting in a secure connection, after which that pump and its motor worked to full satisfaction.

In connecting a motor to a pump it is essential that the parts be very firmly secured, so that vibration may be avoided. Instances in which the set-screws for forming the connection are too long are not infrequent. Fig. 5 gives an example. The mechanic puts the set-screw into its place, but the tip engages with the seat of the hole at H before the shoulder of the head of the screw presses on the

1. From the London Electrical Review.

part it is intended to hold. This is a simple imperfection, and may be avoided by sinking the hole a little deeper, or by using shorter screws; yet this type of defective work is frequently found to exist in machines which are claimed to rattle and otherwise exhibit signs of looseness at some point.

Fig. 6 is a design for the end of the shaft bearing of a motor which is patterned to be attached to the framework of any apparatus for supporting the shaft. It is made from wrought-iron and provided with holes in the flat ends to receive the one or more set-screws for attaching the piece to the frame.

Storage Battery Regulation.

Many unusual conditions in modern practice have been satisfactorily overcome by the use of the storage battery. An example of this kind is furnished by the experience of the New York, New Haven and Hartford Railroad company in lighting the Hartford station. It will be remembered that the company operates a large section of its suburban service electrically, employing a third-rail system at 500 volts, subject to all the fluctuations of voltage incident to such a system on account of the current required for starting and accelerating the trains.

The fluctuations in the voltage on the railroad circuit are extremely violent at the Hartford station, which is located at the end of the third-rail system, there being no feeders and the current being supplied from the third rail only. Lamps could not be operated from an ordinary motor-driven generator, and a combination of the motor-driven generator and regulating battery was finally decided upon.

The generating unit consists of a 45-kilowatt shunt-wound generator direct-connected on a common bed-plate to a specially compound-wound 500-volt motor, the compounding being so designed as

Opportunities for the Establishment of Electrical Supply Houses in North Brazil.

By C. PAULO REI.

The valley of the Amazon, that vast region bordering the 4,400-mile course of the Amazon River and comprising the larger portion of the states of Para and Amazonas, may truthfully be said to possess a charm for the engineering world, containing, as it does, so many almost insurmountable difficulties in preparing it for the abode of man.

The development of the greater portion of this region will constitute a problem for future generations, and for the present the cities of Para and Manaus and the small towns on the Amazon between them will demand chief attention.

The city of Para (official name Belem), situated only about 100 miles from the mouth of the Amazon River, is in reality on the east bank of the river Para, which forms one of the many channels by which the waters of the Amazon and of the Tocantins find their way into the ocean. It is the key to an enormous stretch of wealthy country, and indications are that it will become the Chicago of South America. The river is 20 miles wide opposite Para and 40 miles wide at its mouth, and although the internal communication afforded by the Amazon and its branches is extensive (no less than 150 steamers being employed), railroads and other means of transportation on land will soon be needed in order to assist in handling the ever-increasing commerce of Para and Manaus.

Although situated only about one degree south of the equator, the climate of Para is by no means so hot nor so unhealthy as might be supposed. But the air is exceedingly moist. The rainy season extends over two-thirds of the year. Generally the

daily newspapers, eight banks and a fine library and museum.

The principal electric-lighting company is the Companhia Luz Electrica Urbana, of which Signor Lucio Freitas do Amaral is the general manager. Three triple-expansion engines of 400 horse power each and one vertical compound condensing engine of 600 horse power are used. The electrical machinery was purchased in Germany, and is operated by Brazilian and Portuguese workmen. Although the company seems to favor Germany in purchasing supplies, it might be well for American manufacturers to correspond with the general manager, either in French or Portuguese.

Another prominent lighting company is the Companhia Luz Electrica Paraense, of which Signor Joao Alves de Freitas is the proprietor and manager. One 400 horse power engine and one of 200 horse power, both compound condensing, and of American manufacture, are used and are giving satisfaction. In fact, this is essentially an American plant, although some few purchases are made in Europe. Most of the plant was purchased from the Western Electric company of Chicago, and orders for supplies are sent direct by Signor Freitas, who is both prosperous and reliable. A really good opportunity now exists for the establishment of a large supply store for the sale of electrical machinery and apparatus, and were this establishment placed in the hands of competent electrical experts success would be doubly assured.

It is well known that the municipality is anxious to sell the waterworks of the city, with a view to its being taken up by a company and considerably extended. It is also known that the authorities are desirous of having a complete system of drainage for flood water and sewerage. This should be a good opportunity for a contractor, and it is clear that there would soon be a large demand for sanitary appliances. There are other opportunities offered live young Americans with a small amount of capital, such as the establishment of cold-storage and ice plants. At present beef must be eaten immediately after killing, as no such plants exist. For steam laundries and brick plants, equipped with up-to-date machinery and managed by persevering and active Americans, there are also good openings. Owing to the fact that money appears to be made so much easier in rubber, it is difficult to induce the Brazilians to enter any other business, and for this reason mainly so many opportunities exist in a city of over 100,000 population.

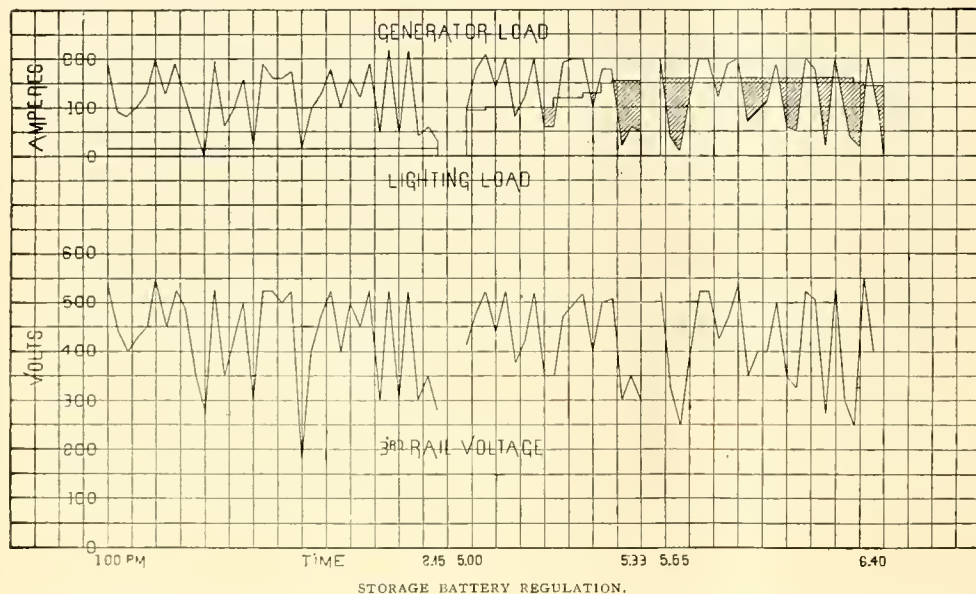

From Para runs the only railway yet constructed in this part of Brazil, known as the Braganca railway, the concession for which was granted in 1879. It is a single line of one meter gauge, with American rolling stock, and was intended to reach Braganca, a distance of 209 kilometers, but only about 60 kilometers has been constructed and opened for traffic. It is the property of the government, and, as usual with government lines in Brazil, the traffic does not pay working expenses. The freight consists mainly of building stone, sand, lumber and firewood. Braganca is east of Para, on the seacoast, but has no harbor. The district abounds in agricultural products, and the line may be made to pay when it is completed. It is also intended to prolong the line to Maranhao, so as to form part of a continuous line along the seacoast to Rio de Janeiro.

At Manaus there are similar opportunities for energetic and brainy young Americans as at Para, although, as the population is considerably smaller (the city now containing about 25,000), the demands are more limited. For an electrical supply house the prospects are nearly as good here as at Para, as the city has electric light and a system of electric tramways. It has fine public and private buildings, and the same spirit of development and enterprise is to be met with here as in Para. The population is rapidly growing and is becoming quite cosmopolitan, and even now quite a number of Americans (a large number of whom are dentists and clerks in rubber houses) are to be met with in the streets daily.

Municipal Street Railways.

[Special correspondence of the Western Electrician.]

Detroit, April 24.—Prof. E. W. Bemis of the College of Agriculture, Kansas, arrived at Detroit last Saturday, to begin the work of computing the value of the Detroit Street Railway company's 179 miles of electric-road franchises. The professor declares that he can make the estimate in about five days, working day and night. Concerning the general question of the municipal ownership of electric railways, now agitated in Detroit, Mr. Bemis expressed himself as follows: "There are but two views," he said. "I refer to the ownership of street railways, gas plants, telephone systems and water works. One is the private ownership and operation, the other public ownership and regulation. While the latter is better than nothing, it has proven in the past little better than a failure. In the majority of cases the municipal commissioners, receiving comparatively small salaries, soon find the millionaire corporation liberal, and the regulator becomes the regulated. The Interstate Commerce Commission is a fair sample of this sort of failure. The aggregate influence of the tremendous monopolies has governed many a commission, and the regulation by the public has therefore become of little use."

to run the motor as nearly as possible at a constant speed through large variations of voltage in the motor circuit, which is derived from the third-rail system of the railroad.

The plan of operation and the results obtained are well exemplified in the curves shown in the accompanying illustration. The lower curve gives an excellent idea of the extreme variations in the motor circuit. It will be noticed that this covers a range of 375 volts, or from a minimum of 175 volts to a maximum of 550 volts. The battery is directly across the system as a regulator, receiving its charge through the hours of light load, as will be seen by reference to the left-hand set of curves, and is required to furnish a small amount of current only when the generator current drops off, due to fall in the voltage on the motor, to a point below the lighting load shown by the straight line across the curve. As the lighting load increases, it will be noticed from the right-hand set of curves, there is a large portion of the time when the generator is unable to furnish the current required for the lighting load, which is in turn supplied by the battery, which thus keeps a practically constant pressure on the lamp circuits, discharging whenever the generator current falls below the load and charging when the reverse occurs. In addition to this service, when the lighting load falls off to a minimum the generator is shut down and the battery furnishes all the current required, constant potential being maintained by the ordinary method of cutting in reserve cells.

The installation was supplied by the Electric Storage Battery company of Philadelphia.

In the reports of the recent tests of the Austrian War Office in the use of liquid air as an explosive, it is stated that the experiments foreshadow a complete revolution in the application of explosives. The experiments made in Austria were conducted in a quarry by a technical committee from the War Office, and the results were said to be remarkable.

temperature is delightful in the early morning, and about midday thunderstorms occur, which flood the streets and cool the atmosphere. In the evenings heavy dews fall.

As Para has for many years been the principal emporium for the Amazon trade, both for the exports of produce and for the supply of the interior towns and cities with foreign goods, it has naturally had an extensive commerce. Of late years this commerce has been greatly increased, owing to the increased trade in rubber, and as a result the city has flourished exceedingly. No other city in South America, with the exception of Buenos Ayres, has made such rapid progress. In 1872 the population of the city was about 35,000; in 1888 it was 60,000, and at present it is over 100,000. Few people have any idea of the wealth, advancement, luxury and activity which are to be seen in this remote equatorial city. Both lines of steamships running between Para and New York are increasing the number of their ships, as they are entirely unable to carry the heavy freight billed to and from Para. In August, 1898, the two lines made one trip each a month, which they later increased to two, then three, and now weekly trips are being made. No better evidence could be brought to show the greatly increased commerce, as the ships are not only heavily loaded with rubber, etc., from Para, but they also bring return cargoes of all kinds of American manufactured goods from New York. As the freight rates from New York are much cheaper than from Europe, this demand for American goods is likely to grow to large proportions, as both the mercantile community and the government are rich and daily growing richer. Money has in reality literally poured into the place, and both public and private funds are being lavishly spent upon works for improving and beautifying the city. It has now magnificent public buildings; the theater is said to be the finest in South America, and the Bourse is also a splendid edifice. Street-railway lines run in all directions, and the telephone and electric lights are everywhere used. Para has five

A Great Carbide Factory.

By ORRIN E. DUNLAP.

The new plant which the Union Carbide company is building on the property of the Niagara Falls Power company is rapidly assuming its proportions, and already it is seen that it will be one of the largest manufacturing plants at Niagara Falls. The site selected for the works covers several acres west of the Niagara Junction railway and north of the tracks of both the New York Central and Erie railroads, but the terminal facilities will be furnished by the Niagara Junction railway. In all three buildings will be erected, two for factory purposes and one to be used as an office. The factory buildings are very large and extend back 864 feet. They stand about 80 feet apart and are principally of iron and brick. The roof is now being put on the first building, while the second building is rapidly assuming size.

The front section of the first building is three stories high, or 53 feet to the eaves. Here will be located the pulverizing department, the dimensions being 132 by 75 feet. Next will come a two-story section, 30 feet to the eaves, in which there will be one large room 30 by 75 feet, and this probably will be used as a dust-collecting department. Next to this, in the rear, will be the furnace room, which will be 395 feet long and 75 feet wide. In the rear of this still will be the packing and shipping department, 300 feet long by 75 feet wide. Up through the center of this room railroad tracks will be run alongside of platforms to facilitate shipment of the

current for the Carbide company's use. These transformers will be similar in pattern to those installed by the Westinghouse company for the Cataract Power and Conduit company in the Ohio street station in Buffalo.

The contracts call for the operation of the plant by July 1st. The Niagara Falls Power company is now building a cable conduit from the power house to the carbide works. This conduit will consist of 36 vitrified-tile ducts, each 3 1/4 inches interior diameter, laid in a nest and sheeted with cement. The total length of conduit will be 12,000 feet. Thomas Dark & Son of Buffalo are doing the work. Beneath the cable tile in the trench a sewer pipe is laid, in order to afford good drainage. The structural iron for the factory buildings is furnished by the Berlin Iron Bridge company, and the Penn Bridge company will furnish the storage bins. The elevator and conveying apparatus will be supplied by the Jeffrey Manufacturing company. The contractors on the building are Wentworth & Taylor, who have had many important contracts in factory construction at Niagara Falls. They have a very large force of men at work, and rapid progress is being made in the erection of the buildings.

The superintendent of the Union Carbide company at Niagara Falls is Mr. E. F. Price. He has been connected with the industry ever since its beginning, and thus he has had great experience in the manufacture of carbide. It is under his careful supervision and that of Mr. I. R. Edmonds, the company's electrician, that the new plant is being built. The general manager of the Union Carbide com-

West Australia's Electrical Activity.

[Prepared for the Western Electrician by the Philadelphia Commercial Museum.]

Perth, the capital of West Australia, and Fremantle, the chief port of the colony, have recently adopted electricity; the former for lighting and as the motive power for its newly introduced system of surface cars and the latter for public lighting. Construction of the Perth electric-railway system was begun in February, but the introduction of the electric light at Fremantle has only just been agreed to by the Municipal Council and bids for the installation called for.

By direction of the Fremantle Council the "plans and any other available information have been ordered to be forwarded to the leading manufacturing firms in England, with a view to obtaining estimates of the cost of the plant installed." This action was taken in the middle of January, and, presumably, the English manufacturers are by this time sending in their bids. American manufacturers were not barred from making bids, but it is only natural that an English colony should draw its supplies from the mother country. At the same time, it may not be too late for Americans to interest themselves in the matter, either directly or through their English or colonial representatives.

The scheme for lighting adopted by the Fremantle Municipal Council is the continuous-current system, with a potential of 400 volts, on the three-wire system. The wires are to be carried on poles. G. A. Wright, the engineer who prepared the report on which the council acted, says: "There is at the present time a great demand for electric light in the town, and I am certain that the committee can look for a large private consumption of current from the start." He estimates the cost of installation as follows: Power station, buildings, foundations for plant, chimney, etc., \$10,000; boilers, condensers, engines and dynamos, \$35,000; storage batteries, \$7,500; switchboard, \$2,500; cables, wires, arc and incandescent lamps, poles for street lighting (erected), \$30,000; total, \$85,000. It will be interesting to add his estimate of the cost of operating the plant for a year, which is: Coal, \$7,000; oil, waste and engine-room stores, \$750; repairs and maintenance of plant, \$1,000; salaries, \$7,550; allowance for depreciation for first year, at 2 1/2 per cent., \$2,125, making a total of \$18,425.

The Municipal Council discussed a combined scheme of electric lighting and street cars, which was not adopted. The railway scheme will undoubtedly be taken up later. Fremantle is a growing city and has boomed since 1897. At the end of 1898 there were, approximately, 2,120 permanent buildings in the municipality of Fremantle, 520 in East Fremantle and 473 in North Fremantle, a total for Fremantle and its suburbs of 3,113. The buildings are of a permanent character, and two-thirds of them are constructed of brick or stone.

The Perth City Council has called for bids on or before May 1st for lighting the streets and municipal buildings with electricity. Bidders must quote, first, a lump sum per annum to be paid by the council for lighting streets and municipal buildings during the first five years, and lump sums for the same service during three following periods of five years each. At the completion of the 20 years the concessionaire must be prepared to hand over to the council, free of all cost and in good working order, the whole of the plant, conduits, cables, etc., used for streets and municipal-buildings lighting, to be entirely separate from the commercial lighting which may be carried on. The successful bidder will be granted a concession to supply commercial electric lighting within the city, the concession to last for 20 years, after which he must hand over to the council, free of cost and in good working order, the whole of the plant, conduits, cables, etc., used for the commercial lighting, the plant to be entirely separate from the other. The street and municipal-buildings lighting system must provide for the lighting of all streets, lanes, parks and municipal buildings within the city boundaries, and the plant must include 250 arc lamps, each of not less than 1,200 candle power, 200 incandescent lamps, each of 50 candle power, 150 of 32 candle power and 250 of 16 candle power. All cables are to be placed underground, and must be conveyed through the streets in jarrah troughs or boxes or other suitable form of conduits, to be approved by the city engineer.

The Perth street-railroad scheme calls for the construction of 13 1/4 miles of line within two years, and the total length of 17 miles within five years. The initial work of construction was begun on the first of February. It is worthy of note that the Railway Department of the colony refused to allow any of the lines to cross the railroad system at grade.

Havana Street Railway.

According to a dispatch from Havana, a court in that city has just rejected an appeal from the decision of a lower tribunal that the sale of the Ferro-carriil Urbano (City Railway) by a minority of its stockholders to the syndicate headed by Colonel George B. M. Harvey of New York was null and void, having been fraudulently obtained. The sale was effected on December 27th, the value of the stock being placed at 92, and the total sum paid being \$1,472,000. It was declared at the time by members of a competing syndicate, made up of Canadian capitalists, that they would have paid 125 for the stock, and they will probably bid for the property if the recent sale shall be annulled.

A GREAT CARBIDE FACTORY.—VIEW OF THE NEW PLANT OF THE UNION CARBIDE COMPANY AT NIAGARA FALLS.

product, while an upper floor will be used for storage purposes. It is not the thought of the company, however, that much storage room will be needed, considering the great and growing demand there is for carbide. In and about the plant there will be about 3 1/2 miles of railroad track, and the company will have a locomotive of its own to do its switching, so that there will be no delay in handling cars. When in full operation the output capacity of the plant will be over 100 tons of carbide a day, and it is the company's expectation that in raw material and product it will handle from 30 to 40 cars every day.

The second building, with the exception of the three-story front section, will be a duplicate of the first, and the two buildings will have over 100 furnaces, which are now being made by the Dobbie Foundry and Machine company of Niagara Falls. In the course of time it is expected that the company will use 25,000 electrical horse power in these two buildings. The furnace rooms in each building have six distributing points for current, three on each side.

Mention has been made in the Western Electrician of a portion of the transformer equipment to be installed in this plant. The Wagner Electric Manufacturing company of St. Louis will furnish seven static transformers of 2,000 horse power capacity each and two static transformers of 500 horse power capacity each, all complete with switchboards for operating them. These transformers will be of the oil-insulated type, with water coils for lowering the temperature of the oil. The Westinghouse Electric and Manufacturing company of Pittsburg will furnish nearly 10,000 horse power output capacity in transformers to the Union Carbide company, while it will also supply the Niagara Falls Power company seven 2,500 horse power transformers, to be used in stepping-up the two-phase, 2,200-volt current from the generator to three-phase, 4,400-volt

product is Mr. W. P. Martin, at the main office in Chicago.

Street-railway Ownership in Detroit.

A committee of 62 citizens of Detroit has filed a bill of complaint in the Circuit Court asking that Governor Pingree and the other members of the Detroit Street Railway Commission, and the city of Detroit, be temporarily and perpetually enjoined from taking any further steps toward purchase and operation of Detroit's street railways under the McLeod act, authorizing the same, and asking that the McLeod act and all proceedings thereunder be decreed to be void.

The discovery of an alleged flaw in the McLeod act authorizing acquisition by the city of Detroit of the street railways has raised another point against the project. The engrossed bill does not contain a clause which was in the original, providing that nothing in the act shall affect the granting of franchises by the City Council. Governor Pingree says the omission of the clause is of no consequence, but the attorneys of the Citizens' company assert that the alleged discrepancy is a strong point in the proceedings they are about to bring to test the act.

Paris Exposition.

The United States Commission to the Paris Exposition of 1900 states that all who desire to exhibit in the exposition are requested to immediately notify the commissioners, if they have not already done so, in order that they may be considered in the allotment of space which will soon be made. While there are many applications on file in every line of industry, it is desirable that the American sections be not only representative of this country, but also represent the largest possible number of producers. The Chicago office is in the Auditorium; the New York office is in the Equitable building.

EVERY SATURDAY.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the entire contents of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, \$3.00 for a full year of 52 numbers; in clubs of four or more, \$2.50, with free extra copy for eight subscriptions; foreign countries, \$5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—the only general electrical paper published in the West—thoroughly covers a territory exclusively its own. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers desiring to reach the trade will appreciate the UNEQUALLED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

HIGH WATER MARK CIRCULATION, 20,000.

CONTENTS OF THIS NUMBER.

Table listing contents of the issue with page numbers. Includes: Marconi System in Chicago, Professor Jerome J. Green, Marconi Experiments with French War Vessels, Copper Trust Said to be Formed, British Trans-Pacific Cable, Wireless Telegraphy, Operation of Electric Pumps, Storage Battery Regulation, Opportunities for the Establishment of Electrical Supply Houses in North Brazil, Municipal Street Railways, A Great Carbide Factory, Street-railway Ownership in Detroit, Paris Exposition, West Australia's Electrical Activity, Havana Street Railway, Editorial, Relative Dynamo and Motor Capacities, Electric Street-lighting Extensions in Chicago, Stealing Electricity, Development of the Telephone Field, History of the Telephone in Canada, New England Telephone News, Michigan Lines, Mendacity of Bell Management, Telephone Line an Additional Burden, Telephone Apparatus, Telephone News from the Northwest, Telephone in Mississippi, Telephone Beats Telegraph, New York Telephone Rates, No Consolidation of Independent Companies, Manufacturers and Dealers, Knottson Gravity Clutch for Arc Lamps, Relay Circuit-breaker, Westinghouse Company to Make Corliss Engines, Electrical Equipment for Street Railways in Mexico, Fort Wayne Electric Manufacturing Company.

DEPARTMENTS.

Table listing departmental contents with page numbers. Includes: Correspondence, Electric Lighting, Electric Railways, Electric Vehicles, Publications, Power Transmission, Technical Schools, Electrical Securities, Foreign Electrical Notes, Industrial Combinations, Miscellaneous, Trade News, Business, Illustrated Electrical Patent Record.

Frequently of late attention has been called to the fact that many English municipalities are engaged in the work of transforming their old horse-car systems into modern electric systems. As a natural consequence there has arisen a great demand for "trolley poles," the iron posts to which are attached the overhead wires. This demand has increased the activity among transportation lines, and freight steamers arriving at Liverpool from the ports of New York and Boston have been carrying large consignments of these poles. It is a noteworthy fact that one such shipment was consigned to Birmingham, the seat of England's iron industry.

An obstacle in the way of American inventors and manufacturers, who desired to introduce their products of the newly acquired possessions of the

United States was found in the statement that the patent regulations did not apply to these islands. To eliminate these difficulties the War Department, acting upon suggestions made by the secretary of the interior and the commissioner of patents, has determined to extend the patent laws of the United States, so far as they relate to the protection accorded owners of patents, etc., to all the islands which are now under military government by the United States. This action is tentative, and is regarded as a measure of martial law that will be superseded by provisions of a more comprehensive scope when the Patent Commission, now engaged in an examination of the United States patent laws with a view to their amendment and codification, makes its final report.

An interesting process is presented in the modifications recently introduced in the electrolytic manufacture of permanganate. The original cells required frequent recharging; they did not lend themselves to a continuous process and did not directly yield solid salt. The cells now used form troughs with funnel-shaped bottoms. In these the trough serves as an anode, while the cathode cells, which are suspended in the upper part of the trough, are narrow boxes with porous walls acting as diaphragms. The additional anode plates are near the porous walls, but are themselves separated from one another by boxes with perforated bottoms. The anode trough is charged with the mother liquor of the last permanganate crystals; the cathode cells are filled with water and the intermediate boxes are charged with crystals of manganate of potassium. This salt passes into solution, as its solution is converted into permanganate. It has been observed that the caustic-potash solution which collects in the cathode cells may also be left in the anode compartment to a strength of 40 per cent., without disturbing the reaction, and, in fact, with a beneficial effect, as it hastens the crystallization of the permanganate. Thus, the electrolysis proceeds until the funnel is full of permanganate crystals, or until the caustic becomes too concentrated. Crystals and liquor may continuously be withdrawn, and fresh mother liquor used for refilling, if preferred, however.

Chicago has had an opportunity to witness a practical test of the Marconi system of signaling through space without connecting wires between stations, both "on land and at sea," and the results were highly satisfactory and successful. The test made in this city on Saturday was one of the most difficult that could have been devised, not only on account of the disturbing elements of a large city, but also because the apparatus employed was crude and the experimenter was hardly familiar with it; moreover, the time allowed for making the preparations for the test was exceedingly limited. Under the circumstances, absolute failure would not have been surprising and partial success would have been gratifying, but no one anticipated that the initial exhibition would prove as satisfactory as it really did.

Professor Green certainly achieved notable distinction in securing such results in the face of adverse conditions. He succeeded in sending signals 650 feet between the Tribune office and the Marquette building, which is regarded as conclusive evidence that steel structures and electrical conductors do not interfere with transmission by electric waves. On Sunday even better results were obtained between the life-saving station at the mouth of the Chicago River and a tug-boat sent out on the lake for the purpose of determining the range of influence of the electric waves. It was claimed that signals were received at a distance of two miles from shore, and within that limit no trouble was experienced in communicating by this method, although the lake was rough and a high wind was blowing. This would seem to support Marconi's belief that the maximum results will be obtained over water.

With improved apparatus and experience in operation better results will doubtless be secured. The instruments used in the Chicago experiments were hastily constructed in a college laboratory, and were not intended for such service as that to which they were applied. In view of these facts and other adverse conditions, it is surprising that such

an excellent record was made. Lieutenant Della Riccia, in Brussels, after much experimenting and with improved instruments, succeeded "in one case," to which Marconi makes special reference, in sending signals "400 yards through nine houses and a hotel constructed largely of iron." This was considered a noteworthy achievement, and was cited by Marconi as a remarkable performance in the discussion before the Institution of Electrical Engineers in London last month. In view of these facts Professor Green should feel encouraged by the success he has attained, and American experimenters should attack the problem in their usual energetic manner. The tests in this city have doubtless started a series of systematic experiments by American investigators, and these examinations and studies should be fruitful of results.

The depression noticed in the stocks of the Eastern Telegraph syndicate has given rise to much speculation, and one of the causes to which this decline in values has been attributed is the successful experiments and remarkable advancement that have been made in developing the Marconi system of telegraphing without connecting wires. A much more reasonable explanation would be the fact that the monopoly now enjoyed by the English capitalists would eventually be ended by the building of the Pacific cable. But this should not influence these securities at this time; on the contrary, the failure of Congress to enact legislation looking toward the establishment of telegraphic communication across the Pacific might reasonably be expected to exert a beneficial influence upon the market.

It is probable, however, that in spite of this failure of Congress to act, investors in this class of securities realize that the time is near at hand when this work will be undertaken. The attitude of the present administration is significant. Preparations have been made for completing the survey of the Pacific in anticipation of the action of Congress next winter. The researches of the Thetis and Albatross several years ago, supplementing those of the Tuscarora made long before, assured the practicability of the route from Monterey or Point Conception, south of San Francisco, to Honolulu or Hilo Bay, and the present expedition is intended to examine the route between Hawaii and the Philippines.

The government has selected for this work the Nero, a steel vessel built a few years ago at Sunderland and bought for the auxiliary navy. She has been overhauled at Mare Island lately and refitted for survey work. The stretch between Hawaii and the Philippines is not only far longer than that between California and Hawaii, but has been less studied, while such soundings as have been taken in it indicate some very deep places. This is especially true along the eastern shores of Japan, from the Kurile Islands southward, where a trough has hitherto defied soundings. Admiral Belknap's survey reported that it exceeded five miles and a quarter in depth. It lies under the Kuro Siwo or Black Stream. In other parts of the Pacific, too, sharp changes of level are found, in striking contrast to the bed of the Atlantic. The Japanese current, however, is the chief obstacle, and it may increase by its force the difficulty in laying a cable successfully, apart from the depth of the Kuro Siwo channel under it.

Some difficulty, it is anticipated, will be experienced in securing suitable intermediate stations. Necker Island may be the first stopping point, but Midway Island, which was once favorably considered, is not now looked upon as particularly desirable. The Marshall group is favored, but it belongs to Germany, and it is asserted that the same power is to acquire from Spain the island variously known as Strong's, Kusaie and Ualan, in the Carolines, which has long been looked upon as an ideal landing-place for a cable. Johnston Island looks practicable, but it is a British possession. Marcus Island has been well spoken of, and Guam is to be on the line, but the long stretch between Honolulu and Guam makes it desirable to break up the distance. It will be seen that there are still many problems to be solved before the Pacific cable project is assured, and the government is acting wisely in taking up the subject thus early.

Relative Dynamo and Motor Capacities.

By ALTON D. ADAMS.

It is sometimes of practical importance to determine the capacity of a given dynamo, when used as a motor or vice versa, and it is of general interest to understand the relation which should hold between the dynamo and motor capacities of the same frames. At first glance this problem may seem too simple to be worth solving, but a little consideration will show it worthy of careful analysis, and an examination of manufacturers' catalogues will probably deepen the impression.

A common presumption is that the manufacturer of an electric machine is better able than anyone else to state its capacity for any service, but when each of the catalogues of several manufacturers gives a dynamo of a certain kilowatt capacity a different rating as a motor, it is fair to conclude either that no definite relation exists between dynamo and motor capacity or that the relation between these capacities is not always given the consideration it merits. To illustrate the variation in the relation of dynamo and motor ratings, the kilowatt capacities of generators, each rated at 10 horse power as motors, have been selected from the catalogues of three prominent manufacturers, as follows:

Type A—Motor rating, 10 horse power; dynamo rating, $7\frac{1}{2}$ kilowatts.

Type B—Motor rating, 10 horse power; dynamo rating, eight kilowatts.

Type C—Motor rating, 10 horse power; dynamo rating, 10 kilowatts.

Each of the foregoing machines is rated at from five per cent. to 10 per cent. higher speed as a dynamo than as a motor, but as this speed variation is common to all three machines, it cannot be said to account for the variation of 33 per cent. in their stated kilowatt capacities. If there be any necessary and general relation between dynamo and motor capacities, it is obvious that all of the ratings cannot be correct, and the object here will be to point out, if possible, such a relation. To correctly consider this matter it should be held in mind that the kilowatt capacity of a generator is measured in electric energy delivered to the line, while the horse power of a motor is determined by a brake at the pulley. The kilowatts of a dynamo are the mechanical power spent in driving it minus the internal losses, and the horse power of a motor is the electric energy delivered to it minus the internal losses. The losses in both dynamos and motors are divided into two classes—winding losses, which occur in the armature and magnet coils, and frame losses, which comprise friction, hysteresis and local currents in the iron.

The total frame losses are nearly the same in a motor and dynamo, when each operates at the same speed and with the same amperes in their windings; the heating tendency is therefore the same in each machine, also the sparking. As the rise in temperature and the sparking tendency are the real load limits in both dynamos and motors, it seems reasonable that the rating of a given electric machine, whether as dynamo or motor, should be based on the same armature current and the same or nearly the same magnet-winding current. A little more energy may be allowed for the magnet winding of a dynamo than a motor on the same frame, in some cases, because of the series winding or additional shunt needed by the dynamo. If the winding losses and temperature rise in a given frame are the same whether it is used as a dynamo or a motor, the electrical horse-power output of the dynamo will be greater than the mechanical horse-power output of the motor, because while the frame losses of the dynamo are supplied by the driving power in addition to the electrical output, these same frame losses must be deducted from the electric power supplied to the motor, as must also the winding losses, to find the capacity of the motor for mechanical work.

Another cause which slightly reduces the output of a given frame as a motor below what it would have as a dynamo is found in the fact that, while motors usually have exactly the same armature winding as dynamos of corresponding capacity, they are very seldom supplied with electric energy at the same voltage or pressure as that on which the dynamo capacity of the same frame is based, but at a slightly lower pressure, due to line loss, so that, with a fixed maximum for the armature current, less watts are delivered to the motor than the same machine would deliver if used as a dynamo. The lower volts at motor terminals and the fact that the dynamo armature must generate volts enough to overcome the pressure lost in its own windings in addition to the volts at brushes, while the counter volts generated in the motor armature is the line pressure minus the pressure lost in armature windings, account for the difference in speed between a motor and a dynamo on the same frame. To compare the power of a given machine as a motor with that which it would deliver as a dynamo, it is desirable at first to know the rate at which energy is consumed in the magnet windings. Taking the case of a shunt-wound magnet and assuming the same watts in the winding for both dynamo and motor, it is evident that the dynamo armature must furnish the amperes required in shunt coil plus the amperes at which the dynamo is rated. For the same armature current in the motor as in the dynamo, therefore, the total amperes delivered to the motor will be the rated dynamo amperes plus twice

the amperes taken by the shunt-magnet winding, or, in other words, the watts delivered to the motor should be the rated dynamo capacity of the machine at the same volts plus twice the per cent. of watts consumed in the magnet coil. It is now evident that with motor and dynamo ratings, each based on the same winding losses, and, consequently, very nearly the same temperature rise, the motor capacity of any machine may be found from its dynamo rating by adding to this rating twice the watts in shunt winding and then multiplying this sum by the efficiency of dynamo, provided the motor and dynamo ratings are based on the same volts at brushes. If, as is frequently the case, the volts at the motor are less than the volts on which the dynamo rating is based, then motor capacity as found heretofore should be reduced by the per cent. in which the volts at the dynamo exceed the volts at the motor brushes. Were the above rational relation between dynamo and motor ratings generally followed, a variation in the ratio between different machines would indicate at once a variation in magnet-coil loss, efficiency or both.

The present variations in the relation between dynamo and motor ratings cannot be due to different efficiencies alone, as so great a range of efficiencies is neither practical nor possible. This can be shown by the machine of "A," rated at 10 horse power as a motor and 7.5 kilowatts as a dynamo, since a motor to deliver 10 horse power when drawing only 7.5 kilowatts plus twice its shunt-coil loss from the line must have about 96 per cent. efficiency, which, in a practical commercial machine of this capacity is very nearly impossible. Again, the machine of "C," rated at 10 horse power as a motor and 10 kilowatts as a dynamo, when drawing 10 kilowatts plus twice its shunt-coil loss from the line and delivering only 10 horse power would have an efficiency of only about 71 per cent., which is absurdly low. Taking the dynamo ratings of the machine mentioned to be correct, the motor rating of machine "A" is too high and that of machine "C" is too low, and it is absurd to offer these machines to do the same horse power of work, when one is one and one-third times greater in capacity than the other. If it be said that the motor ratings of these machines are the correct ones, then the dynamo capacities are incorrect in the reverse order.

In view of the several dynamo ratings quoted for machines of 10 horse power motor capacity, it is interesting to note the dynamo rating which corresponds to a 10 horse power motor, with the same amperes in the armature and the shunt-magnet coil, assuming the volts at motor and dynamo terminals equal. A motor working at the rate of 10 horse power delivers the mechanical equivalent of $10 \times 746 = 7,460$ watts, and at an efficiency of 86 per cent., which corresponds with good practice, the total watts delivered to the motor at full load is $7,460 \div .86 = 8,674$ watts. It is fair to assume about 250 watts in the shunt-magnet winding for a machine of this size, and since for the same amperes in armature and shunt coil the watts delivered to the motor may be greater than the rated watts of the corresponding dynamo by twice the amount consumed in the shunt coil, the dynamo rating for this case should be $8,674 - (2 \times 250) = 8,174$ watts. If, however, as is usually the case in practice, the motor must take energy from the line at about five per cent. lower voltage than that at which the dynamo is rated, the watt rating of the dynamo corresponding to the 10 horse power motor will be $8,174 \div .95 = 8,604$ watts. Dynamo ratings being more easily checked by volts and amperes than is the motor horse power, which is not so quickly determined, are probably more conservative and within desirable limits of heat.

Electric Street-lighting Extension in Chicago.

Contracts have been or are about to be let by the city of Chicago, to the extent of about \$150,000, for extending the municipal arc-light plants for street illumination. A new plant will be erected at Sixty-third street and Wentworth avenue, in Englewood, and existing plants will be extended. Two engines of 700 horse power each have been ordered from the Elmes Engineering company of Chicago at a total cost of \$12,375. They are of the vertical, compound-condensing type. One will go in the new Englewood plant and the other in the existing station at Halsted street and Blue Island avenue. Boilers for the new plant will be transferred from city plants where there is a surplus capacity, and none will be bought.

Ten 150-light arc dynamos are under contract at the low price of \$2,360 each. There will be five Brush machines, built by the General Electric company, and five Western Electric machines. Four dynamos will be placed in the new Sixty-third street station, two in the Halsted street plant, two in the station at Rice and Lincoln streets and two are as yet unassigned.

Bids have been received for the arc lamps, of which about 800 will be required. These lamps are to be of 2,000 nominal candle power each and planned for all-night service with single carbons 14 inches long and five-eighths inch in diameter. The bids for supplying each lamp are as follows: Charles E. Gregory, \$12.50; General Electric company, \$18.40; Western Electric company, \$19.30. The lamp contract had not been awarded at the beginning of this week. Specifications for wire and general line supplies will soon be issued.

Stealing Electricity.

By a verdict rendered by a jury in the Criminal Court of Cook County, Judge E. W. Burke presiding, on April 17th, the first conviction, after trial, was secured under the Illinois statute relating to the fraudulent taking of electric current from the wires of another. A defendant had been arraigned and pleaded guilty in a previous instance, but the case in question was the first in which the offense was proved to the satisfaction of a jury. The misdemeanor is a troublesome one to prove legally, owing to the intangible nature of the electric current and the difficulty of establishing that connections were willfully made to wrongfully divert the current. The case just decided was carefully worked up, and is of unusual interest.

The language of the law under which the prosecution was carried on is as follows:

Any person who, with intent to injure or defraud any company, body corporate, copartnership or individual, shall injure, alter, obstruct or prevent the action of any meter provided for the purpose of measuring and registering the quantity of gas, water or electric current consumed by or at any burner, office or place, or supplied to any lamp, motor, machine or appliance, or shall cause or procure or aid the injuring or altering of any such meter, or the obstruction or prevention of its action, or shall make or cause to be made with any gas pipe, water pipe or electrical conductor any connection so as to conduct or supply illumination or inflammable gas, water or electric current to any burner or office or place or motor or other machine or appliance from which such gas, water or electricity may be consumed or utilized without passing through or being registered by a meter or without the consent or acquiescence of the company, municipal corporation, body corporate, copartnership or individual furnishing or transmitting such gas, water or electric current through such gas pipe, water pipe or electrical conductor, shall be punished by imprisonment not exceeding three months or a fine not exceeding \$250, or both.

The complainant in the case was the Chicago Edison company and the defendants were Fred Potthast and Edward Bach. Potthast is a saloon-keeper and has or has had several places in Chicago, including one at 254 State street, where it was shown that current was stolen. Bach is an electrician, formerly employed by the Chicago Edison company, and he was employed by Potthast to connect the wires so that the consumption of current for lights would not be registered by the meter. Potthast and Bach were indicted, and the prosecution was conducted by Assistant State's Attorney Olson, with Roy O. West as special counsel. Mr. C. R. Taylor, an attorney associated with Mr. West, also gave material assistance to the state. The defense was represented by ex-Judge Longenecker and Mr. Arnold Heap. One of the interesting features of the case was the fact that the statute under which the case was prosecuted was drawn up in 1895 by Mr. Longenecker, the attorney for the defense, who was formerly state's attorney of Cook County.

The prosecution introduced maps of the basement in which the fraudulent connections were made, and, in connection with expert testimony, demonstrated by the use of a connection to the lighting circuit in the court-room that the electricity used was taken from the mains of the Chicago Edison company, showing the jury that by removing the plugs at the Edison company's service box the lights in the saloon were extinguished.

Another point in the testimony of the prosecution, which was introduced to prove that the connections were made to the Edison system, was that of blowing the service fuse by connecting the positive or negative wire to the ground, thereby extinguishing the lights in Potthast's saloon. This was due to the fact that, as the neutral wire of the Edison three-wire system is grounded, a direct short-circuit was caused on Potthast's lighting circuit. This method was explained by a witness, who, in company with other witnesses, visited Potthast's saloon the latter part of last December and extinguished the lights in this manner. Edward Bach, the electrician, was seen by witnesses in the act of wiring the premises and connecting lamps to the live wires. The prosecution also proved that Potthast had practically supported Bach for a year or two at his various saloons, and that the two had been very intimate.

The defense attempted to prove that the light was obtained from a small nearby plant. The difference in the light of the Chicago Edison company and that of the other plant was testified to by witnesses, who swore that the light of the Edison company was easily distinguishable from the other light, being of a steady, even quality, while that of the small plant fluctuated, owing to the use of a gas engine for motive power and the slipping of belts. Bach himself testified to an alibi, but the evidence did not support him. The jury, after retiring for less than half an hour, brought in a verdict of guilty for both defendants.

The number of cases in which the Chicago Edison company has been defrauded has increased to such an extent within the last few years that the company has been forced to protect itself by prosecuting all cases where intent to defraud the company is apparent. The company has several cases which will shortly come to trial, and it intends to vigorously prosecute all such offenders, with the hope that it may reduce its loss. It is known that there are electricians who solicit the work and obtain money for connecting lights to the company's mains, without its knowledge, in such a way that the lights do not register on any meter. It is said that these persons also sell appliances for placing shunts around meters.

DEVELOPMENT OF THE TELEPHONE FIELD.

History of the Telephone in Canada.¹

By W. L. SEWELL.

The Bell Telephone company of Canada was incorporated April 29, 1880, second session of the fourth Dominion Parliament, with a capital stock of \$500,000. Only limited rights were granted to manufacture, but the act gave the company the privilege of taking stock in manufacturing concerns. On the 17th of May, 1880, the original incorporation act was amended; and by this amendment the company was granted privileges to manufacture telephones and all other appliances connected therewith.

On March 10, 1882, an act to confer certain powers upon the Bell Telephone company was assented to by the Ontario government, and privileges in relation to the erection, construction and maintenance of its system were granted. On July 9, 1892, an act was assented to by the Dominion Parliament, granting the Bell Telephone company power to increase its capital stock, not to exceed \$5,000,000, including the original stock.

It was also provided in this act that the issuing of bonds and debentures from time to time should be limited to a sum not exceeding in the whole \$500,000, and that the then existing rates should not be increased without the consent of the governor in council.

By the original act of incorporation the Bell Telephone company was allowed to operate in every municipality in the Dominion. The act did not grant it an exclusive right; the system, however, to-day practically controls the telephone business throughout the Dominion. By an act passed July 23, 1894, the company was given the power to issue bonds or debentures to the amount of 75 per cent. of its actual paid-up capital. In 1891 capitalists in Toronto combined and applied to the City Council under the name of the Toronto Telephone company for the privilege of constructing and operating a telephone system in Toronto. As soon as this proposed company had made an offer to the city of Toronto the Bell Telephone company, realizing that the offer might be accepted, immediately made counter propositions to the city authorities, greatly reducing the previous rates and granting the city a percentage on all its gross earnings within the municipality in exchange for the exclusive privilege of operating in Toronto for five years and other considerations. The agreement entered into between the Bell Telephone company and the city corporation was substantially as follows:

The corporation agreed that it would not, during a period of five years, give to any person, firm or company permission to use any of the streets or lanes of the city for the purpose of placing in, upon or under such streets or lanes any poles, ducts or wires for the purpose of carrying on telephone business, the Bell Telephone company agreeing to pay to the city on December, March, June and September 1st of each year five per cent. of its gross earnings for telephone service within the city limits or any extension thereof, not to include the receipts for business transacted between the city of Toronto and the offices outside the city. The company further agreed that the rate to be charged for leases of telephones—to wit, dwelling houses within the city limits, for one year or more—should be \$25 per annum; similar leases for business houses, \$45 per annum; such rates to apply to all telephones then in use, as well as to those leased during the period of the contract. A pro rata rebate for the unexpired term was granted for telephones in use at the time of the making of the said contract, on which rent was paid in advance. The company agreed to place its wires under ground as rapidly as possible, with the exception of lines on small back streets, required for distribution purposes. The company further agreed not to allow any other person or company to use its poles without the consent of the city engineer and the approval of the council, except where the company has already existing contracts covering the use of poles. It also agreed to furnish the city with one duct from the conduits constructed in any of the streets, etc., to be used for the city fire-alarm service, making no charge therefor, and to give the city free of cost the use of any of its poles, when required, for the fire-alarm system. The company agreed to provide efficient telephone service, with all modern appliances, including metallic circuits, to the satisfaction of the city engineer.

The Bell Telephone company and the city of Toronto continued to act under this agreement for the period of five years, and at the expiration of the contract the company would not renew the agreement, and now declines to allow the city any percentage upon its gross receipts, so that, at the present time, it is operating under the rights conferred by the statute. The rates provided for in the agreement are charged. The system in Toronto consists of a main station and two exchanges, the single-wire system having been changed in 1892 to the double-wire metallic system. After the agreement was signed, all the lines in the central district were laid under ground, and a 2-5 mile, installed and substantially covered by aphalt pavement. In almost every case the installation of underground work preceded the laying of the asphalt. During the pe-

riod of the agreement between the telephone company and the city of Toronto the following sums were paid to the city treasurer:

Year.	Amount.	Year.	Amount.
1891 (2 months).....	\$1,172.46	1894.....	\$7,883.42
1892.....	7,303.43	1895.....	7,999.98
1893.....	7,455.67	1896 (10 months).....	6,791.78

These represented five per cent. of the gross earnings of the company during the five years.

Previous to 1891 the rates to subscribers were \$50 for business houses and \$30 for private telephones. From September 17, 1891, to the present time, the rate of \$45 and \$25, as per expired agreement, has not been changed. The present number of subscribers within the city is 8,300, with an average daily call of 13,02. Rates for long distances are charged according to a sliding scale, 25 cents being the lowest figure for five minutes' conversation. Direct telephonic communications can be had with the principal cities, towns and villages in the provinces of Quebec and Ontario and the United States. Up to 15 miles, rates are 15 cents; from 15 to 150 miles, 25 cents; from 150 to 225 miles, 50 cents. For each additional 20 miles or a fraction, half of the above tariff is charged. The telephone company, from 1880 to 1898, had plant in Toronto, "which does not include land and buildings, or \$306,220.21, the value of useless and ruined material which was not counted during its time," which appears to be worth about \$1,000,000.

The services rendered by the company are first-class, and all materials and equipments are in excellent condition in every particular. According to the directors' nineteenth annual report, 1,637 new subscribers were added during the last year, the total number of instruments now earning rental in the Dominion being 32,082. The company operates 343 exchanges and 340 agencies. Six hundred and sixty-six miles of wire has been added to the long distance lines in 1898. Of this 326 miles is in the Ontario department and 340 miles in the eastern department. Long-distance lines now owned and operated by the company comprise 17,233 miles of wire on 6,096 miles of poles. During the year 1898 they were divided among the shareholders at par 7,920 shares of new stock, in proportion of one share of new for four of old, all of which, with the exception of 160 shares, were sold and the premium divided pro rata.

The stock of the Bell Telephone company of Canada now sells readily at 178, whenever placed upon the market.

New England Telephone News.

[From the Boston correspondent of the Western Electrician.]

The Massachusetts Telephone and Telegraph company reports good results in the canvass for subscribers in Boston, and canvassers are still soliciting actively. President Holbrook has issued a prospectus, in the form of a handy pamphlet, declaring that the company is sanguine of success from present indications, and will undoubtedly have 15,000 telephones in operation within two years in the city of Boston, and a proportionate number in the suburbs. He states that there are more than 3,000 independent telephone exchanges in operation in the United States. The estimated cost of the construction of the system in Boston alone is about \$2,000,000.

The Cambridge City Council, at its last regular meeting, gave a hearing to the independent company on its petition for the privilege of establishing an exchange there, but reserved decision.

The Taunton (Mass.) Telephone company has been incorporated under the laws of the state, capitalized at \$50,000, with Peter H. Con, Clinton Sproat and H. H. Shumway named as incorporators.

Michigan Lines.

[From the Detroit correspondent of the Western Electrician.]

The Michigan State Telephone company has decided not to increase its capital stock from \$1,000,000 to \$1,500,000, as recently proposed. Instead, the managers will sell \$200,000 worth of unissued stock for the desired extension.

A strike of 150 linemen of the Michigan Bell company took place last Saturday in Detroit, and the strikers were to secure the co-operation of all the men working on the suburban lines about the city. They demand a uniform scale of \$2.25 per day, eight hours' work. It is stated as one of the grievances that the Detroit Telephone company, which for two years has been paying \$2.25 for ten hours' work, to-day signed the eight-hour agreement.

Mendacity of Bell Management.

The Bell interests have mailed circulars to subscribers of the Cumberland company, containing an attack upon the independent industry. The document purports to be an article reprinted from the Cincinnati Times-Star, and professes to give an account of the industry, but it is in reality a tissue of falsehoods, and is a disgrace to the newspaper which printed it and the company circulating it. One statement will fairly represent the character of the circular. It says:

"As a matter of fact, not a single opposition company in the country has ever paid a dividend."

Telephone Line an Additional Burden.

The Court of Errors and Appeals of New Jersey has had under consideration the question of whether the acquisition by a telephone company of a right to erect poles and place wires and other fixtures for telephonic purposes along a public street, wherein the fee of the land belongs to private persons, without the consent of such persons, is the taking of private property. It says that if the land were not subject to the easement of a public street the matter would not be debatable; but, it adds, it is equally clear that whenever the property of the owner of the fee in a highway is subjected by law to an additional servitude, it is taken, within the meaning of the prohibition of the constitution. This reduced the question in the case of Nicoll against the New York and New Jersey Telephone company to one as to whether the right to be acquired would be an additional servitude upon the fee, or was embraced within the public easement, and hence, grantable by the public for public use, without regard to the owner of the fee.

The argument to support the proposition that the right to construct and maintain a telephone line for common public use is within the public easement, the court states, is that the structures required for the exercise of the right are mere adaptations of the road to the passage of the electric current, which thus travels along the highway.

But the resemblance between this use and that ordinarily enjoyed under the easement, the court continues, scarcely goes beneath the words by which it may be described. In reality the electric current does not use the highway for passage. It uses the wire, and would be as well accommodated if the wire were placed in the fields or over the houses. The highway is used only as a standing place for the structures.

Such a use, the court says, seems to it to be so different from the primary right of passage as to be essentially distinct. Nor does it think that it rests on the same footing as those secondary uses which, though their relation to the right of passage is remote or even fanciful, are so generally advantageous to the owners of the fee—the owners of abutting property—that, rather by common consent and custom than by logical deduction from the primary design, they are now recognized as legitimate, such as the construction and maintenance of sewers, water pipes and gas pipes, for the convenience of persons occupying neighboring lands. Telephone lines in a street do not afford to the occupants of neighboring property such general convenience, nor have they been permitted such common and continued acquiescence as sanctions these other uses.

For these reasons, the court holds that the right of a telephone company to erect a telephone line within the limits of a public street, upon land the fee of which is owned by private persons, is not within the public easement, and can be acquired, against the consent of the private owner of the fee, only by condemnation under the power of eminent domain.

Proceedings to acquire such a right under the telegraph and telephone companies act of New Jersey, the court further holds, are regulated by the eminent-domain act.

Trials of Telephonic Apparatus.

[From the London Electrical Review.]

Experiments with new forms of telephonic apparatus, the results of which are duly published in the prospectuses of exploiters of the same, are often extremely misleading to the public, and also, we should add, to the experimenters themselves. We have, for instance, a statement that such and such a telephone has worked with great success through a length of 2,000 miles of wire, which to the public seems a marvelously good result, when they are ignorant of the fact that a very bad telephone would work equally well through 5,000 miles if the wire were of a sufficiently large gauge. The all-important element of gauge, in fact, being left out, makes the test practically valueless for indicating the true value of the instrument. Again, the (what ought to be) well-known erroneous method of testing through a looped wire with the transmitter and receiver at the same end of the loop, and without using earth, is by no means knocked on the head; it is often quoted as being a severe test, when it is actually perfectly useless. Tests through artificial cables are also by no means to be relied upon. These cables may be perfect as regards their K and their R, and may be entirely satisfactory for experiments on telegraphing through cables, but for telephonic experiments they are not to be relied upon, as there is often a reaction between the bobbins of which the resistances are composed, which, for telephonic purposes, practically cuts down the effective length of the cable to a very marked extent. In fact, we are actually working through K R, diminished by inductive reaction, this reaction being by no means an inconsiderable quantity. The only test of real value is to pit one telephonic instrument against another through the same artificial cable, and determine which is the better of the two by adding in resistance and capacity until one of the two on trial commences to fail. We have seen this done on more than one occasion, to the complete discomfiture of the vaunted improvement.

¹ From a pamphlet issued by United States Consular Reports.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The St. Paul Board of Aldermen has finally yielded to the demand of the business men in that city and granted the American Telegraph and Telephone company a franchise for a local and long-distance telephone connection. The franchise of the present local company expires soon, and the council has felt that to grant the long-distance company a local franchise would be the same as extending the present company's, owing to the close connections of the two companies. But the business men wanted long-distance connection, and petitioned for it and kept up an agitation until favorable action was taken. The franchise provides that no stock in the company can be transferred without the consent of the council.

The Standard Telephone company has connected McGregor, Ia., with neighboring towns.

The Germania Telephone company has been formed at Germania, Ia., with \$5,000 capital stock, to build toll lines over Kossuth County. The same incorporators have formed the Northern Kossuth Telephone company.

The Northwestern Telephone company of Sheboygan, Wis., has been reorganized as the Sheboygan County Telephone company. All the floating stock has been gathered in by local business men, to prevent the absorption by the Wisconsin Telephone company of the company.

The Little Wolf River Telephone company has secured quarters in Fond du Lac, Wis., for the central office for the exchange about to be established.

The Winona (Minn.) Telephone company has 536 instruments in service in Winona, and a total of 670 with the toll lines.

The Wisconsin Telephone company suffered \$2,000 damage at Oshkosh, Wis., in a recent heavy fire, by reason of 400 wires being melted by the heat.

The Western Electric Telephone company of Algona, Ia., expects to rebuild its lines in that vicinity on a metallic basis and make numerous extensions.

The Wright County Telephone company has been granted a franchise at Belmond, Ia.

The Nevada Mutual Telephone company has been incorporated at Nevada, Ia., with \$3,500 capital stock. Contracts have been let for constructing the new telephone system at Garner, Ia.

Chase & Achatz will soon rebuild the telephone system at Algona, Ia.

A mutual telephone company has applied for a franchise at Humboldt, Ia., and the Iowa Telephone company has renewed its request for similar privileges.

The Home Telephone company of Sioux City, Ia., is building a toll line to Spirit Lake, Ia.

Arrangements are about completed for a farmers' telephone line between Keota, Ia., and South English.

The Wisconsin Telephone company is preparing to put in a metallic circuit north from Two Rivers, Wis., to Sturgeon Bay.

The Northwestern Telephone Exchange company has made an experimental low rate between the Twin Cities and Fargo of 25 cents for a day message of one-half minute.

The People's Telephone company of Superior, Wis., is now in full possession of its franchise for a local exchange. It is to have not less than 100 instruments in use by August 1st.

Work has been started on the long-distance telephone company's line between Superior and Minneapolis.

A local telephone company is being formed at Montevideo, Minn. Over 40 subscribers have been secured.

The Northwestern Telephone Exchange company will begin work on improvements to the system at Grand Forks, N. D., and vicinity about May 1st, and will continue all summer rebuilding the local exchange.

Farmers and merchants of Prospect, Wis., will build a telephone line to Big Bend, Wis., to connect with the Wisconsin Telephone company's lines.

An additional switchboard of 50 drops has been put in for the Valley City, N. D., telephone exchange. The exchange has 153 subscribers. An exchange is projected by Manager Beaman of the Valley City exchange, to be established for Coopers-town, N. D.

The telephone company of Lake Mills, Ia., has added 10 cents a month to the cost of service, making it 70 cents for business houses and 50 cents for residences.

The Ogden (Ia.) Telephone company, composed of local people, has been formed and materials for the exchange ordered.

Brighton, Ia., has voted a franchise to the Jefferson County Telephone company.

The Rocky Mountain Bell Telephone company is preparing to do a large amount of work on its lines this season. The Dillon, Mont., line will be extended south to connect with the Utah system. Lines will be extended from Sheridan to Virginia City, Mont., at once.

The Michigan Telephone company has materials at Menominee, Mich., for a metallic-circuit extension to the copper country in the Upper Peninsula.

The business men of Tracy, Minn., came to the conclusion they had no use for telephones in their stores, and ordered them out, but desired to retain their residence connections. The company announced that it might as well take out the entire exchange as to remove the business connections, and

issued an ultimatum to the business men to that effect.

The Bon Homme County Telephone company has been granted a franchise in Bon Homme County, S. D., and expects to connect distant towns in the county with Tyndall, the county seat.

Senator J. T. McGowan of the Minnesota Legislature has been investigating the matter of telephone rates in several cities.

Telephony in Mississippi.

[Special correspondence of the Western Electrician.]

The Canton Warehouse company, which also owns the telephone plant at Canton, Miss., and over 200 miles of lines throughout the adjacent country, recently sold its telephone business to the Cumberland (Bell) company, which had unsuccessfully attempted to put in a local exchange in order to secure the toll business for the trunk and local lines recently completed between New Orleans and Memphis. The people stood by the home concern, even in the face of the Cumberland's offer to put in telephones free of charge. The Cumberland company secured only 23 subscribers, with a solicitor in the town nearly three months, while the home people had over 130 local subscribers. After the Cumberland company bought out the plant it raised the business rate from \$2 to \$2.50 per month and discontinued free service to the adjacent country, which the local company had been furnishing to its subscribers without charge.

At Crystal Springs, Miss., the Citizens' Telephone company continues to increase its business, although already having a good list for the size of the town in which the exchange is located. The business in the adjacent country is also increasing.

The Hazelhurst company, after a contest with the Hazelhurst, Miss., authorities as to their privilege of installing a local exchange, finally came to terms with the Town Council and, by the terms of its franchise, agreed to furnish the citizens service at rates which will be fairly satisfactory, but, notwithstanding this, the Cumberland company is not making very much progress with the local exchange. Meanwhile the agitation seems to have benefited the local concern, whose business has been considerably increased since the Cumberland company came into town.

McComb and Summit, Miss., are situated only about three miles apart, and the Cumberland company is installing exchanges at both these points, but the fight has not been on long enough to determine what will be the measure of their success, though it is quite probable that the home people, especially at McComb, where the independent concern is in strong hands and has a very large list of subscribers, will probably hold their own.

Since the local telephone company at Natchez, Miss., sold out to the Cumberland (Bell) company in January last, as previous reported, the rates have been advanced to \$2 for residences and \$3.50 for business telephones, being an advance of 50 cents on residences and \$1 on business houses from the rates charged by the home concern.

Both the Cumberland company and the Citizens' company at Vicksburg, Miss., continue to hold just about the same number of subscribers as they have had for some months past, although the Cumberland company offers a 50-cent residence rate.

The Mutual Telephone company at Yazoo City, Miss., continues to hold its own, occasionally adding more subscribers, while the Cumberland company has only a few subscribers.

In Jackson, Miss., the People's Telephone company, which has nearly three times as many subscribers as the old Bell company had when the People's began operation, still picks up a few subscribers from time to time. The independent company has a great many more business concerns than the Cumberland company, and while the Cumberland has as many residences, yet the better class is nearly all found exclusively on the People's line.

The company operating the local exchange, which recently reorganized at Meridian, Miss., is doing a very good business, continually gaining new business, and is very favorably regarded by the general public, though a great many of the business concerns still find it desirable to keep both the local and the Bell company telephones. C. M. H.

The Cumberland Telegraph and Telephone company has lately put a telephone exchange in Greenwood, Miss., in competition with the one installed by George W. Scheuing of Memphis. Mr. Scheuing has cut the price to \$1 per month, and is holding his subscribers.

L. B. Camp of Amory, Miss., an old telegrapher, has about completed an exchange of about 50 telephones. He has a 100-number switchboard installed.

The Tennessee and Arkansas Telephone company will in a few days put under the water of the Mississippi River, at Richardson's Landing, Tenn., a two-conductor cable, manufactured by the Standard Underground Cable company of Pittsburg. The lines of this company run in Tennessee to Richardson, and from there in Arkansas through Osceola and on to Barfields. R.

Telephone Beats Telegraph.

[From Iron Age.]

The telegraph is too slow for modern business methods. At least that is the experience of a western dealer in old rails. It happened on a recent

holiday that two dealers in the same city went to their respective offices to look over their morning mail. Both received an offer of a lot of old rails from a railroad manager 200 miles distant. Mr. A immediately called up the railroad manager by long-distance telephone, caught him in his office, and in a few minutes closed the transaction, involving about \$50,000. Mr. B meanwhile called a telegraph messenger and sent a telegraphic offer for the rails. The telegram was delivered at the manager's office in due time, but as he had gone home it was held over until the following morning for his scrutiny. Mr. A, however, suffered no grass to grow under his feet, but on the same holiday called up a rolling-mill 400 miles away, found the manager ready for business and sold the rails, thus cleaning up a profitable transaction within comparatively few hours, and long before the message sent by telegraph reached the person addressed. It is unnecessary to state the moral, as this is no fable.

New York Telephone Rates.

The New York Telephone company will put into effect on May 1st a general reduction in its rates of service. The rate for a telephone in a private house is to be reduced from \$90 a year to \$60 a year. The rate now prevailing permits the sending outward of 500 messages, which is equal to 15 cents a message. More than six months ago the rate for a message from a pay station was reduced from 15 cents to 10 cents within Manhattan Borough, but no change was made in the house rate. Thus it cost 15 cents to telephone from home, while by going to a pay-station a saving was effected of five cents.

In Brooklyn and New Jersey, where telephones are operated by what is to all intents and purposes the same company, the house rate is \$50 a year for 500 messages. A reduction was made one year ago from \$65 a year. Rates are even lower in parts of New Jersey where there is competition.

It is said that the new scheme of reduction contemplates a lowering of the rates for business houses, both for the long-distance and the ordinary city service, but the figures cannot be learned.

It is believed that the organization recently of two or three corporations with large capital, which announced that they would enter the field as active competitors of the existing companies, and which have been assured of right-of-way under the city streets and also of generous patronage, has moved the New York company to lower its rates.

No Consolidation of Independent Companies.

The report that Hopkins J. Hanford who was in New York for a few days recently, was arranging for a combination of the independent telephone companies, has been formally denied. It was said that one of the largest banking houses of New York had agreed to finance the consolidation, which would involve a capital of about \$20,000,000. Mr. Hanford says the independent companies are not ready for consolidation; that such a movement could not now be successful, and that it will be two or three years before it can be contemplated.

MANUFACTURERS AND DEALERS.

J. A. Williams, president and general manager of the Williams Electric company of Cleveland, is spending a few days in Chicago, in the interests of his company. Mr. Williams is stopping at the Great Northern Hotel.

Mr. P. C. Burns has decided to publish a monthly house organ to promote his several telephone interests. The first number contains a full-page portrait of the publisher and several illustrations of apparatus made in his factories. The new publication is called the American Telephone, and is modeled on the same lines as the defunct Telephone, formerly published by Mr. Keelyn and his associates.

C. H. and Gus Hintz are promoting a telephone line between Chico, Cal., and Magalia, taking in intermediate towns. A petition for the privilege to maintain poles on the streets of Chico has been filed with the city clerk, and a similar one will be presented to the supervisors, asking for the privilege of setting poles along the county road. It will cost between \$600 and \$700 to construct the line. Work on the construction of the line will be begun soon.

The Monarch brand of galvanized telephone wire is meeting with great success, and it is said, has given satisfaction wherever used. This wire is made exclusively for telephone purposes, and is put up in half-mile bundles. The Loschen Macomber-White company carries a large stock in Chicago. The company also handles galvanized steel strand, Crosby clins turnbuckles and Boston cable hangers, all of which it carries in stock.

The Eriesson Telephone company of New York has issued a new catalogue, presenting the merits of its specialties. The company announces to the independent telephone exchanges a series of information letters which will be mailed from time to time, in circular form, to all who may be interested. They are free of cost, and those who wish the full series should mail the company a postal or letter to that effect. The company will occupy its new offices, 206 Broadway, New York, about May 1st.

Knutson Gravity Clutch for Arc Lamps.

Electric-light managers and users of arc lamps in general will be interested in the Knutson gravity clutch for arc lamps, which is illustrated herewith. Every arc-lamp trimmer in the country has experienced more or less difficulty in connection with clutches, and these difficulties are said to be entirely overcome where the Knutson clutch is used. The clutch is very simple, and was devised by Alfred W. Knutson of Galesburg, Ill., after an experience of 15 years with arc lamps. It is claimed to possess many points of superiority over other clutches, and although in practical use but a short time, it is said to have an entirely satisfactory record.

The device is especially adapted for Thomson-Houston and Brush arc lamps, and can be readily fitted in arc lamps without taking the mechanism of the lamp apart. It can be readily engaged with, and disengaged from, the carbon rod without removing the upper end of the rod. The clutch, while firmly holding the rod, is at the same time exceedingly sensitive, so as to readily release its grip from the rod to allow the latter to feed at the proper time. The clutch has only one pivotal hinge, and has no lost motion. It has a sure grip and is sensitive to feed. It will not pit a rod, and will take up the full arc instantly after feeding, thus insuring a brilliant, steady light. Moreover, it is said that the clutch will last as long as the life of the lamp and that the life of the lamp will be prolonged, as it is impossible for the rod to bind and the coils to burn up. Mr. Knutson, the inventor, has been an arc-lamp trimmer, and his wide experience has enabled him to overcome the difficulties of arc lamps caused by inefficient clutches.

A. W. Knutson & Co., Galesburg, Ill., who are manufacturing this clutch and placing it on the market, are anxious to have every electric-light company give it a trial, and guarantee it to be absolutely satisfactory. The firm is willing to send a trial order on approval, and if the clutches are not satisfactory they may be returned.

Relay Circuit-breaker.

The illustration shows a type of circuit-breaker equipped with two magnets. One is arranged for opening the circuit at a predetermined overload, and the other is wound with a number of convolutions of fine wire, to be placed across the line circuit and to be used in connection with one or more push-buttons for opening the circuit at various points distant from the instrument. This magnet may also be wound for almost any voltage and to open at rise of voltage above a predetermined limit.

The instrument shown is single-pole, but it can be made double-pole by placing another switch at the right of the overload magnet, both latches being tripped at overload by the same plunger. The Ward

has numerous other orders for large work. The works are so crowded that the company has been obliged to contract for the extension of its shops, the contract having been let and work progressing. These extensions more than double the present plant. The plans contemplate the extension of foundry, machine shops and erecting shops to double their present capacity, besides which the power house, smithy and forge departments are to be trebled in capacity. The company is also building a warehouse for finished product, 400 feet in length. These improvements will make the machine shops, erecting shops and foundry 1,200 feet in length, with the present width of 230 feet. The warehouse

KNUTSON GRAVITY CLUTCH FOR ARC LAMPS.

and forge department will be nearly 700 feet in length.

For very large work the Westinghouse company will build Corliss engines, but for the present, at least, it will build no moderate-sized Corliss machines.

Electrical Equipment for Street Railways in Mexico.

The company owning the street railways in Mexico City is about to substitute electric power for animal traction, according to United States Consul-general Barlow. There are about 300 miles of track in

H. P. Bradford is president. The conductors and drivers are Mexicans.

The franchises granted are about the same as in other cities. The capitalization is \$10,000,000. The street-car fares vary according to distance. In the city proper they are five and six cents. Some of the suburban fares are as high as 30 cents.

The electric power will be obtained from coal. There will be no connection with the electric-light plants now in operation.

Fort Wayne Electric Manufacturing Company.

It is authoritatively announced that the Fort Wayne Electric Manufacturing company is being organized as the successor of the Fort Wayne Electric corporation, and that the business will be continued as heretofore at Fort Wayne, under the direction of Messrs. Wood and Hunting, with improved facilities for manufacturing.

CORRESPONDENCE.

New York Notes.

New York, April 24.—The amended rapid-transit law is still pending in the Legislature. Governor Roosevelt has sent a message to the Senate and Assembly at Albany, stating that, in his opinion, the franchise should not be given for more than 50 years. He is opposed to a perpetual franchise. If the people approve a constitutional amendment separating the debt of New York city from that of its constituent counties, the city may be permitted to build the terminal road itself, the debt limit being thus extended. Were the constitution so amended, Controller Coler asserts that the city could easily devote \$10,000,000 a year for the tunnel without in any way interfering with the municipal improvements already contemplated. The Tribune says that public opinion is confessedly in favor of delaying the beginning of the tunnel for a few months rather than accepting such exacting demands as were made by the Metropolitan company. It was this knowledge which led Mr. Whitney and his associates to withdraw their offer. But, despite the aggrieved attitude which they take, it is generally believed that when the time comes for the city to invite bids for the contract one of the competitors will be a syndicate of Metropolitan railway capitalists.

It is said that the Sprague multiple-unit system of electric-car propulsion will be adopted by the Manhattan Railway company, and that all idea of extending the elevated structure north of the present termini has been abandoned. Instead, the Manhattan company will operate its cars in the upper part of the city on the tracks of the Union Railway company, which is in harmonious relations with the Third Avenue Railroad company. The Sprague method enables cars to be run either in trains or as individual cars, and the plan contemplated is reported to be to run its trains to One-hundred-and-seventy-seventh street on the East Side and One-hundred-and-fifty-fifth street on the West Side, where they will be broken up, descending a grade to the street level as individual cars, and thence going over the tracks of the Union Railway company to various points in Westchester County.

The Municipal Street Railway company of New York city was incorporated last week with a capital stock of \$250,000, to construct a street surface railroad about nine miles long. The termini of the road are One-hundred-and-sixteenth street and Eighth avenue, Kingsbridge Road and West Two-hundred-and-thirtieth street and Riverdale avenue and the northerly line of New York city, and there are to be branches to connect the main line with the junction of Eighth avenue and One-hundred-and-twenty-fourth street and the junction of Eighth avenue and One-hundred-and-forty-fifth street. The directors are James D. W. Cutting, James W. Gerard, Jr., Robert McM. Gillespie, Arthur C. Hume, Thomas Stokes, Charles A. Hamilton, John B. Stewart, M. L. Bouden and William E. Findley of New York city. The new company, in order to get the franchise, will have to get the consents of a majority in value of the property-owners along the line and the consents of the city authorities and the Rapid Transit Commission. It is declared to be the intention of the company to operate an electric road on a three-cent-fare basis in connection with the rapid-transit road's express trains.

The Staten Island Rapid Transit railroad was sold at auction on April 20th. It is understood the purchasers represent the Baltimore and Ohio railroad. The road runs from St. George to Arlington on the north shore and to South Beach on the south shore. It connects at St. George with the Staten Island ferry which is an independent corporation. At Clifton it connects with the Staten Island railroad which runs to Tottenville, and which it has operated under lease for some years. The sale included all the property of the company including a portion of the ferry. The only bid made was \$2,000,000, and at this price D. T. Cornell who conducted the sale, knocked the property down. The present management of the road, it is said, will continue. The policy and traffic schedule are to remain as in former years. The Staten Island Rapid Transit Railroad company owned and controlled one-half of the Staten Island Ferry company. The other half is held by the Staten Island Electric com-

RELAY CIRCUIT BREAKER.

Leonard Electric company of Bronxville, N. Y., which is prepared to furnish circuit-breakers suitable for nearly every kind of service, is the manufacturer of this device.

Westinghouse Company to Make Corliss Engines.

The Westinghouse Machine company of Pittsburg has recently secured a number of large orders for steam engines of very large capacity, notably the equipment of the Third Avenue street-railway power plant now building in New York, there being 16 engines of 4,500 horse power each, with a maximum capacity of about 7,000 horse power each, in this plant alone. Besides this plant, the company is building two engines of the same capacity for the Bay Ridge plant of the Brooklyn Edison company, and

the district, which includes the city. One line of 1½ miles is called the "Baños" or Baths line. The rest belongs to the Compañía de Ferrocarriles del Distrito Federal.

Until recently mules have been used to move the cars. They are small, hardy, well-fed animals, and travel rapidly. On the outskirts of the city their usual gait is a gallop. For communication with suburban towns the company has some large 16-wheel cars. Arriving at the outskirts of Mexico City, these cars are coupled into trains of five or more cars, and are thence drawn at good speed by American dummy engines. Most of the cars of the company are constructed in the United States, though at the city workshops of the company they make all repairs and have built some cars. The steam suburban lines will probably be retained and used chiefly for freight. The management is American.

pany, which operates some of the electric railroads on the island. M. S.

Detroit, Mich.

Detroit, April 24.—The Detroit Public Lighting Commission has decided to install closed arc lights. Many of the trimmers will be thrown out of employment.

Dan L. Davis of Pontiac and A. A. Talmadge of New York have been before the City Council at Holly, Mich., trying to secure a franchise for an electric railway. The council wants a forfeit of \$5,000 that the road shall be built by next fall. The intention is to run a line from Holly to Pontiac.

The electric road from Ann Arbor to Saline will be built this spring. A change in the route has been made.

The City Council of Battle Creek has decided to assess the street-railway company for any damage to water pipes caused by electrolysis.

In the annual report of the Eastern Asylum for Michigan Insane at Pontiac it is announced that the lighting plant now operated in the building has made a saving of \$4,000.

Representative J. N. McLeod's bill at Lansing, requiring all street-railway cars to be equipped with air brakes, has met with considerable opposition by the street-railway companies. Detroit and Grand Rapids companies are lobbying against the bill.

The Detroit, Mount Clemens and Marine City electric road has been incorporated for \$600,000.

The incorporation of the Detroit and Orion electric road is being "held up" in the secretary of state's office. The question is raised whether such roads can be operated from town to town through different counties. It will be taken to the Supreme Court to decide. G.

Northwestern Notations.

Minneapolis, April 24.—The Humboldt (Ia.) Electric Light and Power company has placed orders for equipment for its new system.

A bill has been introduced in the Minnesota Legislature allowing cities to contract for electric lighting for five years, the plant to be transferred to the city at the end of that time, free of charge.

W. A. Holt has made a proposition to the city of Oconto, Wis., to install an electric-light plant and light the streets for \$3,600 per annum, of which amount \$2,400 is to apply on the purchase of the plant by the city.

The council of Elroy, Wis., will probably be petitioned to submit the matter of an electric-light franchise to the public.

The litigation between the city of Tacoma, Wash., and the Commercial Electric Light company has been ended and the matter settled on the basis of the agreement made several weeks ago. The city has received \$100,000 cash in the settlement.

Local capital at Mankato, Minn., is taking an interest in an electric car system for that city. Eastern capitalists have made an offer for a system, conditional on a stock subscription of \$10,000 to \$15,000.

The Twin City Rapid Transit company recently paid to the city treasurer of St. Paul \$8,064.07. This includes three per cent. on gross earnings, real estate and personal taxes.

The Electric Light company of Missoula, Mont., offers to contract to furnish electric lighting for 10 years at the rate of \$8.33 a month each for 30 lights. The company's present contract does not expire until next September, and calls for \$15 per month per light. The company explains that the cost of lighting is cheaper now and present conditions justify the reduction.

The city of Aberdeen, S. D., has made a proposition, which has been accepted, for the purchase of the electric-light and gas system. The plant is bonded for \$35,000. The city will assume this debt and pay the owners \$3,500.

A new dynamo of 1,250 lights capacity is about to be put in for the electric-light plant at Pipestone, Minn. It is double the capacity of the present dynamo.

B. H. McCray of Browns Valley, Minn., is an applicant for a franchise for electric lighting at Osakis, Minn.

The St. Cloud (Minn.) street railway finds this a profitable year. There has not been any money expended for removing snow, and the extreme cold has made a large number ride who ordinarily walk. As the company has had hard sledding to keep a balance on the proper side, and frequently has failed to do so, this is pleasing to the management.

The Keelyn & Smith General Electric company of Milwaukee secured the contract to furnish the electric equipment for the municipal electric plant for Boscobel, Wis., at \$2,173.

The Humboldt (Ia.) Electric Light and Power company has been incorporated to establish an electric-light plant.

N. H. Crowell has been appointed receiver for the Sioux Rapids Electric Light and Power company of Sioux Rapids, Ia.

An amicable agreement has been reached at Chippewa Falls, Wis., between the Chippewa Valley Electric Railway company and the Wisconsin Central Railroad company, and all litigation over the disputed right-of-way will cease.

The council committee on electric lighting at Co-

lumbus, Wis., recommends the issuance of \$10,000 bonds for the construction of an electric-light plant.

M. J. Mandelbaum of Cleveland, O., has been granted a franchise in Stillwater, Minn., for the construction of an electric interurban line to St. Paul and Minneapolis; also for a local line. The Twin City Rapid Transit company was also an applicant for the franchise, but refused to construct a local line. Finally, when Mandelbaum came into the field, the Twin City company agreed to the local line, but it was then too late, for the council has agreed to the Mandelbaum proposition.

A reformer in the Superior, Wis., City Council proposed an ordinance making it an offense for any city official to use passes on the street-railway lines. The council voted it down with an overwhelming vote.

The consolidation of all the street-railway companies in Sioux City, Ia., under one management has been effected. There are a number of improvements contemplated.

The council of Neenah, Wis., after favoring first the Citizens' Traction company of Oshkosh and then the Fox River Valley Electric company of Appleton, has finally pledged itself to grant the former company a franchise as soon as the matter can be got into shape to be done legally. The company is also authorized to proceed to award contracts for work and materials.

H. F. Whitcomb and others are desirous of having the franchise for an electric-car system in Fond du Lac, Wis., amended, and offer to construct a system if it is done.

Stilwell & Bierce of Dayton, O., have secured an option on the Apple River Falls water power, near Hudson, Wis., and propose to transmit the power to Stillwater and St. Paul, Minn.

The street-railway company of Sheboygan, Wis., contemplates extending its system to Sheboygan Falls.

Charles Bowick contemplates putting in an electric-light and water-works system in Ward, S. D.

F. R. Lloyd has been granted a franchise for an electric-light plant at Kasson, Minn., and will proceed to put it in at once.

The agents for the St. Louis Water Power company of Duluth, Minn., announce that work will be begun soon to develop the power and transmit it by electricity to Duluth and Superior.

Negotiations have been completed for the consolidation of the Green Bay Gas and Electric, the McCartney Electric Light and the Fox River Electric Lighting companies at Green Bay, Wis., under the title of the Green Bay Gas and Electric Light company.

The Twin City Electric company has been incorporated at Grand Rapids, Wis., to supply light for Grand Rapids and Centralia. The company is co-operative and has a local company to compete with.

The Electric Light, Power and Telephone company of Garner, Ia., has been incorporated, with \$10,000 capital stock.

A stock company is to be formed at Cambridge, Minn., to absorb the Gouldberg and Anderson electric-light plant and enlarge it to meet the needs of all the village.

The street-railway company of Burlington, Ia., offers to make the extension of its lines to West Burlington, as requested, if the council will extend its street-lighting contract for 10 years, and offers a reduced figure for lighting. The company says that the proposed extension will not pay at first, and asks the extension of the contract to make up for the loss which would ensue.

Nathan O. Ross sued the cities of St. Paul and Minneapolis for alleged infringement of a patent electric-magnetic tripping and recovering mechanism, used in releasing horses in fire-department service when an alarm is received. He sued to ascertain the savings, profits and gains accruing from the use of the device. The special master in chancery, Henry D. Lang, heard the case and awarded Mr. Ross damages of \$1 from each city, considering the damages as merely nominal.

The Commercial Club of St. Paul is working to secure the establishment in that city of an electrical supply house.

A resolution was introduced in the St. Paul Council asking the Legislature to pass an act permitting cities of over 100,000 population to prohibit street-car companies from collecting fares from passengers unless the latter are provided with seats and reducing the fares between 6 and 9 a. m. and 5 and 7 p. m. to three cents. It was smothered by reference to a committee, which it was expected would not report until after the Legislature had adjourned.

The Baker franchise for electric power, which has been before the council of Tacoma, Wash., for nearly a year, has finally been granted.

The Tri-city Railway company has asked for an extension of its franchise in Davenport, Ia., for 25 years. The company has bonds falling due soon, and wants its franchises extended in order that it may be in a position to issue new bonds and improve its system.

The Hildreth electric-light plant at Charles City, Ia., has been sold to A. L. Dodd, and will be consolidated with the other electric-light plant there.

A resolution has been offered in the City Council of Superior, Wis., declaring the franchise of the Superior Rapid Transit company void. It cites that

the company has failed to run cars as the franchise requires. The company is in the hands of a receiver at present, and the belief is that it is doing as well as it can under present conditions.

Louis Wiese of Davenport, Ia., picked up a loose wire in the alley behind his livery barn. While carrying it, the wire came in contact with a live wire, and Mr. Wiese fell to the ground at once. Help was near and he was soon released, but not before he received burns on the hands and forehead.

An ordinance has been offered in the Minneapolis council extending the underground district for wires materially, and requiring that the telegraph, telephone and electric wires in the district included shall be underground by July 1, 1900.

The Riceville (Ia.) Electric Light and Power company has been incorporated, with \$10,000 capital stock.

The Citizens' Traction company of Oshkosh, Wis., announces that it will push matters in the construction of the interurban line to Neenah, and expects to have the line in operation by July 1st. George K. Kobusch, president of this company, announces that he has just closed a contract with the Third Avenue Railroad company in New York city to furnish 300 electric cars. Each car is worth \$2,200.

E. A. Young, a prominent St. Paul wholesaler, has applied for a franchise for an electric road from St. Paul to White Bear Lake.

There is talk in Minneapolis of converting the West Side pumping station into an electric-lighting plant. The station has 300 horse power from the water power, which would be quite an aid in furnishing street lighting. Nothing definite has been done in the matter, but the change is under consideration.

Major R. C. Bement of St. Paul has been appointed manager of the Water, Light and Power company of Superior, Wis., succeeding ex-Governor W. R. Merriam of St. Paul. The latter has been appointed director of the census.

The Cannon Falls (Minn.) Electric company announces to its patrons that it is negotiating for the purchase of machinery of about twice the capacity of the present equipment, and expects to have it installed soon.

The Electrical Workers' union in St. Paul will endeavor to have a bill passed by the state Legislature, providing for licensing masters, journeymen and specials.

C. S. Barlow and others have made application to the council of Tacoma, Wash., for a franchise for a street-railway system, to be operated by power from the Snoqualmie water power. The system, as proposed, means the expenditure of about \$100,000 in the city. A counterweight device will be used in overcoming the Seventeenth street hill.

The official report of the city recorder of Moorhead, Minn., for 11 months ended March 1st, shows the water and electric-light plant to have a surplus of \$818, after repairs and new construction to the amount of \$1,133 had been paid.

The differences between the city of Algona, Ia., and the contractor who put in the electric-light plant have finally been settled. The city has all along contended that the engine was not up to the specifications, and the contractor denied it. The latter died recently, and the settlement was with his estate.

The council of Minneapolis awarded the contract to the Minneapolis General Electric company to furnish street lighting at \$108.50 for all-night service and \$82 per light for a moonlight schedule.

The electricians of the Twin Cities, to the number of about 100, sat down to a banquet at the West Hotel, Minneapolis, recently. Toasts were responded to on electrical topics, and a very enjoyable time was had.

The city electric-light plant of Grand Forks, N. D., cost to operate for 46 days, from December 14th to February 1st, \$27,435, running 402 hours and lighting 84 lamps.

A company of Tacoma, Wash., is understood to be preparing to construct a dam and develop water power to produce 40,000 horse power at Lake Tapps.

A number of discharges among the older men of the street-railway employes in Duluth, Minn., leads the men to think the company is trying to break up the union. The company denies any desire to break up the union, and says the discharges were all for cause.

Stone & Webster of Boston have been granted a franchise for an electric line in Hancock, Mich. They propose to build a line to connect the towns in that vicinity, and expect to begin work as soon as the weather will permit.

B. H. McCray will establish an electric-light system in Osakis, Minn. He has been granted a franchise for five years. Work will be begun at once.

The earnings of the Twin City Rapid Transit company in Minneapolis and St. Paul for 1898 were \$2,145,002.05. The net earnings were \$1,010,302.14. The percentage of operating expenses to earnings was 46.96, or, including taxes, 49.92.

There is talk at Rat Portage, Ont., of developing the water power there and transmitting it by electricity to the mines within a radius of 60 miles.

The city of Mayville, N. D., is taking bids, until April 5th, for constructing an electric-light and water-works plant.

The council committee on electric light at Albert Lea, Minn., favored installing a municipal electric-light plant.

There is a proposition to put in an electric-light plant at Holmesville, Neb., to be operated by water

power, from which light would be furnished for Blue Springs and Wymore, Neb.

A bill is before the Minnesota Legislature giving county commissioners the right to allow the building of electric railways along country roads, under certain conditions.

The Twin City Rapid Transit company announces a raise in wages to all conductors and motormen in Minneapolis and St. Paul to 18 cents an hour. Those entering the service will be paid 16 cents an hour for the first six months, 17 cents an hour for the second six months and 18 cents after the first year.

PERSONAL.

A cable dispatch from London announces that Signor Marconi, the distinguished electrician, whose experiments in wireless telegraphy have aroused a world-wide interest, will visit the United States next October.

H. L. Doherty, the president of the Northwestern Electrical association, called on his Chicago friends last week. Mr. Doherty is already planning to make next year's convention of the association the most successful in its history.

W. J. Clarke, general manager of the General Electric company's foreign department, has sailed for Europe. He will remain four months to extend the field of his department and to superintend the installation of General Electric apparatus on London, Bristol and Dublin railways.

Mr. A. P. Trotter, for six years editor of the London Electrician and later electrical adviser to the colonial government at Cape Town, has been appointed electrical adviser to the English Board of Trade—a responsible and difficult position, until recently held by Major Cardew. Mr. Trotter is an engineer of ability and a writer of much force and charm. His friends are congratulating him and themselves on his return to England.

Announcement is made of the marriage of Mr. J. R. Cravath and Miss Ruth Myra Rew, at Grinnell, Iowa, on April 19th. Mr. Cravath is an electrical engineer of Chicago and a well-known contributor to electric-railway literature. The Western Electrician extends congratulations to the young couple, and voices the good wishes of many friends for a happy and prosperous career. Mr. and Mrs. Cravath will be at home at 5519 Monroe avenue, Chicago, after June 1st.

Colonel Danforth Phipps Livermore of Hallowell, Me., probably the oldest telegrapher in the country, died on April 19th. Colonel Livermore was in his 95th year. He had long been identified with the telegraph business, and retired from the management of the office in Hallowell about seven years ago, having been manager and operator for more than 45 years. His daughter was his first pupil, and was, it is said, the first woman to receive or send a message in the United States. His son is manager of the Western Union office at Portland, Me.

ELECTRIC LIGHTING.

According to a Chicago Record correspondent, the municipality of Carlruhe, Germany, is going into the electric-lighting business. It has been decided to erect an electric-light plant and waterworks, for both public and private use, at an estimated cost of 2,500,000 marks (\$595,000).

The Rochester Gas and Electric company held its annual meeting April 18th, at which officers were elected as follows: President, J. Lee Judson; first vice-president, William Runkle; second vice-president, Frederick Cook; treasurer, George Archer; attorney, A. H. Harris; secretary and assistant treasurer, W. L. Cole; directors, J. L. Judson, William Runkle, Frederick Cook, Walter S. Johnston, George Archer, H. G. Runkle, Harry L. Brewster, A. H. Harris, George C. Hollister, Granger A. Hollister, John N. Beckley, George A. Redman and W. L. Cole.

ELECTRIC RAILWAYS.

The New York, New Haven and Hartford Railroad company has undertaken the work of extending its third-rail system between Nantasket and Cohasset. The Nantasket Beach line has been a marked success and this has encouraged the company to apply the electrical equipment over a still greater extent of trackage.

It is now said to be possible to travel from New York to Boston entirely by trolley, with the exception of four small breaks. A recent trip took 49 hours and cost \$2.30 in fare—46 nickel fares. The distance by rail is 217 miles; by trolley it is one-third more, though the railroad fare is more than double what it costs to journey by the electric car. The longest continuous stretch of trolley road was from Boston to Worcester, Mass., a distance of 44 miles.

It is said that the Rochester (N. Y.) Railway company has passed under the control of the Cuyler-Morgan syndicate of New York. The deal, it is reported, was consummated by the syndicate buying up the stock owned by Sellers McKee of Pittsburg. The new owners of the road are said to contemplate the building of an electric line over the Ridge Road from Lockport to Rochester, a distance of 60 miles,

and the completion of the line from Rochester to Sodus Bay, another line of 38 miles.

The Chicago Tribune thinks that consolidation of all the Yerkes street-railway interests may be brought about under the charter of the Consolidated Traction company. There is a proposition now being considered to this end, it says, and the plan partially agreed upon is to consolidate the North and West Chicago street railroads with the lines in the Consolidated Traction company, taking in all of the surface lines on the North and West sides, and to issue bonds in place of the stock of the North and West Side companies.

The street-railway consolidation scheme which contemplates the absorption of half a dozen lines to the north of Boston, with the Lynn and Boston as the Boston terminal line, is progressing rapidly in its plans. If the promoters secure the Gloucester road, which they are after, the projectors will control every transportation line on the North Shore as far as Ipswich. Their next objective point is Haverhill, and thence to Newburyport, taking in the Haverhill, Merrimac and Amesbury and the Haverhill, Georgetown and Danvers companies, the latter having an extension to Rowley and Ipswich.

The Chicago City Railway company is considering the advisability of building an elevated loop from its Halsted or Root street line through the Union Stockyards to the center of "Packingtown." The idea originated with the big packers, and the street-car company has surveyed two routes for the proposed structure. The elevated structure, as proposed, is to carry a double track. Transfers are to be issued from the cars on this loop to all lines of the Chicago City railway. The Chicago Livestock Exchange favors the plan. The death of President Bowen has made it uncertain when the plan will be perfected.

ELECTRIC VEHICLES.

The International Automobile and Vehicle company has bought the tire factory of L. C. Chase & Co. of Boston and Chelsea and the Newton Rubber Works of Newton Upper Falls, where pneumatic tires are made.

The 10 per cent. paid in on the capital stock of the New England Electric Vehicle company, amounting to \$1,500,000, will be devoted to the construction of 600 electric vehicles for a starter and six power stations, it is stated.

It is announced that papers have been prepared for the incorporation of the Boston Auto-truck company, with capital of \$10,000,000, to engage in a general trucking business in Boston. As soon as this concern has been incorporated it is proposed to form the Massachusetts Auto-truck company, also capitalized at \$10,000,000.

The motor-carriage department of the Pope Manufacturing company of Hartford, Conn., has charge of the manufacture of the Columbia automobiles, and although it is generally known that business in this line has increased wonderfully within the last few months, the visitor is hardly prepared for the amount of machinery which a visit to this factory reveals. Mr. Goodrich, the manager of the Pope company's motor-carriage department, is much impressed by the extraordinary development of the business. He says that in this department 350 men are at work, in day and night shifts. The company is also erecting a new building, and when this addition is completed 200 additional hands will be employed. J. M. Hill, formerly of Chicago, is connected with the sales department for the Columbia automobiles in New York, and he is very enthusiastic over the actual business secured and the outlook for the future. He predicts a great development of the motor-carriage industry.

PUBLICATIONS.

The lighting transformers of the S. K. C. system are the subject of Bulletin No. 101 of the Western Electric company. The general features, regulation, efficiency and insulation of these transformers are described in a handsome eight-page circular. There are also observations on frequency, aging of iron and the use of oil. The illustrations in this bulletin are particularly fine.

The new price-list of N. I. R. rubber-covered and other insulated wires gives data for the different sizes, including the new standard requirements of insulation. The amendments to the National Wiring Code adopted at the recent meeting of insulated-wire men, electricians and fire underwriters in Chicago are given in the pamphlet, which is issued by the National India Rubber company of Bristol, R. I.

Dr. Franz Peters has compiled and the house of Arnold Bergstrasser of Stuttgart has published a manual of the "Progress of Applied Electro-chemistry and of the Acetylene Industry in the Year 1898." The volume contains 412 pages and 63 illustrations in the text and seems to have been prepared with German thoroughness. The development of the various electro-chemical arts is carefully indicated under appropriate headings, and there are indexes of subjects, names and patents.

On May 1st Charles H. Besly & Co.'s new 1899 catalogue will be ready for distribution, and will be sent free to any address on application. The firm

calls special attention to its revised list on all metals that will appear in this book. Furthermore, all lists have been corrected to agree with the present market. Among the new additions to the catalogue may be mentioned the Badger die stock set complete, Besly adjustable tap-wrench, new Brown & Sharpe tools, new Starrett's tools, laboratory specialties, Gardner grinders, Tanite grinding machines and emery wheels, Pecora machinery prints, Perfection and Bonanza oil cups and Helmet oil.

POWER TRANSMISSION.

The El Dorado Power company of San Francisco has been incorporated for the purpose of furnishing electrical power. The capital is \$150,000, and the directors are G. Lambert, H. O. Marvin, W. A. Bell and C. O. Richards of San Francisco.

The Spokane, Wash., Spokesman-Review says that the Washington Water Power company will make extensive improvements to its plant this spring. Work has been commenced. A new brick-and-stone power house will be erected; a new flume will be constructed, and two water wheels and two new dynamos of 1,000 horse power each will be installed.

A Stockton, Cal., dispatch says that the pole line of the Blue Lakes power plant is now completed from Stockton to Mokelumne Hill. It is expected that power equal to 5,000 horse power will be delivered in Stockton over four wires in 30 days. The survey for the line to Oakland is going forward rapidly. If the aluminum wires are entirely successful, the remainder of the great system will be completed in the same manner; if not the company will fall back on the copper wire.

The Tonawanda (N. Y.) Cataract Power company and the Tonawanda Lighting and Power company have been consolidated under the name of the Tonawanda Power company, and with these officers: President, Charles A. Sweet of Buffalo; vice-president, George Davenport of Boston; secretary-treasurer, DeLancey Rankine of Niagara Falls. The directors are C. A. Sweet, E. A. Wickes, William B. Rankine, DeLancey Rankine, C. B. Hill, G. W. Davenport, J. H. Rockwell and F. S. Smith.

B. N. Duke and Julian S. Carr of Durham, N. C., S. T. Morgan of Richmond, Va., and other capitalists have purchased the water power at Lockville Falls, near Lockville, N. C., together with several hundred acres of land adjoining. The purpose of the purchasers, it is said, is to develop thoroughly the 6,000 possible horse power available, erect an electric plant for transmitting the power, build a cotton factory and otherwise industrially promote the property. It is stated that several million dollars will be expended.

The Sacramento (Cal.) Electric, Gas and Railway company has made a contract with the Yuba Electric Power company for the exclusive use of 5,000 horse power for 30 years, the power to be delivered at the power house of the Sacramento company in Sacramento. The plant of the Yuba Electric company will be improved. The dam at the head of the flume will be very substantial. The power station is to be built entirely of stone, and designed so that its aggregate capacity can be brought up to 15,000 horse power. A reservoir will be located two miles back of the power station, which will have a capacity of 100,000,000 cubic feet. This will be connected with the forebay of the power station by two miles of pipe.

The Niagara Electric company of Niagara Falls has been awarded the contract for building a power house and dam for the new plant of the Albion Power company at Waterport, N. Y.; also for equipping the station, reconstructing the line, etc. The power house will contain two three-phase, 60-cycle generators, one of 100 kilowatts, the other of 150 kilowatts. Transformers will be installed to raise the current to 6,600 volts for transmission to Albion, a distance of seven miles, where the present power house of the company will be converted into a transformer station. It is understood that the conductors of the transmission line will be of bare aluminum instead of copper. A 75 horse power synchronous motor will also be placed in the Albion station. W. L. Adams will be in charge of the work. Wallace C. Johnson of Niagara Falls is the engineer of the Albion Power company.

A Toronto dispatch, dated March 31st, says: "In the Ontario Legislature to-day Premier Hardy took steps looking to a transfer to another corporation of the exclusive right to develop the water power on the Canadian side of the Niagara River. In 1892 the Canadian Niagara Falls Power company secured this monopoly, agreeing to pay \$25,000 a year for fifty years for it and to make certain improvements which were to be completed by November next. It has failed so far to make the required improvements, hence the movement to annul the monopoly. An American syndicate, in which ex-State Comptroller Roberts of New York and Mr. Belden of New York city are interested, is preparing to develop the power on the Canadian side of the river. It is said to have made arrangements with certain companies that intend to use 15,000 horse power to manufacture goods for sale in the British colonies."

TECHNICAL SCHOOLS.

The School of Civil Engineering at the New York University has expanded into a school of applied

science, with four distinct departments, a considerably increased income, and the prospect of suitable housing.

The annual catalogue of Purdue University of Lafayette, Ind., shows that 730 students are now attending this flourishing school, which is really Indiana's state institute of technology. The course in electrical engineering, in charge of Professor W. E. Goldsborough, is of four years' duration, practical and thorough. Particular attention is given to the designing of electrical machinery and appliances. A separate building is devoted to the departments of engineering and physics and is well equipped with machinery and apparatus. Purdue University is a state institution, and tuition is free to students who are residents of Indiana. Other persons desiring to attend are directed to apply to the president of the faculty. Moderate fees are charged to cover the actual cost of materials supplied in the various laboratories.

ELECTRICAL SECURITIES.

The Chicago Record notes that on account of the continued high prices of municipals and the consequent low net-interest return, there has been a broad market developed for bonds of electric-light companies in the large cities. A Chicago firm of bond brokers recently placed \$1,100,000 Cincinnati Edison gold fives at 106 1/4, and the recent issue of \$1,700,000 New Orleans Edison gold fives was oversubscribed, and the bonds are now selling at about seven per cent. premium. Judging from the market for Chicago Edison bonds, which have recently sold at 111, or a 3 1/2 per cent. basis, there ought to be a good demand for similar bonds from other cities. The Commonwealth (Chicago) gold fives, which were brought out last fall, are now said to be in good demand at a substantial premium. The electric-light business of Chicago is on such a substantial basis that investors seem to have considerable confidence in such securities.

Five per cent. 30-year gold bonds, to the extent of \$1,100,000, are being marketed by Chicago bankers for the Missouri Edison Electric company. They are part of a series of \$4,000,000 secured by blanket mortgage on the whole property. Mr. Samuel Insull, president of the Chicago Edison company, reported on the property as follows: "St. Louis is an extremely good electric-lighting city. The population is estimated at 600,000. It is compactly built. The people are substantial, and the tendency is to use electric light in both the business and residential districts. The company has the great advantage that its system reaches generally throughout the city, and also the fact that the climatic conditions are such that it is a very desirable thing to use an illuminant that does not throw off a great deal of heat. The property, as a whole, is a good one; the outlook for the business in the future is promising, and the company's earnings should show a steady increase from year to year."

FOREIGN ELECTRICAL NOTES.

The municipality of Teplitz, Bohemia, has called for bids for the establishment of a municipal electric works.

A hanging railway over the Seine will be one of the attractions of the Paris World's Exhibition. The railway will connect both banks of the Seine and be driven by electricity.

The Montan und Metallindustrie Zeitung of Vienna says that a stock company has been formed in Thorn, Germany, under the name of Electricitäts-werke Thorn with a capital of \$357,000.

Electric light has been put into the Vatican, and was used for the first time on February 20th. The total number of lamps is 6,000. The pope is reported to have said that "no one can say now that the Vatican is an enemy of enlightenment."

The palaces of the queen of England have all been provided with electric light. The queen long opposed this, but her Scotch palace at Balmoral and Buckingham Palace in London had installations put in last year, and Windsor palace was connected with the town station early this year.

A syndicate has been formed by the Mediterranean Electricity company (Thomson-Houston), the Societe Generale Belge d'Enterprises Electriques and the Societe Financiere des Transports d'Enterprises Industrielles, with \$600,000 capital, to furnish electric-motor street cars in Bologna, Italy.

A Cape Town newspaper says that "the demand for electric lighting in Cape Town appears to be considerably on the increase. We learn that one firm of contractors, Messrs. Bull & Sinclair, have secured the following large contracts, namely, Ronderbosch town hall, the new premises of the Cape Times, the permanent lighting of the opera house, the extension of Stuttford & Co. and Messrs. Duncan & Co.'s new premises in Adderley street. The work is being carried out by the firm's electrical manager, Mr. Morton."

"Preparations for the introduction of the electric light into Calcutta are going on apace," says the Calcutta Pioneer. "Mains are being laid, and the central station, where 1,500 horse power will be employed in generating the current, is approaching completion, though the whole of the apparatus has not yet arrived. Excellent accounts are being received

of the efficacy of the electric fan, the difficulty which first existed, of regulating the draft, having apparently been completely overcome by a simple arrangement for changing the angle of the blades of the fan, making it possible by doing little more than touching a button to produce anything from a 'norwester' to the gentlest of zephyrs. If this be the case, it will indeed be a boon to perspiring Calcutta in the rains, and may be expected to widely replace the coughing, slumbering punkah coolie. The engines, powerful as they are, which are being set up, will be entirely devoted to the production of the electric light and the driving of electric fans, a further installation being contemplated for the trams, when these come to be driven by electricity."

INDUSTRIAL COMBINATIONS.

It is said that plans are maturing for the consolidation of the several iron and steel interests. It is said that the capitalization of the consolidated company will exceed \$500,000,000.

The United Power Manufacturing company, with an authorized capital of \$12,500,000, was incorporated in Trenton, N. J., on April 20th. The company has for its purpose the merging of the Reading, Lebanon, Chestnut Hill and Roxborough electric railways, and to eventually connect Reading and Philadelphia by trolley. Richmond L. Jones of Reading is at the head of the corporation.

The gas and electric-light interests and all except one of the street railways of Washington, D. C., have been absorbed by a syndicate headed by Frederick C. Stevens. A deposit of \$250,000 has been made with the Fourth Street National Bank of Philadelphia to secure a consummation of the sale of the gas company. The gas deal involves an expenditure of about \$7,200,000, all of which the syndicate obligates itself to pay upon what are substantially cash terms. Including the gas deal, the holdings of the syndicate in Washington represent \$30,000,000.

A new electric-railway promoting company, which is to be called the American Railways company, and is to have an authorized capital of \$25,000,000, was incorporated in New Jersey on April 19th. The company is empowered to "build, construct and operate electric and other railways." The incorporators are Frank R. Hansell, George H. B. Martin and William S. Eidell, all of Camden, N. J. The real interests of the company are said to be represented by William F. Harrity, William H. Shelmardine, James J. Sullivan, Edward J. Matthews, Edward Lee, A. A. McLeod and Silas W. Pettit of Philadelphia. While the question of officials has not been definitely settled, it is said that A. A. McLeod will accept the presidency. The first assessment will give the company \$1,250,000 to begin business, and the remaining shares will be issued as occasion requires. The business of the company will be confined to the purchase and control of existing electric railways throughout the country.

MISCELLANEOUS.

A new plan for raising sunken cargoes of metal, such as steel rails, will shortly be tested in the Delaware Bay, if the Philadelphia Record tells the truth. A suitable crane boat will be equipped with dynamos and large electro-magnets incased in water-tight coverings, capable of lifting 4,000 pounds each. The magnets will be lowered to the sunken cargo from cranes and connected to the dynamos by flexible cables. They are expected to lift the submerged metal with ease. It is also claimed by the inventor that by letting magnets drag over the beds of channels valuable cargoes which have lain submerged for years can be located.

The Chicago Chronicle says that engineers and their engines are to be separated hereafter on the Chicago, Milwaukee and St. Paul and the Atchison, Topeka and Santa Fe railroads. All engines will be pooled and run continuously, regardless of the engineer in charge, instead of being run by one driver and lying up in the roundhouse while he sleeps. Since the time when railroading began engines have been assigned to particular men. But in the interest of business, traditions are to be thrown to the winds by the pooling plan. It is a fact not generally known that the railroad companies lose thousands of dollars every year by adhering to the custom of keeping one engineer to an engine.

The Vienna correspondent of the Chicago Record telegraphs that Vienna's new system of urban and suburban railways is now assured. The Official Gazette publishes the text of the concession from the minister of railways, Dr. von Wittek, to the Siemens & Halske company for the construction of a network of subways under the business center of the city, the lines which run in these subways rising to the surface in the less congested districts and changing from underground trolley to overhead trolley when the suburbs are reached. Vienna has now 30 metropolitan horse-car lines. In place of these, 60 urban and suburban electric tramways will be constructed, the work of transformation taking, it is expected, about five years.

The London Telegraph relates that at the Westminster County Court a claim was made for payment for making an electric table for a bear to dance on. The animal stood on the structure, the music played and an apparatus placed under the boards gave forth electric shocks which caused the bear

to dance. The claim was disputed on the ground that the current was not strong enough to make the animal dance sufficiently, but the electrician said that the defendant had told him that as bears had very tender feet, the shock required would not be so strong as that required to make a human being jump. Both he and the defendant were "shocked" on the table before the bear was put on it. The court gave judgment for the plaintiff.

TRADE NEWS.

The Aaron Electric company, 141 South Canal street, has taken the Chicago agency for the Eagle Electric Works of Peoria, Ill.

The American Electric Manufacturing company of Philadelphia has been incorporated in Delaware to manufacture all kinds of electric motors, engines, etc. The capital stock is \$1,000,000.

F. H. Whitman, Samuel H. Couch and E. B. Seeley have incorporated a company for the manufacture of electrical appliances in Boston. The capital is \$10,000. The name of the concern is the Couch & Seeley company.

Mr. J. H. Cooke, western representative for the Buckeye Electric company, gives notice that the office of his company will be moved from the present location to room 1537 Monadnock building, Chicago, on May 1st. He reports an excellent demand for the Buckeye incandescent lamp.

The Western Electric company is installing in Hillman's department store, Chicago, one 60 kilowatt and one 100 kilowatt 110-volt generator and a two-panel five-circuit switchboard. One hundred and twelve Petite arc lamps and 1,500 incandescent lamps will be used for the interior illumination of the store.

The Charles E. Gregory company of Chicago has found it necessary to enlarge its quarters, owing to the steady increase of its business, and has leased the building located at 54 and 56 South Clinton street, next door to its present location. The reputation of the Gregory company for ability to supply anything in the second-hand line is widely extended.

The Western Electric company of Chicago is making fire-alarm boxes, and has just secured an order for 50 keyless boxes from the city of Chicago. The price for each box is \$65. Other companies made these tenders for the same type of box: United States Fire and Police Telegraph company, Boston, \$90; Gamewell Fire-alarm Telegraph company, New York, \$135.

A Cleveland dispatch states that the National Carbon company has raised the wages of about 400 men employed in its West Madison avenue plant in that city. The advance ranges from five to 15 per cent. Prior to the announcement of the increase a strike was threatened. Some of the men are satisfied with the new scale and some are not. It is estimated that about 50 men dissatisfied with the new rate left the company's service upon the posting of the wage-scale.

Since the first of January, it is claimed that the foreign business of the General Electric company has increased more than 100 per cent. over the corresponding period last year. This branch alone, it is estimated, will aggregate \$4,000,000 for the current year. Last year the total business was at the rate of \$1,500,000 a month. So far this year it is at the rate of nearly \$2,000,000 a month. All departments at Schenectady are working night and day, and orders are said to be six months ahead of the capacity of the works.

The annual meeting of the stockholders of the Joseph Dixon Crucible company was held at the company's main office, Jersey City, N. J., on April 17th, and out of a possible vote of 7,345 shares there were 7,069 shares voted for the re-election of the old board, consisting of Edward F. C. Young, John A. Walker, Daniel T. Hoag, Richard Butler, William Murray, Alexander T. McGill and Joseph D. Bedle. President E. F. C. Young, Vice-president and Treasurer John A. Walker and Secretary George E. Long were re-elected by the directors. Judge Joseph D. Bedle was also re-elected as counsel.

BUSINESS.

The Garton-Daniels Electric company of Keokuk, Ia., reports a good business in Garton lightning arresters. It calls attention to a new railway type of pole arrester, mounted on a porcelain base and enclosed in a wooden box, which is fitted for attachment to a pole.

The Ball Engine company of Erie, Pa., has recently sold Ball engines for electric plants to the L. Wolff Manufacturing company of Chicago and the Jones Bros. Electric company of Cincinnati, and also for the Parlin & Orndorf building of Kansas City and Ayers & Son's store in Philadelphia.

J. G. Hickey, secretary of the Cutler-Hammer Manufacturing company, Chicago, states that the month of March was the best for business in the history of his company. The Cutler-Hammer company's well-known rheostats, controllers, etc., are in use in every civilized country, and they are giving the best of satisfaction.

The season for thunderstorms is at hand, and the Electric Appliance company is reminding the station manager that it is high time to look for lightning

protection. The company has prepared a complete catalogue of Garton lightning arresters, which it will be glad to send on application. The Garton lightning arrester has a long record of success, and is one of the best known lightning protectors on the market.

The Electric Machinery company has leased the premises at 135, 137 and 139 South Clinton street, Chicago, and will handle a complete line of dynamos, motors and arc lamps, both new and second-hand.

It will also make a specialty of rebuilding machinery. This company recently installed for the Slag and Gas company, Hammond, Ind., two 100-kilowatt, specially wound alternating-current generators, to be used in the manufacture of calcium carbide from slag.

The Western Electric company, in addition to its fan motors, is also building a complete line of power motors from 1-36 horse power up to 15 horse power in the encased and semi-encased open-type

style, and larger sizes in the open-type style. The same company directs attention to its large supply of Samson spot cord. This cord is especially adapted for the suspension of arc lamps, for use as bell ropes in cars and for trolley cord. Its smooth and pliable finish, combined with durability, lightness and strength, recommend it for many uses. A sample of this cord will be mailed to anyone in the business by applying to the Western Electric company.

ILLUSTRATED ELECTRICAL PATENT RECORD.

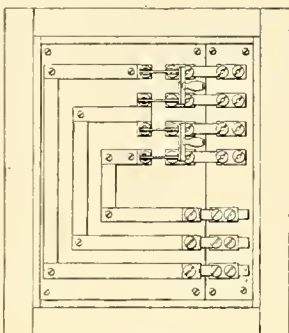

Issued April 18, 1899

623,136. Safety Cable System for Electric Railways. Harry B. Cox, New York, N. Y. Application filed February 12, 1898.

An important feature is an insulated grooved conduit having insulated conducting sections, with a continuous live conducting wire loosely and movably arranged in the conduit and without mechanical connections which would prevent its free movement.

623,141. Apparatus for Starting Electric Elevators. David H. Darrin, Cranford, N. J. Application filed August 1, 1898.

An auxiliary circuit is connected with the motor and an auxiliary switch controls the circuit. A rope leads to the car and is connected with the switch. When pulled the rope will close the switch and when released the switch will be allowed to open. A working circuit is connected with the motor, and means operated from the car for simultaneously shifting the belt of the motor to the tight pulley of the apparatus, releasing the brake and closing the working circuit.

NO. 623,172.

623,142. Electric Elevator Switch. David H. Darrin, Cranford, N. J. Application filed August 1, 1898.

In a switch the combination of a pivoted carrying blade and one or more straight contact jaws located within and at a tangent to the circle of movement of the blade, the end or ends of the jaws extending beyond the circle.

623,172. Junction Box. Thomas J. Murphy and Benjamin F. Neilson, New York, N. Y. Application filed December 9, 1898.

An improved junction box has a removable section carrying the conductors which connect the main circuit with one or more consumption circuits, terminals on the removable section, stationary terminals carried by the junction box and flexible safety fuses connecting the stationary terminals with the movable terminals.

623,195. Electric Accumulator. Alexis Werner, London, England. Application filed July 12, 1898.

In this accumulator the electrolyte consists of a solution of sulphates of magnesium, cadmium and of a zinc, with a positive formed of a metallic support on which alloy is electrochemically deposited from such solution and with a negative constituted of a leaden grid having covering fabrics of lead wire gauze burned to the grid and embedded in the active material on both faces on the grid.

623,223. Electric-railway System. Wilhelm Stein, Hamburg, Germany. Application filed October 3, 1898.

The combination with a plurality of controllers is described of a plurality of constantly running motors, each controller being associated with a motor, and means for simultaneously engaging the motors with and disengaging them from the controllers.

623,242. Means or Apparatus for Producing and Exhibiting Animated or Changing Pictures on Advertising Appliances, etc. William Friese-Greene, London, England. Application filed July 7, 1898.

A hat having a body of translucent material in combination with a cylindrical picture-bearing sheet within the body, a cylinder concentric with the cylindrical picture-bearing sheet situated between it and the hat body, and having equidistant openings around it, a lighting device in the hat body, and means for simultaneously imparting rotation in reversed directions respectively to the picture-bearing sheet and the cylinder.

623,275. Electric Letter for Signs. Charles A. Chauncey, Chicago, Ill. Application filed April 8, 1898.

A letter for signs and the like, comprising a face provided with a series of spaced openings arranged to form the letter desired, a casing connected with the face, a back attached to the casing, and a series of electric-light sockets between the face and the back, the ends of the sockets projecting into the openings in the face, the back and face engaging the sockets so as to hold them in position without the aid of other holding devices.

279. Arc Lamp. Thomas E. Drohan, Chicago, Ill. Application filed August 8, 1898.

The arc lamp described has a clutch mechanism serving to support the upper carbon, a clutch-releasing device pivotally mounted in the lamp, the device having a part normally engaging the carbon, whereby the arms are held in position to release the clutch mechanism, the device being adapted to swing out of its releasing position and support the carbon in its final position within the clutch when a predetermined portion has been consumed.

623,203. Electrically Connected Printing Machine. Christopher A. Shea, Milton, and John J. O'Lalor, Medford, Mass. Application filed April 20, 1896.

The system of electrically connected printing machines includes a mechanical typewriter containing a mechanism which is moved from a determinate position one definite distance farther by the depression of each succeeding key of the machine, and which is restored to a determinate position upon the release of the key, a series of contacts over and upon which the mechanism passes, a source of electricity and a live wire.

623,316. Induction Apparatus. Thomas B. Kinraide, Boston, Mass. Application filed May 5, 1898.

A magnetic core and a coil adjacent thereto are essential features, the core presenting curved surfaces adjacent the coil, curving therefrom in a direction away from the coil, whereby the lines of magnetic force leaving the core perpendicular to the surfaces are widely distributed about the coil.

623,317. Electrical Break. Thomas B. Kinraide, Boston, Mass. Original application filed May 5, 1898. Divided, and this application filed September 24, 1898.

An electric break comprises an arm carrying a hammer, an anvil opposite the hammer, the arm being yieldingly supported and provided with means for regulating the tension or resistance thereof, an interrupter for engaging the free end of the arm, and automatic means operated by the current being broken for driving the interrupter.

623,318. Electrical Spark Gap. Thomas B. Kinraide, Boston, Mass. Application filed September 24, 1898.

A spark gap of the kind described for use in a condenser circuit presents opposite parallel discharge surfaces of relatively large areas and means for regulating the discharge distance between the parallel surfaces, whereby a condenser charge may be automatically governed.

623,329. Electric Arc Lamp. Adolphe Mougin, Paris, France. Application filed October 21, 1898.

In an electric arc lamp there is the combination of a pivoted frame, clock mechanism supported thereby, the same comprising a spring barrel provided with an arbor, a ratchet wheel on the arbor of the barrel, a train of gears operated from the arbor and a pawl pivoted on one of the gears and taking into the ratchet wheel, and a pinion on the arbor, with a starting electro-magnet, an armature carried by the pivoted frame and adapted to be attracted by the electro-magnet, an endless chain passing over the pinion, carbon holders operated by the chain, and a brake acting on the train of gears and suitably operated from a derived circuit.

623,352. Duplex Switch for Telephones. George C. Buell, Boston, Mass. Application filed August 15, 1898.

A two-part switch lever for telephone apparatus, one part of which is movable independently of the other in one position of the latter, and moved and controlled by the movement of the latter, and means as springs normally tending to move the two parts in opposition to each other.

NO. 623,195

623,363. Electric-light Hanger. William Gerth and Frederick Peters, Newark, N. J. Application filed October 13, 1898.

An electric-light hanger, comprising a hanger box having on two opposite interior walls similarly disposed integral curved ribs each approximately semi-circular with an extension on the convex side, a pulley arranged vertically above the ribs, a single supporting rope passing over the pulley, and a suspending link attached to the rope and having an approximately spherical enlargement of a diam-

ter greater than the distance between the ribs and a shank small enough to pass therebetween, the lower end of the link being perforated for attaching a lamp.

623,383. Motor-vehicle. Francis A. Pocock, Philadelphia, Pa. Application filed April 13, 1898.

In a vehicle the combination with the body and the rear running gear of the front running gear pivotally connected to the vehicle whereby it can be used for steering, the electric motor below the vehicle body, and movable vertically relative to the running gear, and power-transmitting devices for connecting the motor to the front wheels.

623,393. Electric Current Controller. James B. Breeding, San Antonio, Texas. Application filed August 13, 1898.

NO. 623,316.

An electric-current controller, comprising a number of resistance blocks arranged in the form of a cylinder and connected in series, caps of insulating material between which the blocks are arranged, a rod extended longitudinally through the blocks but insulated therefrom and forming a portion of an electric conductor, a contact carried by one of the caps and adapted for electrical connection with the blocks and a conductor leading directly from one of the blocks.

623,433. Electric Fan. Samuel L. Shellenberger, South McAlester, Indian Territory. Application filed April 21, 1898.

Claim is made for the combination of a support, a sleeve, a central shaft, rotatable in the sleeve, a motor having a rotary fan, a frame for the fan, having a ring or band provided with face brackets, and the blades extending across the face of the fan and secured to the face brackets.

623,437. Telephone-switchboard Circuit. Edwin H. Smythe, Freeport, Ill. Application filed February 23, 1898.

The switch-plug and cord-circuit connection comprises two terminal switch plugs, each having two main contact surfaces adapted to engage spring-jack contacts, two inductively continuous but conductively discontinuous main-lead conductors extending respectively between the corresponding contacts of the plugs, and a disconnecting signal device for each of the conductively divided cord-circuit sections, bridged between the two strand conductors of its own section.

623,441. Automatic Fire and Burglar Alarm. Henry E. Thompson, Cameron, N. C. Application filed April 16, 1898.

A main-line conductor is normally energized by the battery. Electric alarms are included in circuit with the conductor and the battery. Fusible conductors are in circuits that are short to the alarms. An office alarm is controlled and operative by the breaking of any of the fuses. A second battery is provided and means for manually introducing it into the circuit of the other battery.

623,444. Electric-railway Signaling Device. Daniel Valentine, Brockton, Mass. Application filed September 23, 1898.

Features of this invention are: Movable rail contacts or switches, a source of electrical energy or line feed, solenoids, semaphores or signals, solenoid bars within the solenoids and operatively connected to the semaphores, springs for actuating the bars in opposition to the solenoids, automatic locking devices for the semaphores, solenoids for releasing the locking devices, and circuit-closers actuated by the bars for automatically conducting the current from one of the solenoids to the other one in the system.

623,480. Electric Cigar Lighter. William F. Kessler, Auburn, Ind. Application filed October 17, 1898.

An electric cigar-lighter consists of a horizontally arranged containing case or shell pivotally mounted in or from a proper support, and provided with a suitable opening in its upper face for the purpose specified, a pendant wick tube and oil reservoir fixed in the shell, a hand lever pivotally fulcrumed on the reservoir carrying an extinguishing cap upon its inner end in co-operative relation with the burner of the wick tube, and provided with a pivoted sparking device adapted to throw the ignition spark within the shell, and means for normally securing the lever in position.

CHICAGO, MAY 6, 1899.

No. 18

Great Northern Electrical Plant.

The Great Northern buildings on Jackson, Dearborn and Quincy streets in Chicago consist of five connected and adjoining structures bearing a common name and conducted, in a general way, under one management. These are the Great Northern Hotel, on Dearborn street; the Annex to the hotel, on Quincy street; the Great Northern baths, also on Quincy street; the Great Northern office building, on Jackson street, and the Great Northern Theater, between the office building and the Annex and with entrances from both Jackson and Quincy streets. The picture (Fig. 5, page 252) shows the older portion of the hotel and the office building, the frontages being on Dearborn and Jackson streets. The buildings are erected about a central court over the theater. With the exception of the bath-house they range from 14 to 18 stories in height, the latter on the interior court, where a palm garden on the Annex and a roof garden on the office building add to the height. The street frontages are: Jackson street, 200 feet; Dearborn street, 167 feet; Quincy street, 225 feet. In the hotel establishment there are three kitchens, five large dining-rooms and a large number of rooms for private dinner parties, seven bar-rooms and 618 sleeping rooms.

A lavish use of electric light is made in the Great Northern buildings, both for general illumination and for advertising and embellishment. All told, the buildings are wired for 18,000 incandescent lights, mainly of 16 candle power each, as well as 34 low-tension arcs and 46 horse power in electric motors. Formerly the load was carried on central-station mains, but within the last few weeks a private plant has been put in operation, and this installation now furnishes about all the current needed for light and power. Owing to the character of the buildings supplied, only a comparatively small proportion of the lights connected are apt to be thrown on the machines at one time. The large office building, for instance, is practically deserted before the demand for theater lighting commences. Thus, the generating plant installed is only about half that which would be required to operate all the lamps and motors at once.

The new steam and electric plant is on the Quincy street side of the buildings, in the basement. Steam is raised in three boilers of the Scotch marine type (Fig. 2), each 92 inches in diameter and 20 feet long and rated at about 250 horse power. Each boiler is equipped with two Morrison suspension-flue furnaces and has 92 three-inch flues. An ordinary quality of soft coal is burned for fuel. Draft is obtained by a 250-foot stack, all in the building except about 30 feet, which projects above the roof. These boilers supply steam at 150 pounds initial pressure for the dynamo engines, some of the elevator pumps and kitchens and the Great Northern baths. They are provided with a four-inch covering of magno-bestos block. The Scotch type of boilers is not often seen in isolated plants in the West, but these provide a large amount of power in comparatively small space. They were built by the Phoenix Iron Works company of Meadville, Pa.

Exhaust steam is used for heating. The Irving steam-loop system is installed, and all drains are automatically returned to the boilers. The boiler and house pumps were built by the Laidlaw-Dunn-Gordon company of Cincinnati, and are of the tandem-compound type. There are 12 hydraulic elevators in the buildings and four elevator pumping engines—one Crane, one Worthington and two Dean. The elevators in the newer buildings are operated at a water pressure of 250 pounds to the square inch; those in the older portion of the hotel at 85 pounds to the inch.

On the Jackson street front of the buildings there is another and older steam plant, quite distinct from

the one illustrated and having no connection with the electrical plant. It consists of tubular boilers of 320 horse power, supplying steam to elevator pumps, house pumps, laundry machines, steam power fans, kitchens and numerous small engines and air compressors. The exhaust from this plant is also used for heating. It is interesting to note that in all the buildings there is no less than 124,000 square feet of radiating surface in 2,500 radiators. The combined capacity of the steam-generating plants is 1,070 horse power.

Three engine-dynamo units supply the electric current consumed in the building. They are placed under the pavement of Quincy street, the excavated space extending to the center line of the street. They are illustrated in Fig. 1, and, as the picture shows, they are very compactly fitted into the space assigned to them. Ball cross-compound, horizontal, non-condensing engines of 250 horse power each are directly coupled to 150-kilowatt Western Electric multipolar generators, wound for 115 volts.

Front and rear views of the marble switchboard are shown in Figs. 3 and 4. The board is fitted with Weston instruments and switches of the latest type. The distribution system of the buildings is on the three-wire Edison system, but the machines are con-

FIG. 1. GREAT NORTHERN ELECTRICAL PLANT.—ENGINE-DYNAMOS.

nected to the board by the ordinary two-wire leads. The transformation is effected on the back of the board and not at the centers of the wiring distribution, as is sometimes the case.

The total number of arc and incandescent lights has been already given. It may be mentioned that there are about 1,800 incandescent lamps of 10 candle power each in theater and hotel signs alone. In the hotel there are a number of large oil paintings, and over 360 lamps are studded in the frames of these pictures to obtain special illuminating effects. There are 10 electric motors, ranging from three to eight horse power each, used to drive ventilating fans and for the machine shop connected with the plant, a dishwashing machine, the organ pump in the hotel lobby and the fountain pump and water systems of the palm garden on the eighteenth floor of the Annex. The heaviest load on the plant comes about 9 p. m., and the maximum so far recorded is about 2,400 amperes.

Mr. Alexander Davidson, one of the principal owners of the Great Northern property, has taken a great interest in the new plant, which was installed largely through his efforts. F. W. Cole is the chief engineer.

It is asserted that an Austrian engineer named Pollak has made a discovery rendering it possible to telegraph 1,000 words a minute over a single wire. But a Washington dispatch says that the synchrograph of Squier and Crehore was tested in General Greely's office in the War Department last month and that a speed of 2,000 words a minute was attained.

\$10,000 Damages for an X-ray Burn.

In September, 1895, Frank V. Balling of Blue Island, Ill., was thrown from a buggy and the bones of his ankle were dislocated and broken. He is a large, stout man, and the doctors were unable to diagnose the injury with sufficient accuracy to effect a cure. A year later, on September 19, 1896, acting on medical suggestion, Mr. Balling went to the Röntgen X-ray laboratory in Chicago managed by Mr. W. C. Fuchs to secure a skiagraph of the damaged joint. This was but a few months after the first experiments in this country with the X-ray, and practitioners were still in large measure ignorant of the best and safest manner to handle the radiation when permeating human tissues. As shown by sworn testimony later, three exposures were made, varying in duration from 30 to 45 minutes each, and the Crookes tube was but six inches from the skin of the foot. At the present time, in the same laboratory, no exposure of over three minutes is made, and the tube is placed 12 or 15 inches from the flesh. Mr. Balling swore that at the time of the long exposures to the X-ray he experienced a tingling sensation. A few hours afterward the skin became discolored over the exposed surface and blisters formed. Then, according to

testimony, the deeper tissues showed that they were affected; the flesh decomposed and sloughed away. Later there were two amputations to remove the dead bone and tissue—one at the ankle, and later at a point five inches below the knee. After the last amputation Mr. Balling recovered.

Through his attorneys, Stirlen & Dickson, Mr. Balling brought suit against Dr. Otto L. Schmidt, principal proprietor, and W. C. Fuchs, manager, of the X-ray laboratory, for \$25,000 damages for the injuries that he claimed to have sustained as the result of the improper use of the X-ray. The case was tried from April 17th to April 27th, before Judge Chetlain and a jury. It was bitterly contested and turned largely on the expert testimony of scientific men and physicians, which was entirely contradictory. The X-ray expert for the plaintiff was Professor H. P. Pratt, while Dr. John P. Webster, Dr. Bacon, Dr. Robert L. James and Dr. Evans gave evidence on that side as physicians.

For the defense it was claimed that the serious injury to the deeper tissues did not result from the X-ray burn on the skin, if there was one, and that the plaintiff had had the benefit of the latest knowledge in the art at the time he applied to have the skiagraphs made. The X-ray experts who testified for the defendants were Professor Wilbur M. Stone of Swarthmore College, Philadelphia, formerly of Armour Institute, Chicago; Truman P. Gaylord of the Chicago Edison company, formerly of Armour Institute; Samuel G. McMeen, chief engineer of the Central Union Telephone company, Chicago, and Professor Launcelot W. Andrews of the Iowa State University. The physicians called for the defense were Dr. A. Church, Dr. James Burry, Dr. A. D. Bevan and Dr. L. L. McArthur, all of Chicago.

But the jury accepted the plaintiff's side of the case and brought in a verdict against the defendants for \$10,000 damages. A motion for a new trial was made, and the defendants say that they will fight the case to the court of last resort, if necessary.

This is one of the first X-ray damage suits to be tried in this country. In the amount of damages awarded, length of trial and vigor of contest it is undoubtedly the most important. The trial attracted much attention.

Reports of the combination and sale of the North and West Chicago street-railway systems to various eastern groups of capitalists have been circulated in New York and Chicago; but nothing definite seems to have been thus far accomplished.

Arc-lamp Department of Central-station Business.

By H. W. HILLMAN.

There is no one branch of greater importance to the central-station business to-day than the arc-lamp department. While many of the larger central stations have realized the need for such a department and appreciated its importance, the majority of the electric-lighting companies throughout the country

FIG. 3. GREAT NORTHERN ELECTRICAL PLANT.—SWITCH-BOARD.

have not as yet given this subject the attention it deserves.

To create and maintain a successful arc-lamp department, one of the most essential requirements is to secure the services of some bright, active solicitor, well posted on the subject of modern arc lamps, the cost of operating, arguments in their favor, as well as against other forms of artificial light. Often the lighting company has some energetic man, either in its office or station, who can be educated to take up this work to the advantage of the company and great assistance to the central-station manager. In other cases the managers are able to devote considerable personal attention to the matter of soliciting. There are many lighting companies, however, which are suffering in this respect, for the reason that the manager is not only too busy to devote much time to the arc-lamp business, but has not as yet considered it sufficiently important to place a man on this particular work.

Some of the prominent subjects with which the solicitor should be familiar, in order to make a good showing for the arc-lamp department, are as follows:

- The relation of the central station to the merchant.
- Adaptability of electric arcs to store illumination.
- Familiarity with modern methods of illumination, also candle-power ratings.
- Importance of careful installation.
- Specialties in arc lighting; low current, lamps, etc.

FIG. 2. GREAT NORTHERN ELECTRICAL PLANT.—SCOTCH BOILERS.

central station and the merchant should be very close. There is an extensive demand among the merchants for the very best light obtainable, and the solicitor who keeps in touch with this demand, studying carefully the needs of the merchants in every way, is of invaluable assistance to the station manager. Such practice is conducive to a prosperous business and the use of light in great abundance.

Where central stations have not as yet introduced the modern interior arcs among their merchants, it is the duty of the solicitor to study the situation carefully. Do not "beat around the bush" and attempt to temporarily discredit new lamps which some energetic merchant of your town has seen when visiting New York.

Urge your superintendent or manager to favor the most important customers you have, introducing the new arcs gradually and after careful consideration. The electric-lighting company should lead and the merchant follow, in the adoption of a first-class light. Create the pleasantest relations with your merchants and maintain them strictly. By so doing, your commercial circuits will always afford you handsome returns.

ADAPTABILITY OF ELECTRIC ARCS FOR STORE ILLUMINATION.

Artificial light was never known to have been used so freely in the commercial world as at the present

FIG. 4. GREAT NORTHERN ELECTRICAL PLANT —SWITCH-BOARD, REAR VIEW.

time, and the adoption of arc lamps for interior illumination has encouraged this new lighting era. There never was a period in the history of the electrical industry when the central station was enabled to furnish to the merchants so suitable and attractive a lamp—a light pleasing to the eye, perfectly suited to the display of all classes of material, quick to illuminate and easy to extinguish; its design chosen with care that its size and appearance might harmonize with the surroundings common to the modern department store. Evidence is not lacking to demonstrate the perfect satisfaction with which this form of light has met among merchants. The rapid-

25,000, has between 200 and 300 lamps in use among its merchants. The close relationship between the central station and the merchant as well as the perfect adaptability of the interior arcs for store lighting partially account for these remarkable results.

FAMILIARITY WITH MODERN METHODS OF ILLUMINATION, ALSO CANDLE POWER RATINGS.

As there are a great many classes, styles and finishes which go to make up the full line of lamps for alternating and direct-current circuits, it becomes somewhat of a study to know what to recommend, when submitting propositions for lighting a department store. In the old days, when the ordinary series arcs were used, the amount of light produced depended upon the current of the machine. In one town 6.6-ampere arcs furnished the stores with a certain volume of light, while the adjoining city stores were favored with 10-ampere lamps of greater illuminating capacity. The size, dimensions and adornment of the lamps were likewise unsuited to the commercial needs. To-day, however, the solicitor is favored with the most artistic shapes and fancy designs. Great long lamps have been replaced by those of short and attractive size. It is the pleasure of the merchant to highly commend the lamp design as well as the character of the light.

Opportunities are afforded for skillful arrangement in the matter of installation. Fig. 1 shows the single-globe style of lamp, which is most popular for many classes of business, whereas the double-globe type can be highly recommended for certain work, especially in the display of materials exhibited among the various departments in dry-goods stores. Merchants will highly appreciate the extra time spent by the solicitor in studying his requirements for light and the earnest efforts put forth to furnish the most modern and up-to-date lamps known to the trade. Let the lighting companies all over the coun-

FIG. 5. GREAT NORTHERN BUILDINGS.

try advertise these points, for they are strong arguments. The lighting industry of the world has been revolutionized, and the arc-lamp department has now become one of the most prosperous branches of the central-station business.

Merchants frequently ask, "What is the candle power of your lamp?" and are greatly confused upon being advised that it is 1,200 or 2,000 candles; in fact, the solicitor and station manager likewise meet with considerable difficulty in touching upon this subject. Reference to a 1,200 or 2,000 candle power rating means but very little to a merchant. A much easier, clearer and more satisfactory method is to refer to the number of square feet of surface which can be satisfactorily lighted by each arc lamp. As an illustration, a room is fitted containing 2,800 square feet, well lighted by four alternating, six-ampere lamps, each lamp lighting an area of 700 square feet. The lamps are suspended eight feet from the floor.

This method has been practiced by many solicitors to advantage. As to the meaning of the term satisfactory illumination, it has been stated that what might be considered satisfaction by one merchant would not be acceptable to another. This point can easily be settled by selecting a representative store and installing lamps according to this method of rating. The solicitor can then refer to this installation, and induce prospective customers to investigate the satisfaction as experienced by the proprietors themselves.

This rating, of course, would not apply where materials such as draperies and curtains are supported from the ceiling, tending to obstruct the light and detract from its best distribution. In such places a lamp of less illuminating capacity should be installed and a greater number of lamps furnished. A solicitor, well posted on the subject of light distribution and best methods of illumination, will command the respect of the store proprietor, greatly increase the efficiency of the arc-lamp branch of the

Thorough knowledge of arguments against Welsbach burners.
Maintenance expense, quality of light and cleaning of inner globes.

RELATION OF CENTRAL STATION TO MERCHANT.

The solicitor is the backbone of the arc-lamp business. Upon his attitude toward the merchants depends to a great extent the increase of customers on the commercial circuits.

It is of vital importance that the relation of the

ity with which central stations have introduced the lamps is indicative that the light is pleasing, and the business mutually satisfactory. In a city of medium size in New York state 400 alternating enclosed arcs were installed during a period of from six to eight months. A central station in Ohio introduced 300 direct-current enclosed lamps in the short space of 90 days. A large plant in the South has placed on its circuits in excess of 1,000 alternating lamps since the spring of '98, while an aggressive station in Michigan, operating in a city of only about

lighting company, and reduce to a minimum the number of complaints due to poor artificial lighting.

IMPORTANCE OF CAREFUL INSTALLATION.

The good results accruing from the exercise of special care in the installation of lamps fully warrant giving special attention to this point. In this connection a wide-awake solicitor will interest himself in the matter when the installation is being made, by inspecting the lamps thoroughly before being satisfied that they are right. His duty is not ended simply because he has secured a new customer, for if the lamps give trouble then the merchant expects the solicitor to see that they are made satisfactory. A close co-operation between the solicitor and the arc-lamp testing man at the station will produce excellent results and obviate trouble before it exists.

Infrequently it happens that trouble commences when the lamps are being placed on the circuits. One case is cited where lamps were recently installed in a large clothing store, without a switch to throw the lights on and off, either collectively or individually. It was arranged that they should be lighted by using a long stick to strike the switch attached to the top of each lamp. As distinct from this method, Fig 2 shows a modern arrangement in the form of an incandescent-lamp cord, suspended from the arc lamp, attached to which is a push-button switch. This furnishes a most convenient arrangement, and at the same time is inexpensive to install. Another point essential to satisfactory service is to inspect the frequency and voltage connections before installing. The frequency of the circuit is of course known, but the lamp may be connected wrong when received from the manufacturer, and by testing at the station the matter is given attention and trouble

Fig. 1.

money; the low-current arcs do not give a sufficient volume of light, and, finally, it results in throwing out electricity for gas, or else a compromise in the price of current. There are 750 three-ampere lamps used for interior lighting in the city of Hartford, Conn., with satisfaction to the merchants as well as the central-station management. A solicitor can secure or lose business in proportion to the amount of study and time devoted to modern methods of interior lighting.

ARGUMENTS AGAINST WELSBACH BURNERS.

Where competition is keen, the price of gas low and a good solicitor employed by the gas company, it requires energetic work and effective arguments to increase the number of arcs in service, or even to hold business already secured. One very good way of creating a stir in the matter of lighting is to equip the windows of some representative store with a first-class arrangement of lighting, installing the arc lamp so that the source of light is not shown, but that the material on exhibit is displayed to perfection, as in Fig. 3. Then select some window lighted by Welsbachs for comparison (Fig. 4). The argument seems conclusive that a merchant having considered it sufficiently important to light his windows for evening advertisement can well afford to have the best light obtainable.

These photographs were taken by the artificial light from the lamps at nine o'clock in the evening, each having had the same time exposure. By introducing lamps in the front of the store the light is called so forcibly to the attention of the store proprietor that not infrequently it is an entering wedge toward displacing gas throughout the entire store; especially is this true where colors have been accurately matched

Fig. 2.

ARC-LAMP DEPARTMENT OF CENTRAL-STATION BUSINESS.

beneath the rays of the electric arc. There are many arguments against the use of Welsbachs for commercial work which are within easy access of solicitors earnestly anxious to learn all their weak points. One of the most annoying and dangerous as well as expensive features seems to be that of "burning off the wax" from the new mantles. Coupled with the use of matches for igniting the gas, and compared with the enclosed arc, so conveniently lighted, there would appear to be no reason why Welsbachs should be used for commercial lighting.

MAINTENANCE EXPENSE, QUALITY OF LIGHT AND CLEANING OF INNER GLOBES.

There is no one thing which is of greater benefit to central-station lighting business than the maintenance of a high grade and character of light. It is this superiority which first attracted business men to the modern arc lamp, and the maintenance of its high quality of light will cause a continued satisfaction among the mercantile trade. All forms of artificial light which have heretofore developed a commercial success have required maintaining at more or less expense and annoyance. When, in the old days, oil lamps were common among the business houses, lamp chimneys were generally cleaned by the "boy" in connection with other duties, such as cleaning of windows, sweeping the store, etc. Welsbach mantles are either removed by the gas company's employes, at the expense of the merchant, or some employe of the store is given this duty. As a result neither the chimneys nor the mantles are cleaned regularly; in fact, negligence and lack of care in connection with renewal of Welsbach mantles is so well known that it has effected great injury to the gas business. The uniform character of light, the poor distribution and the dissatisfaction on account of inattention to mantle renewals are all contributing to the gradual displacement of gas for mercantile lighting.

The central station has a remarkably strong ar-

gument, therefore, in respect to the care and attendance of arc lamps. The merchant is required to give no attention whatever to the matter of light. He is assured that its quality cannot deteriorate, for the station attendant visits each store frequently and regularly for the purpose of either changing globes or renewing carbons. The care exercised in this matter insures a uniform light continually.

While the foregoing deals particularly with suggestions to solicitors, there are many subjects relating to the arc-lamp department which demand the personal attention of the central-station management.

It is safe to assume that these subjects have not had the attention of all station managers, and as arc lamps were never more popular than at the present moment, it seems a fitting time to consider thoroughly this important subject.

PROFITABLE YET POPULAR RATE OF CHARGE SHOULD BE ENCOURAGED.

Wherever central stations have been most successful in introducing interior arc lamps, the most careful consideration has been given to the cost of operating, the selling price for current and the profits under various conditions of operation. Not only is a central station bound to furnish an appropriate illuminant, but the price for current must be within the reach of the smaller merchants as well as encouraging the extensive use of light among the largest customers on the service. It is surprising how easy the clerks in a store acquire the habit of throwing on the lights at any hour of the day in order to more effectually illuminate their counters. Where the price of current is high, the clerks are severely criticized for the liberal use of light, and are given to understand that the greatest economy must be

Fig. 3.

Fig. 4.

remedied at your own door. It is much more businesslike to ascertain and know the line voltage at the point of installation, carefully adjusting each lamp before installing, for the proper length of arc. While these points may seem so simple as not to require mention, yet it is certainly a common thing among the stores to see lamps operating at too high or too low an arc voltage, necessitating adjustment and altering at the customer's place of business. To obviate these troubles establish a testing rack at the station, have it understood that some one man is responsible for the lamps sent out and that each lamp is thoroughly tested before installation.

SPECIALTIES IN ARC LIGHTING, LOW-CURRENT LAMPS, ETC.

Opportunities are afforded for meeting competition against other forms of lighting by the use of lamps of low energy consumption. For example, a four-ampere, alternating, enclosed arc, consuming but 300 watts at its terminals, is attractive to the merchant by reason of its low cost of operating. By using the single-globe type of lamp the volume of light is of a very respectable amount, and offers a first-class illuminant at small expense to the customer. The same holds true of the 3/4-ampere lamp for direct-current circuits, consuming about 360 watts on a 110-volt line. Here is another instance where it is of importance that the solicitor should study the matter of installation and exercise good judgment as to when and where to use a low or high-current lamp. The manager of the station is generally too busy to go into details and must rely entirely upon the efforts of the solicitor to please a customer. The writer is familiar with a case not long ago where three-ampere lamps were installed alongside of and to replace lamps of much higher current. The trial was a failure, and the station manager received the idea that he could not use the low-current lamp. Such cases are not uncommon. The merchant feels that the high-current lamps are costing too much

exercised. On the contrary, a reasonably low rate for all customers, and special rates for large and long-hour customers, educate them to use light more liberally; and as good light tends to increase sales, the clerks favor its use.

Where rates are high the inevitable result follows, namely, the loss of business and the introduction of Welsbach burners. To regain this trade and conduct an energetic campaign against gas consider the subject of rates carefully. It will be found that while even a slight reduction in rates will decrease the profits, figuring on the same amount of business, yet the amount of business increases rapidly when dealing with arc lamps consuming nearly a half kilowatt per lamp. It may be interesting to know that 100 direct-current lamps operating an average of only four hours daily afford a gross annual income of \$7,920 at a rate of 12 cents per kilowatt-hour. Considerable experience and investigation on this point of increased business shows that about 200 commercial arcs can be introduced in cities as large as 20,000 to 30,000 population, favored with two or possibly three dry-goods stores. In other words, a business is created of approximately \$16,000 annually, offering satisfaction to merchants and driving out of commercial use from 800 to 1,000 Welsbach burners. I have not attempted to couple with this proposition the benefits to the incandescent, power and fan-motor branches of the business, which, if figured out on the same basis, would demonstrate that while the same percentage of profit cannot be reasonably expected after reducing rates, yet a lower percentage figured on an increased gross amount will produce equal, if not increased, profits in dollars and cents.

SHOULD CENTRAL STATIONS PURCHASE LAMPS AND FURNISH THEM FREE TO MERCHANTS?

As a business proposition there seems to be excellent reason why the central station should furnish lamps free. On the basis of 100 lamps an investment would be required of approximately \$2,000. At six

and 10 per cent. respectively, the annual interest and depreciation account would amount to \$320. The gross annual income from 100 lamps, operating a daily average of four hours, would be \$7,920, figuring at a rate of 12 cents per kilowatt-hour. At a fair percentage of profit, the net income is sufficient to more than warrant the small investment referred to. Aside from a financial standpoint, there are many objections to the merchants purchasing the lamps. Circuits are apt to be filled with various forms of lamps; different makes and sizes of carbons and globes must be carried in stock. Central stations must keep on hand repair parts for various makes of lamps. A trimmer cannot be expected to have detailed knowledge of all types of lamps, and sufficient care and attention are lacking. Responsibility is also divided in the matter of satisfactory operation. Only recently the point was brought up forcibly. A merchant having purchased his own lamps, complained to the manufacturer that the lamps were not satisfactory. The manufacturer advised that the station people did not trim the lamps properly. The outcome was considerable trouble, and the station adopted the policy thereafter of purchasing and owning the lamps.

Summarizing, if a central station is not in position to handle interior arc lighting and desires to hold back as much as possible from doing business, there is no better way than by refusing to furnish lamps. On the contrary, if it is desirous of conducting an active, satisfactory and economical arc-lamp business, the lamps should be the property of the electric-light company and furnished free to merchants.

MODERN METHODS OF STREET ILLUMINATION, IDEAS ON LAMP SUSPENSION AND THE USE OF REFLECTORS.

The arc-lamp department is an invaluable aid to the central-station manager, as the time draws near for the renewal of the lighting contract between the town or city and the electric-lighting company. While conducting the business of interior arc lighting, the employes interested can be continually investigating the lamps of this class designed for outdoor service. It is well to order a sample of weatherproof lamp, giving it a trial in front of your office, or, as an aggressive manager recently stated, he had the lamp installed in front of his residence, thereby to better watch its operation from night to night. When installing the lamp do not place it under a hood or upon the old-style lamp pole, but hang it from some attractive bracket or other form of suspension, giving particular attention to the height of the lamp from the ground. A distance of about 18 feet, measuring from the center of the inner globe, will give a very satisfactory distribution. If it is an alternating lamp, equip it with a metal reflector, over the outer globe, in order not to waste the light which would otherwise be thrown upward above the horizontal line from the arc. A reflector properly designed will not unduly concentrate the light beneath the lamp,

The policy here outlined, if pursued in a careful manner by a central-station manager, will tend to eliminate further reference in future contracts to the candle-power rating of an arc lamp. As an illustration, I would cite an actual case where a contract was recently made between a city and an electric-lighting company in the West. The 7½-ampere alternating, enclosed arc lamp was suspended at a point in the main business street of the city, and lo-

FIG. 3. HUTCHISON'S ELECTRICAL AUDIPHONE.

ated between two old-style 9.6-ampere series open-arc lamps. Opportunity was afforded those interested to make comparison of the light distribution, with the result that the contract subsequently entered into called for lamps designated as the 7½-ampere alternating, enclosed arc lamp. No reference whatever was made to candle-power rating.

While the tendency among the cities and towns is gradually in the direction of securing a lower price per lamp per year when renewing the street-lighting contract, yet the remarkable increase in the last few years in the amount of light used for interior lighting should encourage a liberal extension in the number of lamps required for street service. To educate the city fathers along these lines and to consummate a plan substantially on this basis will preserve the electric-lighting business and offer bright prospects for central stations, approaching the time when another contract must be made with their city government.

Hutchison's Electrical Audiphone.

The common interest manifested in the subject of affording relief to those afflicted with deafness has encouraged many attempts to provide suitable apparatus for overcoming this weakness, and in

held together by means of a spring, much the shape of the receiver used by telephone girls, which fit over the ears, and a metal breastplate on which is fixed, just in front of the mouth of the wearer, a transmitter shaped like those to be seen on some telephones. This transmitter is of rubber and is so arranged that it can be turned toward the mouth of the wearer or away from the wearer and made the receiver of sound. On this breastplate there is a switch to cut off the current and cut it in at will, so that the wearer can hear only the instructor, or, if so desired, his own voice and those of the remainder of the class. There is also a switch for controlling the intensity of the sound, as some of the ears of mutes are more sensitive to sound than others. This arrangement is so balanced that if it is found that one ear is more sensitive than the other the volume of sound can be adjusted for each ear.

The principle upon which this instrument operates is thus explained by the inventor: Sound waves upon striking the diaphragm of the receiving instrument produce variations in the current strength of the circuit, thereby producing a corresponding variation of the ear-piece diaphragm. This action is a microphonic one; but the construction of the special parts renders this instrument not only very sensitive, but especially adapted to the use to which it is to be put.

The drum and general auditory apparatus of deaf persons are very sensitive to loud sounds through this instrument, and in order to obviate any inconvenience or pain from this effect the regulator is inserted, whereby the sensibility of the instrument may be varied to suit different sound intensities. This regulator may be placed on the top of the handle.

An idea of the appearance of this instrument is given in Fig. 1, and the details of construction are clearly shown in Figs. 2 and 3. The principal features claimed by the inventor are an electrical ear-piece, a receiving instrument and an electrical circuit, including the ear-piece and the receiving instrument supported by a handle. The device for regulating the intensity of the current and its effect is contained in the handle and may be operated by the subject.

Of the inventor and his work it is reported by a correspondent at Mobile, Ala., that he is consulting and supervising electrical engineer for the Seventh and Eighth Lighthouse Districts, and for the Mobile Light and Railroad company, a native of Mobile, and graduate of the Alabama Polytechnic Institute. His work first attracted general attention when its use enabled Liman Gould and Martin Durant, two young men born totally deaf, to hear and articulate voice sounds, which they repeated as far as they were able. Hutchison is only 22 years old, and has devoted nearly three years to the perfection of his apparatus, which, in the opinion of local medical men, is the most perfect instrument invented for the purpose of enabling the deaf to hear.

On the same electrical principle employed a larger apparatus has been constructed, by which an instructor can communicate speech to any number of pupils at one time without confusion. Hutchison has put together a portable instrument with a small pocket battery, by means of which a deaf-mute was enabled to hear the playing of a piano at a distance of 60 feet and to distinguish a voice in ordinary conversational tones.

The young inventor had previously made a local reputation as an expert electrician, and in order to learn what to avoid as injurious to subjects he has been studying the formation of the ear at the Alabama Medical College and otherwise perfecting himself in this special branch.

Death of Capt. A. E. Hunt.

Alfred Ephraim Hunt, president of the Pittsburg Reduction company of Niagara Falls, died in Philadelphia, Pa., on Wednesday, April 26th, aged about 41 years. He was born in Massachusetts and passed his early life at Hyde Park in that state. He attended the Boston Latin School, and on his graduation there entered the Massachusetts Institute of Technology, from which he was graduated in 1876. His earliest business connection was after he left college and went to Nashua, N. H., and became interested in the steel business there. Later on he went to Pittsburg, Pa. He there started the Pittsburg Testing Laboratory. In August, 1888, he met Charles M. Hall, the possessor of valuable patents for the manufacture of aluminum. In these patents Mr. Hunt saw the road to the cheap production of the much-sought-after metal, and, becoming deeply interested, he organized the Pittsburg Reduction company.

Mr. Hunt was one of the first to recognize the value of the great power development at Niagara, and it was his company that was first to make a lease of power and land from the Niagara Falls Power company, the plant being established before the power was on tap. This plant is known as the Upper Niagara works, and since it was built its capacity has been materially increased, while another plant has been erected on the lands of the Niagara Falls Hydraulic Power and Manufacturing company, which, even while the sands of his life were ebbing away, was being enlarged, thus demonstrating still further the correctness of his appreciation of the electrical service at the falls. It is well known that the company Mr. Hunt organized to make aluminum has practically become the only

FIGS. 1 AND 2. HUTCHISON'S ELECTRICAL AUDIPHONE.

will uniformly distribute the rays over a wide range of area.

As to the best combination of globes, clear inner and outer globe produce a very good lighting effect, but an opal inner globe is highly recommended instead of a clear one. With this combination the glare of light does not seem to be cut off sufficiently to be noticed, even by a keen observer, yet it is away entirely with the violet color of the arc, furnishing a beautiful illumination, free from shadows and desirable in all respects. No hood is required for the modern street lamp, and this feature, among others, contributes to its attractive appearance.

many cases remarkable results have been obtained. The latest contribution noted is that of Reese Hutchison of Mobile, Ala., who has patented a device known as the "akouallion." The invention relates to audiphones, and is intended to provide an efficient instrument to enable deaf people to hear sounds as they are heard by people with normal ears, and to train the ears of deaf persons to hear even without the instrument. It is claimed also that the machine will enable those who have been deaf and dumb from birth not only to hear, but to talk, to articulate letters, then words and finally sentences.

The instrument consists of two rubber ear-pieces

successful concern in the world to manufacture the white metal, the company supplying both the markets of the United States and Europe. During his lifetime he witnessed the price of aluminum drop to its present low stage, thus increasing its popularity.

The deceased was a man well known in Europe as well as America, and he was always pronounced a most successful organizer. In engineering circles of the two continents he was prominent. He was a member of the American Society of Civil Engineers, the American Institute of Mining Engineers, the British Iron and Steel Institute and the British Institute of Civil Engineers. He also belonged to various other organizations.

When a year ago the call came for men to take part in the late war with Spain, Captain Hunt, as he was generally known, responded. He had always been interested in military affairs, and was a member of the Pennsylvania National Guard for 14 years, being the oldest captain in the service. He went to the front at the head of the famous Battery B of Pittsburg. While at Camp Thomas he contracted malaria, but recovered so that he was able to go to Porto Rico with the General Miles expedition. He was, however, forced to ask for leave of absence, owing to poor health. He was a man of pleasing address and great popularity. He leaves a wife and one son. The burial was in Pittsburg, Pa. O. E. D.

Rare-oxid Incandescent Lamps.

F. M. F. Cazin of Hoboken, N. J., contributes some information upon the subject of utilizing the oxids of rare metals in an electric lamp. He has been occupied with this subject for several years, he says, and as early as 1892 he secured a patent bearing upon the problem. Several additional patents affecting different branches of the subject have since been issued to him. Mr. Cazin believes that he is entitled to some consideration as an expert in this field, and he takes issue with Mr. Carl Hering of the Electrical World, whose views conflict with Mr. Cazin's. The following statements are particularly objectionable:

It seems to have been shown that the rare-oxids do not have the valuable property of changing heat into light.

Their utilization in the production of light is dependent on combustion and does not rest on any particular power of emissivity.

Hence it seems to be useless to expect an improvement in the incandescent electric lamp by the use of these oxids as coatings of filaments.

Commenting upon these conclusions, Mr. Cazin says:

"The first proposition, as well as the second and third, were directly based on what a Frenchman named Bunte had said or was understood to have said in a paper published by a physical society to which he belongs. No other authority is quoted in support of the quite extraordinary conclusions to which this paper has led. As will be shown, the Frenchman did not make the statements that are attributed to him, and if he had made them, his paper would deserve less credit than a dissertation on heat written by a high-school pupil after his first lesson in physics.

"The first proposition, as verbally cited, is a formal and general denial of a theorem in physics, which is accepted by the living generation of scientists, and which teaches that all solids convert heat into light, when heated to conditional temperature.

"The second proposition falsely teaches that the heat that results from combustion is a different heat from that produced by the electrical current. This is surely new teaching, and if it be not false teaching, better evidence in its favor must be found than that which is derived from Bunte's paper, though Bunte himself advanced no such teaching, and only his interpreter, Carl Hering, in the Electrical World of April 22d, found the same therein."

Mr. Cazin describes his own experimental work in making "an effective electric-oxid lamp," in the course of which he says:

"The third proposition is a remarkable general denial of the practicability of a technical problem of the very simplest conception, namely, the problem of converting accumulated heat into light, such accumulation being applied to material which at this date is in general use for a similar purpose. The newness of the present problem consists exclusively in the origin of the accumulative heat and in the subtlety of the contrivances which must be dealt with in the solution of the new problem.

"Heat is the lamp's food, and it is too valuable to be allowed to escape indiscriminately into space, in such enormous quantities proportionally as my calorimeter proved had escaped from a submerged incandescent vacuum lamp under current, even when the bulb had been made impenetrable to light. Heat is preserved in my lamp by applying an extra glass-housing, leaving a space, air-filled or evacuated, between the inner and outer bulb, as shown in the cut. By permitting a minor part of the inner bulb to project and to remain in direct contact with the cooling atmosphere the special advantage is secured of condensing within the minor projecting part all the products of evaporation from the luminous body, and of keeping the bulb proper free from all darkening deposits on its inside. Incidentally, and as a matter of greater economy, I designed an all-glass base-part, requiring no cementing and less manipulation in the manufacture of the lamp.

"In the matter of conductivity, it was found that a luminous body of carbon and oxids in direct contact

not only rapidly decreased in resistance, but once having been exposed to the current and then switched out of circuit, and after cooling, had entirely lost its conductive quality. An investigation showed that the carbon filament had almost entirely disappeared, and a very irregular scattering of spots of reduced metal remained on the contact face. When I applied the remedy of chemical insulation by coppering the carbon filament or gilding a filament of a metal, though of an extremely high point of fusion, I had to intercept the insulating coat by ring-shaped in-

RARE-OXID INCANDESCENT LAMP.

tervals, to prevent increase of conductivity. While this resulted in a practical luminant, not only did the exterior, corresponding to the interceptions of insulation, appear in more brilliant incandescence, but investigation showed that also in this case the stated reaction had taken place, but had been confined to the narrow annular interceptions, causing an alloy coating on the contact face. This metal coating, jointly with reduced metal from the oxids, must, in a second use of the lamp, have acted as the conductor, until the oxids, sufficiently heated, filled the gap, or the conductor stubs must have acted as arc pencils, until the oxids became conductive and offered less resistance than the automatically intercepted filament. In this connection attention should be directed to the important fact that no arc lamp proper, or such in its function, can possibly utilize

of pseudo-fibers or fabrics, fritted into adhesive and cohesiveness by an admixture of fluor spar and application of momentary excessive current to the well-protected conductor.

"It is evident that, with a complete protection of the core against oxygenation, the vacuum may be dispensed with, as already provided for in my patent, No. 523,461.

"No. 620,649 secures the luminous body of conductor and oxids with the indispensable intermediate insulating stratum. But the same patent secures also the luminous body of oxids with a filament of material not in affinity with oxygen.

"No. 621,291 secures the use of oxid in the shape of pseudo-fabrics."

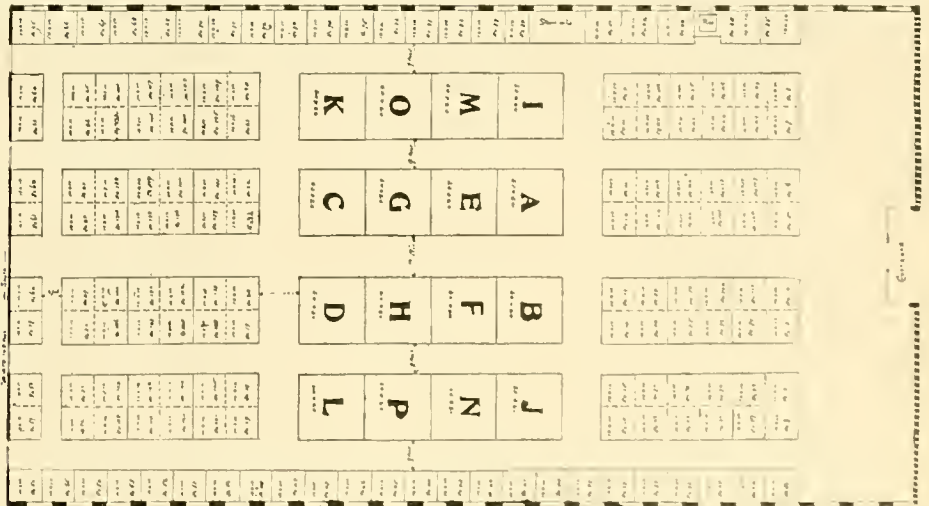

Electrical Exposition in Chicago Next Fall.

Chicago is to have an electrical exposition on a large scale next fall unless the carefully prepared plans of the National Exposition of Electrical Arts company fall to the ground, which does not seem to be likely. This company has been incorporated in this state and has an authorized capital of \$50,000. The officers are: President, N. J. Heinbach; secretary, T. Carrabine; treasurer and manager, W. E. Burnham. Messrs. Carrabine and Heinbach are business men of experience and Mr. Burnham is an energetic young man who has given considerable time to the promotion of enterprises of this character.

The show is to be held at the Tattersalls building on Sixteenth street, near State street, and will be followed by the exhibits shown in connection with the annual convention of the American Street Railway association. The time set for the electrical exhibition is from September 25th to October 9th. The date of the street-railway convention is October 17th to 20th.

It is the intention of the promoters of the exposition to give a general electrical exhibition, paying particular attention to household uses of electricity and displaying likewise the latest advancement of the electrical and allied arts. It is hoped that there will be demonstrations of liquid air, wireless telegraphy, the Nerst electrolytic lamp, X-ray phenomena and the like. These will be conducted in a manner to interest the general public, and it is anticipated that the show will be a great popular success, especially as it will be given at the time of the fall festivities in Chicago, which will excite great local interest and attract thousands of out-of-town visitors. Of course, the illumination of the exhibition hall will be a feature, and there will be interesting exhibits of motor applications of many kinds, heating and cooking by electricity, electric vehicles, new telephone apparatus, methods of telegraphy, etc. The Chicago Edison company will furnish power, in addition to the output of the plant in the building. On Sixteenth street, from State street to the entrance of the building, overhead festoons of incandescent lamps, across the street, will make the night approach to the scene a brilliant one. Band concerts will be given daily.

Space will be leased to exhibitors at rates varying according to its size and location. The Tattersalls

ELECTRICAL EXPOSITION IN CHICAGO NEXT FALL.

rare-metal oxids for increase of light efficiency, for the simple reason that oxid pencils do not conduct and that in order to become fit for such utilization the arc lamp must cease to be an arc lamp and must become a continuous-conductor lamp, or a filament lamp, by inserting the hot oxids, as conductor, though of different success material at intervals. The condition of practical success consists in so regulating the initial resistance that it be higher than that of the heated oxids. Of the experience thus described I took advantage in applying the coat of oxids only to those parts of the conductor where the insulating coat is intercepted, and where they show the higher brilliancy of incandescence. But in locally bridging over the gaps in the insulation I still preferred to decrease solid volume and to increase the light-emitting surface by applying the oxids in the shape

building is 148 feet wide and 205 feet long. It was built for large exhibitions and shows, and is well adapted for the purpose. The accompanying diagram shows the manner in which the floor space has been divided for the electrical show. There are 149 exhibit spaces ranging from 100 to 400 square feet. In case of very extensive exhibits two or more sections may be combined. The aisles are from nine to 12 feet wide, and plenty of open space is left at the entrance of the building.

Among the concerns that have already signified a determination to take part in the show are the Chicago Edison company, Chicago Telephone company, Postal Telegraph-cable company, Woods Motor-vehicle company and the American Electric Vehicle company. It is probable that gold medals will be awarded for excellence of exhibits.

The annual statements of the Chicago Edison company and the Commonwealth Electric company would prove satisfactory to the stockholders of these corporations and gratifying to the management.

the consolidation of the several plants into one company is a high recommendation of the efficiency and practicability of the methods introduced by the new management.

Announcement is made elsewhere in this issue of the decision of Judge Adams of the United States District Court at St. Louis in the case of the Edison Electric Light company against the Imperial Electric Light, Heat and Power company of St. Louis, refusing a preliminary injunction for which application had been made on the ground that the defendant was infringing the Edison three-wire patent.

The case excited a great deal of interest, owing to the fact that the exact value of the patent involved had never been fully established. No court had ever passed upon its merits, although the patent was constantly being invoked and was generally regarded as an important weapon.

The facts thus related seem to have had considerable influence upon Judge Adams, for he bases his action in refusing the preliminary injunction upon these grounds:

First—There has been no adjudication by any court of concurrent jurisdiction of the validity of complainant's patent, after a hearing on the merits.

Second—There has been no such public and general acquiescence in complainant's rights to an exclusive monopoly in the three-wire system of electrical distribution as to raise a fair or reasonable presumption of the validity of the patent.

The result of this decision is to open the three-wire invention to general public use, as the term of the patent has nearly ended, and it will be impossible to secure a decision in a contested case prior to the expiration of the patent—a direct result of the policy of the company in avoiding an adjudication of the merits of the invention.

A significant feature of the experimental work on the Marconi system, now being conducted on the English Channel, was the practical use to which it was put in time of danger by the crew of a vessel disabled in a collision.

A cable dispatch from London, April 28th, announced that the Goodwin Sands lightship was run into by the British steamer R. F. Matthews during a dense fog. The lightship was provided with the signaling apparatus, and by it the crew was enabled to notify the station at South Foreland that the vessel was sinking.

Commenting upon this practical demonstration of

the importance of the Marconi system for this particular service at least, a London correspondent says: "This object lesson has done more than experiments to impress the public mind here with the value of the Marconi system."

The negotiations for a transpacific cable between British Columbia and New Zealand and Australia are not as far advanced as had been supposed. In the House of Commons, on April 28th, the government was questioned on the subject.

The postponement of the Hawaiian cable project at the late session of Congress allowed the British government to take the lead again with its scheme of cable communication between Canada and Australia, and we are likely, therefore, to find two systems where we now have none.

Similar considerations will govern the selection of the route for the American cable, and these will appeal to the United States government and undoubtedly secure the financial encouragement and support necessary for the building and operation of the line.

The delays and disappointments that have met the promoters of the American cable project have been exasperating, but they have been no greater than those experienced by the Canadian and colonial petitioners for a British cable, which has been under consideration for more than a dozen years.

The example of the British government should insure an early settlement on the part of the United States of the question of establishing American cable connection with Hawaii, Manila, Japan and China.

FINANCES OF ELECTRICAL PROPERTIES.

Three important statements of electrical properties are presented herewith, two being central-station plants and the third a manufacturing enterprise. The excellent showing of these three concerns may be accepted as a fair indication of the general condition of prosperity that prevails in all branches of electrical industries.

Chicago Edison Company.

The annual statement of the Chicago Edison company for the fiscal year ended March 31st is appended:

BUSINESS SUMMARY.

Gross income from electric current and merchandise sales.....	\$ 1,954,876.69
Operating, repairs and renewals and general expense.....	1,214,620.72
Net income from all sources.....	\$ 740,255.97

CHARGES AGAINST INCOME.

Interest on bonds and debentures.....	\$262,524.46
Dividends paid.....	398,972.00
Balance.....	\$ 79,659.51

ASSETS.

Plants, real estate and franchises.....	\$ 10,098,421.39
Material in storeroom and unfinished work unbilled.....	180,213.77
Accounts and notes receivable.....	237,432.93
Cash.....	79,095.11
	\$10,595,153.20

LIABILITIES.

Capital stock.....	\$ 4,975,000.00
Bonds and debentures.....	4,808,000.00
Accounts and notes payable.....	332,462.43
Depreciation reserve.....	290,000.00
Insurance fund.....	36,000.00
Surplus account.....	101,698.29
Open accounts.....	51,092.48
	\$10,595,153.20

As shown below, there is an increase of 17 per cent. in gross receipts, in spite of the usual reduction in prices. The receipts for the 12 months covered by the report were only four per cent. smaller than for the 15 months ended March 31, 1894, including the World's Fair period. The net earnings for the year were \$740,255; bond and debenture interest, \$262,524; leaving a surplus applicable to dividends of \$477,731, equal to 9 1/2 per cent. on the outstanding capital stock. After paying the eight per cent. dividend there was a surplus of \$79,659, of which \$50,000 was carried to a depreciation reserve account and \$8,000 to insurance fund, the surplus account being increased by \$21,660.

The principal change in the balance sheet was caused by an increase of \$545,223 in plant account and the issue of \$350,000 more of the new five per cent. bonds. The following table, showing the results of former years' operations, will be interesting, as indicating the steady growth of the company:

Year ending March 31.	Gross.	Expenses.	Interest.	Earned on stock.	Dividends.
1899.....	\$1,954,876	\$1,214,620	\$262,524	\$477,731	\$398,972
1898.....	1,664,803	985,338	226,681	419,844	397,072
1897.....	1,549,608	948,934	280,334	419,340	397,518
1896.....	1,461,031	898,517	158,135	404,432	389,382
1895.....	1,437,942	953,377	155,128	328,537	319,038

It is announced that at the annual meeting on June 12th the question of increasing the capital stock will be settled.

Commonwealth Electric Company.

The first annual report of the Commonwealth Electric company of Chicago, which will be submitted to the stockholders at the annual meeting this month, shows a surplus of \$25,155 over the bond interest, and emphasizes the benefits of combinations insuring a reduction of fixed charges and an economical management. The statement is for the year ended March 31st, but it should be remembered that the consolidation was not carried into effect until June 1st, and it was some time later before the power stations were combined. The net earnings for the first seven months of the year were \$60,919, as against \$68,147 for the last five. The surplus shown will be put into betterments and extensions of the property. The company will probably spend \$200,000 in extending its business this year.

The statistics of the business and financial statement are appended:

BUSINESS SUMMARY.

Gross earnings from electric current and merchandise sales.....	\$ 390,065.51
Operating, repairs and renewals and general expense.....	260,998.77
Net income from all sources.....	\$ 129,066.74

CHARGES AGAINST INCOME.

Interest on bonds.....	\$ 103,910.78
Balance.....	\$ 25,155.96

ASSETS.

Plants, real estate and franchises.....	\$7,323,323.12
Material in storeroom and unfinished work unbilled.....	37,724.56
Accounts and notes receivable.....	228,320.68
Cash.....	5,220.58
	\$7,595,198.21

LIABILITIES.

Capital stock.....	\$5,000,000.00
Bonds.....	2,500,000.00
Accounts payable.....	45,339.41
Open accounts.....	247,902.87
Surplus account.....	25,155.96
	\$7,595,198.24

General Electric Company.

The annual statement of the General Electric company was submitted at the stockholders' meeting at Schenectady, April 26th, by President Coffin, as follows:

"The prosperity which has attended other lines of business during the year has been shared by your company. The important extensions made to its factory plants during the last 18 months have proved to be most timely, and the company is now greatly benefited by the increased facilities they afford.

"The matters of stock reduction and revaluation of the patent account of the company were brought to your attention in the last annual report. Since then a reduction has been made of 40 per cent. in the share capital of the company, by vote of the stockholders at a meeting specially called for that purpose, the common stock being reduced from \$30,-

descent-lamp orders nine per cent. Over 124,000 separate supply orders were received and over 8,499,000 incandescent lamps were ordered during the year.

General Griffin mentions the fact that the Spanish war led to an increase in the demand for search-lights, cables, marine dynamo sets and other apparatus of this class.

The report of the third vice-president deal entirely with questions of manufacturing and engineering practice. Several additions to the company's plant are mentioned.

The financial affairs of the corporation occupy the greater part of the report. They are considered in detail in the statement of the second vice-president, which includes the accompanying summary in the form of "consolidated balance sheet" and "consolidated profit and loss account."

American Institute of Electrical Engineers.

At the meeting of the Institute held in New York on April 26th there was a topical discussion on "The Limitation of Power Subdivision by Electric Motors in Manufacturing Establishments." Mr. Gano S. Dunn opened the discussion. Others taking part were Messrs. R. T. Lozier, H. B. Coho, H. Ward Leonard, Arthur Williams, Jesse M. Smith, Oberiin

ASSETS.		CONSOLIDATED BALANCE SHEET OF JANUARY 31, 1899.		LIABILITIES.

Surplus January 31, 1899.....

The first vice-president's report of the sales department for the fiscal year ended January 31, 1899, showed total sales of \$15,679,430.86; cost of goods sold, general expenses and taxes, including sundry losses and allowances for losses, of \$13,094,534.25; leaving a profit on sales of \$2,584,896.61.

The increase over last year in orders received is 21 per cent. Apparatus orders represent 52 per cent. of this increase, supply orders 39 per cent., incan-

Smith, Douglas Burnett, George Hill and F. M. Petersen.

At the meeting of the executive committee in the afternoon the following-named associate members were elected: Joseph Clement, Johannesburg, South Africa; R. Laurie Ellis, Augusta, Ga.; John Ellis, Lonsdale, R. I.; Albert F. Ganz, Hoboken, N. J.; A. P. Kennedy, Chicago, Ill.; W. H. Lawrence, New York, N. Y.; Oliver S. Lyford, Jr., Pittsburg, Pa.; Raymond S. Masson, San Francisco, Cal.; M. Namba, Kioto, Japan; John S. Peck, Pittsburg, Pa.; Walter Wilson Reed, Houston, Texas; Edward F. Schurig, Omaha, Neb.; Charles Edward Skinner, Pittsburg, Pa.; Gerard Swope, Chicago, Ill.; Walter Farrington Wells, New York, N. Y.; Robert A. Widdicomb, Chicago, Ill.; Walter Douglas Young, Baltimore, Md.

The following-named associate members were transferred to full membership: H. Eugene Chubbuck, Quincy, Ill.; William S. Barstow, Brooklyn, N. Y.

Another new electric road is announced between Saginaw, Mich., and Frankenthum, a distance of eleven miles.

DEVELOPMENT OF THE TELEPHONE FIELD.

Independent Telephone "Trust."

The promoters of the independent telephone "trust" failed to perfect their organization and secure the necessary capital to float the enterprise by May 1st, the date when the options which they held expired. Word comes from New York that an attempt is being made to secure extensions of these options, the first appeal having been for 30 days additional time, but, this failing, 10 days was asked.

Representatives of the consolidation have repeated their efforts to enlist several large concerns in the enterprise, as it is now generally admitted that the companies upon which options have already been secured do not represent a controlling interest in the telephone manufacturing business.

Last week P. C. Burns spent several days in New York with Mr. Blaine, who has charge of the scheme, and Mr. Williams, the assistant United States treasurer of the Chicago sub-treasury, who has been in the East for more than a month in the interest of the proposed "trust." They were unable to bring the negotiations to a successful termination, however.

The only event of real interest connected with the scheme was the announcement in the Chicago papers of April 27th of the incorporation at Springfield, Ill., of the American Independent Telephone company of Chicago, with capital of \$2,500. The incorporators named are George H. Taylor, Albert Martin and George C. Wilder, of the law firm of Taylor & Martin, Chicago. It was at once assumed that the company was a branch of the "trust," and was incorporated in this state for the purpose of doing business here, but Mr. Martin says: "So far as I know, it has nothing to do with the trust."

Not in the "Trust."

The following letter has been received from the Hipwell Manufacturing company of Allegheny, Pa. It is being circulated among exchange managers, and is self-explanatory:

"It has been reported that we have given an option upon our plant to the independent manufacturers' telephone trust. This we emphatically deny, notwithstanding the fact that they have threatened to force us out of the business.

"We have refused all their offers, as we did not deem it to our or your best interests to accept them. We have both been fighting one trust, and we feel confident that you will not foster another whose sole purpose is to raise the price of telephone apparatus.

"Although we have been marketing a complete instrument for a comparatively short time, our business has grown to such magnitude that we have been forced to double our capacity. We are building an addition to our factory, which will be completed in about 30 days. This addition will give us the largest capacity of any independent telephone manufacturer in the United States. We manufacture every part of our telephone and depend on no one for supplies. We feel confident that whether the trust goes through or not, by combining merit with fair dealings, we shall receive the support of the independent telephone exchanges."

The Hipwell company makes a specialty of magnets, bells, receivers, transmitters and telephone supplies, and it has a complete exchange system developed.

Stromberg-Carlson Expansion.

The official announcement was made last week that "the Independent Telephone Manufacturing company, with a capital stock of \$100,000, has been organized, under the laws of the state of New Jersey. It is expected that this company will take up the manufacture of the well-known Stromberg-Carlson telephone apparatus. It will have no connection of any sort with any other company."

The new company will make Chicago its headquarters; the factory will remain in this city and the management will be continued in the same hands, but the business will be conducted on a larger scale and the facilities for manufacture will be materially increased. The new capital will be used for improvements and extensions and for securing new machinery.

The old company has enjoyed a prosperous career and has established a splendid reputation for the character of its apparatus. It is not the intention of the management to wipe out the old concern, but to simply transfer to the new company the rights and privileges of the old, keeping the organization of the Stromberg-Carlson company intact.

MANUFACTURERS AND DEALERS.

The Central Telephone and Electric company of St. Louis has just issued its new instruction book and illustrated catalogue No. 5, which contains much matter of interest to managers and users of independent telephones. As is well known, the company, under the careful and energetic management of Fred H. James, S. Cumling has worked up an important trade, particularly in the western states. The Central company's business has increased in a gratifying manner, and it is now prepared to furnish

anything used in a telephone exchange. Telephone people generally are bound to find something of interest in the Central company's catalogue, which will be cheerfully mailed on request.

F. O. Plummer, formerly of Plummer, Ham & Richardson, Worcester, Mass., will in the future be located at room 20, 620 Atlantic avenue, Boston. Mr. Plummer announces that, having obtained the agency for L. M. Ericsson's Swedish telephones, he is prepared to do all kinds of the finest telephone construction. Microphones, receivers and other parts of Swedish telephones will be kept constantly on hand.

The D. A. Kusel Telephone and Electric Manufacturing company of St. Louis has just issued a new illustrated catalogue and price-list. This catalogue contains illustrations and descriptions of all the products of the company, together with instructions for connecting telephones, estimates of material required for exchanges, testimonial letters, etc. The D. A. Kusel company was established in 1886, and Mr. Kusel claims to be one of the first men to engage in the telephone business outside of the Bell interests. The company reports that it is doing a better business than at any previous time in its history, and its goods are said to be giving entire satisfaction.

New York Telephone Rates.

As announced last week, the New York Telephone company has decided upon a reduction in telephone rates for the borough of Manhattan, applying to all contracts made after April 20th. The new rates range all the way from \$75 for 600 messages a year to \$228 for 4,500 messages, the former rates having been respectively \$90 and \$240 a year. In the 600, 700, 800, 900, 1,000 and 1,100-message classes the new rate for additional local messages is eight cents each, a reduction of two cents. Extra messages in the 1,200 and 1,500-message groups will cost seven cents apiece, in the 1,800 and 2,100-message classes six cents each, and in the remaining classes, including those from 2,400 to 4,500 messages a year, five cents. Rates have also been reduced in the Westchester division.

The general manager of the company, U. N. Bethell, has issued a formal statement to patrons announcing the change and the terms imposed by the company upon those who desire to take advantage of the new rate. He says:

"The New York Telephone company has adopted a new schedule of rates for telephone service in Manhattan—ranging from 600 local messages a year for \$75 to 4,500 local messages for \$228—and has modified in some respects the conditions under which the service is furnished. It therefore becomes necessary to make a new contract with each subscriber desiring to accept the new rates and conditions.

"In making these new contracts it has not been found practicable to do otherwise than follow in general the method hitherto observed when reductions in rate have been made, viz., to make a superseding contract under the new schedule only at the end of the current annual term of the existing contract.

"No previous reduction of rate, however, has affected so many subscribers at one time as the present one. Consequently, a modification of the former practice has seemed proper, in order that all subscribers who make new contracts may practically secure the benefits of the new rates from May 1, 1899. To accomplish this the following method will be observed:

"The new rates will be offered to each present subscriber at the expiration of his current contract year. If a contract under the new schedule is made in accordance with such offer, and the advance payments required by the old contract have been made, an allowance will be made to the subscriber of the difference between the old and the new rates for the number of local messages covered by the old contract for the period between May 1, 1899, and the date of the new contract. The amount allowed under this rule in any case will be placed to the subscriber's credit on account of his new contract. In all other respects the adjustment of the account under the old contract will be in accordance with the terms of the contract and of the old schedule.

"If the subscriber so prefers, a new contract under the new schedule will be accepted to supersede the old contract before the expiration of the current-contract year, the superseding contract to take effect at the end of the current-contract quarter, but in this case no additional allowance will be made from the requirements of the old contract.

"A flat-rate contract may be superseded at the end of any month by a contract under the new schedule. Of the total number of flat-rate subscribers at \$240 a year, it is estimated that about one-half, say 1,250, can obtain a reduction of rate by taking service under the new schedule. These subscribers are invited to investigate the matter, and to arrange for contracts on such basis as may seem to them most advantageous.

"When annual terms under the existing contracts are about to expire, the subscribers affected will be advised in order that they may take steps to secure the advantages of the new rates and rules above mentioned."

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Sheboygan County Telephone company of Sheboygan, Wis., will replace many of its open wires with cables and make other improvements and extensions.

Four different telephone companies are applicants for a telephone franchise at Appleton, Wis.

The Minnesota Telephone company has been granted a franchise for a toll line through Sandstone, Minn.

The People's Telephone company failed to make much of an impression at Grinnell, Ia. It was offered and controlled entirely by Des Moines parties.

The State Center (Ia.) Telephone company proposes to order materials for an exchange at once.

The Oregon Telephone company is installing a telephone exchange at Goldendale, Wash.

The local exchange at Marshfield, Wis., started in last August with 89 connections and now has 109.

The Wisconsin Telephone company will make extensive improvements to the toll station at La Crosse, Wis.

The Western Electric Telephone company will extend its toll wires west from Mitchell, S. D., to Chamberlain and to Woonsocket, S. D. Pierre will also be reached.

The Enterprise Telephone company has been formed at Edgerton, Minn., and it will build toll lines along the Omaha and Milwaukee railways as far as Heron Lake, Minn.

The Iowa Telephone company is joint defendant with the street-railway company at Keokuk, Ia., in an action for damages brought by little Johnny Tighe. A telephone wire broke and fell across the trolley wire, the loose end striking the boy and inflicting what is claimed to be permanent injury.

The council of Dubuque, Ia., has granted the Standard Telephone company a franchise for a local exchange, after an extended fight.

The local telephone exchange at Boone, Ia., will put in an additional switchboard of 500 drops.

F. E. Fee was voted a franchise for a local telephone exchange at Hartley, Ia.

The Fort Dodge (Ia.) Telephone company has added 70 connections to its exchange since March 1st.

The Ogden (Ia.) Telephone company expects to have its new exchange in operation by June 1st.

C. L. Parkhurst and Mr. Thorsrud of Eureka, S. D., have perfected a telephone-switchboard drop shutter which is said to possess many advantages.

The Minnesota Central Telephone company has combined with the Western Stearns County Telephone company of New Paynesville, Minn., and will proceed to construct the toll lines projected by the latter.

The local telephone exchange at Forest City, Ia., has over 100 instruments in use, and the cost for both office and residence service is only 35 cents per month.

E. B. Smith of Omaha has been selected for superintendent of the system of the Iowa Telephone company, succeeding John M. Baker, deceased. Mr. Baker was at the head of the organization for a number of years.

The Blue Earth Valley Telephone company of Winnebago City, Minn., has sold its toll lines in Southern Minnesota to the Northwestern Telephone Exchange company, but retains all the local exchanges. It contemplates extensive improvements to the local systems, including continuous service.

The Scott County Telephone company has been formed at Jordan, Minn., to build lines from Jordan to Lydia and other points in the county.

The Western Electric Telephone company will extend toll lines from Pipestone, Minn., to Heron Lake, making connections there with the Twin Cities.

The People's Telephone company has begun constructing a line from Stewartville, Minn., to Spring Valley, Minn., and also to High Forest.

The Dwelle Telephone company will rebuild the exchange at Plainville, Minn.

The Park Region Telephone company has been granted a franchise for a local exchange at Alexandria, Minn.

Minneapolis druggists have concluded that the profits from the use of nickel-in-the-slot telephones are too small and uncertain to risk the probable loss of trade that their introduction might cause, as the new arrangement is very unpopular.

NEW COMPANIES.

The new telephone exchange at Greer's, S. C., will give direct communication with Arlington, Gilreath Mill, Reece's and other nearby points.

The Marion (Va.) Telephone company, recently organized by D. D. Hull, Jr., of Pulaski, will build a continuous line between Bristol and Roanoke.

Among the incorporations reported from Dover, Del., April 22d, was the New York Telegraph and Telephone company, with capital stock fixed at \$5,000,000.

Since work was begun on the system of the West Virginia Telegraph company at Parkersburg, W. Va., the Bell Telephone company has reduced its charges more than 50 per cent.

COPPER AND ZINC.

The copper combination that has caused so much speculation and apprehension is now in existence. It was incorporated under the name of the Amalgamated Copper company, by the laws of New Jersey, on April 27th, with a capital stock of \$75,000,000. The officers are: Marcus Daly, president; Henry H. Rogers, vice-president; William G. Rockefeller, secretary and treasurer; Henry H. Rogers, William G. Rockefeller, Marcus Daly, Frederick F. Olcott, James Stillman, Roswell F. Flower, Robert Bacon and Albert C. Burridge, directors.

The articles of incorporation filed at Trenton state that the business of the company will be the mining, milling, converting, smelting, etc., of copper, silver, zinc, brass, iron and steel. The provisions of the charter cover practically everything the company is ever likely to want to do, and permits the company, among other things, to buy and sell buildings and smelting plants and acquire properties. It was reported at the time of the incorporation that the capital stock of the company will be increased on or before June 1st to \$250,000,000 with the possibility of an ultimate increase to \$400,000,000.

Marcus Daly, the president of the new company, is a well-known mining man, and one of the chief owners of the great Anaconda copper mine of Butte, Mont. H. H. Rogers and William G. Rockefeller are Standard Oil men, and A. C. Burridge, who is a Boston man, is one of the counsel of the Standard Oil company. Robert Bacon is a member of the firm of J. P. Morgan & Co.; Roswell F. Flower is the head of the firm of Flower & Co.; F. D. Olcott is president of the Central Trust company, and James Stillman is president of the National City Bank of New York.

The company has already purchased large interests in the Anaconda Copper company, the Parrott Silver and Copper company, the Washoe Copper company, the Colorado Smelting and Mining company and other companies and properties. It is asserted that among the properties which the company has taken over, or will soon secure, are all the Michigan copper mines and the Butte and Boston, and the Boston and Montana, and there are rumors that negotiations are pending also for the acquisition by the Amalgamated Copper company of a controlling interest in Senator-elect W. A. Clark's great United Verde mines in Arizona. But it is also asserted that the Calumet and Hecla mine of the Lake Superior region and the United Verde mines will not go into the trust.

The stock of the company is offered for sale at the par value of \$100 a share.

The Engineering and Mining Journal does not believe that the new company will be able to control the market. In relation to the demand and prices for copper that journal, in its issue of April 29th, says: "Business continues very active, and, as a result, values have improved still further. We quote Lake, 18½ to 19 cents; electrolytic in cakes, bars and ingots, 17¼ to 17½ cents; in cathodes, 17 to 17¼ cents, and casting copper, 17 to 17¼ cents. Consumption in this country keeps up on an unprecedentedly large scale, and notwithstanding the extremely high prices ruling there are as yet no indications that the business of manufacturers is being interfered with. As far as the London market is concerned, we have had a much steadier week than for a considerable time past. Values have not fluctuated as widely as they did the previous week; in fact, the changes have been of an infinitely small character, and conditions in general, considering the high prices that have recently been established, have been remarkably normal."

A London dispatch of April 26th says that the rise in the price of copper is seriously affecting the mid-land industries. The Kynoch company of Birmingham, manufacturer of arms, munitions, etc., has discharged over 1,000 hands, and the remainder of the employes of the factory are working half time. The government has ceased placing orders for copper, and the electrical firms are greatly hampered in filling orders for which contracts were made some time ago, based on a low price of copper. The Rothschilds and J. S. Morgan & Co. deny that they have any connection whatever with the American copper combination.

At Trenton, N. J., on April 25th, articles of incorporation were filed with the secretary of state for the Tennessee Copper company, with an authorized capital of \$5,000,000. The company is empowered to mine and work copper and other ore. The incorporators are Charles W. Welch, Joseph Reichert, Charles M. King, John B. Fisk and R. G. Ingersoll of Jersey City.

Zinc is also booming in price, 60 per cent. ore selling as high as \$56 a ton last week. The production of zinc is treated in an interesting manner in the following article from the Bulletin of the Boston News Bureau:

The recent rise in the price of zinc ore, which has been greater than the advance in foot copper, has brought American zinc properties before the public as never before.

This week [about April 22] zinc ores sold at \$52 per ton for 60 per cent. ore, which is the standard, or price paid by the smelters' agents at the mines varying above or below this price, according to the increase or decrease of the percentage of zinc in the ore. The previous highest was \$48.50 per ton. A year ago

the price was \$26 per ton, or one-half the present extreme price, and a few years ago the price was well below \$20.

The advance in zinc has been due to the exhaustion of important mines abroad, especially in Belgium, where they have been worked below the sea level and flooded; also to the increased consumption of brass, which is made of zinc and copper, and the expansion of the electric field and the development of the cyanide process for gold extraction. South Africa alone is said to consume 10,000 tons of zinc in the extraction of gold through the cyanide process. There is no such thing as zinc scrap. Zinc is eaten up or vaporized, and is more distinctly consumed than any other metal. It is estimated that in the production of \$10,000 in gold by the cyanide process two tons of zinc are eaten up. In the electric field the zinc is the only negative metal, and there is yet no substitute for it. It is very volatile, and in the ore-smelting process it is first vaporized, and then condensed. It requires three tons of coal to smelt one ton of zinc, and, therefore, zinc ores are carried to the coal fields or to the natural gas wells.

A few years ago we exported no zinc in ore or pig. The government reports show for the calendar years the following as the zinc exports of the United States in the last four years:

Year.	Ore, pounds.	Pig metal, pounds.
1895.....	48,000	3,060,805
1896.....	4,150,000	20,260,169
1897.....	16,520,000	28,490,662
1898.....	21,040,000	20,993,413

The world's production of zinc is said to be about 400,000 tons of zinc ore of which the United States is producing 255,000 tons per annum. Last year the United States produced 235,000 tons of zinc ore, an increase over 1897 of 53,000 tons. As three-quarters of the American supply comes from the Missouri-Kansas district, which will run above 50 per cent. of metallic zinc in the ore, the American production of zinc can be safely set down as now about 270,000 pounds, which was the American production of copper but a very few years ago.

As in copper, the positive metal in the electric field, so in zinc, America now controls the markets of the world. It would appear that America had not only the telegraph and telephone development of the world, but the electric-railway development, the electric-machinery development, and the control of both the positive and negative metals essential in the production and distribution of electricity. We make the following comparison of the present annual American production of copper, zinc and lead, compared with ten years ago and 1880:

	1880.	1889.	1899.
Copper, lb.....	60,480,000	231,246,214	560,000,000
Zinc, lb.....	46,478,000	117,720,000	270,000,000
Lead, lb.....	195,650,000	363,934,000	450,000,000

The great zinc field of America is at Joplin, Mo., and a radius of fifteen miles from the center of Joplin embraces the entire territory of zinc production in this region, so far as is now known. Smelting profits and mining profits here have been something astonishing, and miners who cannot read or write have been made millionaires from a few hundred acres of land.

It is said that the present high price of zinc ore is stimulated by the increased smelting capacity of the district, as smelters once started can close down only at considerable loss; but, as the foreign markets lead us in the advances in zinc or spelter, as the pure metal is called, the present industrial prosperity and electrical development may be looked to as the main spring of all other causes for advancing prices. It is said that there is 32 pounds of brass in the car bearings under each of the 1,500,000 cars of the United States, which have to be replaced four times a year, and this uses up a tremendous amount of both zinc and copper. Zinc is coming into use very largely for seal coverings. It has the clinging quality for the foothold, wears well and is not affected by the weather, but under strong heat it vaporizes and leaves no residuum as do other metals. Probably the largest use for zinc is in coating iron through the manufacture of galvanized iron. Galvanized nails are rapidly supplanting all other iron nails.

Dr. Hopkinson's Visit.

Dr. Edward Hopkinson of Manchester, England, brother of the late John Hopkinson, whose sudden death while mountain-climbing in the Alps last summer is still fresh in the minds of electrical men, is visiting the United States and was in Chicago last Saturday. Dr. Hopkinson is a well-known engineer, and has designed many improvements in dynamo-electric machinery. He also planned several of the English electric-railway systems. He visited the Harrison street station of the Chicago Edison company and several other electrical plants in Chicago, and was particularly interested in the Sprague multiple-unit system of electric-railway operation and the storage-battery installations. He expects to sail for England about May 13th.

Dr. Hopkinson says that the next four or five years is bound to witness a great advance in the electrical industry in Great Britain, particularly in the building and extension of electric-railway lines. The extent to which municipal control of street-railway enterprises is exercised in English cities has tended to discourage the investment of capital in new plant and apparatus, as the time permitted for returns on the investment is short. But more liberal arrangements are hoped for, and with them will come a large number of electrically operated systems.

The visitor was asked about the prospects of the Nernst electric light, but he was cautious in expressing an opinion about the new invention. He was not enthusiastic over the possibilities of the electrolytic lamp, but thought that possibly it might have a field of usefulness after considerable improvement.

Chicago Electrical Banquet.

Arrangements have been made for the third annual dinner of the Chicago electrical fraternity at the Grand Pacific Hotel, on Thursday evening, May 11th. The banquet committee having the arrangements in charge is composed of B. J. Arnold, Charles A. Brown, C. D. Crandall, Edward B. Ellicott, Angus S. Hibbard, Samuel Insull, George A. McKinlock, E. B. Kittle, W. J. Lloyd, W. H. Merrill, Jr., Fred Sargent, B. E. Sumy, C. H. Wilmerding and F. B. Badt.

An effort has been made to compile a complete list of men engaged in electrical pursuits in Chicago, but the committee realizes that many omissions must have been made. The secretary of the committee, F. B. Badt, requests that those who have not received cards send their names and addresses to him at 1504 Monadnock building. Responses to invitations should be sent to the secretary by May 6th. Tickets for the dinner have been placed at \$7.50.

Important Three-wire Patent Decision.

The motion for preliminary injunction in the suit of Edison Electric Light company against the Imperial Electric Light, Heat and Power company of St. Louis has been decided by the United States District Court at St. Louis against the Edison company. The opinion of the court, which is very brief, was delivered by Judge Adam, and is as follows:

"After a careful consideration of the proof before me I have reached the following conclusions, which I will state in a summary way:

"First—There has been no adjudication by any court of concurrent jurisdiction of the validity of complainant's patent, after a hearing on the merits.

"Second—There has been no such public and general acquiescence in complainant's rights to an exclusive monopoly in the three-wire system of electrical distribution as to raise a fair or reasonable presumption of the validity of the patent. In fact, the proof shows quite the contrary. Divers parties appear to be employing the three-wire system in direct and intentional disregard of the complainant's claim to a monopoly therein. Such being the facts, it is clear that no case is presented for a preliminary injunction. The parties' rights must be determined after proof taken and a hearing on the merits."

Richard N. Dyer and A. C. Fowler appeared for complainant and Charles A. Brown and George H. Knight for defendants.

This decision, it is claimed, practically opens the three-wire invention to unrestricted public use, as the complainant having avoided a hearing of the case upon its merits until so late in the life of the patent, it will now be impossible to secure a decision of the court in a contested case prior to the expiration of this patent.

Detroit Street-railway Ownership.

The opponents of Governor Pingree's plan for municipal ownership of street railways in Detroit have secured the services of Professor C. A. Kent, said to be the ablest constitutional lawyer at the Detroit bar. Professor Kent proposes to bring injunction proceedings against the commission in the Supreme Court. He gave out an authorized interview, in which he said:

"This is the first tangible movement in the direction of socialism. It is the first evidence of a concerted action, and is the first indication of the crystallization of a communistic sentiment, which has been preached and initiated with much vigor for the last decade. We do not know what the limitations of such a movement will be when once it is started. We cannot conceive whether they will result in confiscation and the curtailing of private rights. If the city goes into the street-railway business, there is nothing to prevent it from organizing itself into a socialistic commonwealth.

"This is not a case where the Detroit Street Railway Commission and the street-railway company of this city are alone interested. There is not a great public utility operated by a corporation in the country that is not more or less affected by this experiment, and there is not one of them that will not feel the danger of socialist tendencies if they ever get a start. The decision which will be given by the Supreme Court will spread its influence all over the whole world, into the homes of all classes of people. It is not a decree of the law so much as it is a decree of sociological importance, and places or fails to place the limitation upon socialistic enterprises."

National Electric Light Association.

Mr. C. O. Baker, Jr., master of transportation of the National Electric Light association, gives notice that the Trunk Line association, the Central Passenger association, the Southeastern Passenger association and the New England Passenger association have granted a rate of fare and one-third, on the certificate plan, from points in their territory and return, for delegates and friends attending the twenty-second convention of the association, to be held in New York on May 23d, 24th and 25th. The following-named gentlemen will have charge of transportation matters for their several localities: Mr. W. Forman Collins, 510 Marquette building, Chicago, Ill.; Mr. H. A. Wagner, Missouri Edison company, St. Louis, Mo.; Mr. C. E. Hesser, Cincinnati Gas Light and Coke company, Cincinnati, O.; Mr. Morris W. Mead, city electrician, Pittsburg, Pa.; Mr. R. F. Ross, 620 Atlantic avenue, Boston, Mass.; Mr. H. B. Cutter, 1112 Sansom street, Philadelphia, Pa.; Mr. S. C. D. Stern, city electrician, Denver, Colo.; Mr. H. M. Atkinson, Georgia Electric Light company, Atlanta, Ga., and Mr. E. R. Weeks, Kansas City Electric Light company, Kansas City, Mo.

City Lighting in Ottawa, Ill.

The annual report of the superintendent of the lighting department of Ottawa, Ill., shows that 136 city lights have been maintained at a cost of \$5,484.71 for the year.

Power is furnished by the Thomas Electric Light and Power company, in whose station the city's dynamos are placed. The company furnishes oil and waste and attendance for the city's generating plant, the total charge last year being \$2,803.12.

The pole lines and lamps belong to the city, and

lamp renewals, repairs and replacing of carbons are items of expense.

The original plant was installed April 1, 1891, at a cost of \$13,000, and additions have since been made at an expense of \$3,054.87, bringing the total cost to date \$16,054.87. It is estimated that the present value of the plant is \$10,885.05. In the items of expense no provision is made for depreciation, nor is any charge made for interest on investment. The following paragraph from the superintendent's report shows that the city is now confronted with the serious problem involved in depreciation, etc.: "During the coming year the outside construction will require considerable repairs, the poles, cross-arms and pins having arrived at that stage where age has begun to affect them, principally by rot. The dynamos will require more attention and repairs than formerly; age has affected them also."

A New Mast-arm.

The old method of supporting street arc lamps from a cross-suspension wire, while very good in its way, has three objections, all of which can be avoided

A NEW MAST-ARM.

by using a mast-arm in place of the suspension strand: The supporting strand wears out, and hence has to be replaced after a number of years; the cross-suspension is not nearly as firm or as slightly as a good mast-arm, and it requires an extra pole at the opposite side of the street. All three of these objections are being more strongly felt now than they have been in past years. The decreasing margin of profit on street-lighting contracts makes it necessary to do away with parts that wear out; the demand for a faultless service means that lamps loosely supported will lead to "outage" rebates in windy weather, and the objections raised by property owners to poles in front of their land make a smaller number of poles advisable.

As the natural result of these tendencies, there has been a growing demand for mast-arms in the West, as well as in the East, though this has been checked by the high cost of the older types of such fixtures. Seeing this and knowing the readiness with which its well-known lamp-supporting pulley would lend itself to making a firm and safe fixture, the George Cutter company of Chicago has brought out the new mast-arm represented in the cut.

The steel strain rods run from the rigid wrought-iron strain arm at the back of the pole to the outer pulley, which supports the lamp from its safety knob. The double bracing keeps the lamp from swinging

always in the wind; the pulleys are weatherproof, and the whole mast-arm is very quickly put up. The new form will be known as Cutter's Junior mast-arm, to distinguish it from the Standard mast-arm made by the same company. It is said to be quite inexpensive and is already in use at a number of points in the central western states. Some of the engineers think that it solves the problem of getting the advantages of a mast-arm without the high cost of one which has been on the market for many years.

The Waterbury (Conn.) American announces that a combination of electric-railway interests, including the Waterbury Traction company, has been formed. Just what companies are included cannot be learned, but it is stated that the combination will include nearly, if not quite, all the electric-railway interests in Connecticut.

Cling-surface Tests.

At the request of the Kling-surface Manufacturing company of Buffalo a series of tests has been made at Sibley College, Cornell University, under the direction of R. C. Carpenter, professor of experimental engineering, for the purpose of determining the relative results of the company's product. Professor Carpenter's report is appended:

The tests were made in every case on the belt-testing machine (Fig. 1) owned by Sibley College. This is constructed so that the belt can be tested under ordinary running conditions and measurements can be made for determining the power supplied, the power delivered, the tension on the belt, the arc of contact on either pulley and the slip. This machine has been used in extensive investigations for determining the efficiency of belting, and is described in Vol. xv, Transactions American Society of Mechanical Engineers. Three belts have been tested, each before and after treating with cling-surface, and each under various conditions of loading. In all, over 50 tests have been made; a considerable number of observations have been repeated in order to check the accuracy of the results.

The belts before testing were in every case clean and in good condition and running under rather better than average conditions. The cling-surface was applied on several successive days and in small quantities, in accordance with the directions supplied by the manufacturers before commencing the test. The material was almost wholly absorbed at the time of starting the test, and none has since been applied. The material made the belt soft and pliable and gave it an inner surface somewhat resembling patent leather. This surface was only in the least degree sticky to the touch.

The general results of the test with cling-surface show an increased transmitting power as compared with the same belt in an untreated condition; it also shows an increased arc of contact, and very much less slip. It shows a very high transmitting power when the belt is run extremely loose or with very little tension on the pulleys, the reverse of which is true with the untreated belt. It will be seen by consulting the report that the greatest transmission capacity for the belt treated with cling-surface was found when there was the least possible tension on the belt and when the belt was running so slack that the sides were nearly touched. It will be noted also that as the tension of the belt was increased the transmitting capacity diminished until a tension of about 20 pounds per inch of width of belt was reached, after which the transmitting capacity commenced to increase, and from that point continued to increase with increase of tension.

In the test of the same belt not treated with cling-surface the results were quite different, inasmuch as the capacity with very light tensions was practically nothing and the capacity increased as the tension increased; at no point, however, did the untreated belt have even approximately the same capacity as the treated belt with the same tension; and moreover the treated belt transmitted much more power with a very light tension than the untreated belt with a heavy tension. The test with the belts treated and untreated running on wooden pulleys showed essentially the same characteristics. The general effect of the cling-surface appears to enable the belt to transmit a power equal to its entire capacity without producing heavy stresses on the driving boxes of the pulleys, or in other words it enables the full capacity of the belt to be obtained for transmitting power when the belt is so loose that the sides nearly touch.

The general results of the tests of the untreated and treated

FIGS. 1, 2 AND 3. CLING-SURFACE TESTS.

belts when running on iron pulleys is shown in the accompanying diagrams, Figs. 2 and 3. In Fig. 2 the horizontal distances show tension on the belt in pounds per inch of width, the vertical distance shows the horse power transmitted per inch of width of belt for a speed of 4,500 feet per minute. The lower line represents the results obtained with the untreated belt, the upper line the results obtained with the treated belt. It will be noted that the lower line continually rises, showing an increase in capacity with an increase in tension; the upper line descends at first, showing a decrease in capacity with increase in tension; and later rises. In no place does the transmitting capacity of the treated belt fall below that of the untreated belt. In comparing the respective results it will be noted that the treated belt has a carrying capacity of 13.8 horse power when the tension per inch of width is five pounds, while for the same conditions the untreated belt has no carrying capacity; furthermore, it is noted that the carrying capacity of the treated belt, even at this low tension, is nearly 40 per cent. higher than that of the untreated belt even when the tension has been increased to 80 pounds per inch of belt width. The diagram in Fig. 3 shows the arc of contact and the maximum percentage of slip for belts run both in the treated and untreated condition with different tensions and on iron pulleys. From this it is seen that the slip of a treated belt is much less, and the arc of contact greater for a given total tension than with the untreated belt.

The falling off in carrying capacity with increase of belt tension for the treated belt is doubtless due to the rapid change in

the arc of contact, which diminishes with increase of tension. This causes a diminution in the transmitting power, which is greater than that produced by the increase of pressure due to the increased tension on the belt. With the untreated belt such change is very slight, and consequently a falling off in carrying capacity for light tension takes place.

In regard to the questions raised as to the preservative qualities of cling-surface and to the permanency of the effect produced by its application, the writer would say that our tests have of necessity been of too short duration to give conclusive answers. The general effect of the cling-surface is to soften the belt and to put it apparently in the best condition for transmitting power and retaining its good qualities. The surface produced by the cling-surface remains apparently unchanged after several weeks of use, and the inference to be drawn is that the

INCANDESCENT LAMP MANIPULATOR.

material has an effect which continues permanent for some time at least.

Incandescent Lamp Manipulator.

"An ingenious and simple 'handy tool' " is the description of the instrument illustrated in the accompanying cuts. This manipulator for incandescent lamps is meeting with ready sale in the hands of the Incandescent Electric Light Manipulator company of 116 Bedford street, Boston.

Most incandescent lights in large buildings are at such heights and angles that it is necessary in replacing or cleaning them to erect staging, use long ladders or boatswain chairs, which take two or more men considerable time to handle, and there is also the liability of scratching interior finish and chipping stucco work, to say nothing of the risk of accidents to the men so employed. With the device herewith shown, one can keep burnt-out lights replaced and clean the lamps without the aid of scaffolding, ladders, etc.

The manipulator is light in weight, but mechanically built to last, and all parts can be duplicated. The

nippers are lined with rubber, and can be made to fit any shaped bulb. The ordinary manipulator will remove from 16 to 52 candle power street bulbs and 16 to 32 candle power indoor bulbs of any standard make, and can be built to work at any height or angle. The pole can be telescoped to suit different heights, and it makes it handy for handling street lights or for laying aside when not in use. Every manipulator is tested before being shipped, and is fully warranted. It is recommended for cars, depots, steamboats, street lamps, public halls, hotels, stores, theaters, churches, fine residences, public and office buildings and show windows. The device is now in use in Boston, Mass., at the state house, Mechanics' building, City Hospital, Trinity Church, Mission Church, American House, Paine's furniture warehouses and subway, and by the elevated-railway people and Department of Public Grounds, and also in many other towns and cities all over the United States and in foreign countries.

Elliptical Carbon Patent Litigation.

The United States Circuit Court for the Western District of Pennsylvania rendered a decision on April 24th, in the suit brought by the Elliptical Carbon company of Chicago against the Solar Carbon and Manufacturing company, Joseph K. Cass and F. B. Laughlin, officers of the Solar Carbon and Manufacturing company of Pittsburg. The patent involved in this suit was that of Samuel P. Parmlly, No. 540,800, issued June 11, 1895, upon an electric arc lamp. This patent, although upon an arc lamp, covers more particularly the so-called elliptical carbons, well known to the trade, which are adapted to burn in electric arc lamps and give double duration to the burning time of a lamp with one trimming.

The character of the invention will be understood from the following claims, which are selected from nine which the patent contains, and all of which were involved in the suit:

1. A pair of carbon pencils for an electric arc lamp, burning the pencils by holding them in line end to end and having a feed mechanism adapted to adjust the pencils toward one another as they are consumed, formed each with a total cross-sectional area approximately twice that of the round carbons ordinarily employed on a circuit carrying the same current, and at least one of them formed as a flattened bar or prism of elliptical cross-section with a thickness at the minor axis approximately equal to the diameter of the ordinary round carbon.

6. A pair of carbon pencils for an arc lamp adapted to be presented to one another end to end and to be adjusted toward one another as they are consumed by an arc passing between them, formed each as a flattened bar or prism thickest at the middle and becoming thinner toward the edges as and for the purposes described.

The court sustained the patent, and ordered a decree in favor of the plaintiff, enjoining the defendants from the manufacture of the so-called elliptical carbons and directing an accounting of damages and profits.

The invention of the elliptical carbon by Mr. Parmlly was made at a time when the Brush double-carbon lamp patent was threatening to give a monopoly of the all-night lamp to the Brush Electric company. The application for patent was involved in a series of interferences, but Mr. Parmlly was ultimately adjudged to be the inventor, and was awarded the patent which was involved in the suit referred to.

The patent had been generally respected. One suit had been begun against the Calumet Gas company in Chicago, but no adequate defense was made, and a decision was reached by the court giving the Elliptical Carbon company an injunction. Subsequent to this decision at Chicago, suit was brought against the Solar Carbon and Manufacturing company, which has just been decided in favor of the complainant.

The case was elaborately argued on November 29, 1898, and the effect of the dimensions of the carbons set forth in the patent was demonstrated to the court by a practical exhibition of the arc projected by means of a lens upon a screen. In this way it was shown that when the dimensions of the carbons differed from those set forth in the patent to Mr. Parmlly, instead of getting the arc which gradually weaved back and forth across the ends of the carbons, lingering slightly at the ends of each excursion, but not becoming localized at any other place (which was the action of the arc with the carbons of the Parmlly patent), the arc between carbon plates would become localized and would leap from one place to another, causing a momentary extinction of the light, and thus render it intolerable for use. This demonstration made to the court was in direct contradiction of the statements of the experts for the defendants and of counsel for the defendants, who asserted most positively that this traveling arc, which had been described as the result secured by the elliptical carbons of the Parmlly patent, was "an impossible action." The court decided that the defenses set up by the Solar Carbon and Manufacturing company, including prior public use, prior publication, prior invention and non-infringement, were none of them sustained by the proofs.

The complainant was represented by Charles A. Brown & Cragg; the defendants by the well-known attorneys who represent the Westinghouse Electric and Manufacturing company, Kerr, Page & Cooper.

Cable from the United States to Germany.

President McKinley has approved the project of landing a direct German cable on the coast of the United States, and his action brought a cordial message of appreciation from the German kaiser. The new company is to be known as the German-American Telegraph company, and among those interested in it are prominent firms in Germany as well as a number of Americans. The details of organization have been in charge of Mr. Sporer, in New York. The German terminus of the new cable will, it is understood, be at Ems, a town and watering-place in the province of Hesse-Nassau, Prussia, near Coblenz. The American terminus is expected to be at New York. The route of the line is by way of the Azores, a Portuguese possession, so it is presumed that concessions have also been obtained from Portugal. This will be the first cable ever laid between Germany and the United States, and, with the exception of the Franco-American cable, will be the only transatlantic line not touching on British soil.

Cable Ship for the Philippines.

(From the New York Tribune.)

Washington, April 28.—General Greely says that the United States transport Hooker will be placed under the orders of Major Joseph E. Maxfield on Saturday. She will sail from New York on Monday, carrying Major Maxfield, Lieutenant Clarke and 25 men of the regular Signal Corps to replace Signal Corps volunteers in the Philippines. The ship carries 212 miles of deep-sea cable and all the gear necessary for laying, recovering and repairing the submarine cable. The cable is entirely of American manufacture. It will be used to connect such islands and points as General Otis may deem necessary for military administration. It is expected that this system will supplement the cable lines of the Eastern Extension Telegraph company to such an extent that General Otis will be able to communicate speedily with all the important islands of the Philippine archipelago. Major Maxfield, who is in command of the expedition, is a graduate of Harvard, has served 17 years in the Signal Corps, and performed gallant and distinguished service in Cuba.

The progress of the expedition will be watched with interest, it being the first effort of American manufacturers and American officers to lay a deep-sea cable of such length in distant waters. In addition to the cable, the Hooker carries materials and instruments for 1,000 miles of land lines, 100 telegraph offices and 100 telephone stations. These supplies, with those already in the Philippines, are sufficient for the construction of 2,000 miles of telegraph and cable lines. The present Philippine system consists of about 300 miles of cable and 1,850 miles of telegraph lines. The cables are those of the Eastern Extension Telegraph company, laid and maintained under concessions and with promises of subsidies from Spain. The land lines are now the property of the United States, but fully 1,000 miles are occupied and operated by the Filipinos. The Hooker will go through the Suez Canal, and should reach Manila about June 20th.

The Hooker is the old Spanish prize the Panama, the second to be taken in the war with Spain. The little lighthouse tender Mangrove had the credit of the capture, and her crew made a neat little sum in prize money. She still bears many reminders of the Spaniards in the decorations of her cabin. Only one design was removed, and that was a handsomely executed Spanish coat-of-arms. The Hooker has been entirely refitted from stem to stern, and is said to be a model cable ship. She is 325 feet long and 35 feet beam. Her tonnage is 2,935. On her stern are mounted two six-pounder rifles, and in the magazine is a large amount of ammunition. She also carries magazine guns.

Electrical Production of Aluminum.

It is expected that the somewhat famous suits over the patented process for the manufacture of aluminum will be heard on appeal in the United States Court for the Northern District of New York, at Utica, N. Y., next October, Judge Cox presiding. The case is entitled the Cleveland Electric Smelting and Aluminum company against the Pittsburg Reduction company, and is some years old. The suit is one wherein the Pittsburg Reduction company is sued by the Cleveland Electric Smelting and Aluminum company for alleged infringement on two patents issued about January, 1892, to Charles S. Bradley, involving, as claimed, the process practiced at Niagara Falls in the manufacture of aluminum. In all there are 10 claims attached to the papers being prepared by the Cleveland Electric Smelting and Aluminum company in the case. The patents were applied for in February, 1883.

The nature of the claims set up may be judged from the following paragraphs taken from the patents:

"The process of obtaining aluminum from its ores or compounds consisting in passing an electric current through a forced portion of the aluminum ore or compound contained in an unfused body or heap of said ore or compound."

"The continuous process of separating or desiccating aluminum from its ores or compounds consisting in fusing and maintaining the fusion and electrolytically decomposing the ore or compound by the passage of the electric current therethrough, and charging the pots with fresh quantities of the ore or compound as the reduction proceeds, substantially as set forth."

It is understood that these patents were purchased by the Cowles people, who are interested in the Cleveland Electric and Smelting company, but who were then in Lockport, in 1885. After their issuance from the Patent Office, in 1892, a long litigation followed between the Cowles Electric Smelting and Aluminum company and a patent lawyer in New York, Grosvenor P. Lowry by name, who had also made a purchase of the patents from Bradley, probably under the assumption that the so-called original assignment to the Cowles people was not perfect. This suit against Lowry was decided in favor of the Cowles company, and it then began the present suit against the Pittsburg Reduction company.

In 1891 the Cowles company sued the Pittsburg Reduction company, under patents covering the same ground practically as those issued to the Cowles Brothers, but that suit had to be with-

drawn because the Bradley patents, bearing an earlier date of application than the Cowles patent, issued from the Patent Office, a signed to Lowry, who was then the American representative of the great aluminum company at the Falls of the Rhine, in Switzerland.

Charles M. Hall, the inventor of the process now used by the Pittsburg Reduction company, is now with that company at Niagara Falls. It is said that his early experiments were carried on in the Cowles plant then in operation in Lockport, N. Y. In 1892 the Pittsburg Reduction company sued the Cowles company under a patent that Mr. Hall secured. On trial, the United States Court in Cincinnati construed the Hall patent very broadly and enjoined the Cowles company from continuing the manufacture of aluminum, since which time the plant in Lockport has been closed. This suit has not as yet reached an appeal.

The process of making aluminum consists of fusing the materials from which the aluminum is produced in a large iron tank open at the top and lined over the bottom by a heavy mass of carbon. The electricity passes into the material fused by means of a number of heavy carbon rods three or four inches in diameter, the ends of which hang down into the liquid bath. The aluminum is deposited very much the same as nickel is deposited by electrolysis and collects as a mass of molten metal below the fused bath by aluminous material. No heat but that evolved from the electric current is used.

CORRESPONDENCE.

New York Notes.

New York, May 1.—The amended rapid-transit bill became a law last week. As it finally passed, the law embodies the governor's suggestions that the period of the franchise be limited to 50 years, with 25-year renewals at the discretion of the city authorities, and providing for free competitive bidding. Governor Roosevelt expressed himself as much pleased at the passage of the bill, and asserted that its enactment would not only give the people of New York city the rapid transit which they have long looked forward to, but would also provide an adequate return to the city for the valuable franchise thus granted if a private corporation is empowered to build the road. It is considered probable that the Third Avenue company will bid for the franchise for building and operating the road, and the owners of the Metropolitan street-railway system may renew their offer in modified form. The only offer now pending before the Rapid Transit Commission is that of the Metropolitan Contract company, of which Frederic B. Esler is president.

Anthony N. Brady has been made president of the New York Gas and Electric Light, Heat and Power company. The company has given to the Central Trust company a mortgage for \$21,000,000, covering its property at Ninety-seventh street and First avenue and its franchises and privileges. The mortgage runs for 50 years. The bonds are issued to take up the stock of the Edison Electric Illuminating company. The company filed a mortgage for \$15,000,000 on its property in December. This older mortgage is held by the State Trust company.

A week from to-day the electrical show in Madison Square Garden will be opened. The exhibition will continue until June 3d. On May 23d, 24th and 25th the annual convention of the National Electric Light association will be held in this city, and members and visitors will have an opportunity to see the show. Several popular features are planned, including a demonstration of the work of the Signal Corps of the regular army.

Senator Ford's bill taxing corporations operating under municipal franchises is now a law, and it is exciting a great deal of discussion. The theory of the measure is that profitable franchises should make a return to the people in taxes, but as the manner of arriving at the taxable value of franchises is left to local assessors, it is feared that there will be as many plans of fixing the value of franchises as there are boards of assessment. Street-railway, gas, electric-light, telephone and telegraph companies are affected by the law.

The Brooklyn Rapid Transit company assumes the management of the Nassau electric system and the Brooklyn Union elevated road to-day. Both will be operated in connection with the Brooklyn Heights road. President Rossiter has issued a general order announcing these appointments: Ira S. McCormack, general superintendent of transportation; J. C. Breckinridge, chief engineer of the construction and maintenance department; F. S. Drake, superintendent of shops, and Lincoln Van Cott, purchasing agent.

Canadian Intelligence.

Ottawa, April 29.—It has been decided by the Grand Trunk railway authorities to work the traffic over the new Victoria Jubilee bridge, across the St. Lawrence, at Montreal, on the electric-block system. The contract for the erection of the necessary plant has been placed in the hands of the Royal Electric company. The question of electrical block signaling has occupied a good deal of attention in railway circles recently.

The Town Council of Barrie, Ont., having just

gone into the municipal electric-lighting business, has fixed the lowest prices in Canada probably. Store lights start at \$5 per annum for single light, and grade to \$2 per light for 20 and over; residences, \$4 for one light, and \$1.50 each for 20 or over. Churches are given lights at \$1.50 each per year. Meter rates for 10 lights and over have been fixed at 10 cents per thousand watts, which is a reduction of 7½ cents on the light companies' rate. The town will spend \$10,000 in addition and improvement to the plant.

The Metropolitan Electric company of Ottawa, Ont., will in a few weeks place an order amounting to \$350,000 for the machinery in the power house to be erected at Britannia, eight miles from the city. The power house, when completed, will surpass any other in the Dominion, and will be thoroughly equipped with the most improved machinery. The plant will include 20 water wheels of 240 horse power each, four large generators, two small generators and switchboards, regulating machinery and appliances and safety devices.

Mr. Frank A. Cote of the firm of Cote & Coursoles, electricians of Ottawa, Ont., has invented a new lightning arrester, especially adapted for telephone lines. Mr. Cote's device was tested recently in the presence of the experts of the Bell Telephone company and proved highly successful, the strongest current being intercepted.

A project is on foot to build an electric railroad between Trenton and Westville, Pictou County, in the province of Nova Scotia, by way of the towns of New Glasgow and Stellarton.

It is stated that the various electric companies doing business in the city of Montreal, Que., in lighting, power distribution and passenger transportation, will be amalgamated, with a probable capital of \$10,000,000 or \$15,000,000.

The property holders of the city of Winnipeg, Man., voted a few days ago on a by-law to raise \$60,000 for the establishment of a civic lighting plant. The vote polled was 876 for and 231 against. It is claimed, however, that a number of those voting were non-residents, and that the necessary majority to carry the by-law has not been received.

Ahearn & Soper of Ottawa have received the contract for the equipment of the electric railway between Quebec and St. Anne de Beaupre, via Montmorency Falls and Beauport, a distance of 28 miles. The contract includes the power house, generators at Montmorency Falls, rotary transformers at St. Anne's and all the cars and electrical apparatus in connection therewith. The cars will be 55 feet in length and will be manufactured in Ottawa. The electrical apparatus is to be manufactured by the Westinghouse company. The line will be the longest electric railway at present in the Dominion.

A bill to incorporate the Nova Scotia Electrical Light and Heat company has passed the Legislature of that province. The company proposes to light by electricity the whole of the Annapolis valley from a power station to be situated on the Gaspereau River. The estimated expenditure is placed at \$400,000. One of the incorporators is the Hon. F. W. Borden, minister of militia for Canada.

A syndicate of Toronto capitalists, headed by Mr. J. A. Culverwell, electrical and mechanical financial broker, is reported to have purchased the Burleigh Falls water power, near Peterboro, Ont. The purpose is to develop the power and transmit it to Peterboro and Lindsay, 20 and 30 miles distant respectively. There is a head of 25 feet and an estimated power of between 300 and 500 horse power. The dam and power house will be located at Perry's Creek, at a point where the channel is so narrow that a concrete dam for the purpose can be built at a cost of about \$5,000. At Lindsay the town lighting contract has been secured for 10 years and business from power and light amounting to some \$15,000 per annum. The company will be capitalized at \$200,000.

The Ottawa Metropolitan Electric company has commenced the work of construction on its canal end power house near Britannia, five miles from Ottawa. The operations will be continued over a period of six months. W.

PERSONAL.

George F. Porter, secretary of the National Electric Light association, was in Chicago early in the week. He says that the convention of the association in New York this month promises to be a successful one. The programme will be issued in a few days.

S. Fugita, superintendent of the Tokio City Street Railway company of Tokio, Japan, was in Chicago early in the week. He is said to be visiting this country to investigate the practicability of compressed air as a motive power for street railways and to have been favorably impressed.

Professor Charles F. Chandler of the School of Mines of Columbia University, New York, has been nominated for president of the Society of Chemical Industry, which is now in session at Glasgow. Professor Chandler, it is said, is the first American to be nominated for the presidency of an English scientific society, and a nomination is equal to an election.

On April 27th Seabury C. Mastick, W. T. Morrill, W. K. Sparrow, Clarence Weissblatt, Reginald Pelham Bolton, Julius A. Bychower, H. B. Palmer, A. C. Walter, Walter Hinman Beebe, Frederick

Montgomery Holbrook, H. P. Merriam, E. T. Williams, Lewis B. Marks, F. E. Morgan, Arthur Williams, Solomon Davis and Charles L. Clarke of New York and vicinity were elected members of the New York Electrical society.

Prof. Andrew Jamieson has decided to retire from the position of professor of electrical engineering at the Glasgow and West of Scotland Technical College. It is stated that, owing to the amount of time which he has to give to telegraphic development, he is compelled to devote himself entirely to private consulting work. Professor Jamieson has been connected with the college for 18 years, and is the senior member of the staff. The resignation will take effect on July 1st.

ELECTRIC VEHICLES.

In answer to an inquiry from the French government, the secretary of the treasury has announced that horseless carriages or automobiles, or parts thereof, imported into the United States will be subject to duty at the rate of 45 per cent. ad valorem, "as articles or wares composed wholly or in part of metal, under paragraph 193 of the act of July 24, 1897."

The new Columbia Motor Carriage company of New York, which has absorbed the motor-carriage department of the Pope Manufacturing company of Hartford, Conn., has a capital of \$3,000,000. The officers are: President, Colonel Albert A. Pope of Boston; vice-president, George H. Day of Hartford; secretary and treasurer, Harold Eames, formerly a lieutenant in the United States army. Among the directors are William C. Whitney, P. A. B. Widener of Philadelphia, Stephen B. Elkins, G. B. Schley of Moore & Schley, the bankers; Colonel Pope, George H. Day and Harold Eames. It is said that the company proposes to extend its operations over the whole country, erecting factories in Chicago and on the Pacific coast. The Illinois Electric Vehicle company is said to be affiliated with the Columbia company. The Electric Storage Battery company will furnish the batteries.

ELECTRICAL SECURITIES.

The American District Telegraph company has declared a dividend of one per cent., payable May 15th.

TECHNICAL SCHOOLS.

All friends of technical education will regret the announcement that the electrical-engineering department of the Johns Hopkins University is to be discontinued. Lack of funds is said to be the main cause of the difficulty, as the instructors feel that the department is not able to accomplish its purpose upon its present financial basis. When the department was established, in 1886, funds then appropriated to its use were sufficient for maintaining a first-class course, and were ample up to the last three years. For three years, however, much of the original annual appropriation has been devoted to other departments. Cary T. Hutchinson is the associate professor of electricity; Hermann S. Hering, associate in electrical engineering; and Herbert G. Geer, associate in mechanical engineering. The resignation of Dr. Louis Duncan, the head of the department, who secured leave of absence last fall to engage in engineering work in New York, has already been received.

MISCELLANEOUS.

The Y. M. C. A. Electrical Club of Chicago announces an "electrical evening" at Association Hall, 153 La Salle street, for Friday, May 12th, the entertainment to begin at 8 p. m. Mr. A. V. Abbott, chief engineer of the Chicago Telephone company, will lecture on "Wireless Telegraphy," giving the audience a demonstration of the Marconi system in actual operation. Mr. G. W. Patterson will show his pleasing electrical spectacular effects, and there will be a "gramophone grand" concert.

TRADE NEWS.

A. O. Schoemaker, the New York mica dealer, is now represented in Chicago by the W. R. Garton company, Manhattan building.

The Berlin Iron Bridge company of East Berlin, Conn., gave its sixth annual oyster roast to its employees and their families on April 26th.

W. N. Matthews of 312 Commercial building, St. Louis, is general sales agent for the Ritter soldering iron, for which there is a large demand at the present time. Mr. Matthews reports good sales in second-hand machinery, especially in the Southwest.

The Cling-Surface Manufacturing company of New York will make an exhibit at the Electrical Exhibition, Madison Square Garden, New York, May 8th to June 3d, and endeavor to prove to the satisfaction of everyone that a slack belt with cling-surface will transmit more power than a tight one without it.

The demand for a lightning arrester and kicking coil for the protection of fan motors and other small power motors, at a low price, has encouraged the Garton-Daniels Electric company of Kookuk, Ia., to place on the market a full line of these devices.

The company will be glad to furnish full information and prices upon application.

George W. Patterson, the Chicago agent for the American Circular Loom company and Gordon batteries, has removed his office from 1539 to 1533 Marquette building. Mr. Patterson is an expert swinger of the electrical Indian clubs, and he is distributing to his friends and customers photographs showing the beautiful light effects thus obtained.

The Western Electric company has installed in the Robert Law building, 132 Water street, Chicago, two 100-kilowatt direct-current dynamos to furnish light and power for tenants. The same company has sold a 100-kilowatt dynamo to the Wolff Manufacturing company of Chicago and has built a 24-circuit arc-light switchboard for the Ottawa Electric company of Ottawa, Ont.

President H. K. Gilman of the Western Electrical Supply company is one of the busiest men in St. Louis, looking after the constantly increasing business of his company. The Western company has on hand a large stock of everything in the electrical line, and has the reputation for ability to fill all orders promptly. The company is certainly to be congratulated in having the services of such energetic men as H. K. Gilman and R. V. Scudder.

The Montauk Multiphase Cable company of New York has recently opened a Boston office in the Brazer building, 27-29 State street, at which place the various electrical adaptations of the cable are shown upon individual boards and sections of the dangerous parts of buildings. The Montauk Multiphase Cable company's business field is very rapidly developing, and many installations are now being made in various parts of the country. The recent disastrous fires in New York and Boston have created a notable demand for this cable.

The Groshon High-duty Pumping Engine company of New York has applied to the Supreme Court for a voluntary dissolution of the corporation. Judge Truax has set down the order to show cause for August 3d, and appointed Gilbert M. Speir referee. The application was made for Louis E. De La Vergne, Louis Baron and Adolph Bender, directors. The liabilities are \$214,947, of which there is due the De La Vergne Refrigerating Machine company \$214,196 for money advanced, and to John A. Groshon \$751 for services. The assets are about \$4,120. The company was incorporated in July, 1891, with a capital stock of \$10,000, to manufacture a high-duty pumping engine. The largest stockholders are Jacob Ruppert, as trustee for the De La Vergne Refrigerating Machine company, 666 shares, and John A. Groshon, 300 shares. The total number of shares is 1,000.

J. Holt Gates and R. J. Randolph, both widely known and experienced electrical salesmen, have formed a partnership as Gates & Randolph, with offices at 1420 and 1422 Marquette building, Chicago. Mr. Randolph has resigned his position as manager of the sales department of the Sterling Arc Lamp company of New York, and about the middle of this month expects to arrive in Chicago, where he was for several years western representative of the Excelsior Electric company. The concerns which Gates & Randolph will represent are the Sterling Arc Lamp company, the Warren Electric Manufacturing company of Sandusky, O., the Triumph Electric company of Cincinnati, Elmer Morris, the American Electric Specialty company and F. A. La Roche & Co. of New York.

R. J. Randolph, Jr., succeeds his father in the Sterling Arc Lamp company, and on May 1st took the position of general eastern agent for that concern. Mr. Randolph will look after the interests of the sales department of the Sterling company, and, in fact, do everything in the line of the general business of the company that might be expected of a "chip of the old block." R. J. Randolph, Jr., is a young man in the electrical business, but his rise has been a quick one and greatly to his credit. He started about three years ago in Chicago as city salesman for the Wallace Electric company. At the suggestion of his father he gave up this position to go East into the factory of the Excelsior Electric company in New York, with the view of fitting himself along the line of expert electrical work. His talents as a salesman, however, predominated, and he soon commanded the position of city salesman in New York for the Excelsior company, and he held that position until his present promotion to succeed his father.

The electrical fraternity will be interested to learn that the Commercial Electrical Supply company of St. Louis, which recently passed into the hands of William F. Nolker, sons and associates, has completed all its arrangements, and is now in a better position than ever before to make an active canvass for business. The company has unlimited capital and intends to push most energetically for its share of the supply trade. President William F. Nolker is one of the most widely known business men of St. Louis, and is actively interested in some of the largest St. Louis companies, such as the Mississippi Valley Trust company, Kinloch Telephone company, St. Louis Brewing association, Gilsonite Roofing and Paving company, and many other prominent and well-known concerns. Louis T. Nolker, treasurer, and William H. Nolker, secretary, are both

energetic young men and give promise of becoming very active in the electrical business. Vice-president Fred C. Laufketter is one of the best known electrical and mechanical engineers in the West, whose experience covers many years, and who now holds a number of prominent positions in the electrical and mechanical engineering line. Mr. Laufketter should prove a valuable acquisition to the staff of the Commercial company. Paul D. Cable, the former manager of the Commercial company, retains his position with the new company, and, as in the past, will leave no stone unturned to increase the business of his company. The company has increased its stock materially, and is now in a position to fill all orders promptly. The Commercial company is preparing a very fine new catalogue, which, it is said, will have no equal. This will be out in a few weeks and should be in the hands of every user of electrical supplies.

BUSINESS.

The A. Beck Electric company, 303 Market street, St. Louis, is working day and night to take care of its large fan motor business.

President Stanhope of the St. Louis Electrical Supply company, like nearly every electrical concern in St. Louis, reports a most flourishing business. The St. Louis Electrical Supply company is well known in the West, and has no trouble in securing its share of the electrical supply trade.

Vice-president A. C. Garrison of the Columbia Incandescent Lamp company, St. Louis, reports that the demand for Columbia lamps was never so brisk as it is at present. The "Columbia" is known the world over, and few users of lamps of the present day are unaware of the superior qualities the manufacturers claim for it.

The Chicago papers published an article last week to the effect that the Farr Telephone and Construction Supply company, 357 Dearborn street, Chicago, had been swindled out of \$14,000 by a man who claimed to be F. W. Montrose of Kingston, Ont. C. W. Farr, president of the Farr company, states that this is a mistake, as the company lost absolutely nothing in its dealings with the individual in question.

The Royal Electric company of Peoria, concentrating its energy on the development of alternating-current apparatus, with which it has been associated for the last 10 years, advances its claim as a specialist in this line. It says that it is the pioneer

in the manufacture of alternators of the inductor type, and lays stress on the advantages of machines of this character. It solicits correspondence from all interested in the installation or operation of electrical machinery.

Fisher & Cramphorn of Boston, manufacturers of switches, have merged their business into a new company, called the Atlantic Manufacturing company, located at Mansfield, Mass., where it will have a fine factory, fitted with all modern machinery, and where it will be able to ship all orders promptly, instead of having to refuse orders on account of lack of facilities. Mr. Fisher will be vice-president, and will take full charge of the new factory. Mr. Cramphorn will act as treasurer. This will insure customers the same goods as manufactured by the old firm. There will be associated with the gentlemen named Mr. J. S. Keenan as president.

The underwriters' rules are largely responsible for the lessening of fire risks in electric wiring. The Central Electric company, Chicago, has frequently anticipated these rules through the excellent selection of high-grade goods. While the use of non-inflammable tubes for wiring has long been enforced, there is a wide range in quality as handled by the different supply houses. The white clay tube, as carried in a full line by the Central Electric company, is highly vitrified and straight and sound throughout. The company reports a very heavy demand for all white clay tubes, and particularly for the most common size of five-sixteenth inch by three inches, with an outside diameter of nine-sixteenth inch. By boring with half-inch bit and driving this tube into the hole, a lasting fit is assured. The insurance motto of "time-tried and fire-tested" is claimed to be applicable to the Central Electric company's white clay tubes.

The hot season having come on suddenly, electric fans are in order, and as the season promises to be a long and hot one, those anticipating the purchase of fans will do well to place their orders early in the season in order to insure an early delivery. The Western Electrical Supply company of St. Louis, Mo., has made ample provision for its customers this season, and is receiving many orders early in the season for the fans which it supplies. The company considers this influx of orders to be due to the excellent reputation these fans have long enjoyed. For alternating current it is supplying the well-known Emerson model, improved '99 type; and the Paragon direct-current fans are being supplied where this current is in vogue. The fan season has a very

promising outlook at the present time, and the Western Electrical Supply company, from present indications, anticipates a phenomenal trade in this line. It is sending out by mail catalogues devoted exclusively to fans, and will take pleasure in naming special prices on application.

An electric recording meter is one of the most important devices in the equipment of a modern electric-light plant. A lack of accuracy in the meters used in recording a customer's consumption of current means a lack of accuracy in the entire financial results of the business. The central-station manager is therefore always alert for anything new in the meter line. The Electric Appliance company claims to have something of special interest in this direction in the Gutmann recording wattmeter, for which it has just taken the general western agency, and which it is now placing on the market. The company claims that the Gutmann meter will record with absolute accuracy on any load, beginning at 20 watts. This means that this meter will start and register the current consumed with accuracy even if the load is only equal to that of 1-3 of a single 16 candle power lamp. This claim is certainly worthy of investigation, and the Electric Appliance company is inviting the most rigid investigation of its claims for the Gutmann meter.

But few people realize the enormous quantity of crude rubber now being consumed annually in the manufacture of rubber goods throughout the world. Owing to the tremendous trade demands, coupled with the fact that the large wild rubber forests have been gradually exterminated by the natives girdling the trees in order to obtain a greater flow of rubber sap, it is claimed that the world is fast facing a rubber famine. The price on the finest grades has advanced 21 per cent. in the last year, and on the lowest grade, that of African flake, the raw product has jumped 62 per cent. It is conceded by experts that the future supply of crude gum must come from private cultivated rubber groves, and it is claimed that the fortunate owners of a producing rubber plantation will realize fabulous profits annually. Among the first to take advantage of the opportunities is a Chicago company, the Mexican Plantation association, which is said to be strongly backed financially. The concern is directed by men who have had wide experience in land development, while among the stockholders in the company can be found the names of many well-known, conservative business men. The complete plan of the association is well worthy careful consideration. The company has offices at 1603, 100 Washington street, Chicago, where full information can be obtained.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued April 25, 1899.

623,511. Automatic Electric Circuit Breaker. Maurice Bouchet, Paris, France. Application filed January 31, 1898.

Circuit terminals and an electromagnet control the action of the switch, a part forming one cheek of the coil having an internal tubular polar extension gap, the other cheek having an internal polar expansion of decreasing section, and a sheath connecting other parts.

623,521. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed January 19, 1898.

The armature, series and volt coils inductively actuate the armature, an impedance coil being in the shunt circuit with the volt coil; a secondary volt coil is inductively energized from the primary volt coil and co-operates therewith to produce a resultant flux acting on the armature, and a secondary impedance coil is inductively energized from the primary impedance coil and serves to reduce the retarding effect of the latter.

623,522. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed March 12, 1898.

A revoluble cylindrical armature, a series coil or coils in inductive relation to the armature, a secondary coil or coils wound coaxially with the series coils and receiving currents therefrom by conduction, a secondary field coil wound upon a multipolar iron core and arranged within the armature and energizing by conduction from the secondary, whereby a shifting magnetic field is established about the armature to actuate it, and a variable resistance in series with secondary coil or coils.

623,523. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed March 16, 1898.

A secondary coil receives its currents by induction from the series or main current, and this current differs in phase from the current in the series coil; a third coil is in coaxial relation to the secondary coil and adapted to receive its currents from the terminals of the series coil; a close revoluble armature is in inductive relation to the coils and adapted to be actuated thereby; a registering train is operatively connected with the armature; an ohmic resistance is in series with the third coil, and an inductive resistance in series with the secondary coil.

623,524. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed March 24, 1898.

The method described of obtaining a magnetic field in quadrature with the impressed or line electromotive force consists in setting up in a single coil a magnetic field that is the resultant of two currents of different time periods, both of the currents being supplied to the same coil, but derived from different sources, one being obtained from the supply mains and the other from the secondary of a transformer whose primary is connected to the supply mains.

623,525. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed May 23, 1898.

The combination includes an induction-motor meter of a revoluble aluminum disk armature, means for retarding the revolutions of the armature, an unwound iron core having its lower surface parallel with and adjacent to the upper surface of the armature, means for varying the distance between the adjacent surfaces of the iron core

and the disk armature, an iron core adjacent to the lower surface of the disk armature, coils for magnetizing the iron core, a spindle and a suitable registering mechanism.

623,526. Phase Adjustment. Thomas Duncan, Fort Wayne, Ind. Application filed June 13, 1898.

As a means of producing a current lag of ninety degrees in an alternating circuit, an impedance coil is connected in the circuit, and a secondary impedance coil is connected in a separate circuit energized from the same source as the first impedance coil and inductively affecting the latter.

no. 623,547.

623,527. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed July 5, 1898.

In an induction-motor meter there is the combination of a revoluble metallic armature, a series field coil, a shunt field coil, an impedance coil in series with the shunt field coil, a magnetizing coil in co-operative relation with the impedance coil, a secondary coil supplying currents to the magnetizing coil, and a primary coil adapted to induce currents in the secondary.

623,528. Electric Motor. Thomas Duncan, Fort Wayne, Ind. Application filed August 6, 1898.

This is a motor for single-phase alternating currents with the combination of a plurality of poles. The coils are mounted upon one-half of the poles in diametric arrangement, the phase-lagging coils are in series with the coils and mounted upon the other half of the poles; a condenser is in series with the coils; the coils are mounted upon the same poles as the latter coils and in co-operative relation therewith, and a revoluble closed-circuit armature is arranged in inductive relation to the energizing coils.

623,529. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed August 8, 1898.

In an induction-motor meter there is the combination of a series coil, a volt coil having a portion of its turns wound in a reverse direction to the balance of its turns, a variable resistance shunted around the reversed portion of the volt coil; an impedance coil in series with the volt coil

and a revoluble metallic armature in inductive relation to the series and volt coils

623,530. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed August 13, 1898.

In an induction-motor meter the combination of a series coil, a volt coil, an impedance coil in series with the volt coil; an iron core upon which is mounted the impedance coil, and is provided with an adjustable portion, phase-changing coils wound upon the adjustable portion, an auxiliary coil in co-operative relation with the volt coil and receiving current from the phase-changing coils, an aluminum disk armature in inductive relation to the series, volt and auxiliary coils, a spindle carrying the armature, a registering train operated by the revolutions of the spindle and a permanent magnet.

623,531. Multiple-rate Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed August 15, 1898.

A double-rate integrating meter comprises a motor, a registering train consisting of two worm wheels, an intermediate wheel and a driving wheel, a worm actuated by the motor and adapted for a co-operation with the registering train, and a double-coil electromagnet for causing either of the two worm wheels to form a meshing engagement with the worm.

623,532. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Application filed October 17, 1898.

A cylindrical armature is employed with a series coil, in inductive relation to a portion of the periphery of the armature, a shunt coil, a second shunt coil in mutual inductive relation to the first shunt coil, a friction-compensating coil in series with the second shunt coil, a variable resistance in series with the friction-compensating coil and the second shunt coil, an impedance coil in series with the first shunt coil, the friction-compensating coil being arranged upon the opposite side of the cylindrical armature from the series coil to avoid mutual induction.

623,547. Ampere-hour Electric Meter. George Hummel, Munich, Germany. Application filed December 31, 1897.

A registering electric meter for continuous currents consists of the combination with the magnet having a constant field of a coil arranged in the constant field, means for supporting the coil to permit its oscillation therein, a damping bell also arranged in the field, a commutator controlling the circuits through the coil and means controlled by the coil for controlling the commutator.

623,570. Terminal Head for Electrical Conductors. Charles H. Sewall, Chicago, and Henry E. Procuier, Oak Park, Ill. Application filed September 29, 1897.

A strip or wire of fusible material with corrugated insulating material having alternate depressions on its edges adapted to support the strip or wire of fusible material and to interpose barriers between convolutions of the strip or wire.

623,570. Differential Electromagnet. John S. Stone, Boston, Mass. Application filed August 6, 1898.

An electromagnet or electromagnet coil having two

windings of different time constants connected in parallel in opposition to each other, and substantially without magnetic leakage between them.

623,583. Telephonic Trunk Circuit. Thomas C. Wales, Jr., Newton, and Henry M. Crane, Boston, Mass. Application filed September 29, 1898.

The reciprocally operated interswitchboard telephone trunk circuit described is provided with multiple switch connections upon the switchboards at both of its ends, a busy-test system adapted to establish a special and abnormal electrical condition as long as the trunk is switched at any one of its multiple connections, at either end thereof, and upon the switch sockets at all of the remaining switch connections of both switchboards.

623,607. Electric-lighting System. Ralph O. Hood, Danvers, Mass. Application filed February 3, 1897. Renewed March 17, 1899.

Provision is made for a constant-potential source of supply, an arc lamp, an incandescent lamp or lamps in series with the arc of the arc lamp, and a regulating magnet applied to the arc lamp having its coil or coils placed in a shunt circuit to the incandescent lamp or lamps.

623,610. Electric Third-rail System. Lowell M. Maxham, Boston, Mass. Application filed April 6, 1898.

In an electric third rail there is the combination of a normally dead rail formed of conducting material and made hollow throughout its length, a naked conductor extending longitudinally through the rail, fulcrumed arms supporting the conductor out of electric contact with the rail and extending through to the exterior of the latter, and means for automatically actuating the arms and moving the conductor into contact with the rail.

623,611. Combined Listening and Ringing Key for Telephone Switchboards. William O. Meissner, Chicago, Ill. Application filed January 4, 1899.

In a combined ringing and listening key there is a single lever, a head thereon and a sliding contact-maker member operated by the lever, together with contact strips operated by the head and sliding contact-maker member.

623,622. Electric-motor Regulation. Oscar H. Pieper and Alphonse F. Pieper, Rochester, N. Y. Application filed October 14, 1898.

The method of arresting the rotation of alternating-current shunt-wound electric motors consists in reversing the current through the armature and coupling the latter in series with the field.

623,623. Incandescent-lamp Base and Socket. Amund C. M. Prueker, Hanover, Germany. Application filed August 31, 1898.

An improved Edison socket-contact device is described comprising a threaded conducting socket, a terminal part at the extremity of the socket having a spiral, upwardly extending tongue, an exteriorly threaded base and a serrated contact part provided on the base with which the free end of tongue is adapted to engage and hold the base in the socket when it is screwed therein under compression of the spiral.

No. 623,529.

623,625. Electric Brake. Charles P. Pushaw, Washington, D. C. Application filed May 18, 1898.

Claim is made for the combination of brake levers, a plunger connected thereto, a solenoid in which the plunger is adapted to reciprocate, a wheel and axle, chains attached to the axle and to the plunger and running in opposite directions, and means for holding the wheel and axle in one of several possible adjusted positions.

623,637. Ship's Telegraph for Transmitting Signals, Orders, etc. Leon S. Thompson, Washington, D. C. Application filed February 23, 1898. Renewed October 1, 1898.

A receiver or indicator comprising a series of solenoids, an armature in the form of a core, to co-operate therewith, adapted to have its position relative to the series of solenoids changed by the energizing of the different solenoids of the series, and indicating means whose indications are produced by the energizing of the solenoids.

623,656. Portable Electric Lamp. Arthur Drescher, New York, N. Y. Application filed January 27, 1899.

A portable electric lamp, consisting of a flexible handle provided with a bore for the conducting wires, the handle being composed of a socket portion, a handle portion and a tapering end portion, a lamp socket to the socket portion, an incandescent electric lamp in the socket, a collar extending around the socket portion of the handle and a lamp guard attached to the collar.

623,659. Electric Belt. William H. I. Geiger, Denver, Colo. Application filed January 19, 1899.

One claim is made for the combination with the copper tubes the zinc rods, the absorbent member surrounding the rods and the insulating washer, with the coupling wires having a spring clamping clip at one end adapted to be manually sprung onto the body of the tube, and a pin or a spring clamp at the opposite end arranged to electrically connect with the zinc rod.

623,672. Railway Signal. John Jorgenson, San Francisco, Cal. Application filed December 22, 1898.

Signals and opaque concealing casings are disposed with relation to each other, globes, counterbalanced levers by which the globes are suspended and normally raised and within the casings, supplemental counterweights with which the armatures are connected and which normally set up in the levers, to retain the globes within the casings, and electromagnets, with means for energizing them whereby the armatures are attracted and the levers are first relieved of the counterweights and allowed to operate by gravitation.

623,678. Trolley Wheel. Chester B. Lebecher, Miles City, Mont. Application filed April 5, 1897.

A trolley circuit-controller consists of a main circuit-closer below the conductor and an auxiliary circuit-closer above the conductor, the latter adapted to change its contact from the upper to the under surface when encountering a cross wire, one maintaining the closed circuit while the other passes the cross-wire, whereby sparking is avoided.

623,689. Pneumatic Electric Safe or Vault Protection. Frank C. Smith, Delaware, Ohio. Application filed April 24, 1897.

Claim is made for an alarm and a safe or vault provided with a pressure chamber and a vacuum chamber, the walls of the chambers being constructed of an electrical conductor and being electrically connected with the alarm.

No. 623,691.

623,691. Process of and Apparatus for Manufacturing Alkali Metals. Charles E. Acker, East Orange, N. J. Application filed March 5, 1898.

The process of reducing metals from their fused salts consists in subjecting the salts to the electrolytic action of an electric current in the presence of a molten metallic cathode with which the liberated metal is adapted to form an alloy, in imparting a forced circulation to the molten metal to conduct the alloy as formed to a separate chamber where it is permitted to stratify, and then volatilizing in an inert atmosphere in the chamber the metal thus liberated from its salt from an exposed surface of the cathode out of contact with the electrolyte, and collecting the volatilized metal.

623,692. Process of and Apparatus for Manufacturing Metallic Alloys. Charles E. Acker, East Orange, N. J. Application filed March 5, 1898.

The process of making an alloy of a heavy metal, such as lead, tin, zinc, etc., with a metal of an alkali or of an alkaline earth, consisting in reducing the heavy metal in a molten state, and employing it as a cathode electrolytically decomposing a fused salt of the metal of an alkali or of an alkaline earth, while superimposed upon the heavy metal, removing the resulting alloy from the region of the electrolyte, subsequently permitting its different portions to stratify, and flowing off the lighter portion from the surface.

623,702. Telephone Transmitter. Peter C. Burns, Chicago, Ill. Application filed January 12, 1899.

In a telephone transmitter a face plate or cover, bolts secured to and extended from the face plate, a solid back piece, having perforations therein through which the bolts pass, locking nuts on the bolts engaging against the solid back and holding it tightly and securely to the face plate or cover, a diaphragm held between the solid back and face plate by the means aforesaid, an inclosing shell having perforations therein, through which the bolts pass, and locking nuts on the bolts engaging against the shell and holding it securely and tightly about the back and in joined connection with the face plate or cover.

No. 623,607.

623,771. Distributing Terminal. Robert S. Donaldson, Pittsburg, Pa. Application filed August 1, 1898.

There is a central supporting stand with a series of inner cable terminal strips supported by and arranged radially around the same and a series of outer terminal strips supported by arms extending out therefrom.

623,730. Electric Incandescent Tube. William J. McCutcheon, Pittsburg, Pa. Application filed February 21, 1899.

An incandescent electric lamp is described comprising in combination a straight tubular glass body having its interior exhausted of air, and a filament arranged therein which connects at each end of the tube to a metallic conductor, a socket cap arranged upon one end of the tube, which has arranged thereon an insulated pin adapted to connect one of the filament conductors, an insulated cap arranged upon the opposite end and an insulated wire conductor connecting the lower end of the filament to the upper cap.

623,778. Electric Igniter for Explosive Engines. James H. Frew, Newcastle, Pa. Application filed October 2, 1897.

An electrode project into the explosion chamber; valves

are arranged in the chamber, means for operating a valve-actuating slide to automatically open and close the valves, and a contact pin pivotally supported on the slide and adapted to be brought into contact with and separated from the electrode to produce the igniting spark by the operating of the valve-actuating slide.

623,801. Combined Electric Arc Lamp and Fan. Joseph Melzer, Cleveland, Ohio. Application filed October 27, 1898.

An electric lamp comprises a solenoid, an armature therefor receiving a carbon, a clutch mechanism, a support for the armature limiting its downward movement, the support being vertically adjustable and having a longitudinal groove, and a platinum point engaging the screw and forming electrical connection.

623,811. Electrical Glow Light. Walther Nernst, Göttingen, Germany. Application filed October 2, 1897.

An improved electrical incandescent lamp consisting of a strip of material which is an insulator at ordinary temperatures and becomes a good conductor and luminescent at high temperatures, combined at its extremities with fixed terminals for conducting current through the same, and with a heat-producing structure separate from the luminescent and operating to raise all parts of the strip between the fixed terminals to a conducting temperature prior to the passage of the illuminating current.

623,820. Electrically Propelled Road Vehicle. Octave Patin, Puteaux, France. Application filed July 28, 1898.

An electrically propelled road vehicle, the combination with the rear axle having a downwardly curved portion intermediately of its hollow ends, the driving shaft having its ends passed through the hollow ends of the rear axle, a motor supported on the depressed portion of the rear axle, the rear wheels mounted upon the ends of the driving shaft, and the band brakes or air brakes keyed on the wheel naves near the inner ends thereof.

623,821. Electrically Controlled Valve Gear for Gas or Other Motors. David W. Payne, Elmira, N. Y. Application filed March 25, 1898.

The combination with an electrically controlled valve gear of a commutator contact plate in circuit with the valve controller, a commutator brush also in circuit, one stationary and the other revoluble, and a centrifugal governor carrying the revoluble member, whereby the latter is made to traverse the stationary member and control the operation of the valve.

623,846. Printing Telegraph. David G. Smyth, Hartford, Conn. Application filed December 31, 1897.

The combination is claimed of a swinging body, means for holding the swinging body at either end of its movement, means for liberating such swinging body, a range of keys for making and breaking the electric circuit, a segmental range of printing types upon and moving with the swinging body, a presser for bringing the paper into contact with the printing type, and an electromagnet at the receiving station for bringing into action the presser, and a circuit-closer at the transmitting station moving with the swinging device for closing the circuit at the transmitting station in connection with the finger keys and effecting the printing at the receiving station.

No. 623,811.

623,887. Mechanical and Magnetic Amusement Game. Herbert Cottrell, Newark, N. J. Application filed January 17, 1899.

A magnet is provided with mechanism to cause it to rotate and to revolve around a common center, and a non-magnetic plate is arranged closely parallel to the plane of rotation of the magnets, having designations upon the face thereof, and an armature piece is intercepted from the magnet by the non-magnetic plate. When the mechanism is in motion the armature will be caused to glide over the face of the plate by the attraction of the magnets and in correspondence with the motion thereof.

623,888. Electro-deposition of Zinc upon Iron. Sheard O. Cowper-Coles, London, England. Application filed December 31, 1897.

The process of depositing zinc electrolytically and preventing the formation of zinc sponge by placing in an electrolytic cell containing suitable insoluble anode and cathode plates an electrolyte containing zinc sulphate and iron sulphate, and passing through the cell an electric current, the oxygen liberated at the anode when zinc is deposited preventing the formation of hydrogen compounds of zinc or zinc sponge.

623,906. Electric Actuating Mechanism for Station Indicators. Andrew Hunter, San Francisco, and Crest Gustafson, Oakland, Cal. Application filed July 26, 1897.

The combination is claimed of the stop wheel having slots in its rim, a stop lever, a spring detent on the stop lever, an electric motor having its armature shaft inserted into the stop wheel, a motor-actuating circuit including the stop lever, an auxiliary or branch circuit including a circuit-closing device and a relay adapted to act on the stop lever and raise it from the stop wheel, a spring latch adapted to engage and hold up the lever when that part is lifted by its relay, and projections on the stop wheel operated by the relative movement of the wheel to throw off the latch and release the stop lever.

623,908. Telephone Transmitter. Edward H. Johnson, Omaha, Neb. Application filed May 9, 1898.

A telephone transmitter comprising a diaphragm, a ring of resilient material bearing against the diaphragm, a series of contacts on the ring and another series of contacts with which the first-named contacts engage.

623,953. Electric Belt. Warren P. Freeman, New York, N. Y. Application filed September 13, 1898.

An electric belt is composed of a supporting strip and a series of elements of diverse character having enlarged ends and narrower connecting portions inserted in slots in the supporting strip and arranged with one plate or end of one element overlapping a plate or end of a diverse element on the opposite side of the supporting strip.

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, MAY 13, 1899.

No. 19

Building a 2,100 Horse Power Generator.

In the new addition to the power house of the Metropolitan West Side Elevated Railroad company of Chicago two direct-connected generator units are building that will be somewhat larger than any other machines of like character in town. They are duplicates and consist of Allis vertical compound-condensing engines and General Electric 600-volt dynamos, and both engines and dynamos have the latest improvements that the experience of the builders has devised. In apparatus of this size it is, of course, impracticable for the manufacturers to deliver finished machines. The parts are made and assembled at the shops in Milwaukee and Schenectady, and then

generator. Their dimensions are 38 by 76 by 48 inches. The floor space occupied by each generating set is 38 by 24 feet. The flywheel is 24½ feet in diameter and weighs 160,000 pounds in the rim. The shaft, with armature spider and disks, weighs 54 tons. The rating of each engine is 2,250 horse power at the economical rate of steam consumption, but, like the generator, the engine will stand an overload of 50 per cent. or even more. The engine will be operated at 75 revolutions a minute, and on a steam pressure of 165 pounds. It has two governors, one on each cylinder, and the valves for both high and low pressure cylinders are double-ported.

The generator has 18 poles and a nominal capacity of 1,600 kilowatts, with an electromotive force of 600 volts at full load. The armature is 10 feet in

room is left for a third of equal size. In the boiler-room six Babcock & Wilcox water-tube boilers of about 600 horse power each are being added to the plant. The older generating equipment consists of two 1,500-kilowatt machines and two of 800 kilowatts each. When the present addition is completed the station will have a generator capacity of 7,800 kilowatts. The additional machinery is needed badly, as during the morning and evening rush hours last winter the power house was sometimes overloaded 60 or 70 per cent.

New York Electrical Show Open.

On Monday evening the electrical exhibition in Madison Square Garden, New York, was formally

BUILDING A 2,100 HORSE POWER GENERATOR.

shipped piecemeal to Chicago for erection by skilled mechanics sent out for the purpose.

One of the generating sets is much further advanced toward completion than the other and will probably be in operation within six weeks' time. This is the one shown in the picture. The main shaft, with armature, flywheel and cranks disks, and the lower half of the magnet frame are in position. At the time the photograph was made the workmen had the task of placing the armature windings or bars well advanced. They worked on the rough platform shown, and the armature was turned for them by attaching to the flywheel a tackle from a traveling crane overhead.

The height of each engine above the floor level will be 31 feet, and the flywheel extends nine feet below it, so that the vertical dimension of the unit will be 40 feet. The cylinders are vertical, as stated, and will be placed on each side of the flywheel and

diameter, and the laminations are very thoroughly insulated from one another. The magnet frame is of cast-steel and strengthened by heavy ribs. Both engine and generator are strongly built, but they will be of graceful proportions nevertheless. They are, in fact, improved and enlarged editions of the power units in the older portion of the Metropolitan plant, which have a good record for steadiness and reliability.

Each of the new units has a jet condenser, which is an imposing piece of machinery in itself, standing 17 feet above the basement floor and having a steam cylinder 16 by 42 inches equipped with Reynolds-Corliss valve gear.

With the new extension the power house is about 600 feet long. The width is unchanged, about 150 feet. The building is divided into engine and boiler rooms by a longitudinal brick wall. In addition to the two 1,600-kilowatt generators now building,

opened. President McKinley and Governor Roosevelt sent congratulatory messages and Senator Dewey made a speech, in which he noted, with happy effect, that he had ridden from his house to the hall in an electric cab. The speaker also made a humorous reference to the possibilities of wireless telegraphy. The officers of the exhibition are: President, C. O. Baker, Jr.; vice-president, H. L. Shippy; secretary and treasurer, George F. Porter; executive committee, H. H. Harrison, L. F. Requa and Mr. Baker. Marcus Nathan is general manager and Luther Stieringer electrical engineer. The exhibition will remain open to the public until June 1d.

The Detroit and Lake Shore Electric Railway company is making surveys for an extension of the line from Lakeside to Marine City—a route that will, it is claimed, save 14 miles.

Automobiles in Paris.

By JOHN K. GOWDY.

On Easter Sunday the first installment of automobile cabs was placed at the disposal of the Parisian public. As soon as they issued from the depot at Aubervilliers, they were eagerly sought after, and gave most satisfactory results. The number of these vehicles is daily being increased, and the Compagnie Générale des Voitures expects, after a month's trial, to be in a position to judge of the convenience or drawbacks of the present type of cabs. Impressions of the wood cuts of the two types at present in use I inclose herewith. These vehicles are provided with accumulators, enabling them to travel from 60 to 80 kilometers (37 to 49 miles) without recharging the batteries.

The tariff varies according to the number of persons. For one or two passengers, the ordinary cab fare is applied, viz., 1.50 or two francs (28.0 or 38.6 cents) per hour; for three persons, two francs the journey, and four persons, 2.50 francs (48.2 cents). Between 12:30 and 6 a. m. the rate is 2.25 or 2.50 francs (43.4 or 48.2 cents) the journey and 2.50 to 2.75 francs (48.2 to 52.8 cents) per hour, according to the number of passengers. Fares beyond the fortifications will be 25 centimes (4.82 cents) above the existing rate for ordinary cabs.

The eventual adoption of automobiles for general use in Paris, as well as throughout France, seems to be a foregone conclusion; but there is no doubt that the tremendous speed at which private indi-

Foreign Trade Development.

[Prepared for the Western Electrician by the Philadelphia Commercial Museum.]

The apparent indisposition of American manufacturers to adopt the business usages and trading arrangements in vogue in foreign countries and their unwillingness to conform to these conditions and customs, in common with their European competitors, seriously retard the permanent establishment of American markets abroad. It may be added that some American manufacturers seriously injure the whole cause of American foreign trade by furnishing goods of a quality inferior to what was stipulated, thus raising a doubt as to the integrity of American business life and sowing distrust in the minds of buyers. It is idle to disguise the fact that, as a nation newly entering the markets of the world in competition with the seasoned salesmen of Europe, there is much to learn. The volume of foreign trade will largely be with the Far East, and therefore the following observations from a man who is well acquainted with the Asiatic markets will be found worthy of serious consideration:

The outlook for American trade in the East is most encouraging, as our products are much appreciated and sought after.

The splendid workmanship and finish to our products stimulate their sale and excite the admiration of all the oriental mercantile communities. With all these encouraging signs and opportunities to build up a big commercial trade with the world, which I see, if properly handled, would be second to none in a very few years, we, by laxity and thoughtlessness, are doing our best to turn it from our doors to our competitors by bad packing,

dealing with us to which we have been used by the manufacturers of other countries who have found out that transactions with us are to their advantage. As long as they do not think this worth while there is no use of trying to establish direct transactions with them.

Here is another comment on American deficiency, this time from Egypt, a country practically unknown to American manufacturers, but affording a great and improving market for their products, written by a correspondent at Alexandria:

A good business might be done between Egypt and the United States, but to bring about this result American manufacturers must conform to the conditions prevailing in this market, and this is just what they will not do. Times without number letters are received from firms in the United States desirous of doing business with Egypt, and in practically nearly every instance nothing has resulted owing to their refusal to accept the conditions of sale in force in this country. They cannot expect buyers in Egypt to send to America for goods on terms which they have never complied with before when they can get the articles suitable for their customers from European houses that grant them the conditions of payment to which they are accustomed. No trouble is experienced in prevailing upon English and Continental manufacturers to do business on the terms ruling in Egypt, and surely there cannot be such a difference between their methods and those in force in America. In order to gain new markets American manufacturers must show enterprise and at the same time undertake a certain amount of risk, but so far they seem to be lacking in the first quality and quite unwilling to take even ordinary business risks, such as the four months' credit against acceptance granted here. The time and money which have been expended in endeavoring to bring about trade will be altogether wasted if American manufacturers do not show themselves more amenable to the conditions of the Egyptian market.

Taking another instance at haphazard from the correspondence on the subject, this is what a New Zealand trader writes:

Trade relations between this colony and the United States could be improved if mercantile companies and firms worked more in accordance with British methods in connection with business affairs. The British manufacturers grant much more liberal terms of credit than the Americans. It is unreasonable to expect representatives of United States firms to place new lines on this market to competition with goods of like nature from other countries and to sell practically for cash when the British manufacturers are willing to give long terms of credit. Then again American representatives frequently decline to supply samples, at any rate unless they are paid for. This is

Electric Brougham.

Electric Victoria.

AUTOMOBILES IN PARIS.

viduals with their motor-tricycles and other experimental automobiles dash about the streets has had a tendency to discourage the adoption of automobiles by those who would otherwise make purchases.

By daily observation in Paris, it is easy to see that improvements are constantly being made in doing away with the objectionable odors, excessive vibration and noise.

The action of the Compagnie Générale des Voitures in establishing the speed of its automobiles in the city at about eight kilometers (five miles) an hour will diminish, if not avoid, the crushing of pedestrians and serious accidents. The element of fear being eliminated, the introduction of reliable and not too complicated mechanism will certainly produce a new era in locomotion throughout France.

I may state that an important and appreciated merit in the new automobile cabs is the brake placed in the interior of the vehicle, by which the passenger can not only check the speed, but bring the conveyance to a standstill, independently of the conductor.

In order to have the trial complete and obtain the consensus of public opinion, registers are placed at each cab-stand for such observations as individuals may see fit to make.

Fort Wayne Electric Works.

Another change has been made in the name of the organization succeeding the defunct Fort Wayne Electric corporation. The company is to be known as the Fort Wayne Electric Works. The change is due to the fact that some years ago a local company was organized and incorporated under the name of the Fort Wayne Electric Manufacturing company, the name chosen for the reorganization. Inasmuch as the former charter has not expired, it was necessary to select another name. It is asserted that the Fort Wayne Electric Works will take an active part in supplying the electrical market under the direction of Messrs. Wood and Hunting. It is intimated that the scale of prices will be revised. The principal owner of the new company will be the General Electric company.

insufficient packages, illegible and incomplete marking, thereby losing our products on the foreign markets to an unmarketable condition.

My attention has been called daily to the condition of the European, British and American products landed in foreign ports, and I regret to say ours bears no comparison to the other two, either in packages, packages or marking.

Goods for the Orient should be well and securely packed in heavy, well-seasoned wood packages, equal to resisting the strain imposed by their contents, the rough handling they will receive and the many climatic changes they must pass through before reaching their destination.

They should be plainly and substantially marked with numbers, shipping mark and port of destination to insure correct delivery, and, part cularly, goods should be delivered alongside the ships in a more perfect condition than at present, and not with the reckless desire to get them out of hands regardless of future results.

The present mode of packing goods for exportation to far-off ports does not differ materially from that used for domestic shipment.

My experience of the East dates back to 1860, and from observation I know that once the confidence of the eastern merchant is obtained, especially the Chinese, our trade is a sured.

We have expectations of a large trade with Russia in most of our lines of manufactured products, but they will scarcely attain fulfillment if other importers have had occasion to form the same opinion of American business methods that caused a trader at Riga, on the Baltic side of the country, to write as follows. He has evidently formed a strong opinion on the subject, and his remarks are the more worthy of attention from the very earnestness with which he expresses himself:

I beg to say in a general way that after the experience I personally have had it is hardly worth the trouble of trying to introduce American manufactures into Russia.

I have bought some machinery from large American manufacturers, but it took a correspondence of many months before the goods were shipped, notwithstanding the fact that I did not ask for credit. Most of your manufacturers seem not to have the slightest idea about the manner business is transacted in this country, and therefore meet us with a suspicion unwarranted by facts and to which we do not need to submit. We can get all we want and on conditions suitable to us from Germany, France, Belgium and England, where they know our trade and have adapted their methods of dealing with us to the conditions of our trade. It takes months to have an order shipped from your side, while the European manufacturers fill them without delay.

For a whole year I have been in correspondence with a number of American firms, answered numberless inquiries, trying to introduce their goods in this country, but my experience has caused me to drop all efforts in this line.

If your manufacturers wish to have a share of the Russian business, they have, first of all, to make themselves acquainted with the conditions of our trade and to adopt the same methods in

a very short-sighted policy and very different from the method adopted by all British firms. Trade between the United States and New Zealand can be increased if free samples are furnished and favorable terms of credit are adopted in cotton piece goods, drapery, boots and shoes, bicycles and materials, hardware and ironmongery, canned fruits, etc.

And again, this time from a South African correspondent, a merchant at Pretoria, Transvaal:

As a matter of fact the great bulk of our manufacturers and would-be exporters are most supremely ignorant of the wants of the foreign markets, as well of the proper means of advancing and enhancing their foreign trade. It is a great misfortune that the idea has become prevalent in manufacturing circles in the United States that no commercial integrity exists outside of their own country and that it is absolutely unsafe to extend a line of credit to the foreign dealer, while as a matter of fact the secret of success of English, German, French and other European manufacturers lies in the assumption that other dealers than those close to their own doors are entitled to a line of credit of from thirty to ninety days after the receipt of the goods. It must be admitted that it is easier to handle the trade nearer home than at the other end of the earth, and so long as the manufacturer has sufficient trade at home to keep his works in operation he had better stay at home. But when he goes into the world for a market for his surplus product he should make up his mind that he must meet competition in prices as well as in terms, and not let him so make up his mind he had better not waste time and money in trying to enter foreign markets.

Very much the same commentaries on American methods reach the Philadelphia Commercial Museum from the South American countries and Mexico. A correspondent in the City of Mexico who was asked to state his opinion of the commercial standing of the United States in Mexico expresses himself in the following blunt manner:

Mexico imports from the United States only such articles as it cannot obtain from Europe. When it is possible to obtain similar articles from Europe it prefers them; first, because they are cheaper; second, because they are better packed; third, because European exporters accord more facilities for payment; fourth, the money exchange is not so high; fifth, our buyers can explain to the European sellers all the particulars which they desire because the European houses all correspond in Spanish, and also constantly send traveling agents with samples who take good note of all our requirements.

The advantages which are offered by the United States markets are the proximity and the promptness with which the orders can be executed, but when it is a question of orders sent in advance these advantages are of no consequence.

As to your packing, an important matter to the importer, I must say that the North American packing is the worst that is known. Its faults are the following: The merchandise is not sufficiently well arranged inside the boxes, which generally contain voids or empty places filled with sawdust or excelsior. The cases should be well made to measure and the goods well arranged. The wood in the cases is too thick, heavy and rough,

all of which is prejudicial on account of the freights as well as on account of the custom dues and the poor condition of the merchandise.

This concurrence of opinion regarding the shortcomings of American manufacturers in their foreign relations is too marked to leave room for doubt that the requisites for successfully prosecuting trade with foreign peoples are not understood in this country. The matter is of the supremest consequence and demands most careful consideration at the hands of American manufacturers.

Electric-railway Building in Mexico.

The illustration, which is reproduced from Modern Mexico, shows that work is progressing gradually on the task of building an electric street-railway system in the streets of the City of Mexico. Evidently there is no distressing hurry about the job at the track crossing shown in the picture, but no doubt in good time everything will be finished satisfactorily. Indeed, it is said that the power plant is all in place and that the track is down for almost the entire length of the first line to be equipped—that from San Angel to Guadalupe. It is believed that the system will be ready for use for the first time on Mexico's Independence Day, September 16th.

Animal power has heretofore been used for the street-railway system of the City of Mexico, which is quite extensive. For suburban service steam dummy engines are used, and these will probably be retained for freight and express service. Fares are five and six cents in the city, but some of the suburban fares are as high as 30 cents.

National Electric Light Association.

In pursuance of the alternative arrangement between New York and Chicago, this is New York's year for the convention of the National Electric Light association. The gathering will be held at Madison Square Garden, with headquarters at the Murray Hill Hotel, on May 23d, 24th and 25th. The electrical exhibition at Madison Square Garden, given under the auspices of the association, is now open, and will be continued until June 3d. The General Electric company has invited members of the association to visit the Schenectady factories and has arranged for a special train on the New

ELECTRIC-RAILWAY BUILDING IN MEXICO.

York Central railroad. The round trip from New York is planned for May 26th.

Papers on the following-named subjects will be read and discussed: "Single-phase Distribution," Herbert A. Wagner, St. Louis; "Underground Electrical Construction," Louis A. Ferguson, Chicago; "Some Notes on Underground Distribution of Two-phase Current in New York City," E. A. Leslic, New York city; "The Development of High-tension Service" (illustrated by stereopticon), Calvin W. Rice; "A Local Transmission System—Development and Operation," W. S. Barstow, Brooklyn; "Alternating-current Generation and Distribution—Changes Contemplated in Atlanta," H. M. Atkinson, Atlanta; "Means of Affording Safety in Electrical Distribution," W. L. R. Emmet, Schenectady; "Rotary Transformers and Storage Batteries, and Their Relation to Long-distance Transmission," Professor W. L. Robb, Hartford, Conn. The discussion on transformers will be led by Professor Goldsborough of Purdue University, Lafayette, Ind.

The committee of the association appointed to effect some readjustment of the freight classifica-

chairman that 'the committee do not permit oral argument before them in support of application for changes in classification of the various commodities.'

It is the desire of the committee of the National Electric Light association that all manufacturers and others interested in tariff changes have someone present at the convention at New York who will meet with the committee, with the idea of taking some vigorous steps calculated to bring about a just and equitable tariff. It is apparent, and has been for some time, that ordinary appeals to the railroad organization, as represented by their classification committee, will prove inadequate to accomplish the desired end. An announcement will be made on the opening day of the convention of a time and place for a special meeting to be held with the committee on this particular subject. During the session of the convention, that steps may be taken other than the usual resolutions that follow a committee's report. "Every central station in any large city, or any considerable user of electrical apparatus, as well as every electrical manufacturer of heavy machinery and electric lamps," says the committee, "should be sufficiently interested in this subject to have some one in attendance at the convention to advise with the committee in carrying out the object for which it was created."

The members of the committee are W. C. Bryant, George W. Davenport and James I. Ayer, chairman.

Southwestern Electrical Men at Austin Next Week.

The annual convention of the Southwestern Gas, Electric and Street-railway association will be held at Austin, Texas, May 17th to 19th. The following list of papers has been prepared: "The Item of Depreciation," by W. E. Hamilton, Shreveport, La.; "Meters," by W. E. Holmes, Austin, Texas; "Transformers," by H. L. Monroe, Dallas, Texas; "The Amount and Extent of Legitimate Investment in Electric-lighting Plants of Certain Capacities," by F. Fries, San Antonio, Texas; "Summer Amusements for Street-railway Companies," by T. H. Stuart, Waco, Texas; "Art and Science of Selling Gas," by T. D. Miller, Dallas, Texas; "A Model Plant Under Model Management; What Both Should be Like," by J. F. Strickland, Waxahachie, Texas; "Alternators," by E. Dysterud, Monterey, Mexico; "The Attitude of a Corporation to the Public," by W. H. Weiss, San Antonio, Texas; "Means for Encouraging the Diversified Use of Electric Current," by C. L. Wakefield, Dallas, Texas; "Electric Lighting and Application of Electricity to Various Purposes in Mexico," by a Mexican delegate; "Arc Lamps," by Max Levy, Galveston, Texas.

An attractive programme of social features has been arranged. The headquarters of the association will be at the Driskill Hotel. In connection with the convention the Commercial Club of Austin has arranged to hold an electrical exposition that will be attended, not only by members of the association, but by citizens generally. E. L. Wells, Jr., of Marshall, Texas, is the secretary of the association.

Electric-railway Consolidation in New England.

[Correspondence of the Western Electrician.]

Boston, May 6.—The syndicate represented by F. Rollins Morse & Bro. and Tucker, Anthony & Co., previously referred to in the Western Electrician as promoters of a consolidation scheme for Eastern New England, are said to hold for the purpose now nearly all the coast lines of electric street railways between Newport, R. I. and Nashua, N. H., with the exception of the Boston Elevated company's plant. The railways thus absorbed number upward of a score, and comprise about 700 miles of track, built or under charter. The estimated gross receipts therefrom are \$4,000,000 annually, and it is proposed to issue \$11,000,000 preferred four per cent. cumulative stock and \$11,000,000 common stock. The underwriting has been largely oversubscribed, and the stock has been taken largely by persons heretofore interested in the various properties to be consolidated. It is officially denied that the syndicate intends eventually to absorb the Boston elevated railway. There is an understanding, however, it is conceded, between the two big factors in the railway situation, and they will work in harmony wherever they come into close contact. The principal lines in the deal are the Lynn and Boston, entering the city from the north by way of Chelsea and Charlestown and having subway rental rights, the Quincy and Boston, touching the city boundary on the south by way of Neponset, the Lowell, Lawrence and Haverhill, the Gloucester, Taunton and Providence, the Bridgewater, Taunton and Brockton, Dighton, Somerset and Swansea, Newport and Fall River, and the Newport Illuminating company, which controls the Newport roads.

Storage-battery Litigation.

In the United States Circuit Court at Boston, on May 5th, Judge Colt granted an injunction upon the application of the Electric Storage Battery company, restraining the Hatch Storage Battery company from the alleged infringement of patent upon an improvement in secondary battery and in the process for making the same. The Brush patent issued in March, 1880, is the one said to have been infringed.

Lightning Flash in South Dakota.

Photographs of lightning flashes have been taken in several instances, but seldom is such a clear, well-defined picture secured as that herewith reproduced. The negative was made by Mr. W. C. Gibbon, at Tripp, S. D., at 10 p. m. on July 22, 1898, during a hailstorm. The buildings shown are on Main street in Tripp. The direct ground connection is exceptionally heavy and well marked, while the forked branches of the discharge also show clearly. The one at the extreme left increases in brightness as it proceeds from the main path of the disturbance and ends abruptly in a peculiar manner. It is said that the Weather Bureau at Washington has pronounced this photograph the best picture of a lightning flash in its collection. The picture is copyrighted and is reproduced in the Western Electrician by the courtesy of Mr. Gibbon.

Probable Consolidation of North and West Chicago Street Railways.

It seems probable that the North Chicago Street Railroad company, the West Chicago Street Rail-

LIGHTNING FLASH IN SOUTH DAKOTA.

road company and the Consolidated Traction company, now controlled by Mr. C. T. Yerkes, will pass into the hands of the group of eastern financiers known as the "Whitney syndicate." If the pending negotiations are successfully concluded, the three companies mentioned will be merged into one and Mr. Yerkes will retire from the management. It is said that none of the elevated roads is included in the present negotiations. Neither is the Chicago City company, although the stockholders of the South Side system are naturally watching the movement with interest.

tion on electrical merchandise has received at the hands of the official classification committee of the railroad companies, C. E. Gill, chairman, a letter from which the following is an extract: "I have to advise that the subject was presented to the classification committee for consideration, but after careful deliberation the committee did not deem it expedient to recommend any change in the classification of this class of property." A member of the committee requested the privilege of personally representing the interests of shippers and those engaged in the electrical trades, in support of the suggested changes in classification, but was informed by the

DEVELOPMENT OF THE TELEPHONE FIELD.

Proposed Method of Telephoning without Connecting Wires.

The fascinating problem of transmitting articulate speech without the use of conducting wires is naturally connected, in the minds of engineers, with the wireless-telegraphy experiments that are now making in various quarters of the world. It is, of course, a much more complicated task to affect the coherer of the Marconi system by the undulatory waves of speech transmission than by the sharp, distinct signals of the Morse alphabet. It is necessary to decohere the particles in the coherer with a rapidity greater than the impulses of the speech-transmitting waves, as, if the particles be cohered but for an instant longer than necessary to transmit a Hertzian wave impulse, the next impulse would not affect the already cohered particles, and the speech would be broken and indistinct.

To attain this essential development in wireless telephony, Mr. J. J. O'Connell, of the engineering staff of the Chicago Telephone company, who has given the subject considerable attention, proposes the receiving station represented diagrammatically by the accompanying drawing. The diagram shows a Wehnelt electrolytic interrupter, operated by a battery and connected to a mechanical oscillator which serves to decohere the filings in the coherer at the rate desired. The plan is to operate a mechanical oscillator by means of a current interrupted by the liquid circuit-breaker. This will decohere the coherer so rapidly that it will be possible to keep up to or ahead of the telephonic vibration, which will be produced by a spark coil at the distant transmit-

Telephone News from the Northwest.

(From the Minneapolis correspondent of the Western Electrician.)

Fire in the roof of the First National Bank building, Duluth, ruined the exchange of the Duluth Telephone company, the loss being about \$25,000. New equipment was ordered at once, but the town will be without service for at least two weeks. Connection will be made with Superior and messengers sent for parties within reasonable distance without charge.

The Central Telephone company has installed a small exchange at Pomeroy, Ia.

T. W. Stone is installing a telephone exchange at Benson, Minn.

There is a possibility that telephone companies in Iowa will escape taxation in all counties except Polk, where the county officials have taxed them. The state is somewhat embarrassed, as the action of the Polk county officials raises the question as to the right of the local boards to tax them.

The Wright County Telephone company's application for a franchise at Clarion, Ia., was defeated.

The Iowa Telephone company will establish a telephone exchange at Ida Grove, Ia.

The A. W. Chamberlin Telephone company of Stratford, Ia., contemplates building a toll line from

have been made by the local agent. The doctor then assumed there was an intention to keep him from having night connection and made a public remonstrance.

The Fairmont Telephone company contemplates a telephone exchange at Heron Lake, Minn.

The St. Paul Board of Assembly granted a franchise to the American Telephone and Telegraph company, but amended it by making it void if the company discriminated against any applicants.

Principal Stockholders of the American Bell Telephone Company.

(From the Boston News Bureau.)

The following table gives the holders of 500 shares or over of stock of the American Bell Telephone company on March 31, 1899, compared with holdings of four previous years:

Holders.	1899.	1898.	1897.	1896.	1895.

PROPOSED METHOD OF TELEPHONING WITHOUT CONNECTING WIRES.

ling station operated by a battery and a solid-back transmitter.

About a year ago Mr. O'Connell tried to telephone without wires, using the coherer, tapped by a vibrating hammer, to receive the speech waves, but the articulation was poor, owing to the slow method of decohering. He has since devised the plan shown by the drawing, and he and other telephone engineers with whom he has discussed the subject hope that it will form the foundation for a successful system. A practical test will soon be made in Chicago, and it is awaited with much interest.

Parrot and Telephone.

(From the Chicago Daily News.)

An antiquated green parrot, the possession of a young suburban miss, is chuckling over his almost successful attempt to break an engagement. Poll's cage is situated near the telephone, and ever since his advent he has regarded it as an "esteemed contemporary." He never fails to say "hello" vehemently a great many times whenever the bell rings.

Ye yesterday morning the young lady wanted to call her fiancé at his place of business on a "very important matter." Of course he came instantly to the phone. Poll had heard the telephone bell ring, and, waddling over to the other side of the bar, looked curiously out at his young mistress.

"Hello, Harry, I wanted—" she began. "Hello, hello, hello, hel-lo," screamed Poll. "Hello, hello, hello," the young lady began again, but again the stream of "hel-lo's" poured forth. Without turning from the phone, but addressing the parrot, she cried, angrily: "Get up! Get up! Oh, no, I didn't mean you!" "Through the phone—" I was talking to this provoking bird!"

It is understood that he forgave her.

The Manchester, England, City Council has decided to send a deputation to the postmaster general supporting the application of the Mutual Telephone company for a license.

Stanhope, Ia., to Jewell and from Homer to Webster City.

Citizens of Maloy and farmers of the vicinity propose a telephone line from Maloy to Clearfield, Ia.

The Fergus Telephone company is constructing a telephone line from Fergus Falls, Minn., to Wadena.

Lightning crippled the system of the Northwestern Telephone company at Oshkosh, Wis. Two lead cables were affected.

The Standard Telephone company, which has numerous toll lines in Southeastern Minnesota, is heading toward Mankato, Minn. The Southwestern Minnesota Telephone company, which covers the southwestern part of the state, is also preparing to build to Mankato.

The Minnesota Electric company of Minneapolis is installing a telephone exchange at Alexandria, Minn., for the Park Region Telephone company.

The Fairmont Telephone company contemplates putting in an exchange at Madelia, Minn.

The Iowa and Nebraska Telephone company is an applicant for a franchise at Sioux Rapids, Ia., and will put in an exchange and a toll line through to Storm Lake and Spencer.

Humboldt, Ia., will vote May 26th on granting a telephone franchise to the Iowa Telephone company, or to the Humboldt Electric Lighting and Power company.

The Hanamo Telephone company will extend its lines from Hopkins to Bedford and Corning, Ia., and an exchange will be put in at Bedford.

Telephone toll rates in Northwestern Iowa and Northeastern Nebraska have been reduced in some instances to one-fourth their former amount, as a result of competition.

The telephone exchange at Anamosa, Ia., has been moved to new quarters and new equipment has been put in use.

A. W. Dieckhoff and H. Jaehnings of New Richmond, Minn., are soliciting subscribers in Sleepy Eye, Minn., with a view to establishing a telephone exchange there.

The People's Telephone company of Waupun, Wis., will build a line from Waupun to Randolph.

The Northwestern Telephone Exchange company is extending its wires to Rollingstone, Minn.

Telephone connection between Gilman and Dunbar, Ia., is projected.

Dr. Gammel of Madison, Minn., announces to the public that hereafter, "owing to the unjust discrimination of the telephone company" against his patrons and himself, all communication with him must be by telegraph. The telephone company presents an explanation of the difficulty. The company says that Dr. Gammel wanted to have the switch turned to his line when the central office closed at night. The company replied it would be all right if it did not conflict with a previous arrangement which might

A feature of the list is the general reduction of holdings by trustees and the division of stock by the William H. Forbes estate. The Forbes family holds 2,536 shares of stock.

Theodore N. Vail still remains the largest stockholder, with 4,384 shares, a reduction of 400 shares from his 1898 holdings. W. Murray Crane is the second largest stockholder, with 4,122 shares. The holdings of J. P. Morgan & Co. have been reduced 400 shares during the year to 1,325 shares. In 1897 J. P. Morgan & Co. held 2,996 shares.

The 13 directors this year hold 3,731 shares, compared with 4,394 shares in 1898, 5,651 shares in 1897 and 7,770 shares in 1896. Under Massachusetts law it is not necessary that directors hold any stock in a corporation which they direct, but stock stands in the names of the present directors, as follows:

	1899.	1898.	1897.	1896.	1895.
Francis Blake	700	700	700	824	824
Alex. Cochrane (& Co.)	1,070	1,200	1,115	1,500	1,500

J. Malcolm Forbes	500	1,033	1,732	1,721	1,496
Thos. B. Bailey

The Bennettsville (S. C.) telephone system has been sold to E. L. Moore of Dillon, S. C., owner of the Dillon exchange, who will extend the line through Cheraw to Chesterfield Court House, and open exchanges at those points.

Private Telephones.

The use of the telephone in large factories and similar establishments in England has not become general and the advantages of an intercommunicating system is not fully appreciated. The London Electrical Review says: "There are thousands upon thousands of warehouses in this country, we imagine, which have no up-to-date method of communicating from department to department or from room to room, and it is sometimes hinted that the trade does not push the business thoroughly and bring it before the attention of likely users. Those who have tried proper methods appreciate the advantages which they carry in their train, and they would not care to relinquish their use. Various firms have for many years been doing their best to improve private telephone apparatus, and have thus brought it to the high degree of perfection which characterizes it to-day, when the fitting-up is properly done." The accompanying illustration represents a telephone set that is now being generally introduced for this class of work. It is known in England as the "Handcom," and resembles in general features the apparatus produced by American makers for the same purposes, though it must be admitted that the cut conveys the impression that the English make is more cumbersome than the present standard American style.

The instrument is handy, however, as it can be fitted to almost any position, this being largely due to the fact that the automatic switching hook of the ordinary form of telephone is entirely dispensed with, so that the hand combination can be suspended or

PRIVATE TELEPHONE.

laid down in any position that may be convenient. The switching arrangement for disconnecting the bell and closing the telephone and microphone circuits is contained in the handle of the hand combination, and takes the form of a lever which has to be kept pressed whilst using the instrument. Inside the containing case is the induction coil, call buzzer and the necessary connecting terminals. The number labels are arranged so that they can be adjusted to read in any direction, according to the position in which the instrument is fixed. As the wires leading into the instrument may come from any direction, it is not possible to make a hard-and-fast provision for their entrance to the interior of the instrument. Provision is therefore made for an entrance on each side and one at the bottom of the case. These entrances are closed by a small nickeled plate, and all that is necessary is to remove the plate from the side at which it is required to enter. The "Handcom" set is made for wall, desk and other use.

Municipal Ownership.

"Taking the case of the telephone as an illustration," says the New York Times, "it would be an abuse of the taxing power and an act of flagrant misgovernment to take the money of 3,000,000 people who never use a telephone to pay the cost of maintaining a system of telephones for the benefit of the other half million who do use it. But our correspondent replies that the operation of a telephone system would be very profitable and the city would make money. That is not the usual result of city ownership. But the argument is worthless even if the assumption of profit is correct. The city ought not to go into business to make money. That is not one of the functions of a city government. If the business is profitable it ought to be left to engage the energies and reward the industry of the private citizen. Any other theory is socialistic and pestiferous."

Another view of the subject is presented in the accompanying cartoon from the New York World which was inspired by the revelations of the Mazet committee of inquiry into the affairs of the city government.

The Chattanooga Chamber of Commerce will secure long-distance telephone connection for that city with Atlanta and North Georgia towns.

Wireless Telephony.

In an endeavor to adapt—even on paper—the principles of "wireless telegraphy" to the sister service, telephony, the first essential divergence of the two systems of communication, telegraphy and telephony, presents itself at once as an obstacle for manipulation. In telephony there must be nowhere in the chain of conversions any gross mechanical agency, such as a relay or the contact breaker of a sparking coil, these and kindred devices being much too ponderous and inert to convey the rapid pulsations of a telephonic message.

The nearest approach to a purely mechanical link in the system is the carbon transmitter in all its many modifications—Blake, Hunnings, etc.

I have endeavored to include these two types (slightly modified) in an arrangement which, if experimented with and developed, would perhaps

FIG. 1. WIRELESS TELEPHONY.—TRANSMITTER.

evolve into a workable system of wireless telephony for moderately short distances.

Briefly, the sparking coil of wireless telegraphy is replaced by an induction coil (I), Fig. 1, whose primary circuit receives its pulsations from an ordinary Blake transmitter when spoken into at the mouthpiece (M). This coil, in order to produce sufficiently long sparks, would require to be much more highly wound than the little coil found in the transmitter of an ordinary telephone instrument.

Its secondary circuit is open, the two ends terminating in brass spheres (SS), or, if these proved to have too great an electric capacity to admit of such rapid alternation, merely in two points.

As regards the length of the spark gap, that is determined by the distance over which the message is to travel to the receiving station. That is all that is comprised in the transmitting apparatus illustrated in Fig. 1.

The receiving apparatus is illustrated in Fig. 2. The two wings (WW) receive the pulsations, but instead of being connected to the coherer of wireless telegraphy, their connecting wires are attached to the two diaphragms (DD) arranged as in the Hunnings transmitter, the interspace being filled with granules of carbon or silver, etc., as experiment might direct. These diaphragms and the granules are included in circuit with a battery, and the coils (MM), which are placed on the arms of a magnet whose poles are in position behind the diaphragm (D), as in the manner of an ordinary telephone receiver. This diaphragm has, however, on the other side of it, the platinum bead and carbon button of a Blake transmitter, and this arrangement serves as a relay, so to speak, to intensify the vibration

FIG. 2. WIRELESS TELEPHONY.—RECEIVING APPARATUS.

received from the wings (WW). The platinum and carbon are circuited in the ordinary way with an induction coil (I) and a battery of, say, six Leclanche cells. The secondary circuit of the coil (I) goes direct to the ordinary telephone receiver (R). A decoherer can, if necessary, be connected in the usual way, if packing should occur. Should the vibrations of the Blake transmitter be too small, an Edison electromograph can be used, as has already been suggested by another writer when dealing with the subject of telephone relays.

The diagrams do not, of course, represent a complete or working apparatus, but it is hoped that the arrangement may be favorable to practical development.

R. H. Polk, formerly manager of the Bell Telephone company at Savannah, has gone to the Georgia Telephone company, a local competitor, and is succeeded by A. T. Maxwell.

1. From London Electricity,

New England Telephone Notes.

[From the Boston correspondent of the Western Electrician.]

The American Bell Telephone company has filed the following report at the state house in Boston, dated March 28th.

Assets.		Liabilities.	
Real estate.....	\$ 1,243,745	Capital stock.....	\$2,000,000
Machinery.....	11,415	Debits.....	9,187,277
Cash and debts receivable.....	5,103,491	Reserve.....	2,935,333
Manufactures and material.....	2,497,392	Total.....	\$6,972,609
Miscellaneous.....	59,029,041		
Total.....	\$67,951,997		

From Dover, Del., comes the information that the secretary of state has received the certificate of incorporation of the New York and Boston Telegraph and Telephone company of New York. It has a capital of \$5,000,000. It is expected that it will work in opposition to the New England Telephone and Telegraph company. Officers of the New York Telephone company said that they knew nothing of the new corporation. The New England Telephone and Telegraph company operates in New England states under a license from the American Bell Telephone company. It is understood that heavy New England backing is behind the new company, which is to build and operate the long-distance line in connection with the new Massachusetts company.

The April statement of the American Bell Telephone company, showing the number of instruments placed and returned, and the net output for one month and for the period from January 1st to April 20th, does not come up to the March record, but it is stated that another record was broken in the number of instruments ordered, namely, 80,519, for the last month. These orders were about 20,000 in excess of the present capacity of the company to man-

MUNICIPAL OWNERSHIP.

ufacture and distribute. The gross output for the month was 61,481 instruments; returned, 13,079; net, 48,402. For four months the gross output has been 224,325, returned, 54,804; net, 169,521. This makes the total now outstanding 1,294,767, against 977,345 a year ago, a gain of 317,422. The Western Electric company, in view of the heavy demand for instruments, is said to be making arrangements to materially increase its capacity.

The new Massachusetts Telephone and Telegraph company has secured upward of 3,000 subscribers for its telephone service in advance of its construction of a plant. The contracts will probably be let, it is announced, some time this month for the necessary construction work.

After a lively fight in both branches of the Legislature, the so-called "telephone supervision" bill was defeated. It aroused a large amount of discussion throughout the state and mustered 85 votes on the final division. The opposition, however, came off victorious, with 105 members on its side. A proposition to put telegraph companies under the same surveillance was made at one stage of the fight, and it is likely to come forward next year with broader scope, so as to include all transmission of messages by wire in its provisions.

The Home Telegraph and Telephone company of Lawrence has been incorporated under the laws of Massachusetts, with a capital of \$100,000, by Edwin W. Burton, George G. Adams and Henry Klous.

The directors of the Mexican Telephone company, which is operated in the City of Mexico and suburbs, and is owned and managed principally by Boston capitalists, have just issued the annual report for the year ended February 28th, from which it appears that the number of telephones now in service is 2,720 against 2,486 a year ago and 2,340 two years ago. Gross earnings, in Mexican currency, were \$1,389,937; expenditures, \$824,407; net earnings, \$565,440. For construction \$38,782 was applied out of the earnings, and taxes amounting to \$6,700 were paid. The City of Mexico alone shows a gain in subscribers of 138 for the year. The company has no floating debt, and reports cash to the amount of \$15,834 in the home-office treasury.

The annual report of the New England Telephone and Telegraph company, whose annual meeting was

CONVENTIONS AND EXPOSITIONS.

New York Electrical Exhibition, Madison Square Garden, New York, May 9th to June 3d.

American Society of Mechanical Engineers, Arlington Hotel, Washington, D. C., May 9th to 12th.

Southwestern Gas, Electric and Street-railway association, Austin, Texas, May 17th to 19th.

National Electric Light association, Murray Hill Hotel, New York, May 23d to 25th.

Exhibition of Electrical Appliances for Household Use, Brussels, Belgium, during May.

American Institute of Electrical Engineers, Boston, June 19th to 22d.

Southern Telephone association, Memphis, Tenn., July 5th.

American Association for the Advancement of Science, Columbus, O., August 21st and 25th.

National Association of Municipal Electricians, Wilmington, Del., September 15th to 17th.

Philadelphia Exposition of American Manufactures for Export, September 1st to November 30th. (Under the Auspices of the Philadelphia Commercial Museum and the Franklin Institute.)

Chicago, Exposition of Electrical Arts, Tatterhall's, September 25th to October 9th.

International Exhibition of Motor-vehicles, Berlin, Germany, during September.

American Street Railway association, Auditorium Annex, Chicago, October 17th to 20th.

The season of conventions and expositions has arrived, and those who are interested in the industrial progress and scientific and mechanical advancement of the times will have ample opportunity to learn the latest developments through these agencies. A list including the principal gatherings in which electrical and mechanical experts and students are interested is presented on this page.

Keely's motor may be relegated to oblivion, but it is not well to be too positive upon this point, as it has survived many seemingly vital attacks. However, Mr. Kinraide, who was persuaded after Mr. Keely's death to continue the experiments, has sent the apparatus and manuscripts of the dead inventor back to Philadelphia, and has withdrawn entirely from the enterprise. Mr. Kinraide enjoys a good standing in the scientific world, and the unpleasant notoriety thrust upon him by the publication of the latest exposure of Keely's methods was considered by him as a serious breach of faith on the part of the men who enlisted his services. Mr. Kinraide says his action should not be construed as a decision that Keely practiced deception, as he has not given the subject sufficient attention to pass upon the merits of the case. It is evidently intended more as a rebuke to the management of the Keely company, which first engaged him to investigate Keely's claims and then, unknown to Mr. Kinraide, published the result of an independent examination by others.

American manufactures have been received with so much favor in foreign markets that many precautions which would naturally suggest themselves to exporters have not been considered. As a result the progress of the movement to secure control of the markets of the world is likely to receive a severe setback unless American manufacturers pay more attention to the details of the requirements of foreign trade. An article prepared for the Western Electrician by the Philadelphia Commercial Museum, which has made a study of commercial subjects and is engaged in promoting the interests of American manufacturers abroad, contains a timely warning to those who have been negligent and who should be alert in the interest of the country's industries. Many of the points raised are repetitions of reports already received, but this merely emphasizes the necessity for impressing the importance of the subject on the minds of those engaged in this class of trade. It is evident that American industries will not be fairly represented and fully appreciated abroad until their promoters seriously study the conditions of trade in the countries invaded, and aim to meet the requirements as they find them.

The Vatican is now entirely lighted by electricity. Up to the time of Pope Leo's predecessor, the palace of the popes was lighted by oil lamps, but under Pius IX. gas was adopted for lighting the court yard, corridors and some of the chambers, while candles and oil lamps were exclusively used in the pope's immediate residence.

When the present pontiff succeeded he desired that the Vatican should not be behind Rome's other fine palaces in the matter of illumination, and he ordered that the electric light should not only replace the gas, but that it should also be used in his own rooms and those of the secretary of state. On February 19th the plans prepared for the installation were sanctioned by Monsignor Piffieri, the Papal sacristan and the major-domo of the palace, and since then the work has been completed.

The electric plant has been constructed in the old mills in the garden of the Vatican, not far from the so-called Eagle fountain, a name derived from the immense stone eagle which spreads its wings majestically over a waterfall supplied from the Acqua Paola. Two machines are employed, one driven by water and the other by gas, and an accumulator plant has been added as a reserve and for regulating the load.

The hydraulic machine consists of a turbine, which obtains its power from a branch of the Eagle fountain, and receives 70 liters of water, which fall from a height of 14 meters, generating a capacity of 10 horse power. The beauty of the fountain has not suffered materially from this application to prac-

tical purposes, especially as the turbine is in motion in the evening only. The gas motor is only used in case the demand exceeds the capacity of the water power and the accumulators. The 59 cells of accumulators are placed in a special room and are charged at night. The whole plant supplies 600 incandescent lamps of 10 candle power.

From the electric plant the wires run in two directions. One group supplies the Papal observatory in the Leonine tower, the Casino in the Vatican gardens, the Vatican printing office and the Specola Vaticana. The printing office will soon have electric machinery. The second group of wires runs over the walls of the Vatican and into the large court of the Belvedere. Here the wires branch off at the ground floor and into the different wings of the Vatican palace.

In introducing electric lighting the pope has not increased his expenditure, but, on the contrary, a considerable sum will be saved by its use. Previously 600 gas-burners were used in the palace, each one consuming about 60 cubic meters, at a price of about \$2.76. The cost of all the lighting amounted annually to about \$3,250. The electric lighting will be cheaper and give much better service.

English medical authorities are seriously considering the suggestion that disease may be spread through electric conduits. It seems that a correspondent to the Lancet has pointed out that in the town where he lives the main cable supplying current is laid in a four-inch pipe beneath the street sidewalk, with branch pipe for house connections, the ends of which are left open. The higher temperature inside the houses induces an indraught of air by these open pipes, and, as different houses vary in temperature and these pipes form a direct communication from house to house, it is declared that a circulation is set up between the houses, the current of air varying in velocity according to the range of temperature. In the case of houses warmed throughout by a hot-water system, the temperature may be 25 degrees higher than the external air, a condition which would cause an influx of air of sufficient velocity to blow out a candle flame. In this way, it is contended, the air of a house where infectious disease is present might easily be drawn into other houses with serious results. The conveyance of smallpox by aerial agency is established, and it is conceivable that it could be conveyed from one house to another in the manner suggested. There is also the possibility of other contagious diseases being spread in the same way. The exercising of a greater degree of care in plugging the house terminals of the conduits is suggested as an effective remedy.

The announcement of the New York Telephone company that it will reduce its rates for service has attracted a good deal of attention. The plan proposed by the company is something like that which the Chicago Telephone company embodied in the ordinance now before the City Council, only the New York measure includes all classes of patrons, whereas the Chicago company's plan is intended to apply merely to small users. The present movement is simply an effort to introduce the measured-service system in place of the flat-rate method of charging.

An examination of the rates proposed in the new schedules shows that these companies have arranged the terms so that any saving effected by the subscriber must be secured by restricted use of the system, and not at the expense of the corporations. The management hopes to induce patrons to practice economy where they are dissatisfied with the present exorbitant rates, and in this way permit it to keep up its relatively high charges for unrestricted service. It is believed that this measure may check the great increase in the average number of calls that has been shown in the reports from exchanges throughout the country of late. Heretofore it has been the policy of many operating companies to encourage the liberal use of the telephone, and business men have been induced to put desk instruments in their offices in addition to the regular wall set. The result of this policy is shown in the increase from 998,000,000 exchange connections made in 1897 by the Bell companies throughout the country to 1,231,000,000 in 1898. It will now be hard to satisfy the public with restricted service, even where a small saving may be effected.

Marconi's Experiments.

Marconi is a familiar name to-day throughout the civilized world, although the distinguished experimenter who bears it and whose work has attracted universal attention was practically unknown less than four years ago.

Guglielmo Marconi seriously attacked the problem of signaling through space when he attained his majority, and he has ever since persistently followed this line of investigation in the face of difficulties made greater by the indifference of many who should have contributed to his progress, and the opposition and detraction of others who were jealous of his success. However, he has succeeded beyond the expectations of his friends, and professional jealousies have given way before the public acknowledgment of his remarkable achievement.

The portrait which is here reproduced from the London Electrician shows Marconi to be a youthful experimenter, but the serious, thoughtful expression which it shows impresses the beholder with a sense of power and determination.

Marconi was born at Griffone, near Bologna, on April 25, 1874. His mother was an Englishwoman, and this probably accounts for the almost entire absence of foreign accent in his speech. Marconi complains only of English technical terms. He has been a student of electrical science since his 14th year, and he has been engaged upon the experiments in "wireless" telegraphy four years, as already mentioned. His first English exhibition, which was of a private nature, was given in 1896.

An up-to-date Chicago preacher found an attractive subject for his Sunday discourse in "The Parable of the Wireless Telegraph."

Announcement is made in London that J. J. Fahie has in the press a "History of Wireless Telegraphy," from its inception in 1838 up to the present day.

The Northwestern Association of the Massachusetts Institute of Technology announces a "wireless-telegraphy dinner" at Chicago, May 16th. It is proposed to transmit orders from the banquetting hall to the kitchen by the Marconi system.

Experiments are being conducted between Washington and Fort Myer, a distance of four miles, by army officers interested in wireless telegraphy. The Wehnelt interrupter is used in these tests, but no information is obtainable as to the results secured.

M. Ducretet, the French experimenter, is credited with having perfected several important improvements in apparatus used in signaling through space, although the published descriptions in the daily newspapers do not convey a very clear idea of their character and extent. He is reported to have said: "Suppose I send a message from the French shore or Eiffel Tower to Forelands. I can make it impossible for anyone else to receive it. The transmitting and receiving wires attached to masts must coincide as to curves."

A special exhibition of wireless telegraphy was given by Signor Marconi at the South Foreland, on April 20th, in the presence of the naval attaché to the Chinese legation in London, who is to report to the Chinese government on the working of the system, with a view to its adoption in the Chinese navy. London Electricity congratulates Marconi upon this indication of universal interest in his work. That journal asks when, throughout the whole history of the world, has any European invention been so quick to attract the serious notice of the "Heathen Chinese." Here, absolutely in a nutshell, is the finest testimonial that the heart of even a great man could desire.

Professor Jerome J. Green, whose exhibitions in Chicago were described in the Western Electrician April 20th, has resumed his experiments at Notre Dame. On May 6th trials were made between the university and St. Hedwidge's Church in South Bend, more than three miles away. The business district of the city, the tall buildings and the mills and factories with high smokestacks along the St. Joseph River intervened in the space through which the electrical waves had to travel, but the signals were clearer and more distinct than those received on the tug on the lake. The instruments were the same that have been used in all the experiments, with the exception of a new relay of the D'Arsonval type, that was made last week in the university laboratory. Professor Green had the vertical wire and metal sphere fixed to the church spire at the university instead of the flagpole that had been used in the former trials.

In London, it appears, the possibility of introducing the Marconi system was seriously considered by investors in cable securities. The Westminster Gazette printed an interview with Mr. J. H. Carson, the manager of the Anglo-American Telegraph company, as to the probable effect of the wireless-telegraph experiments upon the existing cable companies, in which Mr. Carson said: "I fail altogether to understand how Marconi is to counteract the great curvature of the earth met with across the Atlantic; how he thinks he can erect two perpendicular poles high enough on the shore which will permit of the current being transmitted in the way he indicates. There is a great difference between 'cross-channeling' at 30 or 40 miles and 'cross-oceania' at 4,000!

If he proposes to obtain the assistance of lightships, balloons and other aerial instruments in order to lessen the enormous distance intervening between each station, the cost would be something almost inconceivable." Another indication of the uneasiness felt is to be found in the report of the meeting of the Eastern Extension, Australasia and China Telegraph company at London. Lord Tweeddale, who presided, said, according to the London Financial News, with regard to wireless telegraphy, it was not surprising that investors, who had hitherto regarded cable securities as among the soundest in the market, should have been startled and alarmed. It was true that messages could be sent without wires between two places, not very far apart, and it was hastily inferred that the same could be accomplished equally well over long distances. In consequence, a few shares had been thrown on the market, and this had caused a serious fall, recalling what occurred when electricity became a competitor of gas. Professor Marconi's system was interesting from a scientific point of view, and in practice would be of considerable value for shipping and lighthouse purposes; but that it would successfully compete with submarine cables was in the opinion of those most competent to form one, in the highest degree improbable.

The correspondent of the Chicago Record at Glasgow, Scotland, announces that Walter Jamieson, a teacher of science, has developed an invention by means of which a vessel can be kept under full control, steered to port or starboard, stopped, driven ahead or turned back, at the will of the officer in charge of the transmitting mechanism, located at a distant station and not connected by wire or otherwise with the apparatus controlled. This mechanism, Mr. Jamieson considers, should apply more particularly to torpedoes, the uncertain path of which

GUGLIELMO MARCONI.

is the weak point in this branch of coast defense. Communication can also be established by life line through the instrumentality of this "steering power," and, Mr. Jamieson believes, stores may be conveyed to lightships and lighthouses in stormy weather. A great desideratum in wireless communication is the discrimination between one electric vibration and another; that is, a method whereby any given receiver will be influenced by the specific vibration meant for it, and by no other. Mr. Jamieson has devoted special attention to this, and has perfected a method for obtaining the desired result.

The London Electrical Review contains a concise account of the experiments made at the South Foreland, April 24th, in the presence of a French commission, with a view to demonstrating the possibilities of communicating between a moving ship and the land. The receiving and transmitting instruments on board the dispatch vessel Ibis were in a cabin, the wire to take the current being connected with the instrument room from the top of the mast, about 150 feet high. The messages were transmitted to the Ibis from the South Foreland, from Wimereux, and from the East Goodwin lightship, as also from the gunboat to each of these points, and in each instance they were recorded with unerring distinctness, the French commissioners expressing the greatest satisfaction with the system. Hitherto one of the chief objections raised to wireless telegraphy has been that it is impossible to concentrate the current; in other words, to "cut out" and prevent the message from being received at other stations where installations exist within an equal radius other than the one for which it was originally intended. Signor Marconi has now discovered an ingenious but simple arrangement by which this difficulty can be overcome, and it was on the 24th inst. tested before the French commission and at South Foreland. Messages were first sent from the Ibis to the South Foreland, and, as Professor Fleming pointed out on his recent visit, were received simultaneously by the Goodwin lightship. Signor Marconi's new invention was then tried, and the messages sent to the Foreland were concentrated there, and received at no other point, the lightship being cut out. A similar experiment was made with the lightship, the ships communicating with each other, while the Foreland was cut out. As a further test of this important invention messages were sent simultaneously from Boulogne and the lightship to

the South Foreland, where only the Boulogne message was taken by the receiver, the other being cut out at will. This experiment was also tried on board the Ibis and from the other point, and with an instance with complete success. It is stated that negotiations are proceeding with a view to placing Newhaven and Dieppe in communication by means of Marconi's system of wireless telegraphy. The expense of the installation is likely to be defrayed by the London, Brighton and South Coast Railway company on the English side, and the Northwestern Railway company on the French side.

Aluminum Feeders for the Northwestern Elevated Railroad.

On the Northwestern elevated railroad, now building on the North Side, Chicago, there will be one innovation of very great interest to the electrical fraternity. The road is built for electrical operation, and the feeders on the elevated structure conducting the current to the centers of distribution will be of aluminum instead of copper. The usual steel contact rails will transmit the current to the motors on the cars.

The Northwestern Elevated will undoubtedly be the first electric railroad in the country to use aluminum feeders, although bare aluminum wires or bars for power transmission have been used to some extent at Niagara Falls and on the Pacific Coast. But with such a powerful incentive as 20-cent copper there is little doubt that many aluminum installations will follow in places where bare conductors are permissible. The Northwestern Elevated Railroad company has entered into contract for 150,000 pounds of aluminum feeders. The contract is made on the relative weight equivalent of 47 pounds of aluminum equaling 100 pounds of copper. This is guaranteed by the aluminum manufacturer. The price of the white metal in this large contract is not given, but even at 36 cents a pound, compared with copper at 20 cents, the comparative prices for equal conductivities are: Aluminum, \$16.02; copper, \$20. Of course there are the relative costs of installation and jointing to be considered, but it seems evident that at prevailing prices aluminum is much cheaper.

Three sizes of bare aluminum cable will be used on the Northwestern Elevated—785,000, 1,000,000 and 1,300,000 circular mils in area respectively. The largest feeder is about 1 1/2 inches in diameter. Of the two larger sizes the railroad company is buying upwards of 10 miles each. The feeders will be placed in a wooden box or trough covered by the board walk between the tracks, as is the case with the large copper feeders on the Union Loop. They will be supported on vitrified-clay blocks, designed with an umbrella drip and placed nine feet apart. Every 100 feet a special malleable-iron chair is used, the cable being carried in split-spool insulators, thus holding the slack.

Experiments already made under the direction of Mr. J. R. Chapman, the electrical engineer of the Northwestern Elevated Railroad company, seem to show that the installation will be equal in every respect to copper, on a basis of equality of 157 circular mils of aluminum to 100 circular mils of copper.

Detroit Street-railway Ownership.

[Correspondence of the Western Electrician.]

Detroit, May 9.—The Detroit electric street railway deal is now officially declared off. The commissioners appointed to value the roads for the city decided that the properties were worth \$15,500,000, but Tom Johnson has insisted that he must have \$17,100,000. As there is no prospect of closing the deal, the commissioners have decided to file a final report with the Common Council and withdraw from their duties. The original stipulation of Johnson was that his price, \$15,325,000, should be cash, and as the city is not in a position to pay cash, he declared that he would take \$17,100,000 in four per cent. bonds, secured by a blanket mortgage over the assets of the street-railway properties. The mortgage was in turn to be secured by what was to be known as a "security franchise," running 30 years, with workmen's tickets at eight-for-a-quarter during certain hours, a six-for-a-quarter fare and universal transfers. Johnson refused to extend the time for the consideration of the deal 90 days to give time to sell the bonds, declaring that the Wilson interests insisted that the price named be refused or taken by May 14th. The commissioners then offered Johnson an issue of \$16,000,000 in bonds, provided that Johnson would undertake the responsibility of selling them at par. Johnson agreed, so far as he was concerned, saying that he had not a dollar's interest in the road, but adding that the Wilsons would not enter upon such a proposition. Here the matter ends.

The New York Sun relates that three trolley cars provided with the trolley attachments, such as the trolley companies use for carrying lumber, rails and the like, were recently seen going up Washington street from Sands street, in Brooklyn, loaded with furniture. The first two cars were piled high with chairs, tables, desks, rugs and carpets, while the third car was filled with stoves, stovepipe, two or three looking-glasses and a safe and two water-cases. The three carloads were the last of the effects taken from the Union Elevated Railroad company's old office, and were being removed to the Consolidated Rapid Transit company's office in Montague street.

Test of Mechanical Draft.

In the discussion of the problem of chimney versus mechanical draft, the advocates of the latter point to the possibilities in the way of reduction of fuel cost in modern boiler practice, as exemplified by the accompanying results obtained with mechanical draft by the United States Cotton company, Central Falls, R. I. This record covers a period of 52 weeks:

Number of hours run.....	2,998	
Average indicated horse power.....	1,543.84	
Coal.	Pounds Burned	Cost.
Buckwheat.....	6,074,400	\$9,316.89
Anthracite coal.....	1,173,826	800.34
Cumberland.....	565,906	836.00
Total.....	7,814,132	\$8,953.23
Cost per ton.....		\$2.29
Cost per indicated horse power per year.....		5.80

COMPOSITION OF MIXTURE.

Buckwheat.....	78
Anthracite dust.....	15
Cumberland.....	7
	100

The plant consists of three Babcock & Wilcox boilers of 335 rated horse power each, a total of 1,005 rated horse power. The engine is a cross-compound Harris-Corliss, developing, as will be noted, an average of 1,543.84 indicated horse power. The remarkably low fuel cost of \$5.80 per indicated horse power per year in a plant without economizers is primarily due to the employment of a low-grade mixture, costing only \$2.29 a ton, the burning of which has been rendered possible by the introduction of mechanical draft. The draft of the chimney, which was previously employed, lacked the intensity necessary to the free combustion of this fuel, and, as a consequence, it had been necessary to use Cumberland semi-bituminous coal.

The installation of the fan, costing less than \$600, is said to have brought about an annual saving of no less than \$6,500 in the fuel bill. The fan, which was built by the B. F. Sturtevant company of Boston, is provided with a direct-attached engine, the speed of which is regulated by a device of the chief engineer, Mr. Thomas P. Burke, whereby a scarcely noticeable change in the steam pressure immediately alters the speed of the fan, and consequently the intensity of the draft, and instantly brings the pressure back to normal. As a result the steam pressure remains almost absolutely constant.

Vesta Electric Bicycle and Carriage Lamps.

Electrical men will be interested in the Vesta electric bicycle and carriage lamp, several styles of which are illustrated in the accompanying cuts.

The bicycle lamp is neat and compact. It has been thoroughly tested for three years, and has given universal satisfaction. The Vesta Accumulator company of Chicago recommends it to all who wish a first-class light and one which is clean, always in order and which cannot be extinguished by wind or jarring. The lamp has no odor and is always ready for use. The manufacturers guarantee it to burn 12 hours. Every time the lamp is recharged it will burn for 12 hours and the recharging costs only five cents. The bicycle lamp is made in two sizes, the smaller using a four-volt Vesta storage battery, while a more power-

by surgeons, doctors and experimenters. It will enable a traveler to carry his own lighting system from town to town.

D. P. Perry is the president and principal stockholder of the Vesta company, and through his untiring efforts the portable storage battery and lamp have been perfected and brought into commercial use. Mr. Perry is constantly receiving testimonials in the highest possible terms from users. The company will be pleased to send further particulars of its lamps and batteries to all who are interested in the subject.

A New Supply Company.

There has recently been organized in New York a new supply company to furnish general street-railway, electric-light and contractors' supplies, under the name of the National Supply company, with offices at 54 John street. It will be under the manage-

MAXSTADT SINGLE-POLE CARBON LIGHTNING ARRESTER.

ment of E. L. Dougherty. Mr. Dougherty, it may be mentioned, is a son of Mr. John Dougherty, the well-known railroad man of the Mills building, New York.

One of the specialties that is offered the trade by the National Supply company is its Standard white cold-water paint. This paint comes in the form of a powder ready for immediate use, and has only to be mixed with cold water; but it must not be confused with whitewash and other cheap materials. This coating, it is stated, will not rub off; is not only tenacious and waterproof, but absolutely fireproof. One coat will give better service than two or three coats of whitewash. It gives a smooth, even, absolutely white finish, and effects a large saving in labor, with results incomparable with anything else of the kind. The National company does not claim it to be better than oil paint, although it keeps its fine white surface when exposed to the action of gases, etc., better than any oil paint will. It is guaranteed not to crack or peel off.

No risk is run, it is claimed, in using it for coating surfaces directly over fine goods, machinery, and racking and jarring will not cause this paint to come off. It is eminently suitable for service in engine rooms, central-station interiors and other electrical institutions. It should be remembered, too, that the Standard cold-water paint can be purchased in any color. As it is a peculiar compound and worth inspection, the National Supply company offers to send, free of charge, samples, and will send a sample card so as to facilitate a choice.

In addition to handling the above-mentioned specialties, the National company will furnish roofing and roofing materials, roof paints, preservative coatings for iron, enamels, all kinds of paints, varnish, shellac, alcohol, pipe covering, brushes, iron pipe

of electrical applications. His remarks, however, will be read with interest:

I have already trespassed too far and too long to attempt to deal with the applications of electric power. The difficulties which have been experienced in getting suitable labor have led the Americans to have a supreme faith in machinery as against hand labor, and perhaps I could not better convey the idea of the part played by electricity than by stating that it is now a recognized branch of engineering and plays a prominent part in conjunction with steam, compressed air and hydraulics. I had sufficient experience of continental practice to give me far more faith in electrical appliances than most of you here, and I was glad to know the universal experience in America has been that the electric motor has proved quite as dependable as the plant which it replaced. Two of the companies had each on order generators of 1,000 horse power, which size they regard in the same light as we regard machines of 100 horse power. We are beginning to recognize more and more the necessity of knowing American practice, and with no branch is it more necessary to be conversant than with electricity if one would wish to be up to date. Owing to more than one cause, we are perhaps as much behind continental practice as continental practice is behind American. In one particular class of machinery with which we in this country are practically

non-conversant, I found that one of the leading firms in America had already manufactured and set to work over 250,000 horse power. I was surprised to learn that I was probably the first purely electrical man who had gone over their works with a set view of seeing the applications they had made of this motive power, and their practice is so far ahead of ours that I feel it a necessity to go over frequently, and perhaps after my next visit I may, if it appears desirable, then give a contribution to this society on "Electrical Applications of Power."

One of the most striking features in which they have developed labor saving is in the use of cranes and innumerable carrying and lifting appliances, and in this direction electricity has proved one of their most valuable servants. I remember in the stock yard of one works a man in an elevated cabin controlled about eight sets of live rollers. It was a pleasure to me to see many of the machines at work, and driven electrically, about which papers are read in this country, and on which discussions, often unfavorable, are not wanting. Among these were the Uehling casting machine, Wellman charger, blast furnace chargers, cranes and travelers, in various forms, and a very general use of motors where we employ small engines. I must say, however, that it was not the least valuable to me to know and see to what they had not applied motors, and it speaks well for the candor of our friends that they were not slow to reply to my oft-repeated question, "Now tell me of all your failures."

Maxstadt Single-pole Carbon Lightning Arrester.

The American Electric Fuse company, 345 South Canal street, Chicago, has just perfected and placed on the market its latest improvement in a single-pole carbon lightning arrester, illustrated by the cut, which is claimed to be superior to anything on the market to-day for the protection of telephone, telegraph and fire-alarm instruments. The device has many features which will appeal to the user and should prove of special value to telephone managers. Furthermore, the manufacturer says that it costs less than any other cut-out made.

TRIFLING TECHNICALITIES.

First Coachman—"Did yez get the job?"
Second Coachman (unemployed)—"I did not. Sez

VESTA ELECTRIC BICYCLE AND CARRIAGE LAMPS.

ful light can be obtained by the use of a six-volt battery.

The electric carriage lamps, which are also manufactured by the Vesta company, have been used by the Chicago Fire, Electrical and Police Departments for the last 18 months. They have been adopted by such firms as the Chicago Edison company, Montgomery Ward & Co., Carson, Pirie, Scott & Co., Marshall Field & Co., Siegel, Cooper & Co., the Fair, Sears, Roebuck & Co., and the Columbian Field Museum. Another product of the Vesta company which has found favor is an electric lantern which can be used about the house, in mine, in gas-houses and in other places where a safe lamp is required.

The Vesta storage battery which is used in connection with these lamps is clean, compact and convenient in form. The manufacturers claim that it does not corrode at the terminals and that it is the only portable battery on the market which is entirely reliable. It can be used for supplying light or power

and fittings. Contracts will be taken for laying roofs and for belting, National wall finish, railway, mill and contractors' supplies, insulating compounds, tape, poles, cross-arms and general street-railway, electric and contractors' supplies.

American Management, Labor and Resources.

Walter Dixon of Walter Dixon & Co., electrical and general engineers of Glasgow, made a very careful study of the methods employed by American manufacturers during a recent visit to this country. Since his return Mr. Dixon has presented his impressions in a paper entitled "Some Conditions of the American Iron and Steel Industries: A Comparison," which he read before the West of Scotland Iron and Steel Institute. It is to be regretted that he touched only incidentally upon the subject

he, 'Kin yez run an autumn mobile?' 'I kin not,' sez I; 'I've druv horses twinty-six years,' sez I, 'an' whin the horses quit the business, I'll quit too,' sez I.'—Puck.

The National Light and Power company of Jersey City, N. J., with a capital of \$15,000,000, has been incorporated.

New England Telephone Notes.

[Continued from page 269]

held last week, resulting in the re-election of the board of directors, shows gross earnings for the year 1898 of \$3,425,858; expenses, \$2,735,595; net, \$690,263; dividends, \$677,010; surplus, \$12,654. The report states that the public pay-station service has increased materially during the year, 301 being added, thus bringing the number up to 1,961. The big sleet-storm in January of last year cost the company for reconstruction, partly at the time and partly in progress since, in the neighborhood of \$200,000. The total expenditure during the year for equipment includes \$880,293.17 for new construction and properties purchased and \$1,210,022.71 for repairs and maintenance.

The underground system in the city of Boston now extends through 305,100 feet, about 58 miles of street, the total length of duct being 1,973,000 feet, or 374 miles.

During the year 191,761 feet of cable have been drawn into ducts in the city of Boston, and 59,994 feet have been removed for various causes.

The length of underground wire in use in the city of Boston at the close of the year was 28,760 miles.

In thirty-three of the exchanges outside of the city of Boston the company had, to the close of 1898, constructed 541,800 feet of conduit, containing 2,666,400 feet of duct; making the total underground system to consist of 846,900 feet of conduit and 4,639,400 feet of duct, with a wire capacity of 105,400 miles.

The balance sheet, December 31, 1898, was as follows:

DEBIT.	
Property and franchise, January 1, 1898	\$14,559,151
Construction for year 1898	889,293
Supply department	334,447
Real estate	25,219
Stocks and bonds	36,000
Accounts receivable	1,024,100
Cash	237,809
	\$17,100,023
CREDIT.	
Capital stock	\$11,976,000
Surplus	1,114,897
Bonded debt	3,282,000
Debt, accounts payable	193,369
Reserve	533,756
	\$17,100,023

The company issued \$1,049,100 additional stock during the year and retired \$150,000 five per cent. 1916-year debenture bonds and \$500,000 five per cent. 1919-year bonds. The outstanding bonded debt is \$3,549,000.

Michigan Lines.

[From the Detroit correspondent of the Western Electrician.]

The striking linemen are still at outs with the Michigan Telephone company, but the indications are that all differences will soon be adjusted. At present 51 linemen are involved. There seems to be no foundation for the rumor that the telephone girls will go on strike to show their sympathy for the linemen.

The Michigan Telephone company's gross valuation this year was fixed at \$782,000, and the Detroit Telephone company's at \$362,000. On these sums the taxes will be, respectively, \$11,730 and \$5,430.

John H. Fry, the new manager of the Detroit Telephone company, assumed his position May 1st. Mr. Fry has had experience as a street-railway manager in this city in the days of horse cars, under the Hendrie regime.

The Michigan Telephone company has offered a reward of \$500 for the conviction of the men who have been cutting its wires. The trouble is attributed to the strike now on.

The Michigan Telephone company will build two new sub-stations. The first, to cost \$13,500, will be of press brick, cut stone and terra cotta. Donaldson & Meier are the architects. The building will be erected at the corner of Cass and Milwaukee avenues. The second, of the same general design, is to cost \$7,500, and to be built on the six-mile road, near Woodward avenue. These improvements will be made at once.

The recent act of the Michigan Legislature makes it the duty of town officers to fix the value of telegraph and telephone equipment, for the purpose of local instead of state assessments. This is a radical departure from the law in operation for the last 17 years. Under the old system poles were assessed at 30 cents each and upward, sometimes as high as \$4 each. Senator McMullen of Cheboygan, in whose district the great cedar belt of the state is located, says that poles have greatly increased in price since the old law went into effect 17 year ago, and that to-day telephone poles should be assessed at about \$1.50 each. The poles are supposed to be set 32 to a mile. A line across a six-mile township, making allowances for the configuration of the land, etc., would now be assessed at about \$300 by the town board. The assessment problem in villages and cities where there is a perfect network of wires and valuable telephone and telegraph apparatus becomes extremely complicated. Another fact that adds to the embarrassment of the township officials is that the time for assessments on this year's rolls is extremely short. The new law prescribes that the assessment rolls must be completed by the third Monday in May, or May 15th. The Board of Review, to hear objections to assessments, meets on the day following.

The Detroit assessors levied taxes aggregating \$1,000,000 on local telephone and telegraph properties. This is a considerable advance over previous years. A strong light will be made before the Board of Review at the last moment. The law was

passed in such a hurry that it is not likely that many of the back-country districts will hear of the changes in time to levy assessments under the new system.

After being shut off from telephone connection for nearly a week, the residents of Gross Ile, Mich., can now use the new cable of the Michigan Bell company.

Wyandotte will have a 24-hour telephone service. The Michigan company has secured new headquarters, and General Superintendent Land promises to make the service equal to that of Detroit. Francis Murphy, manager, has resigned, and is succeeded by John McGinnis, for a long time with the Detroit exchange.

NEW COMPANIES.

Among the Illinois incorporations reported from Springfield on May 6th were two telephone concerns, as follows:

Independent Telephone company, Chicago; capital stock, \$2,500; incorporators, Blaechz Hovey, M. G. Musgrave, John R. Lyman.

Standard Telephone company, Chicago; capital stock, \$10,000; incorporators, W. T. Rowell, John Syrten, J. B. Osman.

The Seaboard Telegraph and Telephone company has been incorporated in New York, and its backers say it is the intention of the company to erect and maintain a cheap telephone service on Long Island. The capital is \$100,000, and the directors are all residents of Long Island villages. They are Dr. J. Carl Schmuck of Lawrence, Andrew McTigue, L. T. Walter, Jr., and B. C. Lockwood of Far Rockaway, John Adikes of Jamaica and Samuel R. Smith and George Christians of Freeport. The company is talking of putting in telephones for \$15 or \$20 a year. It proposes to construct a line from Far Rockaway to Montauk, on the south side, thence to Orient and Riverhead and the north side, taking in all the villages to Brooklyn.

The Booneville (Mo.) Telephone company was recently organized by local capitalists, and has been incorporated, with a capital stock of \$8,000. The list of subscribers numbers nearly 200. The promoter of the enterprise is C. J. Townsend, who built an exchange at Franklin, which proved satisfactory in every particular. At Booneville, it is announced that the ultimate scheme is a combination of all independent lines in that section of the state. Mr. Townsend expects to secure connection with Jefferson City by way of Columbia. A meeting of the stockholders was held lately and organization perfected by the election of the following-named officers: President, John S. Elliott; vice-president, Charles A. Sombart; secretary and treasurer, E. A. Windsor. These gentlemen, with J. F. Gmelich and E. W. Chilton, constitute the board of directors. The contract for the building of the line was let to the Des Moines (Ia.) Electric company. Work will be commenced at once, and the company agrees to complete the line in 90 days and turn it over to the home company. Mr. Townsend will remain as general manager.

MANUFACTURERS AND DEALERS.

The Schmidt & Bruckner Electric company of New York has moved into its new factory at 135 Elm street, corner of Howard street. The location is admirably adapted to the company's needs; the facilities for manufacture and shipping are greatly improved and the space available much larger than that at its disposal in the old quarters. Speaking of the change, Mr. Schmidt said recently: "During the last year the demands for our apparatus have increased far beyond the capacity of our old factory at 209 Greenwich street. Often we were compelled to delay orders for some weeks on account of the overcrowded condition of our machine shop. In our new building we are now in a position for handling a much larger trade than we have heretofore been able to undertake, and will also fill orders in much less time. We are pleased that we have been compelled to take this step, as it proves that our apparatus is appreciated in the telephone trade, and that there is an increasing demand throughout the country for the highest class of telephone apparatus. In other words, the telephone buyer has begun to learn that the best apparatus at consistent prices is the most economical. He knows that his income depends on the expense of maintaining the apparatus, and that when instruments are well made the cost of this maintenance must be materially less than with cheaper grades of goods."

EXTENSIONS AND IMPROVEMENTS.

At a meeting of the stockholders of the New York Telephone company, May 2d, the old board of directors were re-elected as follows: Charles F. Cutler, Thomas F. Clark, John H. Cahill, Joseph P. Davis, Thomas T. Eckert, George J. Gould, Edward J. Hall, John E. Hudson, Winfield S. Hutchinson, James Merrilue, Thomas Sherwin, Charles A. Tinker and William H. Woolverton.

L. D. Pitcher of Dixon, Ill., the principal stockholder in the Lee County Telephone company, will begin at once to build a complete telephone system in Jo Daviess County, using Sterling switchboard and Eureka telephones. The toll line will be a metallic circuit and the several exchanges will be on the common-return system. The Bell company will parallel this toll line, but the local interests have no fear of competition, as they give free toll service to all their subscribers and cheap service to all others.

Siemens & Halske Company Sold to Electric Vehicle Company.

The visit of representatives of the eastern group of capitalists known as the "Whitney crowd," who is now taking such an active part in the electrical business of the country, to Chicago last week resulted in important developments in the electrical situation here. The "Whitney crowd" already control the Metropolitan Street Railway company of New York, the New York Gas and Electric Light, Heat and Power company, the Electric Storage Battery company, the Electric Vehicle company, large street-railway properties in Brooklyn, Philadelphia and other cities and other manufacturing and operating companies. It is a formidable aggregation, actively and aggressively improving the opportunity for extending the electrical activities of the country which now offers.

One line in which the syndicate is very active is the manufacture and operation of electric vehicles. The Electric Vehicle company of New York is to be the parent company in this field. The Illinois Electric Vehicle Transportation company, with a capital stock of \$25,000,000, was incorporated in both New Jersey and Illinois last week, as a licensee of the Electric Vehicle company. It will operate electric vehicles in the state of Illinois. Samuel Insull, of the Chicago Edison company, is president of this company. He has resigned the presidency of the Fischer Equipment company of Chicago, which is about to be reorganized and its field extended as the Woods Moto-vehicle company, with increased capital, also for the manufacture of electric vehicles. It was reported that negotiations were on foot for the absorption of the Fischer or Woods company in the new Illinois company, but the deal has not gone through. Likewise, the Chicago Electric Vehicle company, formed by Mr. Insull and his associates in the Chicago Edison company early last month to operate electric vehicles in Chicago, has been dropped, the organizers having become interested in the new Illinois company.

Closely related to these changes is the purchase of the stock of the Siemens & Halske Electric company of Chicago by the Electric Vehicle company of New York, of which Isaac L. Rice is president. The sale was made on May 4th, Mr. C. E. Yerkes disposing of his interest entire, and Mr. Rice is now president of the Siemens & Halske company, Mr. C. S. Knight continuing as general manager. Besides being at the head of the two companies mentioned, Mr. Rice is also president of the Electric Storage Battery company. The manufacturing of the Electric Vehicle company is to be done in the East by the Columbia Automobile company of New York, which represents the combined interests of the Electric Vehicle company and the Pope Manufacturing company of Hartford, Conn. Whether the Siemens & Halske works near Chicago shall be operated directly by the Electric Vehicle company or by the eastern manufacturing company, the Columbia Automobile company, has not been definitely decided. And the further and very interesting question of the disposition of the general electric-light and power business and possibilities of the large Siemens & Halske manufacturing plant has been discussed only in the most general manner. It is said that one building alone of the works in Cicero has capacity for turning out 60 electric-vehicle equipments a day, which will certainly anticipate the western demand for some time to come. The factory is now busy on large work, and it does not seem likely that a large part of it will be permitted to remain idle when present orders expire, if business can be secured. The new owners of the property are very intimately connected with some of the largest consumers of electrical machinery in the country. Indeed, the business of the "Whitney syndicate" alone ought to keep a good-sized factory busy. So it is a fair assumption that, in addition to the electric-vehicle work, the Siemens & Halske works will be kept busy with electric-light and power machinery contracts. In fact, it looks as though the business of the company in all lines would be greatly increased.

The plans of the Illinois Electric Vehicle Transportation company for the car service and other business in Chicago have not been developed. Undoubtedly an effort will be made to make the use of the new vehicle cheap and popular. There will be a number of charging points for the batteries—furnished by the Electric Storage Battery company, of course—and the Chicago Edison company will supply the current.

Temporary Removal of Chicago Edison Company.

About May 15th the offices of the Chicago Edison company will be removed from the company's building at 139 Adams street in order to make way for the workmen engaged upon the job of enlarging and remodeling the building, which has been altogether outgrown by the company's business. During the summer the commercial business of the company will be conducted on the ground floor and third floor of the building at 173 and 175 Adams street, which is very familiar to electrical men of Chicago and vicinity, as it has served as western headquarters for the old Edison General company and the General Electric company, and later as the store and warehouses of the Central Electric company. During the same period the offices of the president, directors, secretary and treasurer, controller, general superintendent, mechanical engineer and attorney of the Chicago Edison company will be on the fifth floor of the Rand-McNally building, just across the street

from the temporary quarters of the other departments. About September 15th it is expected that the enlarged building will be ready for occupancy, and all the officers of the company will be reunited under one roof. The offices of the Commonwealth Electric company are temporarily removed to the locations given with those of the Chicago Edison company.

The Profit of Electric Railway Operation.

Seldom are the financial advantages of the electrical operation of railways so clearly shown as in the case of the South Side Elevated Railroad company of Chicago, which discarded steam locomotives burning hard coal for electrical distribution of power and the Sprague multiple-unit system of train operation. As has been previously shown in the Western Electrician, the change is making a fine, profitable property out of a losing one. It made the cars more attractive to passengers and increased the traffic, at the same time reducing the expenses in a marked degree. The facts are again recalled by a brief review of the first four months' business of the year, as given in the Economist, Chicago's financial journal:

"The road's traffic for April showed a gain of 16 per cent., as compared with April, 1898, and for the first four months of this year the gain in passenger receipts has been 15 per cent. over 1898. The following shows the traffic by months so far this year, compared with last:

	1899		1898	
	Whole No.	Av. Daily	Whole No.	Av. Daily
January	1,820,909	58,762	1,615,627	52,117
February	1,688,176	56,292	1,475,026	52,601
March	1,981,179	63,909	1,999,637	64,828
April	1,916,340	63,878	1,624,440	54,149
Four months	7,405,604	61,721	6,414,799	53,456

"This, however, is only a small part of the situation as compared with a year ago, for during the four months in 1898 the road, with steam operation, paid out 82 per cent. of its gross receipts in expenses, exclusive of bond interest. In November and December last, when the traffic was about the same as during these four months and the line was operated by electricity, expenses were only 57 per cent. of gross. Applying that ratio to the four months this year and allowing \$10,000 for earnings other than from passengers, as in the four months last year, the following comparative statement for the first four months of 1899 and 1898 can be made:

	Gross.	Expenses.	Net.
1899 (4 months)	\$380,330	\$216,788	\$163,542
1898 (4 months)	331,069	273,112	57,957
Gain	\$49,261	\$56,324	\$105,585

"This gain in net earnings is nearly 200 per cent. This ratio of gain, of course, will apply only in the first half of this year, for in the last half of 1898 the road was operated with electricity. The average daily traffic for the first four months last year was a little larger than the average for the whole year, but in view of the way the business keeps growing it looks as though the daily average for 1899 would be close to 60,000, and as though net earnings would be in the neighborhood of \$100,000, after paying bond interest."

Measurement of High Temperatures.

By T. H. WALLER.

In many operations in the industrial field a knowledge of the temperature to which substances must be submitted is indispensable; when we once get to the region of temperatures higher than the boiling point of mercury the difficulties of the determination of temperature rapidly increase. A little step beyond is gained by filling the tube of the thermometer with some inactive gas, such as nitrogen, so that the increase of gaseous pressure as the mercury is pushed along the tube may raise the boiling point of the metal. Again, Baly and Chorley's thermometer, which is filled with the liquid alloy of potassium and sodium, is available for some little way higher. A point, however, is pretty soon reached at which the glass of the bulb and tube softens and melts, and though some of the Jena glasses made by the celebrated firm of Schott are remarkably refractory, a very dull red heat is practically the limit of the use of thermometer of the ordinary construction, using the alloy of potassium and sodium just mentioned. Although this is quite sufficient for many purposes, such as the determination of the temperature of flues, or of a blast-furnace blast, such instruments are fragile and awkward to read; at any rate, as to flues, which, by the very nature of the case, are frequently in places which are very inconvenient to get near enough to read a fine thermometer.

The expansion of a gas may also be used for purposes of thermometry, and if the envelope is made of glass or porcelain the instrument is available up to very high degrees of temperature.

For ordinary use in furnaces, etc., the air thermometer may be considered of practical importance. It is cumbersome and needs fine and delicate apparatus to read its indication, and such are generally quite out of place in the situations where determinations of high temperatures are required.

By taking advantage of what is known of the specific heat of a metal, it is possible to reduce

temperatures in such proportion as to make them measurable by ordinary mercury thermometers. In Siemens' pyrometer a mass of either iron or copper or platinum is placed in the flue, furnace or crucible of which the temperature is required, until it has assumed the full temperature of the place. It is then rapidly transferred to a measured bulk of water and the resulting rise in temperature noticed.

In practice this method, which is fairly convenient of performance, is made uncertain by the fact that balls of either iron or copper burn at a red heat, and therefore are continually altering in weight, while balls of platinum are, especially at present "famine prices," too costly to be thought of.

Another method, based on somewhat similar principles, is that in which a current of air at known pressure issues from a jet in a form of injector and thereby draws in a regulated proportion of the furnace or flue gases to mix with the air of the jet, and so become reduced in temperature sufficiently for the use of a mercury thermometer. The graduation of such an instrument must be empirical, but when it has been performed good indications can, it is said, be obtained. Another similar instrument measures the heat of a furnace by the temperature to which a current of water of known amount per second is raised when passed through a pipe exposed to the heat.

In 1871 Siemens proposed to make use of the change of resistance to an electric current which is produced by heating for determining high temperatures.

The apparatus constructed at first by Siemens had many weak points, and the very principle on which it depended was to some extent in doubt; so far, that is, as to whether the change of resistance per degree is different at different parts of the thermometer scale—and if different, what is the exact law of the variation?

A committee of the British Association examined the whole subject and reported in 1874, not altogether favorably to the method as then proposed. Since that time, however, much work has been done on the questions connected with the platinum thermometer, and such an amount of knowledge has been accumulated, that with the modifications both in construction and in methods of measuring the alteration of resistance which have been made, the instrument has taken a very important place among thermometers.

For temperatures up to 800° or 900° C., a very handy adaptation of this platinum thermometer has been arranged by Messrs. Crompton, in which, by means of a differential galvanometer, the change of resistance produces a deflection of a needle which moves over a dial graduated directly into temperatures. This is not suited for accurate work, as the readings depend upon the voltage of the battery used, but where accumulator cells of fair size are used, so that the voltage may be taken as constant for some time, it gives a convenient means of controlling the temperature of flues or hot-air supplies.

The permanence of the platinum wire is, of course, a matter of the very greatest importance in these determinations, and a change of resistance after prolonged exposure to high temperatures was one of the causes which led the British Association committee to report somewhat unfavorably on Siemens' invention. It was found, however, that this change did not occur when the sheath surrounding the coil was composed of platinum, and it was eventually shown that it arose from the combined action of the atmosphere inside the iron sheath and the silica of the fireclay cylinder on which the coil was wound.

Platinum plays a useful part in the next method of pyrometry which we consider.

It has long been known, having been discovered by Seebeck in 1822, that if a circuit be formed consisting of two dissimilar metals a current of electricity will be set up in the circuit so long as one of the junctions of the two metals is kept at a temperature different from that of the other. If a wire is the means of connecting the metals at one junction, the effect is exactly the same, provided the two junctions with the wire are at precisely the same temperature; otherwise, of course, the inequality will set up another current, which will interfere with that which we wish to investigate.

Such a junction of bismuth and antimony has been extensively used for the detection of feeble heat radiations.

Fortunately, platinum and an alloy of platinum with 10 per cent. of rhodium, both of which metals have melting points beyond any temperatures which it is of practical importance to measure, form a thermo-couple, the indications of which are in many ways extremely valuable for technical purposes. It was brought into notice some 10 years ago by Chatelier.

The construction of such a thermo-couple is as simple as possible. A wire of each metal is taken, long enough to reach out from the place of which the temperature is to be measured to a cool place, and a joint made, either by simply twisting them together, or, better, by fusing in the oxyhydrogen flame. The method of insulating and protecting the wires will naturally vary with the degree of heat to which the couple is to be exposed. For flue temperatures a thin-walled glass tube for the protection and a smaller glass tube as insulation for one wire will be sufficient. If temperatures above the melting point of glass have to be dealt with, iron or porcelain tubes must be used, and in the case of iron

both wires must be kept away from the metal. This can be effected by taking strips of mica, say, six inches long and one-half inch wide, boring two holes at each end and threading the wires through them, so that they keep to their own edge of the strips, but pass through the adjacent holes in opposite directions. It is better to make the holes at the end of one strip coincide with those in the next, and to pass the wires through the two strips, thus, as it were, riveting them together. Mica, when it has been heated to a very high temperature, becomes disintegrated, and will then bear no handling; but encased in a porcelain or iron tube, and with the outside connections made by binding-screws fixed on a collar, there is little to disturb the wires. Roberts-Austen originally used specially shaped crucibles, with a little glove finger, so to speak, in the bottom, by which the couple could be completely surrounded by the molten metal. I am informed, however, that he now uses little clay protectors and crucibles of the ordinary make.

The galvanometer used for the detection and measurement of the current produced should be of high resistance, and be what is called dead-beat; that is, the swinging of the indicator when disturbed from any position should very rapidly cease without much oscillation round the new point of rest. For technical purposes, an instrument of what is called the D'Arsonval or moving-coil type is preferable, from the fact, if for no other, that it is not affected by masses of iron or magnets, as of dynamo, in its neighborhood. What I have used has been a galvanometer of the Ayrton-Mather patent of about 300 ohms resistance, which has worked very satisfactorily for general purposes. The calibration of such a thermo-couple is quite simply performed by taking known temperatures as fixed points, from which a curve is drawn to show the temperature for any deflection of the galvanometer.

Altogether, the thermo-couple of platinum and rhodium platinum seems to me the most practical of the various methods of determining high temperatures, though this may possibly be due to the fact that it is the method with which I have had most to do. Where very accurate determinations are required, and convenience of reading is not so essential, the resistance method is probably superior, though the difficulty of making continuous and automatic records very much reduces its technical importance.

CORRESPONDENCE.

New York Notes.

New York, May 8.—It is confidently stated that the controlling interest in the United Electric Light and Power company was sold last week. It is believed that the property passes to the New York Gas and Electric Light, Heat and Power company, but this is not known definitely, as the Third Avenue Railroad "crowd" was also after the company. Heretofore the United company has been controlled by the Westinghouse interests. As the result of the "gas war" now on, one of the companies offers gas at 50 cents a thousand, and it is possible that the electric-lighting companies may be drawn into the fight.

The advisers of the State Board of Railroad Commissioners have examined the Manhattan elevated-railway structure in this city and report it to be, in general, in good condition. C. R. Barnes was the electrical expert. He made 867 voltmeter tests to determine the difference of potential between the iron columns of the structure and adjacent hydrants, gas-lamp posts or surface rails. All tests were made while the ground was frozen. The greatest difference of potential found was 2½ volts, at the Manhattan end of the Brooklyn bridge. Mr. Barnes concludes his report with this recommendation: "After careful examination I find that there has been no serious damage caused by electrolysis to the structure of the Manhattan Railway company of New York. To prevent damage to the supporting columns of this structure in the future I make the following recommendation: That the Manhattan Railway company immediately put their structure in such condition that at no point will it be positive to other conductors in the ground more than one volt, and at this point be maintained."

It is not often that a pedestrian in a city street is struck by lightning, as the multitude of tall buildings and spires in a large city usually serves to dissipate the discharge. Yet it was the unusual that happened in last Tuesday evening's storm. Sadie Tunic, a Russian girl, 13 years old, was the victim. She was struck by lightning at Rutgers street and East Broadway, while on her way home from work. The girl was with several other companions, when she was seen to fall to the ground. She was picked up and carried into a drug store near by, and a call was sent to a hospital for an ambulance. Dr. Bergen responded, and, after making an examination, said that the girl had been struck by lightning. At the hospital it was found that she was badly burned about the abdomen, right leg, both wrists, nose and right cheek, and that she was suffering from shock. For nearly an hour after her admittance to the hospital both her legs were paralyzed, but she recovered the use of those members. The girl said that she did not have any pain at any time. The physicians do not believe she will recover, and they are greatly surprised that she was not killed outright. S.

A street lamp is shown before the No. 10 Southshire (England) Institute of Iron and Steel Works Managers.

say that she is burned severely, and that in addition to her injuries she is suffering from shock. M. S.

Northwestern Notations.

Minneapolis, May 6.—The Seattle (Wash.) Cataract company has been incorporated, with \$100,000 capital stock. The company will be the sole licensee in Seattle of the Snoqualmie Falls Power company.

The General Electric company has purchased the bonds and stock of the Dubuque (Ia.) Light and Traction company, including the Eighth and Iowa street-car lines, valued at nearly \$500,000. It is believed all the Dubuque street-car lines will be consolidated soon.

It is reported the Seattle and Renton Railway company will extend its line seven miles south from Renton to Kent, and give Seattle, Wash., connection with that town.

F. H. Fitch of Chicago has been selected as general superintendent of the consolidated street-railway system of Sioux City, Ia. This system will be known as the Sioux City Traction company, and includes five companies.

The Electric Street Railway, Light and Power company of Mankato, Minn., has increased its capital stock from \$75,000 to \$100,000.

The Benton Power and Traction company of St. Cloud, Minn., proposes to put in a new lighting plant this year, and next year to put in a public hot-water heating system.

H. F. Fiske of Cleveland, O., has become superintendent of the Electric Light and Power company's system at Muscatine, Ia.

Lighting is said to have burned out 95 of the 96 fire-alarm boxes in Duluth, Minn., in a recent storm.

The plant of the Muscatine Electric Light and Power company of Muscatine, Ia., has been sold to Harry Huttig, general manager of Huttig Bros. Manufacturing company. The plant is valued at \$300,000, and includes the street-railway, electric-light and gas systems.

The street-railway company of Burlington, Ia., has been granted an extension of its street-lighting contract for 10 years at \$85 per arc light. It agrees to extend its tracks to West Burlington.

The Fox River Valley Electric company has concluded not to build a line to Oshkosh from Appleton, since the Citizens' Traction company has started a similar line, but will now turn its attention northward. A line to Kaukauna is projected.

The Iowa City (Ia.) Electric Light company has commenced to rebuild its plant, which was burned out some time ago.

Discharged street-railway employees sought relief in the courts at Duluth. They asked the court to order their reinstatement, but the court held the receiver had acted in good faith, and declined to enter into the justice of the charge.

Luther Mendenhall, as receiver for the Duluth, Minn., street-railway company, has begun suit against the Duluth-Superior Traction company, to recover \$4,741, alleged to be due for goods sold between March 1, 1893, and May 31, 1898.

The Electric Light company of Green Bay, Wis., is preparing to furnish electric power. The company proposed to take the power from the street-railway trolley wires, but a united protest in the shape of a threatened increase of insurance rates headed that off. New wires will be strung to furnish power only, and as soon as they are in place the company will be prepared to render the additional service.

The Washington Water Power company of Spokane, Wash., has begun extensive improvements to its system. A new power house will be erected, a new flume constructed, the dam extended and new water wheels and two new dynamos of 1,000 horse power each put in. It is expected the improvements will be completed and the plant in operation by September.

John I. Willson of Chippewa Falls, Wis., has bought the electric-light plant at Owatonna, Minn., and will assume charge of the business as soon as arrangements can be made.

It is announced at Duluth, Minn., that the money is pledged for the development of the St. Louis River water power, to be transmitted to the industries of Duluth and Superior by wire.

The franchise for a local and interurban line from Stillwater, Minn., to St. Paul has been accepted by Thomas Lowry and C. G. Goodrich of Minneapolis, and work will be begun on the system as soon as possible. It is understood contracts have been let for a large amount of material to be used in the new line.

G. W. Roe, R. E. Willard and A. G. Brown have bought the Pipestone, Minn., electric-light plant. Extensive improvements will be made at once.

The Mankato Electric Railway and Power company is a projected company at Mankato, Minn., to have \$100,000 capital stock. It proposes to put in an electric street railway.

Stephen D. Carpenter has unfolded a scheme of great magnitude to the press of Des Moines, Ia., it being nothing less than an eight-track, double-deck, elevated electric-railway system from New York to San Francisco. Mr. Carpenter has a subtle invention of his own, on the perpetual-motion basis, by which every dynamo is a motor and every motor is a dynamo. All he wants is power to start his car, and he will run it through to the destination by means of his "self-generating" motors. He has the cost of his system figured out, and places it at \$300,000,000. Trains would run through from ocean to ocean in 20 hours for passenger and 40 hours for freight. Instead

of having fares based on mileage he would run it on the street-car system and charge five cents a ride for any distance. The rate per ton for freight would be one-half mill. Based on the present traffic, and moderated some to be on the safe side, Mr. Carpenter places the receipts at \$39,531,428.95. This will pay \$18,000,000 interest on the principle invested, \$6,000,000 operating expenses, and leave a net surplus of \$9,531,428.95. He proposes to tunnel through the mountains which may be in the way and in other ways overcome the obstacles which have been a preventive to rapid transit heretofore. He is endeavoring to interest Des Moines men in a company to carry out this project.

The Crowley Electric company of Duluth, Minn., advertises a dissolution of partnership.

The city of Columbus, Wis., voted bonds for the construction of a municipal electric-lighting plant.

R. A. Davidson of Chicago and E. C. Gibson of Philadelphia were in Dubuque, Ia., recently, inspecting the street-railway and electric systems, with a view to purchasing the plants. The property is worth about \$1,500,000.

The consolidation of the street-car lines in Sioux City, Ia., will result in abandoning all but one power house, which is to be enlarged and improved, and will furnish power for all the different lines.

The Seattle and Tacoma Electric Railway company has been reorganized as the Seattle and Tacoma Railway company, and new men have come in. Preparations are being made to construct the line between Seattle and Tacoma, Wash.

The street cars of Des Moines, Ia., are being equipped with fenders. The street-railway company in Des Moines announces that nearly all the employees in the operating department will have their wages advanced 10 per cent. The increase will come partly in the restoration to full running time and partly in the increase of the actual wages paid.

The Redfield (S. D.) Electric Light company will endeavor to clear its artesian well of obstructions. The well formerly furnished sufficient power to operate the plant, but became obstructed and the force impaired.

A happy thought has been dashed to earth in St. Paul. Under the charter the city can let contracts for street lighting for one year only, and the result is that the existing company is the only one which cares to bid, with the possibility of losing the contract at the end of a year. Prices have therefore been pretty well up. The idea occurred to some city official that the city could purchase the poles and wires in use and lease them to whatever company should get the contract, thus getting competition. The city has the right to place wires in the conduits of the subway companies. But the city engineer now reports that electric-light wires in the same subway with telephone wires would simply ruin the latter. So the idea cannot be used.

The Butte Electric company of Butte, Mont., suffered a loss of \$40,000 by fire in the engine and dynamo room at the Silver Bow station.

The appointment to the Board of Electricity from Minneapolis is causing some trouble. The local contractors had a meeting and agreed on one man, G. M. Jones, it is understood. Soon after W. J. Gray entered the lists and was followed by F. W. Bell. Mr. Jones thinks that, after settling upon him, the entrance of the latter two is hardly fair. R.

Canadian Intelligence.

Ottawa, May 6.—The deal by which a New York syndicate is to obtain control of the electric street railway in the city of Hamilton, Ont., and is to build the projected electric railways to Caledonia and Guelph, is said to be nearing consummation.

Nearly all the electrical energy supplied in Hamilton, Ont., is conveyed from a distance of 40 miles by the Cataract Power company. The works of this company are located at De Cew Falls and were constructed at a cost of about \$600,000. This sum included not only the erection of a power house and the necessary lines for power transmission, but also a canal connecting with the Welland Canal at Altonburg. The company has a distributing station at Hamilton, and it supplies the electric-light company in the city with power, as well as many of the leading manufacturing concerns there. The Hamilton, Grimsby and Beamsville electric railway, a line 25 miles in length, secures its power from the same source. The entrance of the company into the city is one of the greatest boons Hamilton has ever had. There is a charge of \$18 per horse power per year, whereas the cost of securing the same amount of power by coal would be about \$36.

A report from Niagara Falls states that the International Traction company took over its Canadian property last month. A meeting was held in Toronto and officers and directors for the Niagara Falls Park and River railroad were elected. The property acquired is the trolley line which runs along the Canadian side of the Niagara River, from Chippewa to Queenston, a distance of 12½ miles. The Canadians on the directorate are Messrs. T. G. Blackstock, William H. Beatty, E. B. Osler, M. P., of Toronto, and William Hendrie of Hamilton. The line will become part of a system embracing the Buffalo and Lockport and the Buffalo and Niagara roads, and the cars will be made interchangeable, so that passengers will be able to go from Queenston to Buffalo without change. The railway on the American side of the Gorge is

so seriously blocked by rock slides that it may not be operated this season. If this should prove to be the case, the entire traffic on the lower Niagara this summer will be on the Canadian side of the river.

Stealing electricity is one of the most modern offenses against the law, and the Lachine Rapids Hydraulic and Land company of Montreal has recently made a discovery which leads it to believe that it is carried on to a greater extent than it imagined. In one particular instance it was discovered that a saloonkeeper who paid for about five lights had had some 25 more put into his place, and by means of connections unknown to the company obtained that amount of free light.

The Ottawa Electric Street Railway company is installing an improved plant in its power house, which is calculated to operate all the cars at present in use in the city with one-half the water power formerly used. The dynamo, which will shortly arrive there, will be a 1,600 horse power machine. Hitherto, the company has had no reserve machinery, and in case of a breakdown everything was thrown into confusion. By the installation of the new machinery provision is made for this contingency, but the introduction of Sunday cars has rendered it necessary for the increase in the efficiency of the power plant. W.

PERSONAL.

R. J. Randolph, Jr., son of R. J. Randolph of Gates & Randolph, Chicago, has taken a position with the Bryan-Marsh company of New York.

A. J. Little and F. S. Vincent were in Chicago last week, in the interest of the Petoskey (Mich.) Telephone company, with which they are identified.

Mr. Charles E. Bibber, treasurer of the Bibber-White company of Boston, was in Chicago early in the week. Mr. Bibber is making a western trip to look after mining interests in Silverton, Colo.

Dr. F. K. C. L. Büchner, a German philosopher, is dead. He was 75 years of age and a native of Darmstadt. His best-known work is the book "Kraft und Stoff" ("Force and Matter"), first published in 1855. In this book Dr. Büchner insisted on the eternity of matter, the immortality of force, the universal simultaneousness of light and life and the infinity of forms of being in time and space.

Mr. Edwin R. Weeks, the general manager of the Edison Electric Light and Power company of Kansas City, is also president of the Humane Society of Kansas City. He is jubilant over the great outpouring of children at the recent gathering of Bands of Mercy in his city. It is said that 25,000 children and 10,000 adults were present. It was the greatest meeting ever held in the cause of humane education. Mr. Weeks presided and made an address.

A subscription is proposed for the purpose of providing a memorial window to commemorate the work of Clerk Maxwell in the parish church of Corsock, of which he was for many years an elder. In order that all who appreciate Clerk Maxwell's work may have an opportunity of contributing, it has been decided to limit the subscriptions to sums not exceeding half a guinea. The London Electrical Engineer says that Rev. George Sturrock, The Manse, Corsock, near Dalbeattie, N. B., will receive subscriptions.

Henry Sanger Snow, who has been the head of the corporation of the Polytechnic Institute of Brooklyn, has been chosen to succeed Dr. David H. Cochran as president of that institution. In making this selection the trustees have made a radical departure in the practice usually observed in selecting the head of such an institution. Instead of taking a man who has taught and gained a reputation in some other school, they have chosen Mr. Snow, who has been both a successful lawyer and a business man, but who has never been identified with educational work in any other way than that of trustee. Mr. Snow has been treasurer of the New York and New Jersey Telephone company since 1893.

A certificate of honor from the War Department has been awarded Frank Miller of Frederick Junction, Md., who has been an employe of the Baltimore and Ohio Railroad company for many years. During the Civil War Mr. Miller was a telegraph operator at Alpine, W. Va., and rendered efficient aid to the Union troops, who were forced to retire across the Potomac River into Maryland. The young operator succeeded in swimming the river also, and, remembering that the government wire ran along the old national turnpike, he had two of the soldiers lift him up to the wire, which he cut. He then applied his pocket instrument. It only required a few minutes for him to get in direct communication with the War Department through Thomas T. Eckert, now president of the Western Union Telegraph company. As soon as the War Department was acquainted with the facts reinforcements were sent from Williamsport in time to prevent the capture. For his valor and ingenuity on this occasion Mr. Miller was taken into the government service, performing the duties of scouting operator. After 35 years he is further rewarded by a certificate of honor.

ELECTRIC LIGHTING.

Benjamin Rose has closed a contract with the Western Electric company of Chicago to install a

complete electric light plant in the Rose building, Cleveland, Ohio.

Grosse Pointe village, the fashionable suburb of Detroit, will soon have its streets lighted by electricity. Work will be begun at once. Street lamps will be put wherever needed. The estimated cost is \$3,000.

The Municipal Council of the city of Vienna has passed a resolution authorizing the raising of 15,000,000 florins (\$7,500,000) for the establishment of an electric-light and power plant to supply current for both public and private use.

It is said that a new company is to be organized in Rochester, N. Y., to compete with the Rochester Gas and Electric company in supplying gas and electric light and power. John D. Lynn, an energetic and popular lawyer, formerly county judge, is at the head of the scheme, which is said to have the backing of the Western Electric company of Chicago.

"Twenty-five years ago," says the Kansas City Journal, "a Russian lad of 16 years arrived in Hays City, Kan., direct from the River Volga. He was dressed in a sheepskin coat, and his first act on stepping from the train was to light his pipe with flint and steel. Last week Hays City inaugurated a fine electric-light system, of which this Russian lad is the sole proprietor."

The Detroit Electric Light and Power company, formerly a prosperous concern, has gone into the hands of a receiver. Action was taken at the request of the Central Trust company of New York city, on a mortgage of \$350,000 on the plant. No interest has been paid since 1896. The total indebtedness is \$413,000. N. G. Williams of Detroit was made receiver. At one time this concern received over \$400,000 a year from the city of Detroit alone for lighting.

The stockholders of the Brush Electric company, the Northern Electric company and the Edison Electric and Illuminating company of Baltimore have ratified the sale of all the properties to the Alexander Brown syndicate, in which Messrs. Elkins, Widener, Holden and other capitalists are said to be interested. The price paid for the property is \$3,525,000. This will give the syndicate full control of the street-railway and electric-lighting systems in Baltimore. The United Electric and Power company of Baltimore will be organized to take over the properties. Nelson Perin will be elected president. He is also president of the United Railways and Electric company. The board of directors to be elected will consist mainly of the same men who are on the directory of the railway company. To cover the cost of purchasing the plants and to provide for improvements and other expenses an issue will be made of \$3,500,000 $\frac{1}{2}$ per cent. gold bonds, to run for 30 years, and \$700,000 of preferred stock.

ELECTRIC RAILWAYS.

A new electric street-railway line is announced from the Agricultural College to Lansing, Mich.

Active work on the double-track extension of the Chicago and Milwaukee electric railroad from Highland Park to Evanston has begun at Wilmette. It will extend north from the connection with the St. Paul railroad at Llewellyn Park.

The Lansing, St. Johns and St. Louis (Mich.) Electric company has issued a prospectus showing the probable cost of the improvement as \$720,000; estimated yield to investors, \$71,748 a year net income. It is proposed to dispose of stock to those who live along the line of the proposed road.

Archbishop Fechan of Chicago, in whose name the property at 97 to 103 Van Buren street stands, will shortly begin suit for \$150,000 damages against the Union Elevated Railroad company. It will be alleged that previous to the construction of the loop the property brought an income of 6 per cent., but that now it can hardly be rented.

The Chicago City Railway company is building a new overhead-trolley line in Sixty-third street, between Cottage Grove avenue and State street. By the construction of this line direct connection will be made by the Chicago City railway with the Blue Island and Morgan Park cars of the Chicago Traction company at South Park avenue.

What is said to be the first step in the consolidation of all the street railways of St. Louis into one system was taken recently after months of planning and negotiations, when the stock of the Lindell Railway company was increased from \$2,500,000 to \$10,000,000. The increase will be made by issuing \$5,000,000 preferred stock and the remainder in common stock.

There is trouble in Syracuse between people in the northern part of the city and the Syracuse Rapid Transit company. The company laid T-rails over its route in Butternut street without municipal sanction, as is claimed. Citizens tore up the tracks and traffic was stopped. The company threatens to appeal to the court and the citizens have the backing of Mayor McGuire and the city officers.

A syndicate of Colorado Springs capitalists, headed by W. S. Stratton, has purchased the Cripple Creek Electric railroad, and will extend it immediately

to Colorado Springs. It has 25 miles of track, reaching the principal mines. The surveyed route to Colorado Springs is 29 miles, all down grade, favorable to low freight rates. The buyers are all residents of Colorado Springs, whose capital made the great camp. The road will be rushed through to offset the steam road building by New York capitalists to Canon City.

The Milwaukee Light, Heat and Traction company has filed with the register of deeds a mortgage deed of trust to secure the payment of \$5,000,000 for additional property. The deed is made by the Milwaukee company to the City Trust company of New York. The document recites that the Milwaukee Light, Heat and Traction company has or is about to secure the property and franchises of the various suburban lines radiating from Milwaukee, and the sum named in the mortgage is needed for the purchase.

The Postoffice Department has been asked to make a ruling as to whether street-car lines authorized to carry the mails may promiscuously display on their cars the sign "U. S. Mail." It is contended that the sign properly can be placed only on cars when they are actually carrying mail, and that its indiscriminate use is designed to intimidate employees. The Amalgamated Association of Street Railway Employes has telegraphed a protest to President McKinley against this practice of street-car companies in various cities.

In the Supreme Court at Buffalo Justice Titus granted an order, upon the application of the Knickerbocker Trust company, modifying the injunction on the Niagara Gorge road to the extent that the Knickerbocker Trust company may foreclose its mortgage of \$1,000,000 against the property. This mortgage was given to secure an issue of bonds for that amount, the company owning the Gorge road having defaulted in the payment of various sums. The action will probably result in the operation of the road this summer.

The Perth Amboy Railroad company has secured a right-of-way from Perth Amboy to Metuchen, N. J., and from Perth Amboy to Woodbridge, N. J., connection at Metuchen with the Consolidated Traction company of New Jersey. It is stated that negotiations are now in progress for the acquisition of a controlling interest in the Perth Amboy trolley line by the Consolidated Traction company. The absorption of the Perth Amboy company will give to the Consolidated company a line to the Staten Island ferry. The officers of the Perth Amboy company include Leonard Lewisohn, president; C. J. Wittenberg, vice-president, and J. C. McCoy, secretary and treasurer.

The Milwaukee Electric Light and Street Railway company has purchased all the property, real and personal, of the Milwaukee, Racine and Kenosha Electric Railway company. The consideration of the transfer, as stated in the deed, is \$1 and other valuable properties, but as the document contains \$420 worth of revenue stamps the assumed consideration is \$420,000. The same deed was placed on record in Racine County, and with it was filed a deed conveying the property of the local line in Racine to the Milwaukee syndicate. The consideration for the second deal was \$300,000, thus making the price for the entire line of 40 miles of road \$720,000. With these transfers the Milwaukee company comes into possession of a continuous stretch of electric railway reaching from Waukesha, Wis., on the north, to the limits of Kenosha on the south.

It was announced last week that the United States Mortgage and Trust company of New York, with other financial interests, had secured a controlling interest in the following-named street-railroad companies in Washington, D. C.: The Metropolitan Street Railway company, Columbia Railway company, Anacostia and Potomac River Railroad company, Prightwood Railway company, Washington, Woodside and Forest Glen Railway company, Georgetown and Tennyaltown Railway company, Washington and Rockville Railway company and Washington and Great Falls Railway company. The price paid for the stock and personnel of the syndicate could not be learned at the office of the trust company. It is understood that the syndicate intends to consolidate these street-railway properties with the United States Electric Lighting company and the Potomac Electric Power company, both of which companies are controlled by the same syndicate.

An electric railway is proposed to connect Streator, Ottawa, La Salle and Peru, Ill. Naugle, Holcomb & Co. of Chicago are to build the road, and the total length of the line will be 30 $\frac{1}{2}$ miles. Some of this trackage will replace street railways in Streator. It was part of the scheme to absorb the Ottawa street-railway system, but now it is proposed to run the main line through the city, for the Ottawa electric street railway is passing through a reorganization period, and is to be improved and extended. The La Salle County Railway, Light and Power company, incorporated with a capital stock of \$500,000 and authorized to sell \$500,000 worth of bonds, is the corporation that will operate the proposed railway. The charter secured by the corporation is extremely liberal for under it the company can do a passenger, mail and express business, install arc-light and incandescent-light plants and sell electric power. The power plant of the electric-railway system will be built in Ottawa because that city is the half-way station, and also because strong hopes are entertained

that the Ottawa people will be able to install an 8,000 horse power water power plant.

Judge Bishop of Chicago has sustained the defendant's demurrer in the case of the owners of the Chicago office building against the Lake street "L" for \$300,000 alleged damages to the building by the erection of the road. He holds that where the fee of a street was in the municipality and the uses to which the street was put with the consent and authority of the municipality were consistent with the purposes for which the street was dedicated, an abutting property owner cannot recover consequential damages. An appeal to the Appellate Court will be taken.

The Municipal Traction company has been incorporated with an authorized capital stock of \$1,000,000 for the purpose of building a street-car system in Denver in opposition to the new company which has absorbed the two existing systems. Ex-Mayor T. S. McMurray is president. The company has applied to the City Council for a franchise. It asks permission to build street-railway lines on streets now occupied by the lines of other companies, the permission to take effect at the expiration of the franchises under which the other companies are now operating, about five years hence. The new organization offers many inducements in the way of low fares, continuous transfers and heated cars in the winter, and proposes to pay the city a royalty of $\frac{2}{2}$ per cent. of the gross receipts. It is claimed that the new city administration favors the company.

ELECTRIC VEHICLES.

The old "Cyclorama of Gettysburg" building on Tremont street, Boston, has been purchased and will be immediately remodeled for the use of the New England Electrical Vehicle company as an automobile-carriage depot.

The Columbia Electric Vehicle company, with a capital of \$5,000,000, has been incorporated in New Jersey. It is empowered to manufacture and operate vehicles driven by electric or other power. The incorporators are Charles A. Wendell, Andrew H. Seibel, Anthony N. Jeshera, Sherman M. Granger, Francis R. Foraker, Walter T. Dryfoos and Roland B. Harvey, all of New York, and W. B. Greely of New Rochelle.

Articles of incorporation of the Chicago Vehicle company, with an authorized capital of \$1,000,000, were filed with the secretary of state of New Jersey on May 5th. Of the stock \$400,000 is preferred with five per cent. annual dividends. The company is formed to manufacture, sell and operate all kinds of vehicles. The Chicago Vehicle company has been doing business in this city for two years, says the Daily News, under an Illinois charter, with \$25,000 stock. It is organized for the manufacture of automobile electric vehicles, and in the two years of its existence the company has done nothing, says Manager M. M. Chesrown, except experiment with patents, but the officers expect to begin business soon at Liverpool, Ind.

TELEGRAPH.

Members of Parliament and other English "imperialists" propose that the governments of India, South Africa, Australia and New Zealand shall hold a conference with the home government, with the object of reducing the present high cable rates, which, for social messages, are regarded as prohibitive.

The steamer City of Rio de Janeiro, which arrived at San Francisco recently, brought news from Honolulu that at a meeting of the cabinet the contract with the Strymser company for a cable between San Francisco and Honolulu was annulled. This action was taken on a letter from the secretary of state at Washington, declining to consider the matter.

Claims for damages to the amount of \$25,000 have been filed against the Western Union Telegraph company for the alleged non-delivery at Gardiner, Me., of a telegram of warning, which, it is claimed, would have averted a murder. The message was sent by Lizzie Small of Richmond to her sister, Mamie Small, employed in a Gardiner shoeshop, on the day that Mamie was shot and killed by Bradford Knights. The message was a warning to the effect that Lizzie had met Knights on the train bound for Gardiner. It is said that Knights had threatened Mamie on several occasions because she had persistently refused his attentions.

The Legislature of Kansas at its recent session passed a law reducing the legal rate of telegraph tolls in Kansas 40 per cent. The companies have ignored the law and announced that they will fight it. It has been the custom for state officers to run bills with the Western Union and Postal companies and settle on the first of each month. State Auditor Coler announced that he would decline to audit vouchers after May 1st unless the charges complied with the new law. The attorney-general advised this course, and now the telegraph companies must fight the state, a situation which they hoped to avoid. The business men of Topeka have begun 200 damage suits, and similar suits have been commenced in a dozen counties. Any citizen may start a damage suit against the telegraph company. He may write out one or more messages, offer them at 15 cents each, and, upon refusal by the operator, sue the company for damages. It is believed that a flood of these suits will be started. The Western Union

company will close many offices in Kansas as a retaliatory measure.

The record for long-distance practical telegraphing was broken on April 25th by the Associated Press on its regular system of wires leased from the Western Union Telegraph company. A continuous circuit of 6,001 miles, reaching from New York city to the Pacific coast, and from Chicago to New Orleans, touching Philadelphia, Pittsburg, Cincinnati, Atlanta, Memphis, St. Louis, Kansas City, Omaha, Denver, San Francisco and all the larger intermediate points South and West, was successfully worked for several hours. There were 41 operators copying from a sender in New York, with newspapers being served directly from this one circuit in 38 of the leading cities of the United States. Longer circuits had been worked for short periods, but, as far as known, this record has never been equaled, considering the number of operators copying, the number of newspapers served and the territory covered by the circuit.

The proposed all-British Pacific cable, connecting British Columbia with China and Australia, toward which the different governments have recently announced contributions, has received a setback that may result in its abandonment. A copy of an agreement entered into between the British government and the Eastern Extension, Australasia and China Telegraph company in 1893 by Lord Ripon has just been made public. In this agreement the British government agreed not to lay nor permit to be granted any concessions for laying any submarine cables connecting with Hongkong, Singapore or Labuan unless found necessary in the general interest of Great Britain. If the proposed cable from Canada is to be deprived of the large business which it was expected it would receive from a connection at Hongkong it will be seriously handicapped. Great Britain can purchase the cable of the Eastern Extension company on 12 months' notice for the sum of £300,000, and to do this seems the only way to prevent a serious delay to the Canadian cable or its abandonment altogether.

Mr. Cecil Rhodes expects to complete his telegraph line from Cape Town to the Mediterranean long before his transcontinental railroad is in operation. He is the organizer and chief stockholder of the company which will carry out this enterprise, and he says it will be completed in three years. Like the railroad, the telegraph line will connect with other north and south lines, and the company expects to string only about 2,700 miles of wire to connect Cape Town and Alexandria, which are about 5,500 miles apart. The chief stations along the line will be Bulawayo and Salisbury in Rhodesia, Tete on the Zambesi, Blantyre, capital of Nyassaland, Karonga at the north end of Lake Nyassa, three posts on Lake Tanganyika, Fort George on Lake Albert Edward, two stations on Albert Nyanza, whence the line will follow the Nile to Alexandria. It will connect with the telegraph line the Congo State is now building from the Atlantic to Tanganyika, and with others to Victoria Nyanza and the Indian Ocean. When this enterprise brings Central Africa into close touch with the rest of the world it will be a great boon to that continent.

TECHNICAL SCHOOLS.

Circulars of information relating to the courses in mechanical and electrical engineering at the University of Pennsylvania may be obtained upon application to the registrar of the college, University of Pennsylvania, Station B, Philadelphia, Pa.

At the last meeting of the Society of Arts of the Massachusetts Institute of Technology T. B. Kinraide of the Spring Park laboratory, Jamaica Plain, Mass., showed a unique form of induction coil of great power invented by him. This has been especially applied to the study of discharges by the aid of photographic processes, the plate being balanced on the point of discharge in a dark room and being developed after exposure. It reveals in a striking manner the marked difference that exists between the positive and negative discharges. The apparatus was exhibited in operation and photographic plates shown with the lantern. The figures thus produced by the electric discharge were of extraordinary beauty and size, the delicacy of detail being brought out by means of the lantern. It is thought they may be suggestive of forms useful to designers and decorators. A large and interested audience was present.

MISCELLANEOUS.

Professor Henry Carmichael, the expert appointed by the committee in charge of the liquidation of the affairs of the Electrolytic Marine Salts company to make a thorough investigation of the workings of the plant at Lubec, Me., after several months' work, has submitted a report to the committee. He says, according to a Boston correspondent of the Chicago Record, that his experiments go to show that the

Rev. Prescott F. Jernegan's process of extracting gold from sea water was fraudulent. The liquidating committee has paid \$200,000, being a 20 per cent. dividend on the stock, and the total dividend may amount to 35 per cent.

The Meteorological Institute of Denmark has sent a circular to all the institutes in Europe and America, proposing a general subscription to defray the cost of a daily telegraphic weather report from Iceland and the Faroe Islands. The Great Northern company has agreed to lay the cables immediately. Fourteen institutes have already replied favorably to the proposition.

Electricity was tried successfully on a balky horse at Evanston the other day, after the usual methods of making such an animal move had failed. Sand was dropped into the horse's ears and mouth and a fire was set under the animal. Much hair was burned off. Finally, S. Gloss, one of the chemistry instructors at Northwestern University, brought out a dry battery and connected it with the harness. The horse forgot all about balking when the current was turned on.

Speaking at a dinner given by the Institution of Mechanical Engineers in London recently Rear-admiral Lord Charles Beresford said that Great Britain was much behind the United States and Japan in the use of electricity as a motive power aboard warships. He had been amazed to see the great use of electricity aboard American warships, it being employed where the British still used steam. The American vessels were consequently far cooler than the British. Lord Charles Beresford declared that he did not feel the slightest apprehension regarding foreign submarine boats. He believed that they were far more likely to blow themselves up than to destroy the ships of an enemy.

A Washington dispatch of May 8th states that "Mr. and Mrs. Westinghouse have issued invitations to one of the largest private receptions of the season in honor of the American Society of Mechanical Engineers. The preparations are on such an elaborate scale that an addition has been erected to the Blaine mansion on Dupont Circle, which has been the home of Mr. and Mrs. Westinghouse for two seasons. The house is surrounded by a spacious lawn, and this will be illuminated for the evening with fairy-like designs of electric lighting. The house, with its great central hall and spacious rooms, will be transformed into a scene of beauty. Over a thousand invitations have been issued for this entertainment, which is to be one of the most notable in the history of the capital."

Consul Gibbs of Tamatave, in a report to the State Department, warns Americans who may be considering the advisability of promoting trade relations with Madagascar that any circulars relating to the introduction of enterprises into Madagascar should be in French to receive attention, as commercial and speculative transactions are conducted almost entirely in that language. He does not consider the conditions favorable for the introduction of a telephone system there. The government offices are connected by telephone, but the business does not demand its general adoption. Of the existing telegraph system and the prospects for extensions and improvements the report is only a little more favorable. The messages are received on rolls of tape, similar to the stock-quotations tickers in use on American stock exchanges. There are about 1,200 miles of line and wire at present, and the net is being increased. The telegraph connected with the Postoffice Department is controlled by the French government. It is not thought possible to introduce any improved telegraph system into Madagascar, owing to climatic conditions. The present system is out of order about one-third of the time, and a bulletin stating its condition is published in the tri-weekly edition of the Journal Officiel of the island.

TRADE NEWS.

It is said that no less than 4,000 persons attended the annual oyster roast of the Berlin Iron Bridge company of East Berlin, Com., at the factory last month.

W. N. Matthews of St. Louis reports that he finds ready sale for second-hand machinery, especially for the Wood arc dynamos, of which he has several that are in fine condition.

The Diagnostic Electric Lamp company of New York has been incorporated with a capital of \$2,500. The directors are John W. Morrison, New York; Jacob Felsenstein, Baltimore, and Edgar Poe Reese, New York.

The Electric Arc Light company of New York—the pioneer in enclosed arc lighting—has removed to 11 Broadway (Bowling Green building), and with increased manufacturing facilities can promptly ship direct and alternating-current enclosed arc lamps,

Mr. W. C. Hubbard is the general manager of the company.

From Boston comes the announcement that L. A. Chase & Co., the Shawmut Fuse Wire company, the John P. Cushing company and the Linton Manufacturing company have been combined, under the name of the Chase-Shawmut company, which has been formed for the purpose, and will manufacture and deal in electrical specialties. The address of the Chase-Shawmut company is 161-163 Fort Hill Square, Boston.

N. W. Mixer, for many years connected with the Western Electric company, has been appointed western sales agent for Kerite insulated wires and cables, known the world over as one of the best wires on the market. Mr. Mixer's headquarters will be in room 1526 Monadnock building, Chicago. W. R. Brixey, the manufacturer of Kerite wires, is to be congratulated on securing the services of a man so well known to the trade as Mr. Mixer. It is confidently expected that Kerite wires will now become even better known in the West than at any previous time in the history of their manufacture.

Many electric-light and electric-railway managers will doubtless be interested in the announcement of the Hays Construction company, Troy, O., which makes a specialty of remodeling plants and putting them on a paying basis. W. S. Hays, the manager of the Hays company, is an engineer of wide experience and is particularly qualified for work of this kind. The Hays company is taking a leading part in construction and engineering work, and has remodeled a number of plants which for various reasons were not paying dividends and has put them on a paying basis. The company bears an excellent reputation and will be pleased to hear from those who may have trouble with their plants.

The Montauk Multiphase Cable company of New York has arranged for an exhibit of its automatic thermostatic fire-detective cables at the Paris Exposition next year. The company will make a complete display of its fire-detective wires in connection with all interior electrical adaptations, and this will undoubtedly attract much attention. The convention of Municipal Electricians, to be held in September of this year at Wilmington, Del., promises to eclipse any previous convention of this organization in numbers and exhibits. The progress of municipal fire protection, from its beginning down to the present, will be illustrated by apparatus in vogue during the various stages of invention. The Montauk Multiphase Cable company will have a complete display of its product in connection with all interior wiring.

BUSINESS.

The Western Electric company of Chicago has the western agency for the Tuerk alternating-current ceiling fans. These fans are made for 60, 125 and 140 cycles, and for 52 and 104 volts. A complete stock is carried in Chicago.

The Ball Engine company of Erie, Pa., reports recent sales of engines for electrical service to the Elgin Watch company, Elgin, Ill.; Western Union Paper company, Chicago; Edelweiss restaurant, Chicago; George public school, Philadelphia.

The encouraging report that night work is necessary comes from the Triumph Electric company of Cincinnati, which is having exceptionally good business. So far this year, the Triumph business has been almost double that of the corresponding period of last year.

The Emerson Electric Manufacturing company of St. Louis makes direct-current fan motors, as well as alternating-current motors. A descriptive bulletin, with price-list of '99 direct-current fan motors is sent on application. All fans have the improved Parker blade, said to throw more air with less noise than the usual type.

No other concern in its line is said to exceed the volume of business of the Swarts Metal Refining company of Chicago, which makes a specialty of buying scrap-copper wire, for which it pays the highest market price. Electric-light men and other users of copper wire will find it a considerable item to dispose of their scrap copper. The Swarts company is well known in electrical circles, having been in the business for many years.

The H. T. Paiste company's new attachment plug is becoming popular with the trade. It possesses many features of merit. Among these are mentioned the fact that both the base and the cap are made of porcelain, and that it is so constructed that there is no danger of accidental breaking. The Electric Appliance company is general western agent for this plug. It carries a large stock in Chicago and tells of a growing demand for these attachment plugs that cannot but be gratifying to the manufacturers.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued May 2, 1899.

623,968. Pneumatic Transmission System. Birney C. Batcheller, Philadelphia, Pa. Application filed February 7, 1898.

A normally closed gate is situated in the main tube in

advance of the junction, and means are provided for opening and closing the gate in the main tube by utilizing an electromagnet. A normally open circuit includes the electromagnet; means for closing the circuit are actuated

by the approach of a carrier to the gate; an electromagnet is arranged to actuate the means for operating the switch, a normally open circuit including the electromagnet and means for closing the circuit arranged to be operated by a selecting device on the carrier

623,989. Electric Motor. Homer W. Corse, Melrose, Mass. Application filed September 9, 1898.

A series of contact points turn with the armature and are electrically connected with respective sections of the armature coils, and other contacts are electrically connected with the commutator and turn with the armature but longitudinally movable with respect thereto, whereby different sections of the armature coils can be cut in or cut out of circuit as desired, and the speed of the dynamo correspondingly varied.

624,041. Process of Manufacturing Soluble Barium Compounds. Charles B. Jacobs, East Orange, N. J. Application filed October 12, 1898.

The process of making an acid from a sulphate consists in heating a mixture of sulphate and sufficient carbon to extract part only of the oxygen of the sulphate, thereby producing in the first instance a mixture of the sulphid and sulphate, and then continuing the heating in an electric furnace until sulphur dioxide ceases to escape.

624,075. Telephone Switchboard. James M. Over-shiner, Elwood, Ind. Application filed December 17, 1897.

The combination with an annunciator drop and a jack, of an arm intermediate of the drop and jack and adapted to co-operate with the drop and a plug to enter the jack and co-operate with the arm, to restore the drop.

624,095. Telephone Register. Herbert T. Richards, New York, N. Y. Application filed January 19, 1899.

This invention comprises a movable device co-operating with the receiver support adapted to obstruct the return of the receiver after removal therefrom and means for connecting or disconnecting the device with a register, whereby the subscriber after making a call may operate the register and make a record of the conversation

624,124. Electric Line Conductor. Dwight G. Stoughton, Hartford, Conn. Application filed June 17, 1897.

In an electric conduit there is the combination with a line conductor and an insulated base for the same of supports, angle irons within the conduit having their lower arms secured to the inner face of the supports, their upper arms inclining inwardly and upwardly, but not meeting over the conductor, and flexible non-conducting leaves secured only to the upper faces of the supports and resting on the upper arms of the angle irons, completely covering both, extending inward and meeting at a point over the conductor, and their outer edges attached without superimposed elements to the upper faces of the supports.

624,128. Permanently Adjusted Telephone. Ernest H. Thielscher, Brookline, Mass. Application filed September 1, 1898.

In a telephone the combination of a cup for containing the magnet spool, a detachable pole-piece for the magnet, applied to the cup, and means for preventing relative rotary motion of the cup and pole-piece.

NO. 623,989.

624,141. Electric Meter. Roger S. White, New York, N. Y. Application filed September 2, 1898.

This is a motor meter and there is the combination with an armature comprising a flat, non-metallic disk, armature coils carried by the disk, and a flat, annular retarding ring made of aluminum, of a field magnet, with respect to which the armature rotates, the field magnet also influencing the retarding ring.

624,142. Means for Reducing Friction in Rotating Shafts of Electric Meters. Roger S. White, New York, N. Y. Application filed October 5, 1898.

The shaft of magnetic metal rotates in a horizontal plane; there is a bearing for each end of the shaft, a horseshoe magnet, the poles of which carry the bearings and attract the ends of the rotating shaft to relieve the bearings of its weight, and means for adjusting the bearings longitudinally on the magnet so as to increase or decrease the magnetic attraction.

624,154. Electrical Warp Stop-motion for Looms. William H. Baker, Central Falls, R. I., and Frederic E. Kip, Montclair, N. J. Application filed September 7, 1898.

A circuit-closing gravity drop for an electric warp stop-motion is made of thin, flat metal, having an elongated form, a thread aperture, a longitudinally extending guide slot below the aperture to receive the terminals of the circuit, and a narrow lateral thread passage connecting the slot and thread aperture.

624,155. Warp Stop-motion for Looms. William H. Baker, Central Falls, R. I., and Frederic E. Kip, Montclair, N. J. Application filed October 10, 1898.

A circuit-closing device for an electrical warp stop-motion is described consisting of a terminal to extend across the warp and provided with means for straining and fixing in position, and a warp support, connected with the terminal and substantially parallel therewith, the support being vertically adjustable with respect to the terminal.

624,156. Gas-lighter. William F. Kessler, New York, N. Y. Application filed September 9, 1898.

Means are provided for closing the circuit between the terminals of an electric gas-lighter, and throwing the circuit back to a state of a vertically movable wick support, and a spring to hold the lighter at or near the closed position. The wick support is in a sparking chamber is pivoted in the plate and adapted to rise and fall from the spark means for pressing the wick into the gas. The contact with the adjacent end of the wick support, which carries the terminals, is adapted for electrically connecting the lever to the other electrode immediately before the spark is thrown and is provided.

624,230. Secondary-battery Plate and Method of Producing Same. Augustus J. Marquand, Cardiff, England. Application filed December 27, 1897.

The improved method of producing plates for secondary or storage batteries consists of the protection of certain parts of lead plates or foundations against the action of sulphur, the treatment of such partly protected lead plates or foundations in a closed box with sulphur at or near the melting point of lead, and the subsequent reduction or peroxidation by electrolytic means of the prepared surfaces.

624,250. Controller for Electrically Propelled Vehicles. Emil B. W. Reichel, Berlin, Germany. Application filed February 2, 1899.

The electric motors are mounted upon and propel different cars of a train; a conductor extends between and is adapted to unite the motors, and controllers are also provided upon the different cars and associated each to each with the motors comprising resistances, stationary and movable contact parts for effecting the connection of the several motors in series and parallel arrangement, and additional switching mechanism for controlling the control of the motors by means of a given controller, or for connecting the corresponding motor for regulation through an additional controller.

NO 624,141.

624,272. Automatic Circuit-closer. George A. Wall, Providence, R. I. Application filed March 11, 1898.

In a device of this character the combination with a thermostat shell and electrodes of a frame secured at its opposite ends to the face of the shell, and having its intermediate portion raised to permit the circulation of air around the frame, a spring in operative relation to the electrodes, and a fuse constituting a connection between the spring and frame.

624,277. Electro-pneumatic Controlling System. George Westinghouse, Pittsburgh, Pa. Application filed August 20, 1898.

In a car propelled by one or more electric motors and provided with air-brake mechanism it is proposed to have the combination with a motor controller of mechanism for operating the controller connected to a source of fluid pressure, electromagnetic means for controlling the application of fluid pressure to the operating mechanism, and means for automatically returning the controlling switch to the "off" position, depending directly upon the application of the air brake

624,299. Electromagnetic Actuating Device. Byron E. Chollar, St. Louis, Mo. Application filed October 28, 1898.

An electromagnet comprising a base, uprights, cross-piece having binding screws, magnetic coils having core extensions, side supports, armature shaft journaled in the supports and having one of its ends connected with one of the supports by worm screw and worm thread, the armature mounted on the shaft, the check adapted to limit the movement of the armature in both directions, and means for keeping the armature against the check, when the armature is in normal position.

NO 624,124.

624,300. Testing Apparatus for Electric Signal Circuits. Abner Coleman, Taunton, Mass. Application filed May 16, 1898.

Claim is made for the combination with a electric signaling circuit of a normally open branch circuit containing an amperemeter and a normally open shunt circuit containing a voltmeter, and a switch constructed and arranged to include the branch circuit in series with the signaling circuit, and for simultaneously closing the shunt circuit

624,304. Electric Railway. Harry B. Cox, New York, N. Y. Application filed October 31, 1898.

A safety electric railway system comprises a closed insulated conduit, a live movable line wire loosely arranged in the conduit, and raised supports of conducting material on which the line wire loosely rests at intervals, and electric feeder connections to the supports at intervals.

624,306. Electric Water-boiler. Joseph C. Cramer, Los Angeles, Cal. Application filed November 8, 1898.

A water-heater is used comprising a fire box open at the bottom, so that it may be placed over a heater, a series of heating tubes closed at the top and opening into the fire box, a shell inclosing the tubes and forming a water compartment, the shell having a dome-shaped top provided with small perforations to permit water to spray onto the tubes, and a water reservoir surrounding both the shell and fire box.

624,382. Electric Piano. George Schrade and Har-

old W. Shonnard, New York, N. Y. Application filed August 17, 1895.

In a self-playing piano the combination with an electric motor for operating the same of a pulley on the motor shaft, a drum shaft carrying a pulley, a belt passing over the pulleys, a switch lever for controlling the current to the electric motor, a belt shifter for the belt, and a connection between the belt shifter and switch lever.

624,386. Electrical Rosette. Albert P. Seymour, Syracuse, N. Y. Application filed February 10, 1899.

A one-piece porcelain rosette having a solid back has separate channels for the lamp wires and openings respectively at diametrically opposite points in the side walls, and extending therefrom inwardly and downwardly to a single opening in the center of the lower face, and the metallic terminals secured in position on both sides of the rosette for the attachment of the line wires and the lamp wires.

624,390. Electric Signaling System. Eugene S. Simms, Denver, Colo. Application filed October 28, 1898.

One feature is a normally open electrical circuit having conductors extending into the shaft, a signal bell or device located in the circuit, and circuit-closing mechanism mounted on the cage and comprising a shaft mounted to turn on its longitudinal axis, and also capable of movement on an axis extending at right angles to its longitudinal axis, contact arms mounted on the shaft and adapted to engage the conductors of the circuit as the shaft is actuated, and a suitable electrical connection between the contact arms.

624,396. Controller for Electrical Train-signaling Apparatus. William A. Stambaugh, Effingham, Ill. Application filed March 1, 1899.

The combination is described of two pairs of electro-magnets, levers arranged to be moved by the attraction of the magnets and having weighted outer ends, a post, a spring contact arm supported by the post, an adjustment screw located beneath the spring arm, a bracket post, a rocking lever mounted in the bracket post, a contact arm carried by the rocking lever adapted to receive the spring arm, a finger carried by the rocking lever and an insulator carried by the finger.

624,409. Controller for Electrical Elevators. Burton C. Van Emon, San Francisco, Cal. Application filed August 30, 1898.

In a controller for the purpose described a series of fixed contact arms independently movable, a series of series contacts co-operating therewith, means for moving the contact arms so as to make successive contacts, springs for returning the arms and a fluid resistance connected to each arm.

NO. 30,687.

624,413. Watchman's Clock. Albert E. Waggoner, Muskegon, Mich. Application filed November 25, 1898.

A watchman's clock has a revoluble dial with electro-magnets, vibrating armatures connected therewith and carrying contact arms arranged to make an impression upon the dial, a spring-actuated knife in position to puncture the dial if the door of the clock is opened, and an arm on the door to carry the knife from contact with the dial, an arm movably attached to the dial post, a corresponding arm pivoted to the clock frame in position to be engaged by the first-named arm, a contact plate in position to engage the pivoted arm, and an alarm to be sounded thereby.

DESIGNS.

30,686. Electric Arc-light Casing. Charles E. Hartman, Lynn, Mass. Application filed February 7, 1898. Term of patent 14 years.

30,687. Storage-battery Electrode. Theodore A. Willard, Cleveland, Ohio. Application filed March 22, 1899. Term of patent 14 years.

30,688. Converter Box. Ferdinand Schwedtman, St. Louis, Mo. Application filed August 28, 1897. Term of patent seven years.

30,689. Converter Box. Ferdinand Schwedtman, St. Louis, Mo. Application filed October 9, 1897. Term of patent seven years.

30,690. Converter Box. Ferdinand Schwedtman, St. Louis, Mo. Application filed October 23, 1897. Term of patent seven years.

30,694. Manhole-cover Frame. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent 14 years.

30,695. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent 14 years.

30,696. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent 14 years.

30,697. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent 14 years.

Western Electrician.

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, MAY 20, 1899.

No. 20

Underwriters' New Laboratories.

At No. 67 East Twenty-first street, Chicago, are now located the testing laboratories of the National Board of Fire Underwriters and the offices of the Electrical Bureau established by that body. The increase in the work which the underwriters are called upon to do in testing electrical devices and materials, as the specifications in the National Electrical Code are elaborated from year to year, made some change necessary this spring. The old quarters were at 157 La Salle street, and Mr. W. H. Merrill, Jr., the electrician in charge, finally decided on removing from the central business portion of the city and establishing his offices and laboratories in a building leased for the purpose in a locality where sensitive instruments could be employed in the work and the necessary amount of room secured.

The building selected (Fig. 2, page 280) is on

acetylene-gas generators were under test. This laboratory is equipped with a workbench and apparatus used in the testing work, to which additions will soon be made.

Space on the upper floor is about equally divided between the offices, which are on the street front, and the electrical laboratory in the rear. At the head of the stairs, on the left, is Mr. Merrill's office, a glimpse of which, with its occupant, is shown in Fig. 4. East of this room is the general office, illustrated by Fig. 3. The picture on this page (Fig. 1) shows the electrical laboratory. Direct current is taken from the Edison company's three-wire street mains, and operates motors that drive direct-current and alternating-current dynamos, arranged so that practically any voltage desired, either of continuous or alternating current, may be had for the testing of the various electrical devices submitted

of manufacturers and others engaged in electrical enterprises.

Mr. W. H. Merrill, Jr., the chief of the bureau has directed the work since its inception, when it was first established as an outgrowth of the electrical department of the Chicago Underwriters' association. Although a young man, just entering his thirties, Mr. Merrill is well known in the electrical field through his connection with insurance interests, beginning with the Boston board soon after he left the Massachusetts Institute of Technology, in which he was a member of the class of '89, and afterward in Chicago, where he was engaged by the Chicago Underwriters' association, as well as the Western Insurance Union, covering 22 central western states, and later, through the National Board of Fire Underwriters and the Underwriters' National Electric association, forming

FIG. 1. UNDERWRITERS' NEW LABORATORIES.—ROOM FOR ELECTRICAL TESTING

Twenty-first street, near the corner of Indiana avenue, and but two blocks from Lake Michigan. It is of brick and has two stories of unusual height and a capacious basement. The structure is well suited for the uses to which it is being adapted, having light on all sides, with an adjacent yard space for the storage of calcium carbide and combustible oils and the building of high-temperature ovens, the bureau work having been recently extended to embrace acetylene-gas and gasoline-lighting experimentation, as well as electricity. It is quickly reached by the South Side elevated road, the Indiana avenue trolley line, the Illinois Central suburban service and the Cottage Grove avenue cable road at Twenty-second street.

On entering the vestibule from the street, directed by a modest brass sign, "Underwriters' Laboratories," the visitor finds that the offices are on the upper floor, to which access is given by a flight of steps at the right. Directly opposite the street entrance are doors leading to a large apartment, comprising nearly all the space on the ground floor. This room, illustrated by Fig. 5 (page 281), and the greater part of the basement are devoted to hydraulic and gas-engineering experimental work. At the time the photograph was made a number of

for examination. There are also a marble switch-board, a good collection of measuring instruments of both the portable and standard laboratory types, tanks for immersing insulated wire and all other apparatus found necessary or convenient in making the tests for which the laboratory was established.

In addition to the offices and laboratories, the building contains a photographic dark-room, with an outfit of chemicals, and storage rooms, where the articles that have been tested are carefully put away, each with its tag giving date and brief data of test, with a reference to the corresponding entry in the files of the bureau.

Though the new quarters are not as yet entirely fitted up, the removal having been made the latter part of April, it will be seen that the outfit thus far installed shows commendable enterprise on the part of the underwriters in their endeavor to treat the questions they are called upon to decide, which are of interest to the electrical fraternity, in a scientific and competent manner. The work of this bureau since its beginning in this city, five years ago, is well known to electricians throughout the country, and its extension at this time will undoubtedly meet with a favorable reception on the part

of the present bureau. Associated with him and in charge of special departments are Mr. Franklin H. Wentworth, formerly with the General Electric company, Mr. Theodore Varney, a graduate of the Massachusetts Institute of Technology, formerly with the Commercial Electric company, and Mr. Benjamin H. Glover, formerly instructor in electrical engineering at the Armour Institute of Technology. Referring to Fig. 3, Mr. Wentworth is seated at the desk on the right; Mr. Glover is at the desk in the center, engaged with a caller, and Mr. Varney is on the left.

The success of the underwriters' work in this direction has been largely due to the spirit of fair-mindedness which they have shown in submitting questions concerning which differences of opinion have arisen to councils of recognized authority in different fields of electrical engineering practice, and in using their power and influence to carry out the decisions arrived at in a fair and impartial manner. The national conference on standard wiring rules is a fair example of the existence of this spirit, all the associations of a national character in the country being represented at the meetings of this body, and the rulings of its committees having been generally adopted by all the interests affected. The

consultation between the manufacturers of rubber-covered wires and the underwriters' committees at the bureau offices last December is a creditable example of the methods employed in the testing work, which have demonstrated to reputable and honest manufacturers the fact that a properly organized and conducted bureau of this kind is a great benefit to the business.

Plan of Consolidating North and West Side Street Railways.

It is said that an Illinois corporation, to be known as the Chicago Traction company, with a capital stock of \$35,000,000—\$15,000,000 preferred (five per

FIG. 2. UNDERWRITERS' NEW LABORATORIES — EXTERIOR VIEW OF BUILDING.

cent.) and \$20,000,000 common—will be formed for the purpose of leasing and operating the lines of the North Chicago Street Railroad company, the West Chicago Street Railroad company and the Chicago Consolidated Traction company. These companies own what are usually known as the "Yerkes lines," Mr. C. T. Yerkes being a large owner and the principal figure in the management of all of them. They comprise practically all the surface street-railway property on the North and West sides of Chicago, including eight cable lines and a larger number of electric roads. The plan is said to be to issue preferred stock at once at par to the amount of \$12,000,000. Of the amount thus realized \$10,000,000 will be paid to Mr. Yerkes for his holdings, and the remaining \$2,000,000 will be held in the treasury. Subscribers to the preferred stock receive a bonus of common stock equal to 50 per cent. of their subscriptions. Mr. Yerkes is to retire, and the new company will lease the existing companies at rentals given in the shape of guaranteed

FIG. 4. UNDERWRITERS' NEW LABORATORIES.—MR. MERRILL'S OFFICE.

dividends—six per cent. on West Chicago stock and 12 per cent. on North Chicago. The rate on Consolidated Traction stock is not stated. The profits of the newcomers will be found in the surplus net earnings of the roads over the dividends guaranteed. Of the \$12,000,000 of preferred stock to be issued at once, \$2,000,000 has been subscribed in Chicago and the remainder in New York and Philadelphia. The stockholder of the existing companies will vote on June 2d on the proposition of leasing the roads to a new company. It is said that the Chicago Traction company will issue no bonds.

Of course the question of franchise rights is a fundamental one with the proposed new company. The financial aspect is that one of the foundations of the deal is an opinion rendered by eminent lawyers to the effect that the traction companies' claim to a 99-year right to use of the "streets" under their original charters are valid.

National Electric Light Association.

Preparations are actively under way for next week's convention of the National Electric Light association at Madison Square Garden, New York. The association will be called to order by President Young before noon on Tuesday, and will finish its business, according to programme, on Thursday afternoon. The programme of subjects for instruction includes the reading of the following-named papers: "Single-phase Distribution," Herbert A. Wagner, St. Louis; "Underground Electrical Construction," Louis A. Ferguson, Chicago; "Some Notes on Underground Distribution of Two-phase Current in New York City," E. A. Leslie, New York city; "The Development of High-tension Service" (illustrated by stereopticon), Calvin W. Rice; "A Local Transmission System—Development and Operation," W. S. Barstow, Brooklyn; "Alternating-current Generation and Distribution—Changes Contemplated in Atlanta," H. M. Atkinson, Atlanta; "Means of Affording Safety in Electrical Distribution," W. L. R. Emmet, Schenectady; "Rotary Transformers and Storage Batteries, and Their Relation to Long-distance Transmission," Professor W. L. Robb, Hartford, Conn. The discussion on transformers will be led by Professor Goldsborough of Purdue University, Lafayette, Ind.

The headquarters of the association will be at the Murray Hill Hotel. The members and visitors will naturally pay much attention to the exhibits in the electrical exhibition now in progress in Madison Square Garden. The entertainment features arranged promise to be very enjoyable. One is an "automobile ride" for the ladies on Wednesday afternoon. The party will start from Madison Square Garden at about three o'clock, and the route will include Fifth avenue, Riverside Drive, Grant's

vicinity. At this writing it is possible to give the names of only a few of the gentlemen who will make up the party on the special train. It is expected, however, that among them will be the following-named: George S. Searing, J. Scribner, F. N. Boyer, George S. Whyte, W. J. Low, James Wolf, W. F. Collins, C. E. Kammeyer, M. E. Baird, W. R. C. Smith, F. E. Colbert, W. T. Van Dorn, Will Smith, Edward Grier, L. K. Cushing, Chicago; P. H. Korst, Racine, Wis.; E. E. Wade, Colorado Springs, Colo.; R. E. Lucas, Jonesboro, Ind.

Canadian Electrical Association.

At a meeting of the committee appointed to make the local arrangements for the approaching annual convention of the Canadian Electrical association, to be held at Hamilton, Ont., a plan of entertainment was considered and adopted. The dates selected for the convention are the 28th, 29th and 30th of June. A sufficient number of papers, on a variety of subjects of interest to those engaged in the various departments of electrical work, have been promised. Among the features of the entertainment will be a trip over the Hamilton radial railway and an evening excursion on the lake, a trip to Grimsby Park over the Hamilton, Grimsby and Beamsville electric railway and a visit of inspection to the stations of the St. Catharines Power company at St. Catharines and Hamilton.

Fort Wayne Electric Works.

The General Electric company's latest acquisition, the Fort Wayne Electric Works, with principal business office in Schenectady, N. Y., was incorporated at Albany on May 10th with a capital of \$500,000 to

FIG. 3. UNDERWRITERS' NEW LABORATORIES.—GENERAL OFFICE.

tomb, etc. The ladies and their escorts have been invited to visit Columbia University and take tea in the West Hall, as well as to inspect the library, with its unique scheme of lighting, the engineering buildings and the mechanical plant. On the return the New York Electric Transportation company has invited the party to visit its "stables" and see how the automobiles are furnished with their motive power, how the batteries are charged and other interesting operations.

On Thursday a special steamboat excursion will take the ladies up the Hudson as far as Yonkers, to give a view of the Palisades, back through the Narrows, past Tompkinsville, where Sampson's fleet is anchored, up through Buttermilk Channel, past the Brooklyn navy yard, returning in ample time for dinner.

President Young has appointed the following-named committees:

Reception committee.—Thomas E. Murray, chairman; Chas. A. Schieren, H. L. Shippy, C. H. Jackson, L. F. Regua, Geo. T. Manson, J. W. Lieb, Jr., Paul Spencer, E. A. Leslie, E. H. Stevens, William Brock, E. H. Maher, Jr., A. J. Purinton, A. H. Patterson, W. S. Barstow.

Entertainment committee.—Charles W. Price, chairman; W. L. Candee, Theodore Beran, Win. F. Zimmerman, J. W. Godfrey, C. O. Baker, Jr., Prof. G. F. Sever, A. H. Patterson, Fred Vieweg, E. P. Peck, T. C. Martin.

A large western delegation to the convention is assured. A number of westerners who will attend the meeting are now in the East; others will go without regard for the opening day or the "Chicago special," as their business engagements permit, while a large party will take the special train over the Wabash route, arranged to leave the Dearborn station in Chicago at noon on Sunday, May 21st, arriving in New York at 3 p. m. on Monday. Transportation arrangements for this train are in charge of Mr. W. Forman Collins, 510 Marquette building, Chicago, who is the master of transportation for the association for Chicago and

manufacture electrical and other apparatus. The directors are Henry Paul, C. S. Bash and J. W. White of Fort Wayne, Ind.; S. D. Greene, J. P. Felton, E. E. Gilbert and George C. Hollister of Schenectady.

The Fort Wayne papers say that the reorganized Fort Wayne Electric Works are secured for that city for a period of at least to years by the efforts of James J. Wood, the manager of the new company. The new building will be completed at once, and Mr. Wood says that it will not be long until other new buildings will be erected, which will double the size of the present plant. He expects that this enlargement will be accomplished within a year or two, and says that, in that length of time, 1,000 men will be employed in the works.

Chicago Electrical Dinner.

The annual dinner of the Chicago electrical fraternity at the Grand Pacific Hotel on May 11th was an enjoyable affair. The following-named gentlemen were in attendance:

B. J. Arnold,	E. W. Hammer,
F. B. Badt,	Samuel Insull,
Charles A. Brown,	H. L. Ide,
Charles E. Brown,	E. W. Jewell,
Ernest Bookwalter,	A. L. Kuehnstedt,
Willard T. Block,	E. B. Kittle,
W. Forman Collins,	E. A. Meysenburg,
E. H. Cheney,	Charles Munson,
E. L. Clark,	Laverne W. Noyes,
H. H. Cutler,	Lewis J. Osborn,
Edward B. Ellicott,	F. S. Richmond,
E. C. Ferguson,	B. E. Sunny,
F. S. Garton,	H. M. Sloan,
Edward R. Grier,	George S. Searing,
W. K. Howe,	James H. Wolf,
Arthur Hartwell,	George S. Whyte,

B. E. Sunny acted as toastmaster, and speeches were made by several gentlemen, while others related interesting anecdotes. Excellent music was furnished and the decorations were especially attractive.

Standards for Direct-connected Generating Sets.

By J. B. STANWOOD.

An important factor in America's industrial progress has been the extended application of standards. There are standard dimensions for materials, standard sizes, parts and capacities of machines, standard gauges for close measurements, standard systems of inspection and testing, etc.

These different forms or methods of standardization have usually originated or developed in commercial and manufacturing activities, independent of any governmental instigation or control. They are universally recognized and employed wherever industry and commerce exist throughout our land.

This principle, as carried out in our individual shops and factories, has developed the well-known interchangeable system of construction, which, by forcing attention and care upon little things, has further specialized operations, and has stimulated the development of special machines to perform these operations, to the end that the cost of production has been greatly reduced.

Such standardization inside and outside of the shops also aids rapidity of production, inasmuch as standard material can be kept in stock to form standard parts or to complete standard machines, apparatus or goods, all before these are even ordered.

These results—cheap production and prompt delivery—in connection with a high grade of product (to which these methods contribute) are most powerful factors for securing and maintaining foreign trade. Such influences are particularly active in America to-day.

In the steam-engine industry these methods have been largely in use; but within the past few years they have been rendered partially inapplicable by a radical change in the environment, due to the introduction of electricity and the employment of high steam pressure.

By the introduction of an electrical generator attached to and directly driven by the main shaft of a steam engine a new machine has been evolved. But the introduction of this system has brought a world of complication and expense to both the engine and generator manufacturers, while to some serious financial loss has been the result.

The principal cause of these difficulties has been the lack of standard sizes, speeds and important dimensions of electrical generators, so that the adaptation of the steam engine in each case has been made a special problem, frequently requiring special design and construction.

To complicate the matter, the determination of the sizes and speeds of such generators is usually in the hands of a third party who is not in touch with either the engine or generator builder. He may be a co-sulting electrical or mechanical engineer, an architect, a salesman, an agent or some person presumably skilled in deciding upon the necessary machinery to satisfy certain conditions.

If, fortunately, there had existed a list of capacities and speeds for electrical generators that was recommended by proper authorities, this list would gradually be used by such persons in securing and specifying the machine to be employed. As it now is, any odd size and speed may be selected by them; as, for instance, to my knowledge, a 45-kilowatt generator to be operated at 210 revolutions was once specified, almost at random.

STANDARDIZATION

What are the features that need standardization? First, for the use of the outside engineer there is a need for a standard series of capacities and speeds; and, second, those parts of the engine and generator which have to be connected or fastened together should be standardized for each different size to facilitate the assembling of the combined machine or "set."

1. (a) Relative to a standard series of capacities and speeds, the different capacities or sizes should be selected to satisfy the usual demands of the market. The number of different sizes should not be too large, in order that the cost of production may not be enhanced by too great a variety of both generators and engines.

In this connection there might be a standard method of determining the capacity of a generator, which would designate, with a given load or percentage of overload, a given time limit within which a permissible increase of temperature of the field coils, armature and commutator can occur.

(b) Relative to speeds, there should be at least three classes of speeds for each size or capacity of generator, corresponding, in the main, to the three classes of engines now on the market. These are known respectively as slow, medium and high-speed engines. By arranging the generator speed in this manner most of the conditions arising in practice could be met. There would be slow speed for factory, manufacturing or street-railway service, which would be expensive, but durable and easily tended. A medium speed could be used for lighting plants or conditions where lower first cost and a more limited space exist, but which will require closer attention and will probably be less durable. Lastly, the high-speed "set" would be required for limited space, low first cost, but it will require close attention and will probably be subject to heavier repairs.

Perhaps a series of generators could be arranged

so that by a modification in windings only a given size for a standard slow speed could be used for larger standard sizes at standard medium and high speeds.

2. As to the standardization of the dimensions of those parts of the engine and dynamo which are connected together there are: (a) The shaft diameter and armature bore, which should both be expressed in thousandths of an inch; (b) the length of shaft outside of the engine and the location thereon of the outboard bearing should be given in inches and feet; (c) the distance from center of armature to sub-base, in inches, and, (d) the length and width of generator

lar generator and make expensive change of metal plates in a direct-connected set. It is pointed out that in particular there should be some degree of uniformity in engine and armature shaft which are to be coupled and run together. Present practice makes the former much the larger. In this connection the fact must not be lost sight of that the engine is a reciprocating machine, while the generator is a rotary. Professor Aldrich said that while it was difficult to standardize each unit separately, it was more difficult to standardize the dual unit. The trouble has been laid at the door of the generator because of his seeming indifference to the wants of the steam man. He came into the field long after the steam engine had occupied it, and some thought he should sacrifice his own requirements for that reason. It should be remembered that the electrical designer of a generator is governed by capacity—that is, the number of lights, etc.—and the engine man must handle the results but cannot alter the pattern. That is, the engine man must follow the other and give him what he wants.

Mr. Forbes stated that if anything were to be done toward adopting standard sizes, patterns, speeds and capacities it should be done quickly, for he knew that in two foreign countries they were considering the same questions mainly with the view of retaining trade. They appreciated the evil effects of the present hazardous way of manufacturing two machines intended to run together, and proposed to remedy the trouble if possible. The meeting voted to appoint a committee to confer with the American Institute of Electrical Engineers and formulate standards covering the steam engine and dynamo.

NEW CHICAGO MUNICIPAL ARC LIGHTING PLANT

base, and the size and location thereon of the bolts which attach it to the sub-base, are probably all that are required.

Such a system would materially reduce the complication of construction and erection. A fewer number of engines with their sub-bases and generators would be required. These, in the marketable sizes, could be carried in stock ready for any combination, thereby permitting manufacturers to avail themselves of multiple production, so great a factor in reducing costs, improving quality and facilitating delivery.

An American system of standards well introduced abroad and at home might give to us a large share of the electrical and engine business of the world.

In this connection it seems to me that our society and the American Institute of Electrical Engineers are the proper authorities to undertake such an investigation as will, by their recommendation, bring about such a result.

To initiate a movement for this purpose I move that the council be requested to communicate with the American Institute of Electrical Engineers to ascertain if that institute will agree to appoint a committee to co-operate with a similar committee to be appointed by the American Society of Mechanical Engineers, to determine upon and recommend a standard series of capacities, speeds and necessary

New Chicago Municipal Arc-lighting Plant.

Work will soon be begun on the new arc-lighting station for street lighting to be built by the city of Chicago on Wentworth avenue near Sixty-third street. The working drawings for the building and machinery installation are now being prepared in the office of City Electrician Ellicott. The building will be 41 feet wide and 178 feet deep. It will be one story high. The walls will be 20 feet high in the clear and support a steel truss roof. Ordinary brick will be used for the side and rear walls, with the pressed-brick street front shown by the accompanying illustration.

A transverse wall will divide the space in the building into two rooms, one for the engine and dynamo, 100 feet deep, and the other, for boilers and coal storage, 75 feet deep. The initial generating plant will consist of a vertical, compound, condensing engine of 700 horse power, driving, by shaft and belting, four 150-light arc dynamos.

A large territory in the southern part of the city will be lighted from this station. The lamp contract has not been awarded, but the Western Electric company has secured the order for the 50 miles of line wire needed. This wire will be weatherproof, of No. 6 B. & S. gauge and will be supplied at 10 1/2 cents a pound. The other bidders were the American Electrical Works of Providence, the Chicago

FIG. 5. UNDERWRITERS' NEW LABORATORIES—GAS AND HYDRAULIC ENGINEERING DEPARTMENT

dimensions for electrical generators for direct connection to steam engines.

And, furthermore, if a favorable response be received, then the president be requested, with the concurrence of the council, to appoint a committee of the proper size to co-operate with the committee to be appointed by the American Institute of Electrical Engineers for the purpose herewith set forth.

Discussion

This paper caused considerable discussion. A complete system of standardization is of more moment to the engineer than to the dynamo builder. The engine designer must fit his machine to each particu-

Insulated Wire company and the Simplex Electric company of Boston, the tenders ranging from the price given to 20 1/2 cents a pound, or from \$13 to \$112 a mile.

General Electric's Election.

The annual meeting of the shareholders of the General Electric company was held in Selwyn, N. Y., May 10th, 130,000 shares out of a total of 208,000 being represented. The business transacted, except the election of a board of directors. The board is the same as last year, except that J. P. Ord of Schenectady succeeds F. S. Duggins of New York.

Care and Repair of Electric Fans.

By B. F. FELLO.

At a certain hotel one of the electric fans rattled so badly that the noise disturbed the guests. The hub of the fan wheel was fastened to the shaft by means of set-screws (J J) Fig. 1. These rested upon the key (I). This key was too large for the key-seat and every turn of the wheel produced a knocking sound as the edges of the key contacted with the sides of the seat. Screwing down upon the set-screws was only a temporary relief. I removed the key, cut tin pieces to match the sides and bottom and top of the key-seat, replaced the key, which now fitted tight, and reset the screws, after which the rattling ceased.

PERFECTION IN MANUFACTURING

Greater care in manufacturing fans and the adjustment of the parts when the fan is set up will assist in producing better results. Give us ring rails that are short, perfectly straight and level, and stiff enough to obviate all vibration. In fact, build your fan so substantially that, when the fan is set up and running, there will be the least possible amount of

FIGS 1 AND 2. CARE AND REPAIR OF ELECTRIC FANS.

vibration. A fan that vibrates very much will cause the rings to wear rapidly as well as the other parts of the frame.

The very high speed at which many fans are running make it necessary that the machinery should be more perfectly built, and, when set up, correctly adjusted. A higher speed of fans is obtainable and practical. Four thousand revolutions is not above what fans ought to run on medium work. To do this successfully, improvement can and must be made in building the ring frame. All frames should have adjustable feet for ends and sampsons. This would simplify the leveling and cause it to be done more frequently. No one doubts the importance of keeping the machinery level. In Fig. 2 is shown a very careless way of attaching a fan to a wall. The flange (A) is set-screwed to the wall with lag screws, which soon loosen and let down the flange as at (B). This, of course, changes the level of the spindle on which the fan revolves, and causes much trouble. The best remedy is to use bolts (C C), Fig. 3, which pass completely through flange and top piece; loosening is prevented by use of the nuts.

Some of the causes for a fan not running well are as follows: Worn or ill fitting bushings, that is, those not adapted to the style or shape of the ring; loose or worn rings or those of uneven friction surfaces; worn guide wires or guide wires out of alignment with the spindle. The guide wires should be set so as to have the bearing come directly over the top of the spindle and kept straight. In starting new fans they usually run heavy and give uneven tension and cause breakages in consequence of the rings being unpolished. Burnished rings can now be supplied, thus doing away with this disagreeable and annoying feature. Sometimes the rings are not set square on the ring rail, or it may be that the ring rail is not level. Accumulations of dirt or waste and lack of oil on the bearings will cause them to stick and sometimes throw them out of position, making bad work. These faults may be removed by regular oiling and cleaning and may be to a great extent prevented by having the bearings protected with a sleeve. Warped and out-of-true bearings will cause unnecessary trouble and bad work, and all those which are found in this condition ought to be at once refected.

EMERY WHEELS FOR GRINDING.

There is much grinding to be done in connection with the repair of electric-fan machinery. A good way to fix up an emery-wheel for this purpose is shown in Fig. 4. (A) is the wheel, (B) a slide to which is fixed the adjusting wheel (C). The part to be ground is held securely in place at (C) by the clamp (D). For accurate grinding the points to be aimed at are: (1) A free cutting wheel of the proper grade and size; (2) correct speed, so that the inequalities on the surface of the work may be removed with the smallest amount of pressure; (3) the maintenance of a uniform temperature, that the finished surface may be true. In very accurate grinding temperature has a very considerable influence upon the result. Uniformity of temperature is most essential. To maintain this uniformity water should be used especially if the work is revolved upon centers. It is advisable to use water over and over again, as by doing so there is less difference between the temperature of the water and that of the work than there would be with fresh water. A little carbonate of soda

added to the water prevents excessive rusting of the work or the machinery. For grinding internally upon cylindrical surfaces a free cutting wheel must be used and the work revolved slowly. The wheels should be softer than those applied to the external surface, as a much larger portion of the wheel periphery is in contact with the work.

REPAIRING A SPLIT HUB

If the hub of an electric fan gets cracked as at (A), Fig. 5, it may be repaired by turning off a groove near the shoulder and into this groove a ring (B) may be pressed, as in Fig. 6, thus drawing the parts together.

Some Suggestions on X-ray Work in the Brain.

By N B DELAMATER, M. D.

The discovery of the X-ray marked a distinct period, not only in the scientific, but also in the medical and surgical world. The daily press took it up at once and made much of it. While there is not so much said in the secular press of late, yet it

FIG. 3. CARE AND REPAIR OF ELECTRIC FANS.

is still an interesting topic for rather frequent articles. There was and still is a wide discrepancy between what the daily press can accomplish and that which the scientist can do with this wonderful discovery. The art of skiagraphy is really in its infancy, however, and it is possible that science may yet do even more with it than the press claims for it.

The laity expects great things of Röntgen's discovery. You have all been asked to use it, or

whether the X-ray would not reveal the trouble of your patient. It is quite the thing now in any obscure case for the lay brother to think that if you would only use the X-ray everything would be as plain as day. The present limitations of its use are not at all understood. In no field of work is this more true than in the brain. It is my object in this short paper to call attention to some of these limitations of the X-ray without neglecting the useful applications to which it is adapted.

First, I want to call attention to the fact that for brain work the ordinary apparatus is of no use. One

FIGS. 4, 5 AND 6 CARE AND REPAIR OF ELECTRIC FANS.

needs an actual picture to study, and that carefully. You will often be obliged to give careful attention to both the negative and the print of the skiagraph in order to learn what it has to say to you. It requires an expert in the use of the X-ray to make a useful negative and print. The position of the head, the kind of tube to be used, the length of exposure, the development and printing all require experience and skill as well as knowledge.

To-day there is very little danger of any kind of

accident from the use of the Röntgen radiation. In the early cases, with the long exposures, many very unpleasant things occurred. In the hands of novices and amateurs many unpleasant things occur now, but in the hands of an experienced, competent man rarely.

What will the skiagraph tell us? The location and extent of fractures in the skull. In this alone it is of inestimable advantage. A large number of epileptics, of insane or demented, have found relief through operations following the use of the X-ray. We know that in falling the patient was not always particular to strike on a spot that would produce localizing symptoms, nor is the highwayman more considerate; as a result there are many cases in which we are quite sure that traumatism is at the root of the trouble, but are unable to locate the spot from which the convulsion arises or from which the disturbance of mental equilibrium springs. In these cases the X-ray may enable us to operate by locating for us.

There are many cases of epilepsy in which a sufficient cause for the convulsive attacks cannot be found. In these cases we are not doing our duty by our patient unless we have a skiagraph taken and carefully examined. In a fair proportion of them we will find evidences of removable trouble and by operation produce a cure. It is true that you will find many cases in which nothing will be shown, but it pays even then to know that there is nothing that can be shown by any means at our command.

Then, again, in long standing cases of insanity, we should use this diagnostic help. To be sure, in a large majority of the cases we will not find anything, but in a few we will find abnormal conditions, clearly indicating either that nothing can be done or that an operation is hopeful; and if we are able to cure even one per cent. of the cases examined it will certainly pay for all the others.

Bullets or metallic substances in the brain can be located positively. It requires, however, a side and front or back view to make location accurate. Tumors have been diagnosed and located. Sclerotic degeneration, if well advanced, can be determined. Abscesses have been placed and circumscribed thickening of the skull can be located. The latter, by the way, is a very common occurrence following circumscribed cerebral meningitis.

There are various forms of degeneration of brain tissue which alter the density materially that can be determined and located. In this class of cases we determine simply that there is something that will warrant an exploration. Blood clots are very rarely discovered. They do not differ sufficiently in density from the surrounding tissues to be at all clearly defined. There is probably no greater or more frequent disappointment than the statement we are so frequently obliged to make, after having diagnosed a hemorrhage, that we cannot locate by the use of the X-ray.

The next point I want to make is that the various things discoverable are not clearly outlined; they are not well defined. Remember the X-rays show difference in density, nothing more, and you will readily see that exceeding care must be taken in every stage of the process or we shall be misled. All you can see is that one portion is darker than another, and in the outlining of this darkened or possibly lighter area all possible sources of error in the work must be considered carefully.

In very many instances the help will be simply in possibly confirming the evidences of other symptoms in the case. In many instances we will find a sufficient warrant to make an exploratory opening in the skull, while in a few we find position indicated for operation. The day will surely come, however, when we will be able to do very much more with this wonder.

In answer to a number of questions which were put to him after the reading of the paper, Dr. Delamater said that one requirement for successful work was the employment of the proper vacuum tube for

the particular case in hand. One kind of tube was best for making skiagraphs of the hand and another for the brain. Then, too, skulls and brain matter vary in density, and different tubes may be indicated for different patients. Again, the electromotive force and frequency of the current used should be carefully considered for each case. All these requisites for the production of useful skiagraphs showed the need of skill and experience in the X-ray operator.

Touching on the possibility of damage suits growing out of the use of the X-ray in surgical cases, the

Read before the Illinois Homeopathic Association at Chicago, May 11, 1899.

doctor said that while the final decision of this point rested with the courts, it was his opinion that operators could not be held responsible for more than the best knowledge of the art in existence at the time the exposure was made.

Electrical Exhibition.

Following is a revised list of exhibitors and a floor plan of Madison Square Garden, New York, showing the location of the features of interest at the Electrical Exhibition:

- American Engine company, Bound Brook, N. J.
American Electric Novelty and Manufacturing company, New York.
American Vitriol Conduit company, New York.
American Electric Vehicle company, Chicago.
American Miniature and Decorative Lamp company, New York.
American Circular Loom company, Chelsea, Mass.
Adams-Bagnall Electric company, Cleveland, O.
American Mutoscope company, New York.
American Pulley company, Philadelphia.
Allgemeine Electricitaets Gesellschaft, Berlin, Germany.
American Electrician company, New York.
Appert Glass company, New York.
American Electrical Specialty company, New York.

- Frank, I. P., New York.
Fisher Foundry and Machine company, Pittsburg, Pa.
Feddler, John H. (relies from Cuban War), Poughkeepsie, N. Y.
Granger, Francis, New York.
Griffing, A. A., Iron company, Jersey City, N. J.
Gold Car Heating company, New York.
General Incandescent Arc Light company, New York.
Heirath, F., New York.
Hill Electric company, W. S., New Bedford, Mass.
Hardmuth & Co., F., Ratibor, Germany.
"Hub," The, New York.
Harris Safety company, New York.
International Correspondence Schools, New York.
Indiana Bicycle company, Indianapolis, Ind.
India Rubber and Gutta-percha Insulating company, New York.
Incandescent Electric Light Manipulator company, Boston, Mass.
Jones Manufacturing company, H. W., New York.
Johns-Pratt company, Hartford, Conn.
Jones & Son, J., New York.
Kaufman & Alexandre, New York.
Katzenstein & Co., L., New York.
Kieley & Mueller, New York.
Lamble, H. V., Rockaway Beach, L. I.
Libbey Glass company, Toledo, O.
Law company, The, New York.
Machado & Roller, New York.
McGay Engraving company, Baltimore, Md.
Manufacturers' and Inventors' Electric company, New York.

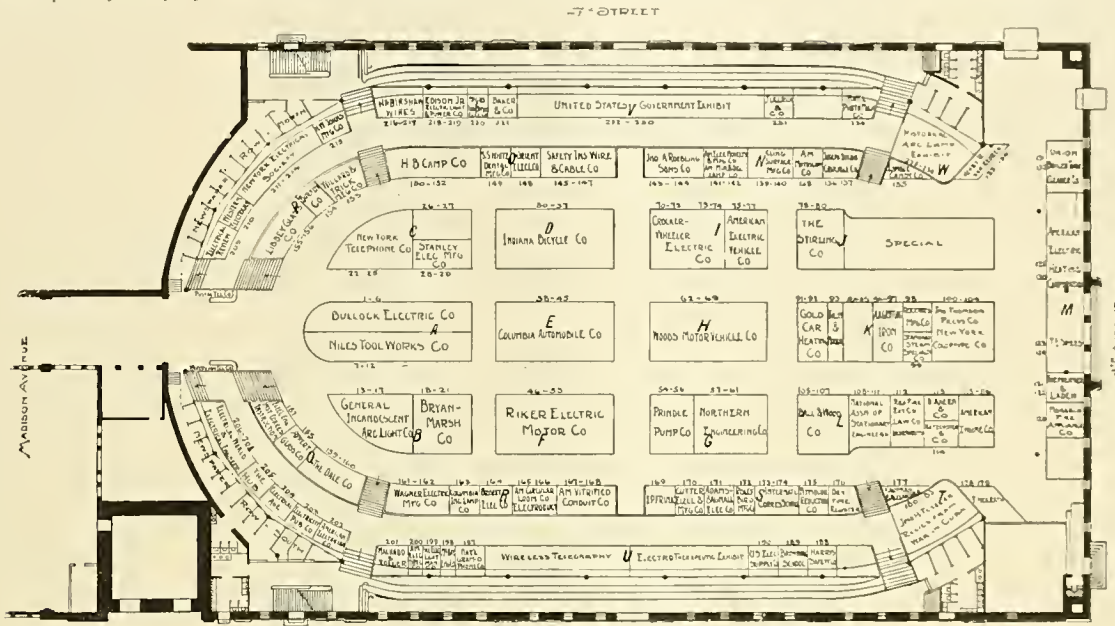

- Van Keuren, Henry R., Brooklyn.
Wagner Electric Manufacturing company, St. Louis.
Williams, J. P., New York.
White, S. S., Dental Manufacturing company, Philadelphia.
Wagner Electrical Manufacturing company, St. Louis.
Willard & Frick Manufacturing company, Rochester, N. Y.
Whitney Electrical Instrument company, Penacook, N. H.
Wright Discount Meter company, Brooklyn.
Western Electrician, Chicago.
Western Union Telegraph company, New York.
Woods Moto-vehicle company, Chicago.

Patent Office Business in April.

(From the Washington correspondent of the Western Electrician.)

The Patent Office has long been recognized as a reliable indicator of the business conditions of the country, and for this reason the following statement of the business of the Patent Office for the month of April, as compared with the same month of last year, compiled from the official records may be accepted as a fair illustration of the improvement in the business outlook.

The number of applications received for patents and for the registration of trademarks, labels and prints for April, 1899, was 3,684, as against 3,542

PLAN OF AMPHITHEATRE AND ARENA CIRCLED ELECTRICAL EXHIBITION.

- American Electrical Heating corporation, Cambridgeport, Mass.
Ahearn, D., New York.
Ball & Wood company, New York.
Buffalo Forge company, Buffalo, N. Y.
Boston Electro-duct company, Boston, Mass.
Bullock Electric company, New York.
Bossert Electrical Construction company, Utica, N. Y.
Bryan-Marsh company, New York.
Baker & Co., New York.
Burnet company, The, New York.
Browning School, New York.
Cling-surface Manufacturing company, Buffalo, N. Y.
Cincinnati Shaper company, Cincinnati, O.
Crocker-Wheeler Electric company, New York.
Camp company, H. B., Aultman, Ohio.
Colliery Engineering company, Scranton, Pa.
Corey, R. B., New York.
Columbia Incandescent Lamp company, St. Louis.
Chicago Rheostat company, Chicago, Ill.
Dietz, Schumacker & Boyd, Cincinnati, O.
Dixon, Jos., Crucible company, Jersey City, N. J.
Dale company, The, New York.
Dickford Drill company, Cincinnati, O.
D. & W. Fuse company Providence, R. I.
Dey Time Register company, New York.
Electrical Age Publishing company, New York.
Estey & Saxe, New York.
Electrical Institute of Correspondence Instruction, New York.
Edison, Jr., Electric Light and Power company, New York.
Electrical Appliance company, Jersey City, N. J.
Electrical World and Electrical Engineer, New York.
Electricity Newspaper company, New York.
Evans, N. R., Portland, Me.
Forbes, W. D. & Co., Hoboken, N. J.
Fayerweather & Ladew, New York.

- National Gramophone company, New York.
National Meter company, New York.
New York Electrical Equipment company, New York.
Northern Engineering company, New York.
Niles Tool Works, Niles, O.
Northern Electrical company, Madison, Wis.
New York Telephone company, New York.
National Association of Stationary Engineers, New York.
National Photographic Machinery company, New York.
New York Colortype company, New York.
New York Aluminum company, New York.
Orient Electrical company, Youngstown, O.
Ohio Electrical Specialty and Manufacturing company, Troy, O.
Puerto Rican Art company, New York.
Prindle Pump company, New York.
Paragon Fan Motor company, New York.
Pope Manufacturing company, Hartford, Conn.
Pittsburg Reduction company, Pittsburg, Pa.
Postal Telegraph-cable company, New York.
Pianophone company, New York.
Rockwood Manufacturing company, Indianapolis, Ind.
Roebling's Sons, John A., company, New York.
Risley-Bird Manufacturing company, New York.
Riker Electrical Motor company, New York.
Rex Fire Extinguisher company, New York.
Standard Steam Specialty company, New York.
Stirling company, The, Chicago.
Safety Insulated Wire and Cable company, New York.
Stanley Electrical Manufacturing company, Pittsfield, Mass.
Sayles, J. B., New York.
Smith & Egge, New York.
Thompson Press company, New York.
United States Supply company, New York.
Union Boiler Tube Cleaner company, Pittsburg, Pa.
Ullrich & Co., J., New York.

for April, 1898, a gain of 442. The number of patents, trademarks, prints and labels issued in April, 1899, was 2,143, as against 1,750 in April, 1898, being a gain of 387.

These figures indicate a healthy condition of affairs throughout the country, and it is gratifying to observe that the electrical fraternity participated largely in the results.

Street-railway Strike in Duluth.

(From the Minneapolis correspondent of the Western Electrician.)

The strike on the street-car system in Duluth, Minn., has resulted as so many strikes do—in violence and unbridled license. It began by cars being stoned and passengers and employes injured. Obstructions were placed on the tracks, and when the cars were stopped to clear the track they were greeted with stones which damaged the cars pretty badly at times. The strikers have been operating bus lines to take the places of the cars, and the company has been doing its best to keep the cars going. The final act of outrage attributed to the men was to blow up a car with dynamite, the front wheels being shattered. The motorman and the passengers were badly shaken up by the force of the explosion, but the car was running slowly and a tragedy was averted. The council will ascertain if the company is living up to its franchise, and, if not, will ask the court to compel compliance with the franchise.

Say When!

(President McCormick's address at the Chicago Commercial Club's dinner to Tesla.)

When the power of Niagara's thundering tide shall be moving the looms of New England; when "ships that pass in the night" shall telegraph messages to each other from distant horizons; when Tesla's "oscillator" shall be sending electrical currents from the top of the Alleghenies to turn the shafts of the Paris Exposition of 1900, etc.

EVERY SATURDAY.

CONVENTIONS AND EXPOSITIONS.

- New York Electrical Exhibition, Madison Square Garden, New York, May 25 to June 3d.
Southwestern Gas, Electric and Street-railway Association, A. B. Texas, May 17th to 19th.
Chicago Electrical Association (annual banquet), Technical Building, May 17th.
National Electric Light Association, Murray Hill Hotel, New York, May 25 to 27th.
Exhibition of Electrical Appliances for Household Use, Brussels, Belgium, during May.
American Institute of Electrical Engineers, Boston, June 19th to 22d.
Canadian Electrical Association, Hamilton, Ont., June 25th to 27th.
American Telephone Association, Memphis, Tenn., July 5th.
American Association for the Advancement of Science, Columbus, Ohio, August 21st to 24th.
International Association of Master Electricians, Wilmington, Delaware, September 16 to 17.
International Exposition of American Manufacturers for Electrical and Mechanical Products, Under the Auspices of the American Institute of Electrical Engineers and the Franklin Institute, Chicago, September 16 to 17.
International Electrical Exhibition, Antwerp, September 16 to 17.
International Exhibition of Marine Electric, Berlin, Germany, September 16 to 17.
International Exhibition of Electrical Engineering, Chicago, September 16 to 17.

The National Electric Light association will meet at New York next week. Many important changes affecting the organization and its members have transpired since last year's meeting in Chicago. The intervening 12 months have witnessed many combinations and consolidations of rival companies, and in some respects, at least, these changes have been for the good of the industry. Rate wars have been stopped, and the electric-lighting business placed upon a paying basis. There have been other changes, however, the wisdom of which may be questioned. The industry is entering upon a new era and gives promise of still further expansion.

It appears that the English government is not to be outdone by this country in the matter of preparation for the establishment of a Pacific cable system. Following closely upon the announcement of the American government's determination to proceed with the preliminary survey of the route determined upon comes the news of a similar expedition under the direction of Great Britain. The British survey ship Egeria is now at Victoria, B. C., with specific orders to start at once surveying a route for the projected cable from Vancouver to Australia. British Columbia is rejoicing, as it is now taken as settled that the cable will be constructed. The Egeria will proceed to the British naval station at Esquimault, where she will provision and start for Fanning Island. The vessel is equipped with modern scientific instruments, and for 40 years has been engaged in charting the waters wherever British ships navigate. The present undertaking will occupy several years, it is believed, for the completion of the records.

Much interest has been displayed by electric-lighting station managers, especially throughout the West, in the attitude of insurance companies and fire departments toward users of acetylene gas. In France the use of the new gas has become even more general than in this country, and some curiosity has been expressed as to the regulations adopted for the protection of the community against explosions. An official investigation through the United States consular department reveals an interesting condition. The user of the gas must apply for a permit at the prefecture of the department in which he desires to operate his plant. This permit is obtainable without the slightest difficulty. If the machine is then installed within a building for which insurance is desired, an additional policy premium of 10 per cent. must be paid. If, however, the machine is located outside of the building, the insurance companies impose no additional tax. Rules for the construction and placing of the gas machines are not prescribed either by the local government or the insurance companies.

At the meeting of the Society of Mechanical Engineers at Washington a paper on "Standards for Direct-connected Generating Sets" was read by J. B. Stanwood of Cincinnati, and an interesting discussion followed, in which the urgency of the demand for the adoption of a recognized plan or system was plainly and forcibly set forth. As a result a committee was selected to confer with a similar committee from the American Institute of Electrical Engineers and co-operate with the latter in bringing about the desired result. It will not be necessary to impress upon electrical engineers, manufacturers and central-station managers the necessity for reaching an early settlement of this important subject. There has been much discussion upon this topic and there is evidently a strong tendency toward this line of thought which is spreading rapidly in the ranks of steam engineers. It was announced that in two foreign countries similar steps were being taken by dynamo and steam-engine builders with the view of retaining trade that Americans may wish to bid upon. This will, doubtless, be taken into consideration and assist in securing an early adjustment of differences. The steam engineers have shown a disposition to treat the subject in a spirit of candor and fairness which promises well for the early solution of the problem.

The National Electric Light association might appropriately take notice of the movement, as it was one of the first organizations to take up the subject

for discussion. At the last convention in Chicago President Insull directed attention to the subject in his annual address and urged the importance of the subject upon the attention of the members. Nothing has since been done toward formulating a plan, but now that the steam-engine men have signified a willingness to co-operate, it is probable that definite action will be taken.

At last Dr. Franklin is honored by a bronze statue in Philadelphia. The arrangements for the unveiling and dedication provide for rather a spectacular event, according to the Philadelphia Record, which says that "numerous kites of huge size will be attached to the canvas covering of the statue, and through the agency of these kites and by means of intricate electrical appliances the statue will be unveiled without any apparent human or mechanical assistance." Justus C. Strawbridge, who provided the funds for the statue, conceived the idea several years ago at a dinner, after listening to a speech in which it was pointed out that there was no memorial in bronze to Franklin in Philadelphia. The post-office pavement was selected as the site because tradition says that on that spot Franklin made his memorable experiment in kite flying, and in later years the University of Pennsylvania, of which he was the founder, was erected there. The statue is six feet six inches in height, and represents Dr. Franklin in a sitting position, holding a manuscript in the right hand and the left arm resting on the arm of the chair. The unveiling ceremonies were placed under the direction of the University of Pennsylvania by direction of Mr. Strawbridge. Franklin has an enduring monument in the Franklin Institute, but it is well that his memory should be cherished and his example impressed upon the youth of the country through individual agencies. Mr. Strawbridge is to be commended for his public-spirited undertaking, and the city of Philadelphia is to be congratulated upon this last acquisition to its public works of interest and historical significance.

Judging by the reports received from Germany lately a great deal of attention is being devoted to the subject of seasoning wood by electricity. One object of the electrical process is to expel the sap from newly cut timber and prepare it for immediate use by obviating all danger of cracking, shrinking or warping. It is also claimed that wood thus treated will last longer, as it absorbs much of the preservative compound in which it is immersed, and that an additional advantage is found in the tendency to increase the tenacity of the wood and its resistance to vertical compression.

The most successful of these processes depends upon the principle of electrical osmose. The electrodes in an electrolytic solution are separated by a porous partition, and when a current passes the volume of the liquid in contact with the positive pole diminishes, while that in contact with the negative pole increases. One of these, the Noden-Bretoneau process, which is now considered the most promising plan, is described as follows:

The positive pole of a dynamo is connected with a lead grating, upon which the wood to be treated is placed. A solution, which is kept at the uniform temperature of 100° F. by means of a steam pipe underneath the grating, is poured into the vat so as almost to cover the log of wood treated. At a public demonstration, the solution used contained 10 per cent. of borax, five per cent. of resin and three-fourths of one per cent. of carbonate of soda, the borax being used on account of its antiseptic properties and the carbonate of soda to help dissolve the resin. A porous tray, the bottom of which consisted of two sheets of canvas with a sheet of felt between, was placed over the log, and a sheet of lead connected with the negative pole of the dynamo was placed above this.

When the current is turned on the solution is drawn from the bottom and the sap is driven out, and its place taken by the borax and resin. The time required for a 10-inch log is about seven or eight hours, and then the wood is slowly dried, which takes in the open air in summer several weeks or even months. It was stated that a unit of electrical energy was required for every six cubic feet of timber treated.

It is reported that by the use of this process wood which has heretofore resisted every attempt at seasoning, such as marine pine, yields to treatment and can be made available like other timber. It has also been remarked that insects do not attack wood that has been electrically seasoned.

Tesla's Visit to Chicago.

Nikola Tesla's visit to Chicago and his published utterances have created a profound impression and have provoked no small amount of comment and criticism. Mr. Tesla came to this city as the guest of the Commercial Club of Chicago and delivered an address before that organization at the Auditorium, where a dinner was given in honor of the distinguished visitor.

The Commercial Club is a conservative organization, the membership being limited to 60 and composed of representatives of the leading commercial interests of the city. It was founded 32 years ago and has consistently adhered to the line of policy originally adopted. The dinner last Saturday evening at which Mr. Tesla was entertained was the 150th event of the kind in the history of the organization, and was therefore a red-letter day in the records of the society.

In addition to the members of the club there were several prominent men present by invitation, and a few electrical experts. Following is a list of those in attendance:

- | | |
|---------------------|----------------------|
| C. H. McCormick. | F. W. Blaisford. |
| Nikola Tesla. | C. H. Blatchford. |
| H. H. Kofskaat. | F. B. Peabody. |
| H. G. Selfridge. | W. J. Chalmers. |
| George B. Swift. | Franklin MacVeagh. |
| Edwin A. Potter. | Von Bismarck Plotke. |
| Melville E. Stooe. | Baroo Heyl. |
| W. G. Collins. | Robert Hotz. |
| C. H. Wacker. | Henry Favell. |
| F. S. Wieston. | E. M. Bartoo. |
| George E. Adams. | Professor Stevens. |
| T. C. Chamberlain. | R. N. Fowler. |
| A. V. Abbott. | F. H. Head. |
| Bruce Clark. | C. Hotz. |
| J. C. Whitney. | J. L. Houghteling. |
| Benjamin Allen. | C. E. Scribner. |
| Samuel B. Downing. | C. D. Craodall. |
| Byron L. Smith. | Eugene Cary. |
| N. B. Ream. | H. J. MacFarlaod. |
| Robert T. Lincoln. | D. C. Jackson. |
| C. F. Kimball. | W. H. Merrill, Jr. |
| John J. Janes. | Henry A. Knott. |

| James MacVeagh. | A. J. Earling. |
| C. W. Cormao. | Eugene S. Pike. |

At the conclusion of the dinner President McCormick addressed the company, saying:

"We shall be much interested to hear from Mr. Tesla of the realm in which he dwells, which seems to us so incomprehensible, and if we become puzzled at the relative importance of 'amperes,' 'volts,' 'ohms,' 'induction' and 'polyphase currents,' Mr. Tesla must remember that, although we may know more about other things, we are still in the primary class in electricity.

"Since this great force of nature has been made subservient to the will of man, electrical progress has opened a wide field for both capital and labor. The Commercial Club will be interested in knowing that in this country alone the capital employed in the manufacture of electrical apparatus is \$50,000,000; the telegraph interests represent \$100,000,000; the telephone systems \$10,000,000; while the investment in electric lighting is \$247,000,000; this statement does not include the electrical equipment for elevated or surface railways."

Mr. McCormick paid a compliment to Mr. Tesla and the work he has performed in this field, and predicted even greater results than those already accomplished.

Mr. Tesla's speech was rather disjointed and disconnected, due partly to the nature of the address, which was punctuated with experiments and side remarks, and partly to his apparent difficulty in expressing his ideas. He took particular pains to make himself clearly understood, however, and the members of the club were highly entertained, although it was evident that they were also greatly mystified by the lecture and the experiments.

"There is no one," Mr. Tesla said, "who does not speculate about the questions of his existence, asking whence he comes, whether he is going and what in reality he is. Soul and matter and their relations have eternal interest for human beings. On the other side, there is always the desire to comprehend the marvelous manifestations of nature in all its phases. Let us talk of all of these."

With such a flexible subject it is not to be wondered that Mr. Tesla strayed from the paths of electrical science frequently during the evening and indulged in much speculation. He spoke for a time of the two terms, animate and inanimate, saying that he could distinguish between them in common language, but that for the scientist the case was not so simple, and he illustrated his meaning by an ex-

periment with two disks, which he said were in-
larly constructed.

"One of these has life in it," he said, "and the other has not." Picking them up, he added: "Which is the active one I cannot tell, but we shall soon see." Then, while his assistant turned on a current, he tested each and determined which one was dead and which one was alive.

Then Tesla talked of the possibility of depriving a piece of iron of all its heat and energy until it had reached the absolute zero and the minimum of motion. "When the motion has ceased entirely," he said, "when the ultimate stage of condensation is reached, the matter would disappear. There may be going on in the infinite depths of space a process of appearance and disappearance of matter. We are working to test this by trying to reach the absolute zero. It may take centuries before we can reach this absolute zero, if ever, for the difficulties are very great."

Turning to another point, Tesla said: "It is necessary for us to assume a universal medium for the transmission of force. This results from the necessity of explaining the action of bodies at a distance. Energy is transmitted from the sun to the earth through some very attenuated medium. To show how such medium may be used under

Turning again to the question of life, matter, and dead objects, he said the two were not synthetic, but that the distinction was one of consciousness. He criticized the superficiality of the ordinary idea of life, saying that if our senses were keener we would entirely lose the feeling of individuality. He said that there were experiments which could prove essentially the question of the continuation of individual existence. But the experiments were impossible to perform. They would consist, he said, in demonstrating that an atom in the body behaved differently to one atom in the same body that toward atoms of the outside. He next described the stages in the appearance of life on the globe, saying that all life was originally generated in the water. Ranging all the way from the lowest forms of animal life to the most complex, he pointed out the impossibility of showing the exact point at which life can be said to appear. Then he discussed the distinction between the phenomena of cause and effect and phenomena which mystify us. He gave his hearers something to see, flashing light in vacuum tube with the aid of wires. Then he took a long tube in his hand and waved it like a flaming sword in the air before the machinery.

Describing many of the phenomena of his life and experience, he told how he had come to the conclusion that he was nothing else but an automaton in every act and sense. He explained how memory could be regarded as automaton, and told his hearers that some time he would write a philosophical treatise based on the facts he had observed.

"If I am an automaton," he said, "why should I not construct an automaton like unto me? What are the elements necessary? I am a heat-generating being, with powers of locomotion, with machinery to direct my movements, with a sensitive mechanism to provide data, and with a governing mind. My automaton must have all these qualities."

Mr. Tesla performed many of the experiments with which his name has been associated, showed his oscillator and explained its principle and operation, and then produced a model of a boat which he used to demonstrate in miniature his system of firing torpedoes and controlling the operation of machinery at a distance by means of electricity without connecting wires. In this connection Mr. Tesla recorded his claim to the invention of the system of "wireless telegraphy" with which Marconi's name is now generally associated.

At the conclusion of his address Mr. Tesla was the recipient of many compliments from members of the organization. Much curiosity was shown over the apparatus employed, especially that used in directing the boat and exploding torpedoes. Owing to the lateness of the hour it was impossible to examine it closely. The electricians who were present refrained from commenting upon the exhibition and the apparatus employed, as they did not have an opportunity to go into the matter thoroughly.

On Monday morning the Chicago Tribune printed an interview with Tesla, in which he was quoted as saying that he proposed to establish communication between the earth and the planet Mars by means of an instrument so sensitive that it will feel disturbances created anywhere on the globe. Mr. Tesla pronounced this instrument "one of the most wonderful things I have discovered."

"The coming century," said Mr. Tesla, elaborating on his lecture before the Commercial Club, "will be the era of the atmosphere. From the moment I discovered that the air under certain conditions was a better conductor than a brass rod, I saw possibilities which made me grow fairly dizzy in their extent. The transmission of force and influence to any distance, the use of the sun's energy for all the needs of man, the possibility of controlling things with which there is no visible connection, these and an endless number of smaller achievements have become facts that in a short time will have their practical demonstrations."

"I am going on to perfect the needs of transmission of energy which I have found in the new and measureless ocean of the atmosphere about us. The sun has furnished us everything yet the energy it has to give is not used in the smallest part. The earth itself can be restored to the condition it was in when the ferns grew as large as trees. Disturbance in the new method of transmission, amounts to little or nothing. The idea of wireless telegraphy which arouses such interest now because it is developed to a new basis, is not wonderful at all compared to the principle of which it is an application."

The Rat Portage (Ont.) Lumber company has just put in operation an electric car system for delivering the lumber from the saws through its yards. It is a great improvement over the horse and cart service heretofore in use.

NIKOLA TESLA.

certain conditions I may refer to a feat I once accomplished of converting a column of gas into a solid body by the application of electricity in a certain manner. The gas became rigid and vibrated like a steel wire. Scientific men have not noticed the importance of this as yet. Again, I have produced a solid body in the air on the end of a wire. I made a flame which consumed nothing and which showed signs of solidification, for it offered resistance to the passage of bodies through it."

He then told of a method he had invented for the production of ozone, which could be made in commercial quantities for sterilization and for purposes of sanitation. It was made by the process he followed in the production of this flame which had the power of resistance.

"The forces of the air may be utilized in a manner now that we have not learned to even contemplate. Nitric acid may be made from the components of the atmosphere."

"This nitric acid may be made to fill our reservoirs and then utilized to produce the energy we need and to transmit energy to almost unlimited distances."

His greatest invention, he said, was in utilizing the forces of the air.

"The air, which is an insulator," he said, "becomes a conductor by means of the millions of volts I am able to produce. It means the using of the air for all purposes and uses of men. Not only for the transmission of messages without wires, but for the transmission of power in any amount to any distance across the earth's surface."

DEVELOPMENT OF THE TELEPHONE FIELD.

Radiophone at the Electrical Exhibition in New York.

[Special correspondence of the Western Electrician.]

New York, May 17.—A special matinee for the benefit of representatives of the press was given at Madison Square Garden last Saturday by the management of the Electrical Exposition, the attraction being the radiophone, which is the joint product of Professor Bell and Mr. Hammond V. Hayes of the American Bell Telephone company. This exhibition included a series of beautiful experiments in transmitting sound along a beam of light projected from an electric searchlight across the garden to a point 600 feet distant.

At one end of the garden, in the upper gallery, was placed an arc light with the familiar conical or parabolic, mirror of the searchlight behind it. When the current was turned on the beam was projected to the opposite end of the hall, where a simple receiving device had been placed. From each of the two main wires supplying current to the arc at the transmitting end short wires ran off to an adjacent telephone booth. Inside the latter was a transmitter.

At the receiving end the apparatus was even more simple in appearance. There was aimed toward the distant arc light another parabolic mirror—a bell-shaped vessel, whose lining was highly polished and whose interior curves were carefully calculated. A tiny bulb, no bigger than that of a thermometer, was fastened in the bell, at the focus of the parabola, and from this there extended back through the metal a short, slender glass tube, that connected with the ear-piece of a phonograph. There was no electrical equipment whatever at the receiving end. A visitor who put the twin rubber-tipped tubes into his ears heard not only the notes of a cornet, but also human speech, emanating from the closed booth at the other end of the hall.

This brief description will be sufficient to identify this system of "wireless telephony" with the apparatus exhibited by Professor Bell at the World's Fair in Chicago, although it is claimed that many modifications have been made, securing marked improvement.

Experiments on the transmission of speech by means of a ray of light were first made by Professor Bell in 1880, and he called the apparatus employed for the purpose the "photophone." The transmitter consisted of a plane mirror at the transmitting station, so arranged as to reflect a beam of light upon a selenium cell in circuit with an ordinary telephone receiver at the receiving station. The transmitting mirror served as a telephone diaphragm, a resonating chamber and mouthpiece being placed at the back. On speaking into the mouthpiece the mirror was vibrated, and these vibrations altered the intensity of the beam of light. The changes in the beam of light resulted in the selenium cell, acting in accordance with its well-known property of altering its electrical resistance under the influence of light, setting up corresponding changes in the receiver circuit, and so producing vibrations in the receiver diaphragm similar to those communicated to the mirror of the transmitter.

Professor Bell's experiments aroused much interest and discussion in the scientific world, and when it was found that the selenium cell could not be relied upon, as its sensitiveness to light changes with age, a very simple receiver was substituted. This receiver consists simply of a glass bulb or tube, containing a small pellet of carbonized fiber. To the opening of the tube is connected an ordinary phonograph ear-tube, and this simple device is all that is required for the photophonic receiver. Further investigation of the action of Professor Bell's invention determined that it was really due to heat effects, and not to light. Mercadier proved that the results obtained were due to heat effects, and suggested the name "radiophone" as more appropriate than "photophone." Hammond V. Hayes, of the technical staff of the American Bell Telephone company, found that, using a mirror and a reflected beam of light, as in the experiments of Professor Bell, the transmission of speech was extremely feeble, and audible to a trained ear only, and he at once began an investigation.

It was found in experimenting with an arc light as the source of the transmitting beam that a noise was heard in the receiver, which was traced to the inductor of the generator to which the lamp was connected. This experience pointed directly to a new style of transmitter. Experiments were made to find a means of directly varying the heat radiated by an arc light in such a way as to cause the light rays to vary to the radiophone receiver the same as the numerous ways of reaching the selenium cell. The simplest and most efficient method discovered being the one used in present practice. That is to connect in a shunt circuit with the telephone transmitter specially designed for a large amount of current. By increasing the current in the arc light the resistance of the transmitter, of course, varying with the temperature of the diaphragm, and the intensity of the current of the arc light, produces corresponding changes in the heat radiated by it, and these

changes affect the material in the glass bulb of the receiver in such a manner as to produce minute variations in the column of air contained in the receiver and ear tubes.

It has not yet been determined how far speech can be transmitted in this way, the distance naturally depending largely upon the power of the light used at the transmitting station. No experiments have yet been made to determine the limits of transmission under the most favorable circumstances, but as an indication of future possibilities it may be said that in Mr. Hayes' experiments in Boston he has succeeded in transmitting Morse signals by means of the radiophone over a distance of two miles.

Michigan Lines.

[From the Detroit correspondent of the Western Electrician.]

The main office at Detroit of the Michigan Bell company now has over 4,000 subscribers, the branches 2,600, making 6,600 in all in the city. Each branch office is now complete in itself, with operating and repair departments, so that calls from branch to branch are not delayed by passing through the main office.

An important change will be the removal of 60 toll lines from various parts of the city to a common station on the Six Mile road, whence they will traverse the state. This will allow the toll service to be handled over a general route with less delay and less of the retarding influences of underground currents. It is expected that the change will greatly improve long-distance work.

Out in the state, the Bell company is now actively engaged in connecting Detroit with Mackinaw, Marquette, Houghton, Calumet and Menominee, and in less than two weeks 2,000 men will be at work on these new state lines. Manager Forbes stated that he would eventually connect Detroit with every cross-roads place in the state. All state lines are being transformed into metallic circuits, so that long-distance telephones will be in use everywhere.

The Detroit Switchboard and Telephone Construction company has just completed a 3,000-line switchboard for the new People's Telephone company of New Orleans, and has accepted a contract for building a 5,000-line switchboard for the Allegheny (Pa.) Telephone company, the latter contract amounting to \$120,000. Superintendent McLeod of the Detroit Switchboard company says that the New Orleans exchange has five-year contracts with 3,000 subscribers, and a 25-year franchise, with rates fixed at \$36 to \$40 a year. Over 200 electrical workers are now employed at the Detroit plant.

Control of Wisconsin Telephone Company in New Hands.

[From the Detroit correspondent of the Western Electrician.]

C. J. Glidden and his associates, who control the Michigan Bell Telephone company, have secured a similar interest in the Wisconsin company, and the control of the North and South Dakota, Cleveland and Southwest Telegraph and Telephone companies, with a list of 80,000 subscribers. In Michigan and Detroit the new owners are expending large sums for improvements.

The syndicate which Mr. Glidden represents comprises the Erie Telephone company, which is formed to invest in Bell securities and build up properties of this character. The company is at present interested in a large portion of the telephone exchanges of the Bell system, and it is extending its operations in all directions.

Attempted Theft of Telephone Cable.

Three boys were arrested in Brooklyn last week for attempting to run off with about 500 feet of telephone cable belonging to the New York and New Jersey Telephone company, resulting in seriously crippling the service of the Bedford exchange for a couple of hours. They climbed up on the structure of the Brooklyn elevated railroad in Grand street, between Myrtle and Willoughby avenues, and proceeded to cut away about 500 feet of the telephone cable which is strung along under the structure. The street is dark at this point, and no one saw the boys at their work, but the falling of the heavy cable into the street aroused some of the people in the neighborhood. They came out and saw the three little fellows trying to roll the cable into a bundle, so that it could be carried away. When discovered, the boys took to their heels, but they were arrested later. The wire which was cut connected the main telephone exchange with the Bedford exchange.

Mexican Telephone Project.

President Diaz of Mexico has refused to charter a long-distance telephone company on the ground that the service would injure the business of the Mexican telegraph system. The stockholders of the Mexican Telephone company held their annual meeting at the Astor House, New York, May 10th, and decided to try to secure rights to use the telephone, not only in Mexico, but between the United States and Mexico.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Clarinda, Ia., telephone exchange has 145 patrons.

The Fort Dodge (Ia.) Telephone company has increased its capital stock from \$15,000 to \$25,000.

The Overland Telephone company is constructing a telephone exchange in Melrose, Ia.

The Ogden (Ia.) Telephone company is about ready for business. Work will be begun on the exchange at once.

The City Council of Clinton, Ia., has ordered the telephone and telegraph companies doing business in the city to be assessed. This is the first local attempt to assess such companies.

The Long-distance Telephone company is working to establish a telephone system in Hedrick, Ia.

T. Dupuis & Son contemplate establishing a telephone exchange at Washington, Ia.

The telephone operators of the Chippewa Valley Telephone company at Chippewa Falls, Wis., struck for higher wages. Foreign talent was imported and their places filled.

F. L. Eaton, T. H. Johnson, R. M. Dott and F. W. Lohr have an option on the Home Telephone company of Sioux City, Ia., with an exchange at Vermillion, S. D., and 225 miles of toll lines in South Dakota and Iowa, as well as the exchange in Sioux City. It is understood the prospective owners will wage relentless war on the Bell interests in Northwestern Iowa and Nebraska and South Dakota.

The Wisconsin Telephone company will entirely rebuild its system at La Crosse, Wis., and the toll lines in the vicinity at a cost of \$12,000 to \$15,000.

The Citizens' Telephone company of Montevideo, Minn., has been organized and has contracted for equipment which is to be installed as rapidly as possible.

The Princeton (Mo.) Telephone company contemplates establishing a telephone exchange in Centerville, Ia.

Owing to increasing business the St. Croix Valley Telephone company will string an additional wire between Balsam Lake, Wis., and St. Croix Falls for the use of business houses exclusively.

Dickhoff & Jaehning of New Richland, Minn., and the Minnesota Central Telephone company made ineffectual attempts to put in a telephone exchange at Redwood Falls, Minn.

The Iowa Telephone company is about to add another section to its switchboard at Fort Dodge, Ia., to contain 100 drops.

The new telephone exchange in Benson, Minn., is in running order.

Sioux Rapids, Ia., will vote June 5th on granting a franchise to the Sioux Rapids Telephone company.

The Wausau (Wis.) Telephone company has ordered a new switchboard of 400 drops.

The Central Telephone company has installed an exchange at Pomeroy, Ia.

The Zenith City Telephone company has secured quarters in Duluth, Minn., for its exchange room. Much of the materials for the system have been purchased and work is to be rushed.

The Lake Park and Ulen Telephone company has been incorporated at Lake Park, Minn., to build a line to Ulen.

The Minnesota Central Telephone company has arranged with the new Citizens' Telephone company at Montevideo, Minn., so that the entire local telephone exchange business will be turned over to the new company.

The Northwestern Telephone Exchange company will make a number of improvements to the system at Faribault, Minn.

M. R. O'Neill of Graceville, Minn., has obtained a franchise for a telephone exchange at Appleton, Minn.

George E. Merrill has been granted a franchise for a telephone exchange at Verdale, Minn.

The Iowa Telephone company is working hard on improvements to its lines in Iowa this spring. A metallic circuit is being constructed between Burlington and Ottumwa and a similar one between Denison and Missonri Valley. The Clear Lake Independent Telephone company has been incorporated at Clear Lake, Ia., with \$3,000 capital stock.

The Sterling-Amboy Telephone company has been incorporated to build a line from Sterling Center, Minn., to Amboy.

Chicago Telephone Company's Extensions.

The Chicago Telephone company, it is understood, will build a new North Side exchange on Chicago avenue. That corporation has purchased from Arthur D. Wheeler a tract of 60 by 100 feet on the north side of that avenue, 168½ feet east of Clark street, for \$21,500, and it is believed that it will eventually serve as a site for a new building which the company will occupy. In the same connection Mr. Wheeler purchased, on April 11th, from E. P. Baker 40 by 100 feet of south frontage on the same avenue, 90 feet west of Dearborn avenue, for \$13,500, and from Angeline A. Cook 20 by 100 feet, adjacent, for \$8,000, both tracts being included in the sale to the telephone company.

Theory of Wireless Telegraphy.

An interesting contribution to the theory of the vertical conductor appears in the Comptes Rendus de l'Association Francais pour l'Advancement des Sciences, in a communication made to the association at Nantes by M. Blondel, which has been summarized by the London Electrical Review, as follows:

M. Blondel remarks that it is no longer possible to look upon wireless telegraphy as Hertzian waves radiating from the spark gap of the transmitter, since Marconi has shown that the range is so enormously increased by the use of "antennae" (the name which he applies to the vertical conductors) with earth connections. It is necessary, then, to attribute the principal effect to an oscillating system, in which the capacity of the transmitting antenna in relation to the earth comes into play.

This antenna and the earth play the part of the two plates of a condenser, which is charged by the coil and becomes the seat of an oscillating current when the spark passes across the air gap. Owing to its position lines of force radiate like a fan in all planes from the antenna to the earth. The displacement currents, produced by the oscillating electromotive forces along the lines of force, are consequently concentrated in a limited space around the antenna, but the Hertzian waves produced by them around the antenna spread straight out into space. The oscillations in the wire are not themselves utilized, but they give birth to those which are utilized by causing a disturbance in the surrounding ether. The direct radiation from the antenna and the earth is very intense, but is quickly damped out, and that, in Blondel's opinion, is the reason why it has hitherto been found impossible to establish resonance between the transmitting and receiving antennae.

The important role played by the capacity of the antennae appears to be supported by the following experimentally ascertained facts:

- (1) The range attained when the antenna is not connected to the earth is comparatively insignificant.
- (2) The range depends upon the height of the antenna and not upon the oscillator.
- (3) The character of the spark changes when the oscillator is put to earth; from being long and slender, it becomes short and thick.

It would appear, therefore, that the capacity of the antenna will determine the length of the waves; the latter is sufficiently great relatively to the height of the antenna as to make it admissible to assume as a first approximation that the oscillating electric current along the conductor is sensibly the same as in the wings of a Hertzian oscillator.

This being granted, it is easy to see that the role of the transmitting antenna is twofold:

- (1) In the first place, it regulates the intensity of the center of disturbance by augmenting the volume of ether disturbed by the oscillator. In fact, the lines of force, being displaced with the same rapidity in the air and along the wires, and abutting always normally on the conductors, according to the known properties of electric oscillations, ought to have the form of hemispherical sheets, diverging from different points of the antenna and abutting normally on the ground. At each discharge they stir up the surrounding ether like the pulsating hemispheres of Bjerkness. The higher the antenna, the greater is the pulsating sphere, the greater is the volume of ether disturbed, and the greater is the distance at which the disturbance is perceptible. It may, therefore, be asserted that the antenna determines the volume of disturbance at the transmitting station.
- (2) In the second place, the antenna directs the magnetic lines of force produced in the direction calculated to produce the maximum effect on the parallel antenna at the receiving station. The magnetic lines of force are horizontal circles concentric with the antenna, and expand horizontally into space till they strike the receiving antenna at right angles, and generate oscillations which affect the coherer at its base. This favorable result is not obtained except the antennae are parallel.

The antennae, it is true, may be placed parallel without being vertical; for instance, they may be horizontal, with a spark gap at the center of the transmitter and a coherer at the center of the receiver. The arrangement is then similar to that of Hertz. The volume of disturbance is still determined by the length of the antennae. But the neighborhood of the ground introduces a disturbing influence, because the magnetic lines of force, instead of moving parallel to the earth, cut it at right angles during their propagation, and generate currents which involve a considerable loss of energy, and rapidly enfeeble the waves. Vertical antennae are, therefore, much to be preferred.

It is, easy to reduce this problem to that of the Hertz oscillator. Let us suppose that the earth, which here plays the part of a conductor along which the waves glide normally, is replaced by a thin metal disk of perfect conductivity. Hertzian waves, whatever their form be, will give place to superficial currents in the wire forming the antenna and in the upper surface of the disk. Let us suppose that an image in the disk of the antenna, fitted with an oscillator having a synchronous equal and opposed electromotive force, is set in operation below the disk. It will produce on the lower surface of the disk superficial currents which exactly annul those due to the real antenna. Everything will

happen, therefore, as if the disk of the earth did not exist, but only the two opposed antennae, the combination of which forms exactly a Hertz oscillator. Hence the conclusion that the combination of a transmitting antenna and the earth (supposed to be a perfect conductor) is equivalent to the half of a Hertz exciter of double the length and potential. The same reasoning shows also that the combination of a transmitting antenna and the earth is equivalent to a rectilinear resonator of double the length, in the center of which a coherer is interpolated.

Following Poincaré in assuming that the current in the antennae is uniform, and applying the formula of Neumann for the mutual induction of oscillating currents, the current induced in the antenna of the receiver is simply proportional to the coefficient of mutual induction (M) of the two antennae, and to the variation (d i) of the current in the receiving antenna.

The effect produced on the receiver will, therefore, be of the form $\frac{H H'}{r} \frac{d i}{d t}$ where H and H' are the heights of the antennae and r is their distance apart.

Experiments appear to confirm this approximate law of proportionality to the product of the heights. But it must not be forgotten that an increase in the height of the transmitting antenna increases its capacity, and, therefore, reduces the frequency of the oscillations, and also the difference of potential at the terminals of the induction coil. The factor $\frac{d i}{d t}$ is thus reduced.

The theory is only approximate, and neglects the loss of energy due to the earth being an imperfect conductor. This theory in Blondel's opinion explains why the range of transmission is greater over sea than over land.

Government Experiments with Wireless Telegraphy.

Mention has been made of the experiments conducted by Signal Corps officers with the view of introducing wireless telegraphy into the army and navy service. On May 11th General Greely published the result of this investigation, which is appended:

Since the announcement of the tests in space telegraphy by Signor Marconi two years ago, the subject has been under consideration by other scientists employed in the States, and recently experiments have been begun with the object of thoroughly testing the value of this means of communication for military and other governmental purposes. Special apparatus has been assigned and constructed for these tests, which have already shown sufficient promise to warrant further and systematic trials. In view of the great public interest and in order to facilitate experiments by other scientists in the States, it is deemed proper to put forth this statement of operations to the present time.

Transmitter.—In the experiments thus far several forms of transmitters for the generation of the Hertzian waves have been used, and much promise has been realized from the use of a large alternating-current coil in oil as a generator, instead of the ordinary Ruhmkorff coil employed by Marconi. This coil is energized by a three-quarter horse power rotary transformer, furnishing 125 volts alternating potential, and this arrangement makes a very powerful and efficient source of Hertzian radiation.

Receiver.—The former receiver used has been substantially the Braokey "coherer," discovered in 1891, and the signals transmitted are recorded upon a receiving tape.

The transmitter, being mounted on the west elevation of the Signal Corps building, and the receiver on the west elevation of the Signal Corps building, utilizing the present wooden flagpole for the vertical wire for the transmitter. The receiver was first placed at the old Naval Observatory grounds, about three-quarters of a mile distant, and later moved to the Signal Corps station at Fort Myer, Va.

During the experiments constant communication by heliograph and flag between the transmitting and receiving stations has been kept up by the trained men of the regular Signal Corps, and this has greatly facilitated the work of experimenting. Signals, letters and words have been transmitted and received between these stations, but the great delicacy and constant adjustment required in the present receiver have made the transmission of regular messages as yet unreliable and uncertain.

The presence of large buildings and masses of iron and steel nearby, and the presence of such places undesirable for carrying on experiments of this character. The distance over which signals may be transmitted by a given apparatus is a function of the height of the vertical wire used at either end, and this has naturally suggested the use of small gas balloons, such as have already been used for signal and other purposes by the Signal Corps. A supply of these balloons has already been obtained and will be used for this purpose in the near future.

That there is a field of usefulness for space telegraphy is undoubted, but that it will supplant to a material extent the use of wire for ordinary commercial telegraphy is not believed. Its value for communication between lighthouses and lightships and the shore, at points where cables cannot now be permanently maintained, will be great. For signaling between ships at sea and to replace ordinary flag methods in use between naval vessels it should prove invaluable, since no kind of weather, neither fog, darkness nor storm, avails to affect its use.

The use of metal reflectors to augment and direct the radiation to particular points has already met with partial success and should be thoroughly investigated. At present the radiation proceeds from the transmitter in all directions and the same message can be received at any point within the proper radius at which a receiver is placed. A satisfactory reflector and a receiver of the proper electrical capacity, or, in other words, tuned to the vibrations of the particular transmitter, would make a great advance in space telegraphy and do much toward the extension of its field of practical usefulness. While secrecy of transmission is among the probabilities, the present stage of experiment does not justify its positive prediction.

SPACE TELEGRAPHY.

In the Illustrated Electrical Patent Record this week a new patent granted to Marconi for wireless telegraph apparatus is illustrated and the inventor's claims summarized. The invention is a modification of a former patent granted Marconi July 13, 1897.

The Lighthouse Board announces that experiments will be undertaken at the headquarters at Tompkinsville to test the Marconi system of wireless telegraphy. The test will be made between the Tompkinsville central station and one of the lightships. For many years the officers of the Lighthouse Board have been desirous of getting some means of communication between the lightship and the central station, to take the place of the present system, which is felt to be inadequate for the recent developments in range. The officers have led them to look into Marconi's system.

Mr. Arthur Vaughan Abbott, chief engineer of the Chicago Telephone Company, delivered an interesting address on 'Wireless Telegraphy' under the auspices of the Y. M. C. A. Electrical Club of Chicago on Friday evening, May 12th. Mr. Abbott explained the nature of the experiments conducted by Marconi and gave a brief history of the development of the branch of telegraphy. He performed some very interesting experiments demonstrating the practicability of the system within limits of the lecture room and explained the essential features of the instrument employed. The address proved instructive and entertaining and was highly appreciated.

The Prince of Wales presided over a dinner in aid of the London Lifeboat Saturday Fund recently, and in the course of a speech on the work of the Royal National Lifeboat Institution he referred to the subject of electrical communication, saying:

One of the most important indirect means of aid to the institution with a view to diminishing the loss of life from wrecks on the coast has been to procure from the Government a system of electrical communication between rock light stations and light vessels, etc., and the shore; also between the coast guard stations and light vessels, and the post offices nearest the life boat stations where there are no coalstead stations. This useful work was commenced in 1893, and steady progress has been made in every year, and it will, it is hoped, before long be completed. The royal commission which was appointed at the suggestion of the institution in 1893 sat for four years during which time they issued five reports, the fifth and final report being issued in the autumn of 1897. The most important recommendations of the commission have already been carried out but in their last report they felt bound to state that they did not feel justified in recommending the connection of more light vessels and the shore than those they had proposed until the etherial system then under trial had been fully tested. I understand that these tests have been satisfactory, and you have all doubtless seen in the press the accounts of the remarkable and successful experiments which have recently been carried out in connection with wireless telegraphy under the superintendence of Signor Marconi, the inventor, which would seem to solve the great difficulties which have been encountered in the effort made to complete so important a system round our coast. I should think, likewise, the use and importance of the telephonic and telegraphic connections which have been established by the institution, and the utility of which each year has been increasingly demonstrated, they being more and more employed for calling out lifeboats when required, for preventing unnecessary launches, and for warning lifeboat crews to be on the alert to render assistance.

Mr. Kang Investigating Electrical Plants.

From the Canadian correspondent of the Western Electrician.

Ottawa, Ont., May 13.—Kang-Yu-Wei, the exiled Chinese reformer, who is at present visiting the Canadian capital, appears to be greatly interested in electrical development. In company with street-railway officials, he paid a visit of inspection this week to the power house of the Ottawa Electric Company at the Chaudiere Falls there. The oriental politician was accompanied by his two secretaries, who made extensive notes of the information gained. The distinguished visitor manifested great interest in the various details and workings of the machinery. Kang-Yu-Wei is desirous of promoting electric interests in his native land, and on his return from the present exile will make use of the pointers he has secured on his travels. Outside the treaty ports Canton is the only Chinese city that has an electric plant, and this one is but an imperfect affair. The Chinese reformer secured from Messrs. Ahern and Soper of Ottawa estimates on the probable cost of an electric-lighting plant for Canton. Kang-Yu-Wei is very much impressed with Canadian railways, both steam and electric, and has intimated that if he ever attains to power again in China it is his purpose to promote a railway policy along the same lines.

A Question of Re-entry.

Some time since George F. Chase of Detroit exported to Canada a dynamo and two hoisting machines of American manufacture. He lately inquired of the Treasury Department as to his right to import the same machines free of duty, although the dynamo has been rewound and the other machines repaired by the addition of new parts in Canada, the work being performed by men from the United States and the material used in rewinding repair and fittings being all of the manufacture of the United States.

Paragraph 483 of the tariff act of 1897 provides for the free entry of "articles the growth, produce and manufacture of the United States, when returned after having been exported without having been advanced in value or improved in condition by any process of manufacture or other means, which shall have been actually exported from the United States; but proof of the identity of such articles shall be made, under general regulations to be prescribed by the secretary of the treasury."

In the opinion of the department, it is immaterial whether the repairs or improvements in condition by any process of manufacture or other means are made abroad by means of American labor and materials or foreign labor and materials, and the fact having been shown that the dynamo and hoisting machines were advanced in value by any means while abroad, free entry thereof could not be accorded on importation.

One Result of Industrial Combinations Illustrated.

[From the Washington Post.]

The first of many changes to be made in the management of the syndicate properties in Washington concerns the clerical forces of the United States and Potomac Electric companies. The executive affairs of the two lighting companies have been brought together, the principal office being located at 1417 G street, headquarters of the syndicate, while the clerical force will hereafter be at the office of the United States company, Fourteenth street and Ohio avenue. L. E. Sinclair, former superintendent of the Potomac plant, has been given the same position with the consolidated concerns, and E. S. Marlow, former cashier and treasurer of the United States company, is made soliciting agent of the two companies. W. S. Terry, formerly bookkeeper of the Potomac company, is made auditor of the combination, and the offices of president, secretary, treasurer and cashier of the United States company have been abolished. It is estimated that the saving accomplished in the reduction of the office and mechanical force will be in the neighborhood of \$12,000 annually.

This reduction in the number of employees is the natural consequence of the syndicate consolidation. When all the properties are formally brought under the one management there will be still further and more important reductions in the working forces, the effect of which will surely be felt. Of the 12 railroads controlled by the syndicate, the mechanical and office forces will virtually be made one. This will result in the doing away with as many presidents, secretaries and superintendents, general man-

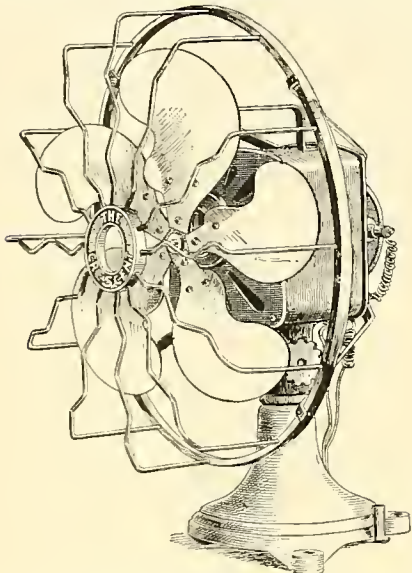

FIG. 1. CRESCENT FANS.

agers and other salaried officers, and the formation of one staff for the control of all the properties. The roads, however, will retain their present identity and will not, according to present plans, be run as one line. The clerical force will probably be brought to the offices of the City and Suburban and Anacostia lines, over the West End National Bank, on G street. These changes will result also in a vast saving in the operation of the various roads. With such reductions and the savings that will follow the doing away with many of the railway power plants the economies resulting will, it is believed, amount to probably not less than \$500,000 annually.

Substantial Marine Generating Set.

In the design of the generating set illustrated herewith the features of compactness, accessibility, economy and stability, with consequent lightness of parts and ability to maintain an excessively high rate of speed during a long period, have been most carefully developed.

The engine is two-cylindere, the cylinders having their axes parallel and being contained within the same casting. The diameter is very large relatively to the stroke, the size represented being nine-inch cylinders with 5½-inch stroke. The valves, which are of the piston type, are two in number, placed in tandem between the cylinders, and actuated from a crank below, which in turn receives its motion from a crank above from the eccentric.

The valves, which operate in unison, are so designed that steam is coincidentally admitted to the top of one cylinder and the bottom of the other. The motion of the piston is transmitted through large piston rods to slipper cross-heads, and thence through marine-type connecting rods to the double crank below.

The crank pins are set at an angle of 180 degrees, so that the vertical action is balanced, one crank moving upward as the other moves downward. This feature is instrumental in the securing of a high rate of speed.

The cylinders are supported upon four heavy col-

umns, as shown, the rear columns supporting the guides for the cross-heads, and all being securely bolted at the bottom to the very substantial bed casting. This bed carries three main journal bearings, brass bushed in their lower halves, and provided with continuous oiling devices in connection with oil receivers beneath. The interior of the bed forms a basin which collects all drip from water or oil.

The regulator is of special construction and arranged to operate the valve in such a manner as to regulate the point of cut-off for all loads. It is said to be exceedingly powerful, although sensitive to very slight changes in speed.

The connecting rod and cross-heads are of forged steel; the cylinders are thoroughly lagged, and an oil tank is mounted upon each end of the cylinder casting and provided with individual sight-feed oilers and connections to the various bearings.

The generator, the armature of which is coupled to the engine shaft, is carried upon a continuation of the engine base, and is of the six-pole type, with outboard, ring oiler bearing. Its capacity at 425 revolutions per minute (the speed of the engine) is 40 kilowatts. The field ring is of cast-steel. The cores are of wrought-iron with cast-iron shoes.

The armature is built upon a spider, and ar-

FIG. 2. CRESCENT FANS.

ranged for thorough ventilation through internal ducts extending out through the armature windings. The armature in operation acts as a blower and causes the passage of air through these ducts.

The series winding of the field coils is of flat copper ribbon, and the shunt winding is of wire. Both windings are placed on the pole entirely independent of each other, and either may readily be removed. Their design is such as to permit of free circulation of air upon all sides.

The generator is designed for sparkless operation

SUBSTANTIAL MARINE GENERATING SET.

under all changes of load from no load to 25 per cent. overload, with a limit of temperature rise of 60 degrees Fahrenheit after full load run of 10 hours.

This set was designed by the B. F. Sturtevant company of Boston, Mas., and is one of a considerable number of types which are now being manufactured by that company.

Crescent Fans.

The accompanying cuts show several styles of a variety of the Crescent fans, designed by Manager D. H. Kulp, and manufactured by the Marietta Manufacturing company of Marietta, Pa. These fans possess features of value to buyers of such goods. After considerable experiment, the Marietta company states it has secured a fan wing which will positively eliminate the humming noise which has heretofore caused so much annoyance, at the

FIG. 3. CRESCENT FANS.

same time increasing air displacement. Former types of desk fans have been abandoned, and the company has adopted a more efficient and ornamental construction, which experience has suggested advisable.

All desk fans (Fig. 1) will be provided with universal joint, readily adjusted to any position, also a neat and unique hand-hold on top of motor for convenience of moving from place to place. This type of motor will be furnished for all voltages on direct incandescent circuits. Three-speed regulators are provided on all desk fans up to and including 230 volts with no extra charge.

Fig. 2 represents type G Crescent fan for bracket use. The regular desk fans of all sizes and voltages are furnished with the swivel joint. It therefore becomes necessary to have extra attachments. The advantage of this can readily be appreciated. But no extra charge is made for this attachment.

In Fig. 3 is illustrated a type of Crescent direct-current fan of the electrolier type, with four lamps.

It is a matter of interest, particularly to the western trade, to know that the Marietta company recently shipped to its exclusive western agents, A. Reiman & Co., 817 Market street, St. Louis, as many as 2,500 of the Crescent fans. Such a shipment as this not only speaks for the favor Crescent fans have found in the West, but, as more are

to follow, insures the trade of enough stock in St. Louis to take care of rush orders.

The Raritan Electric Light and Power company, Perth Amboy, N. J., is said to have been sold to a syndicate supposed to be identified with the People's Light, Heat and Power company of Newark.

Eureka Central-energy Generator.

The Eureka Electric company of Chicago is now placing upon the market what is known as the Eureka central-energy generator. This apparatus is designed to meet the need of a practical, reliable machine, to take the place of hand generators in telephone exchanges. It is especially adapted for exchanges where water power cannot be secured or where the cost for power for operating power generators is such an item as to make it of consequence to secure something more economical but still in no way inferior.

Power generators, up to this time, have been used almost entirely to fill such requirements for furnishing energy from the central station, except the exchanges that have used the slow method of the hand generators. The special object of the Eureka central-energy generator is to fill the requirements of a device that shall prove reliable, efficient and economical, and be ready for service day and night, requiring no attention whatever, excepting an occasional recharging of four cells of sal-ammoniac battery. These four cells (of any ordinary type of sal-ammoniac battery), connected to the machine, give sufficient voltage and output by the closing of the circuit, which is done by a cam lever upon the switchboard, by the use of a foot-push, which is furnished with the machine. They will, it is claimed, throw sufficient current to the lines to enable the machine to ring the bells over lines having resistance as high as 100,000 ohms.

These generators have been thoroughly tested, and the company has received quite a number of endorsements from exchanges using them, which will be furnished to prospective purchasers or others interested. The machine is covered by fundamental patents. The great economy to be considered in the installation of the Eureka central-energy generator is the fact that all the expense and attention necessary is the recharging of four cells of sal-ammoniac batteries once or twice a year, according to the service exacted of the machine. One of the advantages of this generator is that it is consuming no current whatever, except when signaling a subscriber. The instrument is adapted for either series or bridging lines and for any size exchange, from 25 subscribers upward. The size of the machine is 10 by 12 inches, and it can be placed in a small space, wherever it is convenient, either at the switchboard or away from it.

The Pringle "New Style" Receptacle and Attachment Plug.

When William T. Pringle of Philadelphia introduced, a few years ago, the now well-known Chapman receptacle and plug, to quote his own words, he "was laughed at;" the idea was ridiculed. It was too expensive; it would never "take." However, Mr. Pringle felt confident it would "take" when placed before the public, and the results have exceeded his expectations. Many thousands of these plugs are now in use; they have found favor, and are growing in popularity daily. A great many of the large buildings in prominent cities have installed them,

FIGS. 1 AND 2. THE PRINGLE "NEW STYLE" RECEPTACLE AND ATTACHMENT PLUG.

and throughout the country the demand is increasing.

But there were a few deficiencies in this device that have been finally overcome. The "new style" is shown by the cuts.

Most contractors have no doubt been confronted, where floor space is valuable, with the problem of a two-inch partition and a 2 1/2-inch receptacle. This obstacle is overcome by the "new style," it being less than 1 1/2 inches deep. Another inconvenience in the old style was the trouble in pushing slack wire back into the wall. This is also overcome in the "new style," which has face connections. There is no necessity of handling the face plate and per-

haps spoiling it while connecting it, as the plate can be removed, and, after wiring is all finished, it can be put on. This will enable one to present a more creditable job at completion. Notwithstanding these important improvements, there is no advance in price over the old style.

It should be noted, too, as important that the "new style" fits the regular Cutter switch-box. Fig. 1 represents the receptacle open and by itself and Fig. 2 shows it in position.

A Useful Novelty.

The accompanying cut illustrates the Stewart combination socket handle and adjuster for attachment to incandescent lamp sockets. As the manufacturer

EUREKA CENTRAL-ENERGY GENERATOR.

ECO ELECTRIC DOOR SWITCH.

A USEFUL NOVELTY.

of this simple but useful and convenient device reports to date a sale of over 35,000, and all within a period of one month, it would appear as though a "winner" had been found.

This Stewart handle has metal ferrule, no unsightly ball and grips any size of cord. The adjustment is always handy, and it takes all strain from socket. An investigation of a sample is said to reveal its merits at once and to show it to be a "seller" for supply houses.

American Impulse Water-wheel.

The picture shows one of the impulse water-wheels of the American Impulse Water Wheel company of New York directly connected to a generator. This company is sending out a large number of wheels in this country and abroad for electrical transmission plants. Its wheels are of high efficiency and are spoken of in the most complimentary manner wherever used. The company also manufactures small water motors for operating fans, printing presses,

AMERICAN IMPULSE WATER WHEEL

organs, etc., and these motors are designed and built with the same care as the larger wheels. The company is equipped to execute orders promptly.

Western Electric Veterans Banqueted.

On Saturday evening, May 13th, at the Grand Pacific Hotel, a dinner was tendered by the office employes of the Western Electric company to their comrades returning from military service—Lieutenant William J. Unfried, Lieutenant A. Baade and Sergeant J. Furstenberg of Company L, Second Illinois Volunteers. Alderman J. C. Cannon, in an impressive speech, formally welcomed the "boys"

home and the only thing of note here was that the evening was when Sergeant Furstenberg responded for the volunteers, recalled the loss of Charles E. Donley in camp at Tappan, Pa., paying a glowing tribute to his dead comrade. The Western Electric company was well represented at the war, and "Charles" Donley was the only one who did not return. The men will return to their old positions with the company, ready when necessary, no doubt, to respond promptly again to their country's call.

After the dinner there was singing and speech-making. Max M. Wolfarth was the first to address following Mr. Cannon's address of welcome there

was a programme in which Rollo Kearsley, Messrs. Fuller and Wayman, George Chandler, Captain Philip Rust, Fred Uhrig, E. C. Mauermann, J. E. Phelps, William J. Powell, D. L. Harmon, Frank Swan and others took part.

Eco Electric Door Switch.

Edwards & Co. of New York have just put on the market the Eco door switch, herewith illustrated, the invention of Mr. A. Lungen. It is intended for telephone booths, toilet rooms, etc. The object attained is the lighting of an incandescent lamp by the opening of the door and the extinguishing of the light by closing the door. When the door is opened, contact is made and the lamp is lighted. The user of the booth closes the door after him and the light is still burning. By opening the door to come out the light is extinguished. On closing the door afterward there is still no light.

This contrivance has been approved by the Na-

tional Board of Fire Underwriters. It is provided with a porcelain cover and porcelain insulation. The size of mortise required for this switch is 2 1/4 inches long, one inch wide and 1 3/8 inches deep. The size of the front plate is 3 1/4 inches by one inch so that it can be used in any door frame. The carrying capacity for 110 volts is five amperes. This is the first electric-light article which Edwards & Co., who have been manufacturers of electrical house-keeping specialties since 1872, have ever offered.

Work has been begun on the electric railway from Ypsilanti to Saline, Mich. It will be completed within the next 60 days.

CORRESPONDENCE.

New York Notes.

New York, May 15.—Mr. Flower's death had the depressing effect on the "Flower stocks" that was to be expected. The market closed on Friday before his death. Brooklyn Rapid Transit then sold at 118½. On Saturday morning everybody knew that Mr. Flower was dead, and the opening sales of this stock, with which he was so closely identified, ranged from 100 to 110, some 25,000 shares being offered. Other Flower stocks suffered more severely, New York Air Brake showing, at one time, a loss of 60 points. During the morning Rapid Transit fluctuated a good deal, the decline being early checked by a rally, followed by renewed selling. The closing price was 106½, a net loss for the day of 11¼ points. The transactions in Brooklyn Rapid Transit amounted to nearly 200,000 shares. The firm of Flower & Co. had many offers of financial assistance, and it is not believed that its stocks will decline much farther. It is said that the street-railway amalgamation and extension in Brooklyn was Mr. Flower's pet enterprise. When Mr. Flower first became interested in the company three years ago it controlled approximately 200 miles of track and employed 4,000 men. Now nearly 600 miles of railroad is under the direction of the Rapid Transit company, and the list of employees contains over 12,000 names. The system has been correspondingly improved in plant and operation. The lines now controlled by the Rapid Transit company include all the surface trolley companies in Brooklyn, with the exception of the Coney Island and Brooklyn, and both of the elevated companies; that is, the Brooklyn "L" has actually passed into the possession of the stronger company and the Kings County "L" practically so, as it is now being reorganized along lines laid down by the managers of the Rapid Transit company with a view to a more complete consolidation.

Saturday evening's meeting of the New York Electrical society at Madison Square Garden was a Volta celebration and was attended by several representative Italians. Messages of congratulation upon the century of progress that has passed since Volta's discovery of the primary battery were sent to the Italian government, the Volta congress at Como and to the Italian Electrical association.

Another obstacle has been placed in the thorn-strewn path of the Board of Rapid Transit Commissioners. Mayor Van Wyck has vetoed the rapid-transit bill without giving reasons. The board now says that the rapid-transit railroad must be built by the city itself, or not at all. John Claflin has resigned as a member of the board in order that the commission might be free to elect Alexander E. Orr to fill the vacancy, Mr. Orr having ceased to be a member of the commission upon retiring from the presidency of the Chamber of Commerce.

The street-railway companies of the state are endeavoring to induce the governor to veto the Ford bill, taxing the franchise privileges of public-service companies. However, the governor seems to favor the measure and may sign it.

Early next spring the Third Avenue Railroad company will begin the work of converting the Drydock and East Broadway horse-car line into an underground trolley line. When that work is completed, says the Tribune, the company will have discarded every horse and cable car and will be electrically equipped throughout its whole system. Within a couple of weeks at most the Third Avenue main line will be ready for the trolley cars, and the Boulevard and One-hundred-and-twenty-fifth street lines will be in readiness by the end of July. The new electric cars, which have already been delivered, are nearly 10 feet longer than the cable cars. The outside coloring is the familiar vermilion hue which the company has adopted, while the interior decorations are mainly vermilion and cream. The sides are completely perpendicular, not being drawn in at the bottom as are the old cars. At either end are roomy platforms and easy steps. They are double-trucked, and each car will have four motors, each of 36 horse power. The difficulty experienced on the Sixth Avenue line last winter during the heavy snowfall was a factor, it is understood, in determining the Third Avenue company to give the cars enough power to push through any ordinary storm. The vehicles are constructed with an important improvement invented by J. H. Robertson, the company's superintendent. The cars are so made that they can be converted from a closed to an open car, and the company thus expects to avoid the expense of duplicating its rolling stock. The front and rear windows have drop instead of stationary sashes, permitting a free circulation of air when needed. The old-fashioned hand-trap is done away with, and the door has been fixed to open and close automatically, allowing a more convenient method of getting aboard. M. S.

PERSONAL.

deliberations during the ensuing year. Professor W. E. Ayrton has been chosen as honorary treasurer.

Richard McCulloch of St. Louis has been made general manager of the Compagnie des Tramways Suisse, at Geneva, Switzerland. All the horse tramways in Geneva are now owned by an English syndicate. Practically the entire system will be renewed, with additional mileage. It is to be all electric. Mr. McCulloch is to be master of construction, and when the lines are completed he will manage them and represent the syndicate.

Lord Kelvin was entertained at a banquet in his honor by the Associazione Elettrotecnica Italiana at the Grand Hotel, Rome, on Monday, May 1st. Speeches were made by Commandeur Cardarelli (on behalf of the Italian government) and by Professors Ascoli and Mengarini, to which Lord Kelvin responded. A telegram was read from the minister of posts and telegraphs, expressing his great regret at being unavoidably absent in consequence of parliamentary business.

"Speaking of General Funston," says the Kansas City Journal, "it is strange what currency has been given to the statement that his hair is red. The item first appeared in a New York paper, and probably the cause of it was the fact that Funston used to be about New York a great deal in company with Charles Gleed and E. W. Caldwell, the well-known electrician, formerly of the Kansas University. Mr. Caldwell's hair is red, and most likely some newspaper man who was introduced by Gleed to both Caldwell and Funston remembered Caldwell's hair and in due time attached it to Funston's head."

Plummer S. Page, a well-known street-railway man of Scranton, Pa., died suddenly on May 14th from the rupture of a blood-vessel in the head. When stricken he went across the street for a physician, and was explaining his symptoms to him when he suddenly sank to the floor and expired. Mr. Page was 58 years old, and was a native of Vermont. He built parts of the Lackawanna, Delaware and Hudson, Erie and Wyoming and New York elevated railroads, and owned large interests in the Long Island Traction and Cortland (N. Y.) Traction companies. In 1887 he bought the street-car lines in Scranton and substituted electricity for horses as the motive power, giving to the city its first trolley cars.

Roswell P. Flower, one of the prominent capitalists of the country and very actively interested in electric-lighting and street-railway properties in Brooklyn and Long Island, died on May 12th, quite suddenly, at Eastport, L. I. The immediate cause of death was heart weakness, superinduced by acute indigestion. Mr. Flower was ill for only a few hours. He was in his 64th year. His connection with electrical industries was of a financial character entirely. He is credited with the virtual consolidation of all surface and elevated street-railway lines in Brooklyn under the Brooklyn Rapid Transit company and a like combination of the electric-lighting interests of that borough under the Kings County Electric Light and Power company. He was reputed to be very wealthy.

The reception given by Mrs. Westinghouse in Washington on May 11th to the members of the American Society of Mechanical Engineers was an elaborate affair. The ballroom, built for the occasion, covered the entire garden at the rear of the Blaine mansion, in Dupont circle, and had a capacity equal to that of the cast room in the White House. Mrs. James G. Blaine was one of the receiving party, this being the first occasion of her presence in the house at an entertainment since her occupancy of it during the Arthur administration. The others who assisted Mrs. Westinghouse in receiving were the secretary of state and Mrs. Hay, Mrs. Harriet Blaine Beale, Mr. and Mrs. William Boardman, Mrs. Robert Hitt, Mr. and Mrs. Horace Wiley, Mr. and Mrs. Archibald Hopkins, Representative and Mrs. Dalzell and Mr. and Mrs. B. H. Warren of Pittsburg, Pa.

ELECTRIC LIGHTING.

According to a London dispatch dated May 15th, a syndicate, of which Dick, Kerr & Co., Limited, is the head, is erecting and equipping a big electric plant at Preston. It has given the contract to a Belgian firm, which undertakes to complete the work in six months. No English guarantee for the completion of the work in less than a year could be had. The contracts for the machine tools will be placed in the United States, where the principal superintendents of the works will be engaged.

A New Brunswick, N. J., dispatch of May 12th is as follows: "The purchase of the plant of the Edison Electric Illuminating company was consummated to-day. Hobart Tuttle, a Paterson lawyer, who is also private secretary to Governor Voorhees, recently secured an option in the interest of a syndicate, and to-day paid \$109 a share for every share delivered, 427 in all. The new holders of the electric light company will assume a bonded indebtedness of \$50,000, drawing six per cent. The company was incorporated March 14, 1885. Its officers are: President, Charles J. Carpenter; secretary, Peter S. Atkinson; treasurer, Theodore B. Booram. The officers, with John Waldron and

James Deshler, constitute the board of directors. The names of the men who form the syndicate were not revealed."

It has been definitely resolved to carry out the suggestions of the director of public lighting and close the municipal electric-light works of Buenos Ayres. The director, in his report, states that in 1898 the cost of the four power houses was \$63,500, while, at the rate charged by private companies for other public lighting, the work could have been done for \$35,000. He is of the opinion that by increasing the light to an all-night service the companies would do the work for about \$47,000, and concludes by recommending that the private companies be asked to tender for the service.

ELECTRIC RAILWAYS.

The contract for building a new electric railway at Parkersburg, Va., has been awarded to James F. Bradley of Manchester, Va.

President Agassiz of the Calumet and Hecla copper mine has granted a franchise to Edward Ryan and other copper-country capitalists to run an electric railway from Red Jacket to Larium.

A company of Chicago capitalists will build an electric road from Cassopolis via Dowagiac and Sister Lakes to Benton Harbor, Mich., where it will connect with the South Haven and Saugatuck line. Arrangements for making the survey are now in progress.

There is a movement on foot for the consolidation of the trolley lines operating in and about Paterson, N. J. It is said to be quite certain that the Central, which will be sold at receiver's sale, and the White line, which will be disposed of in like manner on June 10th, will be purchased by the combination.

W. J. Hart, general manager of the Detroit, Lake Shore and Mount Clemens electric railway, has handed in his resignation. Hereafter the Shore Line will be managed by T. N. Fordyce, as secretary and manager, Frank A. Draper, superintendent, and L. J. Ranney, superintendent of the mechanical department.

An electric railway is about to be constructed between Saint-Gervais-les-Bains and Chamonix, the well-known Swiss village at the foot of Mont Blanc. The line, which will be of one-meter gauge, will be used for carrying both passengers and goods. The water power of the River Arve is to be utilized to generate the necessary electrical energy, which will be supplied from four power plants.

The Westinghouse company has received an order to equip a trolley line between Philadelphia and Atlantic City. The company will be known as the West Jersey and Seashore Electric Railroad company, and it is expected that it will be in full operation before the summer rush begins. The promoters have not announced the fare, but say it will be much lower than the railroad rate.

The electric railways of Argentina are all supplied with equipments from the United States. During the last two months almost every vessel going to Buenos Ayres has taken \$50,000 worth of car material, a large part of which was received by the Belgrano Tramway company. The Capital company has also been a large buyer in the American market, its entire plant being of American construction.

An Albany dispatch says that the New York State Railroad Commission has received over 50 applications from inventors and manufacturers for participation in the tests to be made of air and other power brakes for street-cars in New York city. The Metropolitan Street Railway company has placed its cars and lines at the disposal of the commission for the test, which will be held with a view to introducing power brakes on surface roads in the state.

It is now stated that Tom L. Johnson, the street-railway magnate, has conceded one of the main points of difference that have been blocking negotiations for the purchase of the Detroit roads by the city. The city's commissioners refused to execute any security franchise to insure payment of the purchase price unless that instrument provide for present rates of fare on three-cent as well as five-cent lines. This concession has now been made. The most important question remaining at issue is whether the proposed 30-year security franchise shall run from the date of sale or from the expiration of present franchises, averaging about 16 years hence.

ELECTRIC VEHICLES.

The first automobile to be operated in the streets of Washington arrived there May 10th from Hartford, Conn., and was used by O. T. Crosby, who had as his guest on the initial ride the French ambassador. The vehicle is a four-seated affair, with the seats arranged back to back, and geared to a speed of 12 miles an hour. The automobile is of the Columbia type. Other automobiles of several types, including two, four and 16-seat coaches, will be put into operation in Washington as soon as they are delivered. The smaller vehicles will be for private use and for hiring purposes, and the larger

ones will be used as public conveyances, following Sixteenth street, Pennsylvania avenue and other principal thoroughfares.

INDUSTRIAL COMBINATIONS.

There is talk in Philadelphia of a consolidation of the lighting and transportation companies of that city. The capitalization, it was said, will be \$150,000,000. The following corporations are said to be in the new organization: Union Traction company, \$30,000,000; National Electric company, \$25,000,000; Electric company of America, \$25,000,000; Pennsylvania Manufacturing company, \$15,000,000; Pennsylvania Electric Vehicle company, \$10,000,000. The proposed consolidation is said to be the outcome of the recent demoralization of the stocks of the lighting and transportation companies when the advent of the National company was announced.

ELECTRICAL SECURITIES.

Announcement is made that \$250,000 first-mortgage five per cent. 30-year gold refunding bonds of the Hudson River Gas and Electric company of Tarrytown, N. Y., have been issued. Interest is payable May 1st and November 1st in New York. The bonds are secured by a first mortgage on the property of the Hudson River Gas and Electric company, supplying gas and electricity in Tarrytown, North Tarrytown, Irvington, town of Greenburg, Dobbs Ferry, Ardsley, Hastings and Pocantico Hills. The total permanent population is about 16,000, with substantial increases in the summer season. The company operates about 25 miles of gas mains and 50 miles of electric pole lines, and does all the public and domestic lighting of the towns mentioned. The net earnings of the company have been in excess of \$20,000 for each of the last three years, as against interest requirements on this issue of \$12,500.

PUBLICATIONS.

The type K transformer of the Pittsburg (Pa.) Transformer company is described in a pamphlet just out and known as "Catalogue B." The apparatus is clearly and carefully described, with good illustrations. A perusal of the 16 pages that constitute the body of the publication will give any alternating-current user a good idea of what the Pittsburg Transformer company denominates "a thoroughly well-made and efficient transformer."

Bulletin No. 8 of the Crocker-Wheeler company of New York was written by Dr. S. S. Wheeler, the president of the company, and is very interesting. It treats of motors with special characteristics for mills or factories and for elevators, and also of the new brake motor brought out by the Crocker-Wheeler company. Under the head of mill motors is also described the company's car motor and under the head of elevator motors its shop motor, they being modifications of the types under which they are described. Reference is made to controllers of the sizes used with mill motors directly after the description of mill motors. The investigation which the engineers of the company have made of the "heating-time average," on page 8, seems to be a careful analysis of the heating of a machine in intermittent use for four hours. The cut which accompanies the description shows curves of continuous and intermittent heating and the resulting rate of temperature rise. The machines advertised in this bulletin are especially designed for exceptional operating characteristics, protective forms and controlling mechanism, which fit them particularly for all work requiring great momentary turning power, safety from external injury or convenient automatic starting and stopping. The development of these types for particular kinds of work, following the universal acceptance of electric power, is a natural case of evolution, by which in time special types spring up for special purposes. The arrangements and illustrations of the bulletin are excellent and reflect credit on the publication bureau of the Crocker-Wheeler company.

MISCELLANEOUS.

The North Chicago Street Railroad company is experimenting with a compressed-air car for night service.

It is said that no subscriber to the Amalgamated Copper company's stock will be allotted over 20 per cent. of the amount of his subscription. Formal notice of allotment calls for payment on May 22d.

It is said that a boy of 19, the son of a Portland (England) grocer, has invented a noiseless, smokeless electrical gun, for which he has refused £75,000 offered by the British Admiralty. The new weapon, it is claimed, discharges explosives at a range of 5 1/2 miles with great accuracy.

It is announced that the annual banquet of the Chicago Electrical association will be held at the Technical Club on the evening of May 10th. Mr. E. W. Jewell, president of the McIntosh Battery and Optical company, will act as toastmaster. Mr. J. M. Hollister is chairman of the banquet committee. This is the 110th meeting of the association.

Michael Jost, a laborer, was struck by lightning at Wrightwood and Hermitage avenues, Chicago, while returning home from work on May 10th

and instantly killed. Within a few feet of Jost when he met his death were Policemen Preuss and Queen. They were thrown to the ground by the shock, and when they regained their senses found Jost lying dead.

TRADE NEWS.

The Electric Storage Battery company of Philadelphia has increased its capital stock \$4,500,000, making its total capitalization \$18,000,000.

The Leschen-Macomber-Whyte company of Chicago is distributing a very useful souvenir in the form of a paper-cutter. The cutter is neatly gotten up and is substantial.

The Swett & Lewis company, formerly of 11 Bromfield street, Boston, announces its removal to 79 Franklin street in the same city. The company claims to manufacture or sell everything connected with electro-therapeutic or X ray work.

The Western Electric company reports the supply business for the first four months of the year 1899 in excess of the corresponding period of 1898. This company carries in stock what is said to be the largest and most complete line of general supplies in the country.

The Board of Trade, Chicago, is equipping its offices with an independent private-plant telephone system, putting in a 200-wire Stromberg-Carlson central-energy switchboard and instruments. This will be, without doubt, the largest independent private plant in the West.

Two notices of removal come from the Buckeye Electric company of Cleveland. One refers to the main offices in that city, which are now in rooms 58-64 Wade building. The other states that the Chicago address is now room 1537 Monadnock building, where a unique exhibit of cellulose filaments is made.

The Graham Equipment company of Boston writes: "We have an order for 135 auto-trucks from the National Transportation company of Boston, to be used under the busses of the various lines that that company is establishing in the suburbs of this city. The trucks will be built with steel frames and will be equipped with Graham's spring suspension and equalized brakes. The National Transportation company frankly admits that our spring suspension is the only one that will enable it to do away with rubber tires and yet allow it to run over the pavements of the city at a high rate of speed without jar and inconvenience to the passengers or damage to the motive-power mechanism."

The co-partnership is announced of Mr. Charles Wirt and Mr. Irving B. Smith, both of Philadelphia, under the firm name of Charles Wirt & Co. Mr. Wirt has been well known for some years in the electrical fraternity, having quite early in the history of the industry come into prominence as an electrical inventor. Mr. Smith has been connected for about seven years with Queen & Co., and as head of their electrical department and as their electrical engineer he has gained some reputation as a designer and constructor of commercial and scientific instruments. The new firm has enlarged the manufacturing plant at 1028 Filbert street, Philadelphia, and is now prepared to fill all orders for rheostats, dimmers and brushes with promptness and satisfaction.

William Roche, manufacturer and inventor of new standard dry batteries, has removed from 259 Greenwich street, to more commodious and better located quarters at 42 Vesey street, New York, where he will be pleased to meet his old friends. There will be no more complaints on account of stairways, as Mr. Roche has now an excellent electric-elevator service. The office is on the top floor. From the windows an excellent view of old St. Paul's, the new St. Paul building, Syndicate building, busy Broadway and the Hudson River are to be had. Mr. Roche says that with the facilities of his new place and the already established reputation of his goods he hopes to be able to keep up with all demands. He feels that, having held his own against such competition as he has had in the past, he has good occasion for hope for the future.

The friends and patrons of the Central Electric company will be pleased to learn that it has accepted the western agency of the high-grade apparatus manufactured by the Bullock Electric Manufacturing company of Cincinnati. This company manufactures generators for power and lighting purposes, both belted and direct-connected, and makes a specialty of the highest grade of motors of all sizes for special purposes and for direct-connection to machinery of all kinds. Its "teaser" system of control for the operation of large newspaper and magazine printing-presses has received the highest praise, both in this country and abroad, and is claimed to be recognized as the most perfect known method of handling this class of work. The Central Electric company has a well-organized department to take care of this branch of its business, and anyone contemplating the building of a power plant, or the installation of motors for any purpose, is invited to take the opportunity of conferring with it before placing the order.

Gates & Randolph, the new Chicago firm for the sale of electrical apparatus, have just removed their office from the Marquette building to 13 and 15

Monadnock block, the old quarters of Street & Lundy, the electrical engineers, who will be better found on the eleventh floor of the Marquette building. One interesting and unusual feature of Gates & Randolph's new show room will be a model central station in operation and in full view through the windows from the main ground-floor corner of the building. A Triumph motor of 25 horse power will drive a Warren alternator, which through transformers, will supply current for four Sterling inclosed arc lamps and 20 or 30 incandescent lights. The plant will be completely equipped with a switchboard, Empire instrument and La Rue circuit breakers and switches. The idea is an ingenious one, and the model station will doubtless attract much attention. Mr. Randolph arrived in Chicago early in the work from New York and is now at work in the new firm's interest with the old cheerful hustle so familiar to the electrical men of Chicago.

BUSINESS.

Owing to the continued high price of copper, the Phosphor-bronze Smelting company, 209 Washington avenue, Philadelphia, has withdrawn all previous quotations on its metal, under date of May 10th, issuing a revised price list instead.

The Stromberg-Carlson Telephone Manufacturing company is reporting a large demand for its central-energy system. Among the orders recently received for complete central-energy equipment are from the exchanges at Brookings, S. D., Elizabeth, Pa., Northwood, Ia., and Nashville, Ill.

The raw-silk wipers manufactured by the American Silk Manufacturing company, 311 Walnut street, Philadelphia, are recommended and endorsed by the boards of fire underwriters of St. Louis and Philadelphia. These silk wipers are used in many electric-light stations, and are said to give better satisfaction than cotton-waste. One advantage of the raw silk is that there is little or no danger of spontaneous combustion.

The United States Express company has ordered for its building, 87 to 89 East Washington street, Chicago, a 30-kilowatt Western Electric direct-connected generator. The plant will be used for running 400 16 candle power incandescent lamps. It is also of interest to note that the Great Northern Hotel of Chicago is installing 10 Western Electric motors to operate the ventilating apparatus, laundry machinery, dish-washing apparatus, machine shop, and to drive the organ.

W. C. Hubbard, general manager of the Electric Arc Light company of New York, reports that his company is very busy at present and has just closed some good orders with such concerns as W. and J. Sloane, the Ogden Goelet estate, Central Railroad of New Jersey, New York; Palais Royal, Washington, D. C.; Campbell & Smith, Herren Bros. and John Daubs & Sons, Pittsburg. The address of the Electric Arc Light company is now, it should be remembered, 11 Broadway, New York.

The Ball Engine company of Erie, Pa., has in hand a number of foreign orders for engines. Russia, Japan, Mexico and Venezuela are the foreign countries now represented on the company's books. Among domestic sales of recent date of engines for electrical service, the following are reported by this company. Oliver Hotel, South Bend, Ind. 200 horse power; Edward Ford Plate Glass Works, Toledo, O., 175 horse power; American Chemical and Spirits company, Evansville, Ind.; West End Trust company, Philadelphia.

Since April 1st the sales of the Garton lighting arresters, manufactured by the Garton-Daniels Electric company of Keokuk, Iowa, have been over double what they have been in the corresponding period of any previous year. The Garton-Daniels company, in order to keep up its stock, has recently doubled its force of employees, and states that it will be able to meet any requirements for prompt shipments. The new kicking-coils and lightning arresters for the protection of small motors, fans, etc., are said to be meeting with a large demand.

The growth of the independent telephone-exchange business has created a large demand for the fine sizes of silk magnet wire used in telephone apparatus. The Electric Appliance company, realizing the importance of this demand, has recently made arrangements with the owners of a large factory devoted exclusively to the manufacture of fine sizes of silk magnet wire to handle their entire output. This places the Appliance company in a position to sell "on the ground floor" to large manufacturers of telephone apparatus, and it has already closed some handsome contracts.

The Ward Leonard Electric company announces a reduction in the price of its Carpenter field rheostats and theater dimmers. This reduction is as much as 30 per cent. in most instances. This cut in price is in strict conformity with the practice of this company of making reductions in price as soon as it is enabled to do so and still maintain a reasonable profit. Although the Ward Leonard company claims to have a practical monopoly in the line of field rheostats and theater dimmers, it has made such radical improvements in the cost of manufacture, due to new design and production in large quantity, that it feels that it can work

large reduction in price and still make a fair manufacturing profit. The field rheostats and theater dimmers of the Ward Leonard company are said to be the standard in those lines throughout the world, and foreign orders, already very large, will no doubt increase rapidly on account of the low price and high standard of quality.

Manufacturers of electric automobiles are invited to correspond with the Mica Insulator company, of 218 Water street, New York, and 117-119 Lake street, Chicago, in reference to Micanite insulation. This concern is especially equipped for the manufacture of commutator rings and segments for motors of this class of work. The Empire and M. I. C. Compound cloths and papers are used extensively by manufacturers of motors for electric vehicles. The company offers to send to any company a set of rings and segments for trial, free,

together with samples of its Micanite and Empire insulating cloth and paper.

The engineering and construction departments of the Chicago Edison company report a good business in wiring and isolated-plant work. Among the jobs now in progress and recently awarded them are isolated plants specified as follows: Oliver Hotel, South Bend, Ind., wiring for 1,800 16 candle power lights in iron-armored conduits, also a complete annunciator and telephone system, marble switchboard, instruments and connections for two 40-kilowatt and one 60-kilowatt General Electric dynamos, direct-connected to Ball engines; Massachusetts building, Baltimore, Md., the latest and perhaps the most modern in style of the fireproof office buildings in Baltimore, one 60-kilowatt General Electric dynamo, direct-connected to a Harrisburg Ideal engines, also wiring for about 1,000 16

candle power lights in iron-armored conduit; Grand Central Depot, Harrison street and Fifth avenue, Chicago, two 75-kilowatt General Electric dynamos, direct-connected to a 250 horse power Ames engine, also one 45-kilowatt belted General Electric dynamo, and a large new marble switchboard, about 21 by six feet, with connections for a complete plant of eight dynamos; Boys' Training School at Glenwood, Ill., wiring for 14 arc lamps and 500 incandescents, distributed among the various buildings, the wiring to be connected to one 45-kilowatt General Electric dynamo driven by an 85 horse power Ideal engine; State Normal School, De Kalb, Ill., one 40-kilowatt direct-connected engine and dynamo unit, marble switchboard and instruments and the wiring for about 1,100 incandescent lamps; Evening Star building, Washington, D. C., and also the electrical work for the new Hearst School, which is also located in Washington.

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued May 9, 1899.

624,463. Incandescent Lamp. Elmer F. Dwyer, Lynn, Mass. Application filed March 9, 1899.

An incandescent lamp having a stem and a coiled or looped filament, the coil or loop of the filament being extended backward toward the stem and attached or secured directly and rigidly thereto by cement.

624,472. Submerged Torpedo Tramway. Christopher T. Finlayson, Denver, Colo. Application filed June 28, 1898.

An endless cable is arranged and adapted to be moved to and fro across the harbor from a suitable station and means are provided for supporting the cable at its terminal end and at desired points intermediate of its terminal end and the station. Means for attaching torpedoes to the cable and for releasing any one or more torpedoes from the cable and for electrically igniting them at the will of an operator are also provided.

NO 624,472.

624,487. Printing Telegraph. Kirk Himrod, Chicago, Ill. Application filed March 25, 1898.

A keyboard transmitter has two or more sets of pole-changers acted on successively by the keys and means for bringing the sets of pole-changers into connection with the main line subsequent to the operation thereof by the keys.

624,513. Battery Electrode. Herbert S. Lloyd, Philadelphia, Pa. Application filed May 19, 1897.

The electrode mold has clamping chill ridges provided upon the oppositely disposed sets on registering with each other for supporting and binding the electrode strips and strips of non-inflammable compressible material provided within the line of the chill ridges to contact therewith to prevent leakage of the hot metal into the interior of the body of the mold.

624,516. Apparatus Employed in Wireless Telegraphy. Guglielmo Marconi, London, England. Application filed January 5, 1899.

The combination of a transmitter, a receiver, an aerial conductor, a metallic box containing the receiver, earth connections to one terminal of the transmitter and to the box, an interchangeable connection from the aerial conductor either to the other terminal of the transmitter or to one terminal of the receiver, a connection between the other terminal of the receiver and the box, a relay operated by the receiver, a telegraph instrument outside the box, a connection between the box and one terminal of the relay, a connection between the box and one terminal of the telegraph instrument, a connection insulated from the box between the other terminals of the relay and telegraph instrument, a coil of insulated wire outside the box in the latter connection and a metallic covering to the insulation in connection with the box.

624,531. Electrically Operated Rudder-controlling Mechanism. Richard B. Panton, Williamsport, Pa. Application filed September 13, 1897.

In an electrical rudder-controlling mechanism a reversible electric motor having operative connection with the rudder shaft is employed, a swinging brake-arm frictionally engaging with the shaft and gearing for retarding the motion of the brake-arm.

624,542. Telephone Register. Herbert T. Richards, New York, N. Y. Application filed March 6, 1899.

A system is employed comprising a registering circuit including a source of current connecting two stations, a current controller at one station, a register controlled by the junction of the operator at the two stations, a movable device obstructing the removal of the telephone receiver at the other station and a circuit closed or actuated by the movable device to close the registering circuit at the latter station.

624,552. Carbons for Electric Lamp. O. Sponinger, Vienna, Austria. Application filed February 15, 1899.

The composition described for carbons for electric arc lamps consists of ground carbon, 200 parts of quartz diamond dust, an amount of 20 to 50 parts of copper salt and 100 parts of water.

624,574. Edison Battery. James Sullivan, New York, N. Y. Application filed January 27, 1899.

A zinc-iron battery cell is composed of a porous zinc electrode and a porous iron electrode, the latter being exposed to the air.

externally to the air and rendered sufficiently dense to prevent the passage of an electrolytic fluid onto its exterior surface and so constructed that the cell may be charged, recharged and discharged through suitable pipes arranged as follows: On the exterior surface of the carbon vessel a glass or rubber discharge tube is partially suok into and cemented to the carbon extending from the top to the bottom of the vessel, and opening inwardly at the top into a slot cut half an inch deep in the top of the carbon vessel; a glass tube is sunk and fastened into the inner wall of the carbon vessel, extending from the top to near the bottom, as a means of charging the cell with acid from the bottom upward, or recharging it and thus forcing up the spent fluid to the discharge pipe; together with the whole forming a primary battery composed of the following elements: A cylinder of amalgamated zinc immersed in a solution of chloride of sodium contained in an earthen porous cup, the porous cup partially immersed in commercial nitric acid contained within the carbon-containing vessel and resting upon the bottom of that vessel.

624,615. Time Cut-out for Electric Lamps. James H. Boardman, Port Huron, Mich. Application filed July 14, 1898.

The combination is claimed with the clock circuit, the break wheel and the contact spring and the electromagnet, of the armature, the main-line circuit and the main-line switch having its free end traveling in the path of the armature, and the leaf springs operatively connected to the switch.

624,652. Alternating-current Motor. Alexander Heyland, Frankfurt-on-the-Main, Germany. Application filed February 18, 1898.

The method of starting and running an alternating-current motor having sets of inducing windings consists in supplying current first to those portions only of one set of the inducing windings in closest inductive relation to the other inducing windings, and thereafter supplying current to the other portion or portions of the set of inducing windings.

624,666. Telephone System. Frank A. Lundquist, Chicago, Ill. Application filed September 20, 1897.

A pointer and a series of insulated contact points, a clock mechanism consisting of a motor spring and an escapement, a disk rotated by the clock mechanism and provided with pins adapted to engage the pointer so as to move it step by step over the contact points, a second magnet provided with connections adapted to raise the pointer so as to release it from the pins on the disk, a spring for returning the pointer to a normal position when so re-leased, and a second spring for returning the pointer to engagement with the pins.

624,696. Telephone Transmitter. James H. Spencer, New York, N. Y. Application filed November 30, 1898.

A telephone transmitter is described having a diaphragm composed of two thin disks, and layers of tissue between the disks, the disks and layers being secured together only at the center.

NO. 624,487.

624,697. Telephone Transmitter. James H. Spencer, New York, N. Y. Application filed March 31, 1898.

In this transmitter there is a frame having an annular seat, a disk or diaphragm lightly dished on both faces and resting on the seat, the disk or diaphragm being of considerable thickness so as to be but slightly flexible, clamps secured to the frame and curved to bear at two points, only on the disk or diaphragm, and buttons, one of which is carried by the disk or diaphragm and the other is supported from the frame.

624,703. Electric Arc Lamp. Christian Tepel, Bennington, Pa. Application filed April 26, 1898.

A lever is suitably fulcrumed and a second lever fulcrumed thereto; a carbon holder is carried by the first-named lever with a clutch on the second lever and means for causing the carbon holder to move faster than the clutch.

624,744. Storage or Secondary Battery. Henry Blumenberg, Jr., New York, N. Y. Application filed August 18, 1898.

In a battery containing two elements of different polarity there is an electrolytic solution containing tersulphate of aluminum and bisulphate of an alkali or alkaline earth, such as potassium, sodium or ammonium.

624,813. Means for Regulating Speed of Electric Motors. Otto C. Immisch, London, England. Application filed March 7, 1898.

A main battery drives the motor, and an auxiliary battery and means for switching the current of the auxiliary battery in opposition to the main current for producing a lower rate of speed are also provided.

NO. 624,516.

624,815. Commutator Brush-holder. Gustave H. Jantz, Wyoming, William Leist, Norwood, and Otto W. Jantz, Cincinnati, Ohio. Application filed February 11, 1899.

In a brush-holder there is the combination of a frame having parallel flat projecting guideways, a brush mounted on the guideways, means carried by the brush and engaging the guideways to hold the brush in place thereon and means to hold the brush in yielding engagement with the commutator.

624,824. Adjustable Vibrator for Magnetic Coils. Charles A. Keller, Cleveland, Ohio. Application filed December 5, 1898.

A vibrator for interrupting an electrical current consists of a vibrator spring, a swiveled post to which the spring is secured and means for preventing the post from turning.

624,838. Annunciator for Telephone Switchboards. William O. Meissner, Chicago, Ill. Application filed November 17, 1898.

The essential features are thus enumerated: A front plate or support, carrying a pivoted shutter, a pair of supporting arms extending rearwardly from and attached to the front plate, a metal cylinder mounted on the arms, a detachable cover closing its rear end, an electromagnet in the cylinder, an armature between the cylinder and the front plate, the armature being pivoted at its lower extremity between the supporting arms; a latch arm extending forwardly from the upper extremity of the armature through the front plate to engage the shutter, and an insulating block lying between the supporting arms and carrying contact springs to co-operate with the shutter.

624,881. Telephone System. Daniel M. Therrell, Atlanta, Ga. Application filed April 5, 1897.

A compound transmitter comprises a diaphragm, a variable resistance in operative relation to the diaphragm, a local circuit including this variable resistance, a source of energy in the local circuit, an induction coil, the primary of which is connected into the local circuit, the secondary whereof is divided into two branches of equal resistance, variable resistance-repeating transmitters in each branch of the divided secondary circuit, local battery circuits controlled by the variable resistance-repeating transmitters, induction coils having their primaries in the local battery circuits and their secondaries connected into the main-line circuit in multiple.

624,895. Automatic Magnetic Circuit-breaker. William M. Scott, Philadelphia, Pa. Application filed July 28, 1897.

The combination is claimed of automatic magnetic means for breaking the circuit upon the occurrence of a predetermined abnormal flow, normally open-circuited automatic magnetic means for breaking the circuit upon the occurrence of a less abnormal flow and automatic magnetic means for bringing into circuit the normally open-circuited means upon the continuance of the less abnormal flow during a given space of time.

Western Electrician

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, MAY 27, 1899.

No. 21

Gen. S. T. Carnes, President of the National Electric Light Association.

This year, for the first time in its history, the National Electric Light association went to a distinctively southern city for its president. Baltimore and St. Louis have furnished presidents in former years, but neither can be said to be so thoroughly in the South and of the South as Memphis, the home of the gentleman now honored with the presidency—General Samuel T. Carnes, the president and manager of the Memphis Light and Power company. General Carnes is a southern gentleman in the best and truest use of that expression. His acquaintance among the leading electrical men of the country is extended, and his friendship is highly prized as that of a man whose motives are lofty and whose impulses are honorable. General Carnes is earnest and cordial in his likes and dislikes. He is a man warmly cherished by his friends, to whom he is devoted; and as an enemy he is not to be despised.

The following brief sketch of the career of the new president was prepared for a recent issue of the Memphis Scimitar: "Perhaps no man in all the city of Memphis is better, more widely or more favorably known than General Sam T. Carnes. The father of General Carnes was one of the pioneers of Tennessee, and the son is worthy of the sire. Barring a brief period of infancy, General Carnes has spent his life in Memphis. He was born in Hardeman County, West Tennessee, in 1850. He was by birth and inclination a military genius, and his early training and tendency have gone far toward making him one of the best-known military tacticians in the country. For a long time he was brigadier-general of this state, thus having charge and control of all the militia of the state. This military talent was both inherited and cultivated. His father before him was quite a military enthusiast and expert, and was at one time at the head of the state national guard. General Carnes was elected captain of the Chickasaw Guards of this city in 1878. This was at the time decidedly the best military company in the state, and one of the best in the nation. Engaging in many contests, it lost but few, and became, under his captaincy, one of the most celebrated companies in the land. To General Carnes is due the first introduction of both the telephone and electric light to this city, and he has been for years the president and general manager of the Memphis Light and Power company. General Carnes was married in 1881 to Miss Kate Kerr of this city and has two daughters, aged 14 and 16."

General Carnes is well known in Chicago, where he is a frequent and welcome visitor.

Convention Entertainments.

Mr. Frank L. Perry of Chicago gave his lecture, entitled "Curious Things Electrical," in the lecture room at Madison Square Garden on Tuesday even-

ing of convention week. Mr. Perry was introduced by Mr. C. O. Baker, Jr., president of the Electrical Exhibition company, and held the attention of those present for about an hour. One feature of the entertainment of novel interest was Mr. Perry's "elec-

trical head"—a cleverly constructed automaton that performs several surprising feats by electro-mechanical means. The "automobile parade" took place on Thursday afternoon and was a great success. Nearly 50 electric carriages, carrying ladies and gentlemen interested in the exhibition or convention, were in line. The party started from Madison Square Garden

GEN. S. T. CARNES

at about 3:30 p. m., and the parade ended at Columbia University a little more than an hour later. The route of the parade was Madison avenue to Twenty-sixth street, to Fifth avenue, to One-hundred-and-eleventh street to Lenox avenue, to One-hundred-and-tenth street, to Morningside avenue, to One-hundred-and-nineteenth street, to One-hundred-and-seventeenth street, to Amsterdam avenue, to Columbia University, where the parade was dismissed. It is said that more different styles of electric carriages were in line than were ever seen anywhere before. A photograph of the carriages is reproduced on page 296. J. M. Hill and J. W. Godfrey were marshals of the parade. At One-hundred-and-nineteenth street and Morningside avenue the parade halted, and most of those in the carriages got out and visited Grant's tomb. At Columbia University they were entertained at tea by Professor G. F. Sever of the department of electrical engineering, after which they visited the university buildings. Those who returned to Madison Square Garden sat down to an "automobile supper" in the garden restaurant.

son's fleet, and from there up the Hudson as far as Grant's tomb. Luncheon was served on board. Among those in the party were Mr. and Mrs. Manson and Mrs. Mansn of Okonite Inc., Mr. Rodman, Mr. and Mrs. John S. Sulloway, Mrs. Henry Cutter, Mrs. Tappler, Mr. and Mrs. Fleming, Mrs. Foote, Mrs. W. W. Low, Mr. Frank L. Perry, Mr. and Mrs. Mosher, Mr. and Mrs. Godfrey, Mr. McKay, Mr. Olsen, Mrs. Scovil, Mr. and Mrs. H. Kins, Mr. Shippy, Mr. Hillman, Mr. Price, Mr. Barron and Mr. Collins. The weather was perfect and the trip was a great success. On returning to the dock the party was met by automobile and conveyed to the Murray Hill Hotel.

Manager Mullen of the advertising department of the General Electric company had organized the trip to Schenectady for the convention delegates, which took place on Friday, and enabled the visitors to spend the entire day in Schenectady, visiting the works of the General Electric company. Mr. Mullen has had charge of the advertising department of the General Electric company for only a comparatively short time, but he has already made a host of friends among the newspaper men, and evidences are already seen of his marked ability. Handling the advertising of so large an institution as the General Electric company is no small undertaking, and the manner in which Mr. Mullen has grasped the many details connected with the intricacies of this department would indicate that a wise choice had been made in his selection for this work.

Attendance at Meetings.

As usual, the greater part of the convention attendants, as well as a majority of electrical visitors at the exhibition, was composed of supply men and manufacturers, yet there was a large number of central-station men on hand. The accompanying group shows the delegates in attendance. There was always a fair attendance at the meetings, and the papers presented were thoroughly discussed. The range of subjects was wide and the interest manifested showed that they had been selected with great care. President Young was personally congratulated by many of the central-station men, as well as the manufacturers, upon the successful convention organized by him and his associates.

The Chicago Delegation.

The ladies and gentlemen in the Chicago party were W. W. Low, Electric Appliance company (with Mrs. Low); E. K. Patton, Perkins Electric Switch Manufacturing company (with Mrs. Patton); M. E. Baird, Eddy Electric Manufacturing company; H. A. Wagner, Missouri Electric Light company, St. Louis; James Wolf, New York Insulated Wire company; George S. Whyte, Leschen-Macomber-Whyte company; Edward Phillips, Detroit Illumi-

DELEGATES TO THE NATIONAL ELECTRIC LIGHT ASSOCIATION CONVENTION, NEW YORK, MAY 23-25, 1899.

ating company; H. Arnold, Illinois Electric Lincoln Park; C. E. Kamteyer, Electrical Engineering; Mr. Runn, Chicago Electric company; Franklin Overbaugh, Chicago General Fixture company; W. F. Collins, Western Electric and

On Thursday a delightful excursion on the steamer Isabel was tendered the ladies. The boat left Thirty-first street at about noon, ran up the East River to Hell Gate and Long Island Sound, then back to Staten Island, visiting Admiral Samp-

NATIONAL ELECTRIC LIGHT ASSOCIATION.

The meeting of the National Electric Light association at New York was, of course, the event of the week in electrical circles. It was the twenty-second convention of the organization, and the first under the rule adopted at Chicago last year, providing for the holding of the meetings alternately in New York and Chicago.

The attendance was remarkably large, many members taking advantage of the convention to visit the exposition at Madison Square Garden, which is being held in conjunction with the convention.

The formal meetings of the association were held in Convention Hall, Madison Square Garden, May 23d, 24th and 25th.

TUESDAY MORNING'S SESSION.

President A. M. Young called the opening meeting to order at 11 o'clock on May 23d, and read the following address:

PRESIDENT YOUNG'S ADDRESS.

"In opening the twenty-second annual convention of your association, I take great pleasure in welcoming you to the city of New York. I shall not attempt to enlarge on the beauties, advantages and wonders of this great city, because you all know

the association, held in New York, in August, 1885, the question of large and small engines and dynamos was discussed, and the late R. T. McDonald of Fort Wayne gave his experience at Peru, Ind., where they were operating a large plant, something like 165 arc lights, with two large engines and two large boilers. After running them a short time, it was found no money could be made operating in this way. Small engines were substituted, after which the company earned good dividends. In some of the large cities at the present time 6,000 horse power engine-dynamo units are being erected, and in most of the electric stations throughout the country large engines and direct-connected dynamos are the order of the day, and only by their use can the best economies be obtained.

"The successful development of high-tension service is making it possible to utilize the water powers that have been so long undeveloped. This service is revolutionizing the power question as to manufacturing business in many of our prominent manufacturing towns, where formerly steam had been altogether employed. As we are all very much interested in the question of high-tension service, I think we shall learn much that will be helpful to us from the papers to be read on this subject and from the illustrated lecture which will be given at this session.

"It has been the aim of your president to secure

for the ladies would take place on Wednesday afternoon, and a sail around the harbor, for the ladies, on Thursday morning. The meeting then adjourned.

TUESDAY AFTERNOON'S SESSION.

The president called the meeting to order at 2:15 o'clock and announced that the first paper for the afternoon's session would be on "Rotary Transformers and Storage Batteries, as Related to Long-distance Transmission," by William Lisenard Robb of Hartford, Conn. Mr. Robb then read the paper, and the discussion was opened by Mr. Leslie of New York, and Mr. Ayer of Boston, Mr. Ferguson of Chicago, Mr. Edgar of Boston, Mr. Wagner of St. Louis and Mr. Doherty of Madison participated.

The president announced the next topic as "Transformer Tests," and introduced Professor W. E. Goldsborough of Purdue University, who read a paper on the subject, which was accompanied by a number of charts. Mr. Leslie of New York opened the discussion with an elaborate review of the work of the Manhattan Electric Light company of New York since 1893. Professor Robb of Hartford made some inquiries, which opened up a new line of discussion by Professor Goldsborough. It was taken up by the president, Mr. Leslie, Mr. Rice, Mr. Wagner, Mr. Ayer, Mr. Corey, Mr. Perkins and Mr. Seely.

WEDNESDAY MORNING'S SESSION.

President Young called the meeting to order at 10:45 o'clock. The secretary read a letter from First Vice-president E. W. Rollins of Denver, regretting his enforced absence from the convention. Similar letters were also read from L. A. Duncan, Birmingham, Ala., C. H. Wilmerding of Chicago and Edward L. Nichols of Ithaca, N. Y. A letter was also read from Mr. Marconi of London, regretting that it was impossible for him to attend the convention.

The feature of the programme was the presentation of two papers, by Herbert A. Wagner on "Single-phase Distribution," and Louis A. Ferguson on "Underground Electrical Construction." The entire session was given up to this discussion and was largely attended.

Mr. Wagner's paper was first in order and the discussion was opened by Mr. Crosby of Washington. Mr. Emmet of Schenectady, Mr. Ferguson of Chicago and Mr. Perkins of Youngstown took up several features of the subject and discussed them in detail.

The chairman next introduced Mr. Ferguson of Chicago, whose paper on "Underground Electrical Construction" was illustrated by lantern slides. Mr. Stetson, who presided at this session, opened the discussion by relating his own experience. Mr. Gille of St. Paul and Mr. Barstow of Brooklyn continued until the time for adjournment.

WEDNESDAY AFTERNOON'S SESSION.

President Young called the meeting to order at 3:20 o'clock, and asked whether the members desired to discuss further the paper of Mr. Ferguson. Mr. Davis took up the subject, asking for data as to the amount of business done per block and what was the income per 16 candle power lamp per thousand feet of duct. Mr. Ferguson replied that he had not these figures at hand, but could easily obtain them from the records. This closed the discussion.

The president announced that the next paper was entitled "Some Notes on Underground Distribution of Two-phase Current in New York City," by E. A. Leslie of New York. Mr. Leslie read the paper, and as there was no discussion, the president announced the next subject for consideration to be a paper on "Means of Attaining Safety in Electrical Distribution," by W. L. R. Emmet of Schenectady, N. Y. The discussion of this paper was opened by Mr. Sachs of New York, and Mr. Barstow and others participated.

In closing the discussion Mr. Greene of Schenectady said: "There is one point which I think you will hardly appreciate unless you have had some experience with extensive secondary mains; that is, the importance of securing united action on the part of electrical interests to secure a modification of the existing Fire Underwriters' rule. As Mr. Emmet has pointed out, it is not only common practice abroad, but it is compulsory to ground the neutral. It is certainly the only practical method for any extensive system of secondary distribution. It seems to me that the underwriters will not act in the matter until pressure is brought upon them, and I think this association is one of the best channels through which to bring pressure to bear. I would like to suggest the advisability of the appointment of a special committee to consider the question, which shall be authorized to settle the matter, or to formulate a report and present it at the next meeting of the association. It seems to me considerable progress should be made during the next few months, and that the committee should take the matter up actively in connection, perhaps, with a similar committee from the American Institute of Electrical Engineers, if that association would be willing to appoint a committee, because any rule opposed to good engineering practice is bound to be modified sooner or later. We want that rule modified before we

GENERAL VIEW OF EXHIBITION HALL.

it stands first among the cities of this country and in many ways is the first city of the world; in electrical progress it has no equal. Within its limits are located 35 electric-light stations, which furnish more than 1,000,000 incandescent lights and more than 30,000 arc lights, and at least 30,000 horse power in electric motors. The capital invested for carrying on this great business is nearly \$100,000,000.

"It may interest you to know that in 1867, in the city of Brooklyn alone, there were 10 street-railway companies, having 678 miles of track and a capitalization of \$55,000,000. In that year these railway companies carried 223,180,504 people. To-day every transit company in the borough of Brooklyn is equipped or about to be equipped with electricity for its motive power; the capitalization is \$150,000,000, and 236,980,010 people were carried by this vast system in 1897. Electricity, together with the inventive genius of honored members of this association, has made this wonderful change possible.

"The electric light," in one of the prominent Brooklyn papers speaking of the trolley, says, "Their power is being performed a heart-like function; they are pumping the blood of the city, through their arteries, where the flow was sluggish—they were almost dead." I think not only are the electric lights entitled to great credit for a work well done, and to the honor of being the first to use the electric light, but the electric light companies are also entitled to great credit for bringing up the electric light to the outside world.

"The success of the electric light business has

for the benefit of this association papers by some of its prominent members on practical every-day subjects which are nearest the hearts of electric-light men and which help them in the operation of their own plants and prove to them the value of this association. It will be very pleasing for you all to know that never in the history of the National Electric Light association has its membership been so great, and never so much interest shown in its success.

"I now declare the twenty-second convention of the National Electric Light association opened and ready for the transaction of business."

READING OF PAPERS.

The first business announced was the reading of a paper on "A Local Transmission System—Development and Operation," by Mr. W. S. Barstow of Brooklyn. The discussion was opened by Mr. Ferguson of Chicago, and he was followed by Mr. Creden of Chicago, Mr. Walker of Brooklyn, Mr. Wagner of St. Louis, Mr. Rice of Brooklyn, Mr. Von Pohl of New Orleans and Mr. Barstow.

COMMUNICATIONS.

The secretary read an invitation from the Edison Electric Illuminating company of Boston, inviting the members of the association to inspect its several stations. The secretary also read letters of regret from Mr. Charles E. Brush of Cleveland and Professor Henry T. Bovey of Montreal, who were unable to be present; also letters from Mr. Samuel Insull of Chicago and Mr. Frederic Nicholls, stating that they would arrive later in the session.

The secretary announced that an automobile ride

burn up several million dollars of property. This seems to me to be inevitable, unless the grounding is allowed formally by the rules and not informally and against the rules, as in some places to-day. The accident which occurred at New Orleans is bound to be repeated under the conditions which exist now, particularly where there are overhead conductors. I would like, therefore, to suggest the advisability of the appointment of a special committee to consider the matter, the committee either to report to the next convention, or to take the matter up with the underwriters."

Mr. Ayer: "I wish to second that motion."
The motion was put and carried.
The president: "We will take that matter up in the executive session and act upon it."

COMMITTEE REPORTS.

The report of the committee on "Standard Candle Power of Incandescent Lamps," of which Dr. Louis Bell of Boston was the chairman, was next in order. Dr. Bell was not present, and Mr. Ayer, another member of the committee, was called upon. He said: "Dr. Bell is chairman of this committee. He is not present, and I have not been able to get any information from him in regard to the progress of the work in the shape of a formal report. As a matter of fact, I know there has been nothing done in the past year. The committee is authorized to go ahead and complete a standard method of testing, and recommend a standard form of photometer, and in a general way carry to a

James I. Ayer of Boston, G. W. Hubley of Louisville and H. H. Fairbanks of Worcester, Mass. The first paper to be read was one by H. M. Atkinson of Atlanta, Ga., on "Alternating-current Generation and Distribution—Changes Contemplated in Atlanta." In the discussion which followed Mr. Crosby of Washington, Mr. Doherty of Madison, Mr. Edgar of Boston, Mr. Scovil of Cleveland, Mr. Dunham of Hartford, Mr. Coughlin of Worcester, Captain Brophy of Boston, Dr. Kershner of Louisville, Mr. Davis of Williamsport, Mr. Ayer of Boston, Mr. Bean of St. Joseph, Professor Goldsborough of Lafayette, Mr. Brown of Columbus and Mr. Hoag of Cleveland took part. Upon suggestion of the president the subject of "Service for Automobiles—What Are We to Do With Them?" was discussed, Mr. Lieb of New York, Mr. Edgar of Boston, Mr. Doherty of Madison, Mr. Scovil of Cleveland and Mr. Crosby of Washington participating.

RESOLUTIONS ADOPTED.

A resolution was adopted embodying a suggestion by Mr. Doherty of Madison that the president be authorized to appoint a committee to investigate the photometric value of arc lamps.

Mr. Wright offered the following resolution, which was adopted:

"Resolved, That the thanks of the Electric Light association are hereby tendered to the New York Electric Vehicle Transportation company, the Columbia Automobile company, A. L. Riker Electric

Crosby and Davis, at the conclusion of which the committee was authorized to take whatever further steps might be deemed advisable in its judgment to secure such amendments to the freight classification as were desirable and proper.

RESOLUTIONS ADOPTED.

Mr. Ayer offered the following resolution, which was adopted:

"Resolved, That the thanks of the National Electric Light association be and are hereby extended to Mr. Charles E. Tripler for his great kindness and courtesy in preparing a lecture, with experimental demonstrations upon the qualities of 'Liquified Air,' for the members and delegates at the twenty-second convention in New York city.

"Resolved, That a copy of this resolution be sent to Mr. Tripler by the secretary."

EXECUTIVE SESSION.

The meeting then adjourned to executive session, where the first business was the report of the secretary and treasurer, which showed the following financial transactions during the year:

Receipts and cash on hand.....	\$7,188.90
Disbursements and liabilities.....	4,551.85
Balance	\$2,637.05

NEW OFFICERS.

The report of the nominating committee was then presented:

For President, S. T. Carnes, Memphis, Tenn.
For first vice-president, O. T. Crosby, Washington, D. C.

For second vice-president, J. B. Cahoon, Elmira, N. Y.

For members of the executive committee, E. F. Peck, New York; William M. Brock, Paterson, N. J.; C. E. Scott, Bristol, Conn.

Mr. Wright moved that the report of the nominating committee be received, and that the secretary be instructed to cast the ballot for the association for the gentlemen nominated. The ballot was accordingly cast and the gentlemen duly elected.

Mr. Crosby of Washington proposed a vote of thanks to Mr. Young, saying: "He has had, as we know, for years a ripe knowledge of the business we are engaged in, and his interest and industry in it have been unremitting. I do not believe that we could have had a better president to keep in for a second term, were it not for the fact that the practice has been established of changing every year. I move that the association tender a vote of thanks to Mr. Young for all he has done for the association during his incumbency." The motion was carried.

President Young acknowledged the compliment, saying: "I sincerely thank you for your kindness in this matter. I did not feel that I was the right person to be selected for this position when you elected me in my absence at Chicago. I thought it was rather hard lines to have the position thrust upon me; but I felt that it was certainly a very great honor. I have tried my best to make this meeting a success, and I wish to thank every member individually for the great help he has given me, as without that help it could not have been a success. As it is, I think the meeting has been a great success and that the interest of the members present has been well sustained. I want to thank every member for his attention and earnest efforts in connection with it."

INSTALLATION OF OFFICERS.

Mr. Crosby and Mr. Scovil were appointed a committee to escort President Carnes to the chair.

President Carnes said: "This is entirely a surprise to me, for I had no intimation of your intention until 15 minutes ago, and if I serve you with any sort of satisfaction, it will be another surprise to me. I am most highly gratified at this honor which you have shown me and will make every effort to serve you rightfully and faithfully. I could not make a speech if I tried, but having assumed the office, I promise you to do the best I can."

Messrs. Crosby and Cahoon were then installed and made brief remarks of an appropriate character, after which the meeting adjourned.

Exhibition and Convention Notes.

Charles E. Hague represented the Ansonia Brass and Copper company.

The Northern Electrical Manufacturing company presented a number of types of Northern motors.

J. E. Way of the New York office of R. Thomas & Sons company of East Liverpool, O., was on hand.

The Adams-Bagnall company of Cleveland presented a most attractive exhibit of its several styles of modern arc lamps.

W. N. Pinckard of the Westinghouse Electric and Manufacturing company's Chicago office mingled with the boys.

Two men who were warmly welcomed were Messrs. Boyer and Scribner of the western office of the General Electric company at Chicago.

The American Technical Book company of New York announced the publication of a new electrical story, "The Lord of the Dynamos," which may be procured by sending a postal card to the company at 23 Duane street.

[Continued on page 302.]

PARADE OF AUTOMOBILES.

conclusion a method of establishing and determining a standard lamp for station work. The work that has been done is considerable and has reached an advanced point, and I think the methods recommended and agreed to should be carried out. It only needs the appointment of a committee that will give the matter further attention, simply executing details. The work has been outlined, and complete data gathered, and our decisions arrived at after consulting with the lamp manufacturers, as well as users. We seem to have arrived at fair recommendations, but only a trial will give them any status in my opinion. I suggest that some action be taken to continue the committee and perhaps change its members, and have the work prosecuted to completion."

The president: "I think we will take that question up also in executive session, and a committee will no doubt be appointed to continue the work, because it should be brought to completion in the interests of us all."

There was no report from Mr. Armstrong, the chairman of the committee on "Legislation Regarding Theft of Electric Current."

A paper was then read on "Tram Formers; Iron Lamps; The Remedy," by G. Wilbur Fisher of Louisville, Ky., and was discussed by T. L. Doherty of Madison, Wis.

EVENING SESSION.

The president, in closing the session, announced that there would be an evening session at eight o'clock. Mr. Calvin W. Rice of Brooklyn presented a paper on "The Development of the Electric Lamp." Slides illustrating the same were shown and the session adjourned to executive session.

THE FOLLOWING MORNING'S SESSION.

President Young called the meeting to order at 10:15 and immediately appointed as the committee on the officers for the ensuing year

Motor company, the Indiana Bicycle company and the Fischer Equipment company, for the courtesies extended by them to the ladies of the convention, in connection with the automobile ride to Grant's tomb and Columbia University, Wednesday afternoon, May 24th.

"Resolved further, That the secretary send a copy of this resolution to each of the concerns mentioned."

Mr. Dunham offered the following resolution, which was adopted:

"Resolved, That the thanks of the National Electric Light association be and are hereby tendered to Columbia University and to Professor G. F. Sever, of its electrical engineering department, for the courtesies and hospitalities extended to the ladies of the convention on the occasion of the automobile ride, Wednesday, May 24, 1899."

THURSDAY AFTERNOON'S SESSION.

President Young called the meeting to order at 3:20 p. m.

The secretary read an invitation from the Edison Electrical Illuminating company of New York, inviting the members of the association to visit its station; also an invitation from the National Association of Municipal Electricians to attend the fourth annual convention of that association, to be held at Wilmington, Del., September 4th.

REPORTS OF COMMITTEES.

Paul Spencer, when called upon for the report of the committee on "Standard Specifications for Electrical Apparatus," stated that while considerable work had been done by the committee, no formal report would be presented, and, on motion, the committee was continued.

Mr. Ayer then made a verbal report of the committee on "Amendments to Freight Classification." The discussion ensuing on this report was participated in by Messrs. Davenport, Young, Bean,

Gates & Randolph.

The firm of Gates & Randolph is new, but it is composed of two of the most experienced salesmen in the electrical business.

Robert J. Randolph commenced his career in the electrical field in the early days of electric-lighting with Chas. J. Vandepoele in the old shop of the Vandepoele Electric company, located on Canal street, Chicago, back in the early '70's. The first machine the Vandepoele company built that would run five arc lights was sold by Mr. Randolph to the Rockford Boat Works, and that machine is still running. Mr. Randolph well remembers the first 40-light ma-

ROBERT J. RANDOLPH.

chine that was made, which was a "Jumbo" and quite a wonder to the electrical fraternity. This machine was installed at Freeport, Ill.

After the Vandepoele company was absorbed by the Thomson-Houston Electric company, Mr. Randolph engaged with the Excelsior Electric company in Chicago until the Chicago office was closed. He then went to Cincinnati and was manager of the municipal lighting and railway department of the Cincinnati district of the General Electric company. When the Excelsior company again opened its office in Chicago, Mr. Randolph resumed the management and remained with that company until the Chicago office was finally closed, slightly over a year ago. He then became manager of the Sterling Arc Lamp company of New York, with which he remained until May 1, 1899, when he formed a co-partnership with Mr. Gates. Mr. Randolph has installed a large number of plants of all kinds, and his list of friends and acquaintances among electrical men is very extended.

J. Holt Gates started his electrical career in Chicago with Westinghouse, Church, Kerr & Co. in 1885. That firm had just taken the agency of the Westinghouse Electric and Manufacturing company,

J. HOLT GATES.

which shortly before this had been organized in Pittsburg. Mr. Gates afterward removed to Pittsburg, where he spent a year in the shops of the company, learning the mechanical and electrical details. He then went to Texas, where he was manager of the Westinghouse company's interests in the South for three years. From there he returned to Pittsburg, and then to Chicago, finally leaving the Westinghouse company after seven years' service with it to take the sales managership of the Siemens & Halske company of America, which had just then been formed. Subsequently, Mr. Gates went into business for himself, being agent for various electrical companies in Chicago during the last five years.

Mr. Gates has been well-known to the trade during the last two years as western agent for the Walker company, having installed some very large plants during that period.

The experience of both the members of the firm in selling, engineering and installing alternating-current, arc-lighting and railway plants is extended, and some of the most successful plants in the country have been sold by them. This wide experience will enable them to successfully handle the projects they have now in contemplation in their new enterprise. They now act as western agents for the sale and installation of the direct-current apparatus manufactured by the Triumph Electric company of Cincinnati, O.; the alternating-current apparatus of the Warren Electric Manufacturing company of Sandusky, O.; the instrument business of the Empire Electrical Instrument company of New York; the switchboard and specialties of F. A. La Roche & Co. of New York; the business of the Sterling Arc Lamp company of New York, and Elmer P. Morris' rail-bond, with various other details. The office and salesroom of Gates & Randolph are at 13 and 15 Monadnock block, Chicago.

Incandescent Lamp Burns Hole in Partition.

It is well known that incandescent lamps give out a considerable degree of heat, but because the filament "burns" in a vacuum and is surrounded by a tightly sealed glass bulb the general user is apt to minimize the fire hazard from the contact of the lamps with, or close proximity to, inflammable materials. Fires have resulted from this fancied security, and it behooves window dressers and others

INCANDESCENT LAMP BURNS HOLE IN PARTITION.

who arrange masses of filmy fabrics near incandescent lamps to remember that the steady heat of the bulbs may cause fire, after a time, to any substance that will readily smoulder and burst into flame. The danger may be a remote one, but it nevertheless exists in some degree and should be guarded against.

The photograph herewith reproduced shows the heating effect of a 32 candle power lamp left hanging against a wooden partition. It was made for George W. Wilson, chief electrical inspector of the Boston Fire Underwriters' Union about three months ago. The lamp was pendant on a 110-volt circuit and suspended from a fusible rosette. For the convenience of mechanics who were at work in the room the cord was attached to a nail and allowed to hang against a freshly finished sheathing. The lamp was left burning at 5 p. m. and the result was not discovered until 7 a. m. the next day. The lamp had burned the sheathing sufficiently to clear itself from contact. Absence of draft prevented serious fire in this instance, but the lesson to be drawn is an obvious one.

Annual Dinner of the Chicago Electrical Association.

About fifty electrical men attended the annual banquet of the Chicago Electrical association, held on May 10th, at the Technical Club, Chicago. Mr. E. W. Jewell acted as toastmaster, and the following-named gentlemen responded to toasts: Mr. C. J. Warner, "Electricity of Long Ago;" Prof. H. S. Carhart of the Michigan University, "Education;" Lieut. F. B. Badt, "Mathematics;" Mr. E. P. Warner, "The Construction of Electrical Generating Apparatus."

Numerous informal toasts were responded to, and Mr. Sewell, chairman of the reception committee, extended to the visitors a hearty invitation to attend the technical meetings of the club in the fall. Mr. J. M. Hollister was chairman of the banquet committee and in charge of the arrangements, and deserves credit for the successful meeting.

The list of the names of those who were present is as follows:

- | | |
|---------------------|-----------------|
| Harold Almert | E. J. Jones |
| S. G. Arnold | F. P. Jewell |
| F. B. Badt | W. G. Hyde |
| H. A. Buebel | G. E. Kane |

American Institute of Electrical Engineers.

The sixteenth annual business meeting of the Institute was held in New York last week. The annual reports of the council and treasurer were presented. The total membership on May 1st was 1,133, being a net gain of 35 during the year. All debts were reported paid. The cash balances in various funds amounted to \$5,702.74. Other assets were \$5,067.75. The counting of the ballots showed the election of the council nominees, as follows: President, A. E. Kennelly; vice-presidents, J. W. Lieb, Jr., Chas. F. Scott, L. B. Stillwell; managers, C. O. Mailoux, S. Dana Greene, C. S. Bradley, W. D.

Weaver; secretary, R. W. Pope; treasurer, Geo. A. Hamilton.

A paper was presented by Frank J. Sprague, past president, on the "Multiple-unit System of Electric Railways," which was fully illustrated by a working model and lantern slides. The paper was discussed by John B. Blood, Jr., A. H. Armstrong, H. Ward Leonard, F. V. Henshaw and others.

At the meeting of the executive committee in the afternoon the following-named associate members were elected: Louis E. Bogen, Cincinnati, O.; Paul Bonyng, Brooklyn, N. Y.; Joseph H. Bowman, Chihuahua, Mexico; Ellis Eugene Brown, Kingston, Pa.; Walter E. Chappell, United States Navy; Louis A. Herdt, Montreal, Canada; Albert C. Johnson, Willmar, Minn.; Thos. J. Johnston, Schenectady, N. Y.; John F. Kelly, Pittsfield, Mass.; Chas. Edwin Knox, New York, N. Y.; John F. Macartney, London, Eng.; Robert D. McCarter, Jr., Schenectady, N. Y.; Robert McClenathen, Ithaca, N. Y.; A. Center Middleton, Schenectady, N. Y.; E. H. Mullin, New York, N. Y.; Harry Nathan Ramsey, New York, N. Y.; Geo. P. Robinson, Milwaukee, Wis.; Frank Robert Schoofield, Boston, Mass.; Chas. Ralph Sturdevant, Lexington, Ky.; S. E. Whitine, Cambridge, Mass.

The following-named associate members were transferred to membership: Henry Ackley Lardner, New York, N. Y.; Arthur E. Kennelly, Philadelphia.

The general meeting of the Institute at Boston will be held on June 25th, 27th and 28th.

Railway Telegraph Superintendents.

The Association of Railway Telegraph Superintendents, which had been holding its tenth annual convention in Wilmington, N. C., left there for Norfolk, Va., on May 18th. The association decided to hold its next annual session in Detroit on the third Wednesday of June, 1900. A feature of the convention was a successful demonstration of wireless telegraphy. Thomas A. Edison attended the convention as guest of the association. The concluding session was held in Norfolk.

EVERY SATURDAY.

CONVENTIONS AND EXPOSITIONS.

- New York Electrical Exhibition, Madison Square Garden New York, May 27th to June 3d.
International Electrical Exposition in Commemoration of Volta Cent. Ita. 7. May 22th to October 25th.
American Institute of Electrical Engineers, Boston, June 26th to 29th.
American Society of Civil Engineers, Stockton Hotel, Cape May, N. J. June 27th to 30th.
Canadian Electrical Association, Hamilton, Ont., June 25th to 29th.
Southern Telephone Association, Memphis, Tenn., July 5th.
American Association for the Advancement of Science, Columbia Ave., Chicago, 27th to 29th.
National Association of Municipal Electricians, Wilmington, Del., September 7th to 10th.
Providence Exposition of American Manufactures for Export, September 14th to November 1st.
Chicago Exposition of Electrical Arts, Tattersall's, September 25th to October 1st.
International Exposition of Manufactures, Berlin, Germany, 1897 to 1898.
American Street Railway Association, Tattersall's Chicago, October 17th to 20th.

In the report of the proceedings of the South-western association's convention at Austin, which is presented on another page, mention is made of the discrimination shown by the insurance companies against electrical interests.

A comprehensive report of the proceedings of the convention of the National Electric Light association at New York is presented in this issue, although the sessions extended beyond the regular day for going to press.

The subjects selected for discussion at the New York meeting proved to be attractive, judging from the general interest shown. It is becoming more apparent each year that the most valuable paper is the one that provokes discussion and prompts inquiry.

A correspondent of the New York Sun advances an interesting theory in explanation of the waves of prosperity and depression in the commercial world.

From years of study and observation, I am satisfied that the different waves of electricity have different effects on men's minds; and if a preponderance of bear electricity prevails, down goes the market, and the bulls lose their courage.

This correspondent does not explain the differences that are noticeable in the duration of these waves, the means through which electricity operates and the source of the power exerted.

Many who have examined the numerous types of mechanically propelled carriages which are now being introduced into general use in large cities have criticized the lack of ingenuity displayed by the builders of these vehicles.

Everything about the automobile is suggestive of the horse—the dashboard, side step and raised box, as well as the general form of the rig, being reminders of that faithful animal.

The cooling action of electric sparks has been the subject of an investigation by E. Villari, the results of which have been announced in a communication which has been summarized by the London Electrician.

It is significant that the American Society of Mechanical Engineers, at the annual meeting in Washington recently, adopted resolutions directing its members to urge upon Congress the necessity for relieving the present overcrowded condition of the Patent Office and providing sufficient room, force and facilities for the prompt and proper execution of its work.

The most pressing need of the Patent Office is additional room. With a sufficiently large building the present working force of the office would be enabled to do its work promptly.

FIRST ANNUAL CONVENTION

Of the Southwestern Gas, Electric and Street Railway Association.

[Special correspondence of the Western Electrician.]

Austin, Texas, May 20.—The Southwestern Gas, Electric and Street Railway association held its first annual convention in this city on May 17th, 18th and 19th. About 100 delegates were present, mostly from Texas. The territory embraced in the association is Texas, Louisiana, New Mexico and Mexico.

The convention held its business sessions in the parlors of the Driskill Hotel. The first day's session was called to order by President Carl F. Drake of Austin, who made a few remarks, welcoming the visitors to Austin. He was followed by Mayor John D. McCall, who made a happy welcoming speech in behalf of the citizens of Austin. The response to Mayor McCall's address of welcome was made by T. D. Miller of Dallas, Texas, on behalf of the association. This completed the exercises of the first day's session, an adjournment being taken until the following morning at 10 o'clock.

The visitors spent the afternoon in riding about the city, visiting Hyde Park and other places of interest.

SECOND DAY'S PROCEEDINGS.

The second day's business session was devoted to the reading of reports of President Drake and Secretary Wells. President Drake's report contained the following interesting statement:

There is scarcely a doubt that the rates of insurance, as they heretofore have been applied by the state board of underwriters, have in many cases been exorbitant and in some cases almost prohibitive. This we believe with proper attention could be satisfactorily adjusted. Your state Legislature appointed committees whose duty it is to investigate and pass upon many bills which are of direct interest to us. These gentlemen, while using their best judgment, are neither practical electricians nor managers of gas and street-railway plants, and in order to arrive at an honest and just verdict they must be educated. There is probably no one within the sound of my voice who is more bitterly opposed to what is known as "lobbying" than your president, but in the many years that I have lived in the capital city I have seen many cases where the legislative body was as anxious to secure information as were the interested parties to give it. We therefore think that a committee on legislation would be wise.

Secretary Wells' report reviewed the period of organization and the details connected with the consolidation of the several interests involved. He urged the members to take a personal interest in the subject of increasing the membership.

Mr. T. D. Miller of Dallas read an interesting paper on the subject of the "Science and Art in Selling Gas," which was discussed by several members.

The afternoon of the second day was enjoyably spent by the delegates and their wives in a boat ride on Lake McDonald and an inspection of the large municipal light and power plant. At night the visitors were tendered a reception and musicale at the Driskill Hotel.

THIRD DAY'S SESSION.

The following-named officers of the association, to serve during the ensuing year, were elected immediately upon the opening of the third day's session: President, T. D. Miller of Dallas, Texas.

First vice-president, J. F. Strickland of Waxahachie, Texas.

Second vice-president, C. A. Yeager of Laredo, Texas.

Third vice-president, W. E. Hamilton of Shreveport, La.

Board of directors, Carl F. Drake and Frank E. Scovill of Austin, Texas; E. Dysterud of Monterey, Mexico; Fred Fries of San Antonio, Texas; E. L. Wells of Marshall, Texas; J. C. Cullinane of Denison, Texas.

Commercial Club of that city, made an address on the subject of "Means of Encouraging Diversified Use of Electric Current."

Among the delegates in attendance were the following-named gentlemen: C. W. Hobson of Waco, G. J. Wille of Marlin, A. E. Rathbone of Victoria, A. E. Judge of Tyler, J. C. Kirby of San Antonio, W. W. Vaughan of Austin, T. F. Harwood of Gonzales, J. S. Bonner of Houston, J. F. Strickland of Waxahachie, J. L. Sale and T. D. Miller of Dallas, Fred Fries of San Antonio, L. J. Palfrey and T.

Volta was a great step in advance in electrical science, and Volta has been honored by electricians by the adoption of his name for the unit of electromotive force. Volta also invented the electrophorus, the condenser and the straw electrometer. He was born in Como in 1745 and died in the same city in 1827. He was acquainted with nearly all the scientific celebrities of his day and received many honors. Now, a century after the date of his great invention, an important electrical exhibition is held by his fellow-townsmen in his native city to do honor to his name.

For two years the preparations for this exposition, held in connection with an exhibition of the silk industry, which is of great importance in that part of Italy, have been in progress. Fig. 1, a reproduction of the beautiful poster is used to announce the event. This is really a work of art, showing intelligent symbolism, excellent draughtsmanship and charming coloring. The mechanical execution, too, is very good. As will be readily seen, one of the female figures, with the voltaic pile and the garland for the great physicist, represents Electricity; the other, with shuttle and fabric, the Silk Industry. The nation but imperfectly represents this fine piece of work.

Fig. 2, reproduced from the New York Tribune, shows the buildings of the exposition. A Como correspondent of the same journal notes that with the exceptions perhaps of the elder and younger Pliny—who were both born there—Volta is the most memorable native of Como. A statue of Volta, by the sculptor Marchesi, may be seen on the west side of the town, near the quay. It is greatly to the credit of the townsfolk of Como that they have organized and got up without governmental subsidies and entirely at their own expense this international exhibition of electricity, which will be open until the end of October.

The exhibition buildings are erected on a large square, called the Piazza d'Armi, and include the public gardens facing the Lake of Como, reaching across the little valley extending from Mount Brunate to Mount Bisbino, and opening on the north with a fine view of the Torno promontory. The exhibition inclosure comprises about 38,000 square meters, and its total area exceeds 60,000 square meters. There are eight large rectangular galleries and three halls. The center hall is circular and forms the main building of the exhibition. It contains a statue of Volta, and has no windows—the light coming in from the top through an elaborate glass-dome roof of various colors.

The scientific instruments, books and manuscripts that belonged to Volta have been collected and may be seen in the southern gallery. Another gallery contains all the portraits of Volta, together with his furniture and domestic relics. At the extremities of the two semi-circular galleries adjoining the façade two large lighthouses have been erected. Each is 40 meters in height, and is surmounted by a huge voltaic pile. One of these lighthouses is provided with an electric elevator to enable visitors to enjoy the superb view of the Lake of Como. Signor Linati, a Milanese architect, designed the exhibition buildings, which do him great credit.

The thrifty inhabitants of Como are justly proud of their electric exhibition, and in one of the rooms may be seen letters from Lord Kelvin and from Thomas A. Edison, encouraging the organizers of the exhibition and expressing graceful tributes to the memory of Volta and recognitions of the incalculable value of his researches. During the coming summer a congress of electricians will meet at the Como exhibition, and it is expected that many interesting papers will be read there, notably one by

FIG. 2. ELECTRICAL EXPOSITION AT COMO.—VIEW OF GROUNDS AND BUILDINGS

Secretary, T. H. Stuart of Waco, Texas. Treasurer, Fred Fries of San Antonio, Texas. Waco, Texas, was selected as the place for holding the next convention.

J. F. Strickland of Waxahachie, Texas, read an interesting paper on "A Model Plant under Model Management—What Both Should Be Like, Viewed From a Practical Standpoint." T. H. Stuart of Waco, Texas, contributed a paper on the subject of "Summer Attractions for Street Railways," and C. L. Wakefield of Dallas, who is president of the

Electricity and the National Exhibition of the Silk Industry at that place on May 20th. The electrical exhibition is held in commemoration of the centenary of the invention by Count Alessandro Volta of the electric pile, which was first described early in the year 1800. The pile consisted of a number of disks of zinc and an equal number of silver or copper disks. The zinc and copper plates were in contact, and each pair was separated by porous matter which was kept moist. From it currents of electricity were procured. The construction of this bat-

teroni in reference to the latest development of wireless telegraphy.

An electrical society has been formed by the members of the Young Men's Christian Association of Montreal. The members of the society are students of the class in practical electricity, presided over by Prof. L. A. Herdt of McGill University. The meetings of the electrical society are to be held monthly during the summer for discussions, excursions and visits to large electrical plants. etc

DEVELOPMENT OF THE TELEPHONE FIELD.

Multiple Switchboard for Large Exchanges.

Among the new features in telephone equipment put on the market by independent manufacturers, the new multiple switchboard of the Stromberg-Carlson system possesses a special interest for large exchange builders. The board is not of the divided-multiple type, but each operator is within reach of every subscriber's jack in the system, enabling any operator to complete every connection received in the position. This eliminates trunking or transferring connections from one operator to another, which is necessary with practically all the connections in a trunking switchboard system.

It is claimed that one-half the usual number of operators can make as many connections and give far quicker service than with the old-style board, which not only increases the efficiency of the service greatly, but also reduces the cost of operating to a minimum.

Fig. 1 shows one of the main-line signals used in the central-energy system in the multiple board and also in the regular trunking boards. The signal is controlled by the subscriber. When the receiver is taken from the subscriber's instrument the signal will automatically indicate the number. The disconnect signal is given when the subscriber replaces the receiver. The operator has no drops to restore and is not required to break into a conversation, as the connection is indicated until the subscribers replace their receivers.

For all systems outside of the central energy a drop shutter is employed in place of the visual signal, using the main part of the drop with a catch on the pin extending from the armature and the ordinary form of shutter.

Fig. 2 shows a form of ringing key used.

Fig. 3 is a bank of 20 multiple jacks. These jacks, while small and very compact, are of ample size to allow every detailed part being made strong and durable. They are made of the very best of ma-

of the arm and base has been a source of trouble in the ordinary pattern, most users finding the iron arm very unreliable to use as one conductor. The spring device in the new transmitter here described, it is claimed, makes the contact always sure, as the spring takes up the wear caused by use.

EXTENSIONS AND IMPROVEMENTS.

The Oregon Telegraph and Telephone company is taking up the proposition to connect Tigardville with its system and extending it to Progress.

The Calhoun County Telephone company of O'Hara, Ala., and the Lineville Telephone company will connect their systems. The former already has lines to Anniston, Oxanna and De Armanville.

A new telephone company has been organized at Billings, according to the Lewiston (Mont.) Argus,

the 100 shares of stock and also to include a percentage of profits. The board consulted City Collector Davis, who objected to the city becoming a shareholder in the telephone business, and the board refused to accept the mayor's advice, withdrew the ordinance, and left it with the mayor to sign or veto. The mayor declared that he would veto it.

MANUFACTURERS AND DEALERS.

The Illinois Electric company of Chicago is at work on a new telephone catalogue, which will be ready for distribution about July 1st. It says that this will be the most complete catalogue ever issued, and asks the trade to send for copies.

The Missouri River Telephone Supply company of Atchison, Kan., has arranged to represent many of the leading manufacturers of telephone apparatus. A. S. Munsell, manager of the company, has had 14 years' experience, first with Bell companies and later in the independent field, and he has built many exchanges and toll lines west of the Mississippi.

An enlargement of factory facilities has been made necessary by the rapidly growing business of the Kellogg Switchboard and Electric company of Chicago. The old shops at Highland Park are running night and day, 200 men being employed, and in spite of these efforts the company has been falling behind in its orders. A new factory at Jackson and Green streets, Chicago, has been fitted up. It consists of three floors, each 125 feet deep and 75 feet wide, with light on all sides and power. This will give the company 28,125 square feet additional floor-space. Milo G. Kellogg says that the demand for the company's apparatus has increased beyond his expectations. The company is now engaged on several large contracts.

Result of the Monopoly.

[From the Chicago Tribune.]

With the establishment and recognition of its monopoly the Bell company was in position to devote its attention to the development and improvement of the service and the extension of the busi-

A NEW TRANSMITTER.

ness. It commanded the telephone engineering and inventive ability of the country, as it afforded the only outlet for the efforts and products of the men who had been trained in this department. It is true that the telephone has had a remarkable growth, but it is also true that this advancement has been made in spite of the Bell company's policy rather than as a result of its encouragement and assistance. Never for a moment was the public permitted to forget that there was a monopoly and that the owners of it were determined to exact the last farthing. No advancement was contemplated, no extension was considered and no improvement adopted that entailed an expenditure that could not be immediately regained with profit. It was only when the old methods of exchange operation became so cumbersome and expensive as to make further increase impossible that the installation of a new system was admitted to be desirable, and even then the charges were increased so as to more than cover the expense of the new equipment.

INFORMATION WANTED.

The manager of a local exchange company in Texas writes as follows:

I am anxious to increase our revenue by interesting the country people in putting in telephones in their homes. We are at the junction of two rivers, and there are some fine farms along these rivers. We cannot afford to build the lines to all their places, though we have some lines that we can make club lines out of, by letting them bridge on them. We offer to meet the others at the corporation line, the principal trouble being to get them to build these lines. Our country is full of barb-wire fences, but I am afraid that although they might work all right in dry weather, they would not give satisfaction when it was wet. These wires are fastened to the posts with staples. If we could find some suitable material to wrap around them and then drive in the staple so as to insulate them, I think the problem would be solved. What kind of material is best adapted for this kind of work?

A California subscriber submits the following problem:

Can cross-talk be prevented on two parallel single-line grounded telephone circuits running side by side? If so, how?

Fig. 1.

Fig. 4.

Fig. 2.

Fig. 3.

MULTIPLE SWITCHBOARD FOR LARGE EXCHANGES.

terial obtainable and by the highest class of workmen, and are considered to be the finest pieces of work in this line. In a 5,000-subscriber plant, 5,000 of these multiple jacks are placed in each section, within reach of each operator, besides the regular main-line jacks.

Fig. 4 is a connecting plug.

The multiple-board system is comparatively simple in general principle, but it was found one of the most difficult problems in independent telephony to evolve a board of this kind that would be practical and reliable and also evade existing patents.

A New Transmitter.

In the accompanying cut is illustrated a new transmitter, which is said to contain a number of superior features, and which is placed on the market by the Transmitter Manufacturing company of Grottoes, Va. This company claims to be the largest manufacturer of transmitters in the United States.

The transmitter, illustrated herewith, has a compact and neat appearance. It cannot be affected by moisture, there being no carbon exposed. It is sensitive and of intense direct force. The coils are mounted in the base and are electrically soldered. The coils are very carefully constructed and encased in a wooden box. The transmitter work and finish of the instrument are of the highest grade and guaranteed. The device is especially recommended for long-distance work and will stand, it is said, the most severe tests. The transmitter cup is cast integral with the arm, affording a complete protection for the instrument. The conductor cord runs throughout the center of the arm and through the joint, which obviates the danger of being stretched from its connections. The joint

for the purpose of building a telephone line to Musselshell, crossing through Roundup, a distance of 110 miles.

J. C. Crowley is preparing to establish an independent telephone exchange in Anderson, Ind. Mr. Crowley is said to be an experienced telephone man. He is now engaged upon the preliminary work of building the circuits.

The Sunset Telephone and Telegraph company has commenced the erection of a fine building at San Jose, Cal. The cost of the building alone will be \$12,000. The building will be equipped with switchboards and other apparatus.

Salem, Mass., is the hotbed of telephone competition, and a company has been organized with Henry A. Hale of Salem as president. A hearing is to take place before the aldermen May 31st. This is the third company formed in opposition to the existing service. If granted a franchise the projectors say they will use an automatic system.

The Kinlock Telephone company of St. Louis claims to have 1,040 more paid subscribers than the Bell company. All of the Kinlock instruments are on complete metallic circuits. The company's switchboard is filled and there are 600 applications now on file in the office. An addition to the original switchboard is now being built by the Kellogg Switchboard and Electric company of Chicago.

The Street and Water Board of Jersey City recently passed an ordinance granting the privilege to the Hudson Telephone company to extend its line. The mayor insisted that the company should pay some compensation to the city, and had a conference with representatives of the company, who offered the city 100 shares of stock. The mayor requested the Street and Water Board to withdraw the ordinance and amend it to include the com-

Combined Arc Lamp and Ceiling Fan

The combination of an enclosed arc lamp and a ceiling fan, shown in the accompanying illustrations, is an ingenious and useful application of electricity to interior decoration and comfort. Its usefulness will be especially marked in restricted spaces where there is not room on the ceiling for both arcs and fans.

The motor armature, as Fig. 1 shows, runs around the upper part of the lamp. It is mounted on ball bearings and carries either two or four blades, the speed being 200 revolutions per minute for the former and 170 revolutions per minute for the latter. The blades are 22½ inches long. In winter the armature and blades may be removed, leaving only the

FIG. 1. COMBINED ARC LAMP AND CEILING FAN.

lamp (Fig 2). By the manipulation of a switch either the lamp or the fan alone may be worked, or both together. The lamp is of the long-burning, enclosed type, requiring trimming only after 150 to 200 hours. The combination is made for 110, 220 and 500 volts, and on the 110-volt circuit is said to consume only 5½ amperes with the fan running and the lamp lit. This interesting combination is made by the Interstate Electric company, Cleveland, O.

New Type of Electric Propeller Fan.

Since the B. F. Sturtevant company of Boston, Mass., entered extensively upon the manufacture of electric motors and generating sets, it has been carefully studying the problem of the manufacture of a compact, efficient and convenient type of electric ventilating fan. Exhaustive tests were made

with different types of fan wheels. The result is rendered clear by the accompanying engravings, showing one of the Sturtevant company's electric ventilating fans just put upon the market.

The fan wheel, shown attached to the motor in Fig. 1, has eight blades, rigidly attached to a spider at the center, and held in place by a hoop at the periphery at an angle of approximately 30 degrees. The angle is increased in such a manner that as the center is approached the theoretical velocity of the air remains practically constant. In other words the delivery edge is helical, and the air is picked up on the inlet edge of the blades at low velocity. When well under the influence of the blades the air is accelerated to its maximum velocity, it is claimed, with the least amount of slip. The result is said to be an extremely efficient wheel.

The motor, shown in Fig. 2, with front and rear casings removed, likewise has been the result of

careful study in the attempt to provide a light machine, entirely enclosed, and at the same time to avoid the excessive temperature which is incident to the operation of most enclosed motors. As the result, the manufacturer claims a machine capable of continuous operation for 10 hours with a maximum temperature rise of not exceeding 30 degrees Fahrenheit. A practical efficiency of over 80 per cent, is obtained even with the small-sized motors, and an excess load of 75 per cent, above the rated

FIG. 2. COMBINED ARC LAMP AND CEILING FAN.

capacity may be carried without sparking and without change of brushes. This feature, combined with the small temperature rise, allows of carrying temporary overloads with impunity. The bearings are self-oiling and self-aligning, and are fitted with phosphor-bronze sleeves which are removable from the outer ends of the boxes.

FIGS. 1 AND 2. NEW TYPE OF ELECTRIC PROPELLER FAN.

The wheel is partially enclosed within a conoidal inlet ring (Fig. 1), which decreases the frictional resistance to the entering air and furnishes at the same time a rigid support for the motor, to which it is attached by the tripod hanger.

These fans are built in sizes from 18 inches to 120 inches, with motors designed for either medium or maximum speed and to run at any ordinary direct-current voltage. A speed controller is always provided, by means of which the fan can be efficiently operated at different speeds.

Dr. Pratt Not Appreciated.

In reviewing the American X-ray Journal, Electricity of London says:

The April number of this journal is disappointing. About half the available space is taken up by a paper which Prof. H. P. Pratt, M. D., Chicago, read before the Erie railway surgeons. Almost at the outset the professor quotes from the Century Dic-

tionary—concerning the possibility of using water as a conductor for electricity. Next, somewhat in a similar way, he quotes the credit popularly ascribed to Professor Pratt for his discovery of the credit of Le. of F. Add. to the order of Pratt, which is that Dr. Pratt, in his famous paper, has shown a great deal of rot. It would be interesting to know whether he received some of the "celestial" light. He is to be congratulated to work to define the matter, referring to his own work on earth, and the water under the earth. There is the question of electricity, a permanent force, which is a part of the atom's structure of matter, and it exhibits the properties of attraction and repulsion. Next time we meet him we shall be glad to recognize it. An electric force, if it is a force of matter, is arranged to parallel, each molecule being a magnet, an equivalent of one. I have only given the best part of this second definition, as there is plenty of room for it. In fact, it is not clear that a suspended needle would not place itself at right angles to the direction of flow, but actually parallel to it. But I must not pile up the agony further. It is necessary to suppose that none of the professor's "hearses" came away under the impression that his were words of wisdom, to which he had been privileged to listen.

McCay Regulating Socket.

The layman consumer asks most naturally in relation to the incandescent lamp, "Isn't there some way to turn it down, so as not to be obliged to burn more

MCCAY REGULATING SOCKET.

light than we want? Isn't there some way to save the current and reduce our bills—some way to apply the current gradually to the lamp and thereby prevent the frequent necessity and expense of lamp renewals—some way to obtain the economy and advantages afforded us by the use of gas, without the many disadvantages of the latter?" And the central-station man with an eye to business propounds to the supply salesman the questions, "Is there no way by which we can supply private consumers with the incandescent electric light on a basis that will enable us to supplant gas and oil as illuminating agents? Is there no way by which we can render domestic electric lighting more economical, and thus open up this large and as yet undeveloped field lying within our reach? Can we not afford the consumer the same advantages and convenience held out to him by the gas companies, and in this way vastly increase the total out-

put of our station and enlarge the revenue derived from the sale of current?" The simple little socket shown in the cut, applicable to alternating-current incandescent lamps, is offered as the solution of this problem. By the use of the McCay socket the candle power of a lamp can be reduced by successive stages from its maximum brightness to a dull red glow, with a considerable saving in current and a greatly increased life of the lamp. An important point is that the amount of electrical energy required by the lamp itself varies according to the light given by it, and can be reduced from 75 watts to less than five watts. In addition to this, the life of the lamp itself is very much prolonged by reason of the gradual, instead of sudden, turning on and off of the current. The importance of these features is apparent.

This socket is manufactured by the McCay Engineering company of Baltimore, Md.

Exhibition and Convention Notes.

[Continued from page 296.]

Stanley & Patterson cigar lighters, most artistically decorated, did considerable "sparking" on their own hook and lighted cigars for convention delegates.

The Morris Arc Lamp company of Chester, Pa., placed its interests in the hands of the Manufacturers and Inventors' Electric company, its New York agent.

It was a pleasant surprise to meet Secretary and Treasurer K. H. Boslog of the Peru Manufacturing company of Peru, Ind. The Peru company is extremely busy at the present time.

The booth of the Western Electrician was decorated with samples of "Modern Advertising in the Most Progressive Electrical Journal in the United States," and attracted universal attention.

W. J. Johnston, former owner of the Electrical World, together with Mrs. Johnston, mingled with their many old friends Wednesday evening at the electrical show after the automobile parade.

Manager of Sales Scribner of the Bryant Electric company of Hartford, Conn., personally represented that concern. To all comers he told of the merits of the new Bryant socket, which he designated "simply perfection."

Ed. Grier, the western representative of the Bryant Electric company, came down with the boys from Chicago, and met Manager of Sales Scribner, who appeared on Wednesday afternoon in time for the automobile parade.

The booth of the New York Telephone company was one of the neatest displays made. This company distributed a circular adapted to interest ladies and others not familiar with the many peculiar advantages of high-class telephonic service.

It was expected that the Diehl Manufacturing company of Elizabethport, N. J., would have its fans at the electrical show, but the company is so far behind with orders that it did not feel warranted in devoting the time and labor to make a show.

Manager R. F. Ross was out with his new electrical paper, the Electrical News, Wednesday morning. Mr. Ross deserves success and starts with the best wishes of his friends. The Western Electrician wishes Mr. Ross every success in his new venture.

Luther Stieringer won praise on every side for his work. His electrical cave proved one of the most interesting attractions. Mr. Stieringer's advice, too, was followed in the festooning of the roof of the garden, and this decoration added greatly to the evening effect.

The hard-working, energetic and courteous assistant to Secretary Porter, Miss Harriet Billings, as usual won the praises of practically everyone present through her painstaking efforts to see that the details pertaining to the secretary's work were faithfully executed.

Where was President Pease of the Hart & Hege-man Manufacturing company? His New York representative, Mr. Taylor, was in evidence, and while Mr. Pease would have been warmly welcomed, he knew his business when he sent Taylor to look after his interests.

New York Manager A. H. Granger of the Orient Electric company, Youngstown, O., gave an example of the energy for which he is noted, by introducing his lamps into a great many of the electric signs used in the show. His design for his own booth was also unique.

The American Electric Specialty company of New York exhibited its direct-reading ohmmeter. This device is admirably designed to measure resistance on a rapidly moving car. Manager Saze of the American company was daily at the booth, explaining this instrument.

Franklin S. Terry of the Weston Instrument company was early at the Murray Hill Hotel Wednesday morning, mingling with his many old Chicago friends. Mr. Terry's work, since connecting himself with the Weston company, has been of a remarkably fruitful character.

The Crocker-Wheeler company of New York made an attractive exhibit. A great variety of the Crocker-Wheeler machines was shown, as well as the frame of one of the company's larger dynamos. This exhibit was really the heaviest in the entire show and did the company credit.

There was never a successful electric-light convention without Messrs. Newton and Baird of the Eddy Electric Manufacturing company of Windsor, Conn. Mr. Baird has been engaged for some months in the West and he reports a most gratifying increase in the company's business in that section.

The Phoenix Glass company of New York took advantage of the presence of so many central-station men to point to its "Catalogue Number 8." The Phoenix company is pushing many attractive forms of electric light globes and shades, adapted for use in an electric light system, both arc and incandescent.

The International Decorative and Mixture Lamp Department of Harrison, N. J., won much praise through its splendid electric-light work, distributed through the show. Few people realize the skill

required in the production of many electric signs. Manager Meadowcroft deserved much praise for his success in this branch.

Dixon Crucible company had an attractive exhibit of graphite specialties. Its lubricating materials are now so well-known that they are always of the greatest interest to the managers of electric-light plants. It is impossible to enumerate the extent of this display, but it is safe to say that every known form of graphite was there presented.

The American Electric Novelty and Manufacturing company made one of the most popular and attractive exhibits. It must have been a revelation to many ladies and gentlemen not familiar with the intricacies of decorative incandescent electric lighting to note the beautiful combination into which can be woven the tiny incandescent lamp.

Secretary Henry G. Adams, Jr., of the Phillips Insulated Wire company of Pawtucket, R. I., in company with J. H. Miller, general manager of the Springfield (O.) Light and Power company, and J. H. Watemann of the United Electric Security company of Boston, was always to be seen on Broadway immediately after the exposition.

The Electric Storage Battery company of Philadelphia made no attempt at a special exhibit, but the battery of this company was used in the Columbia automobiles. New York Manager Blizzard was on hand, and was warmly greeted by his friends from all parts of the country. Mr. Blizzard was one of the pioneers in the electric storage battery business.

The Okonite company made no exhibit beyond some very artistic advertisements in the various electrical journals. "Pick a Good Wire and Enjoy the Music" was the Okonite motto at this convention, and "the banjo," made of Okonite trademarks, played the usual pleasing tune that "never disappoints." Captain Candee and Mr. Manson were on hand.

It was rumored that Captain Frank De Ronde and Purchasing Agent Vandewater of the Standard Paint company were out during the convention with small cans of specially reddened P. & B. paint, but this cannot be vouched for as being absolutely authentic. Nevertheless, P. & B. makes its mark under all circumstances, and this case was no exception.

The Riker Electric Motor company of Brooklyn deserves credit, not only for the exceedingly handsome exhibit made at Madison Square, but also for its splendid pioneer work done in convincing the public of the great value of the electrical carriage propulsion. The company is now simply overwhelmed with orders, and a night shift is being worked.

Early after the opening of the show, President Cutter of the Cutter Electrical Manufacturing company of Philadelphia disappeared, but he turned up again in company with Mrs. Cutter during the convention, and both were warmly welcomed. Mrs. Cutter was one of the ladies who enjoyed the automobile ride on Wednesday, and also the steamboat trip Thursday.

R. B. Corey neglected his duty when he did not insist that Secretary and Treasurer Arthur Garrison of the Columbia Incandescent Lamp company of St. Louis should constitute the "moving portion" of the exhibit of the Columbia company. Mr. Garrison is, undoubtedly, a busy man, as his company is at present rushed with orders. But he will never be forgiven by his many friends for his failure to appear in New York at convention time.

Norman McCarty was constantly on hand and indefatigable in his work for Hugo Reisinger and the Diesel Motor company of America. Mr. McCarty is one of the oldest electrical salesmen in the field, and the Diesel company made a wise selection in choosing him to push its novel motor. No man in the field, it is safe to say, is better equipped to impress the power users as to the peculiar merits of what appears to be one of the greatest factors in the power-producing world.

The Keystone Electrical Instrument company of Philadelphia was represented by President J. F. Stevens, who came over on the opening day of the convention to do the honors for the Quaker City. Someone asked whether Stevens was a Quaker; but, up to date, no replies have been received. The company has recently gotten out a new instrument that is worthy the attention of all those desirous of an indicating device for current and voltage which may be located in a small space.

The Incandescent Electric Light Manipulator company, through the energetic efforts of the Messrs. Morse, gave a most entertaining exhibition on the second floor of the exposition, showing the merits of its manipulator. When one sees this tool for the first time, one cannot understand why such a thing has never been presented to lamp-users before. Messrs. Morse knew "a good thing" when they saw it, and they deserve credit for putting it into general use.

Secretary Thomas R. Mercin of the Northwestern Electrical association came down from Milwaukee, via Baltimore, where his daughter is visiting relatives of Admiral Schley. Mr. Mercin was most energetic in his work of increasing the membership of the Northwestern Electrical association. To his credit, it must not be forgotten that the Northwestern Electrical association is now able to

claim that as an association it embraces a larger number of members than even the National Electric Light association.

James Wolff, western sales agent of the New York Insulated Wire company; George Whyte of the Leschen-Macomber-Whyte company; William M. Smith, secretary and treasurer of the Chicago Insulated Wire company; W. W. Low, president of the Electric Appliance company of Chicago, and wife, formed a merry party, which took advantage of the convention and the electrical exhibition to visit New York. Mr. Wolff is an old New Yorker, and under his guidance the "tenderfoot" members were shown a few "new things."

Too much cannot be said in compliment of Manager Nathan's executive ability in handling the multitudinous details involved in so large an undertaking as the electrical show. Mr. Nathan was on hand daily and nightly; always polite, courteous, and looking to the interests of exhibitors, individually and collectively. For a number of years Mr. Nathan has held this delicate position, and filled it most successfully, winning for himself by his businesslike methods, not only the approbation of his associates, but also of the exhibitors.

If W. N. Matthews, manufacturers' agent, 312 Commercial building, St. Louis, hadn't been so exceedingly busy at home, he would have found the trip to New York a paying one, especially from the fact that Mr. Matthews is now offering a most attractive list of bargains, which he describes as being "good as new." Mr. Matthews has had wonderful success since his appearance in the field as a manufacturers' agent, no doubt due to his previous extensive experience as president of one of St. Louis' oldest and best electrical supply houses.

It was without doubt a great transformation, but the skillful manner in which Mr. Jefferson Wetzler demonstrated the beautiful phenomena of heating metal in a water bath by electricity in the booth of the Electrical Engineer Institute of Correspondence Instruction proved conclusively his fitness as the manager of an electrical correspondence school. Mr. Wetzler, as is well known, recently left the Electrical Engineer to join with his brother, Mr. Joseph Wetzler, in pushing their technical school, and he is making a great success of his new venture.

The American Impulse Wheel company of New York could not have done better than to have presented an exhibit of one of its wheels directly connected to a generator. This company is sending out a large number of wheels for mines and other electrical transmission plants. Its wheels are of high efficiency and are spoken of in the most complimentary manner wherever used. The company also manufactures small water motors for operating fans, printing presses and organs, and these motors are designed and built with the same care as the larger wheels.

One of the handsomest exhibits among the automobiles was that of the American Electric Vehicle company of Chicago, which was in charge of H. G. Osborn, engineer of the company, and C. B. Roulet. A "stanhope," a delivery wagon and a runabout buggy were shown. These vehicles have been in actual operation in Chicago for over a year. A very interesting circular was distributed, entitled "The Twentieth Century Movement." General Manager Corrigan of the company appeared during the latter part of the show and was warmly welcomed by his many friends.

The Manhattan Central Construction company seized the splendid opportunity to advertise extensively the Manhattan arc lamps. The simplicity of mechanism of this company's direct-current lamp is remarkable, as well as the unique trimming devices. The Manhattan General Construction company is meeting with great success with these lamps, and buyers will do well to secure the company's catalogue of the various styles of lamps it manufactures. President Marsh Young and Secretary Harris of the Manhattan company were on hand constantly during the convention.

The International Correspondence Schools of Scranton, Pa., made a very handsome exhibit. This institution gives a complete course by mail in electrical engineering, steam, mechanical, civil engineering, and, in fact, almost every known branch of technical work. The school was established in 1891, and the company claims on its rolls to-day as many as 45,000 students and graduates. The establishment at Scranton, with its magnificently organized equipment and course of instruction, is worth the study of anyone interested in the progress of technical education.

H. K. Gilman of the Western Electrical Supply company has not of late years been a frequenter of conventions, but this time the combined attractions of the electrical show, the national convention and a host of old friends in New York proved too much for him, and he was among the first arrivals from St. Louis. Mr. Gilman has, through his untiring efforts and businesslike policy, combined with his years of experience in the electrical business, brought the Western Electrical Supply company of St. Louis into an enviable position as one of the leading electrical supply houses of the great Southwest. Every year during the past few years has seen recorded a fine increase in the company's total business, and, at the present time, it is safe to say that

no western institution carries on its books a greater number of steady and wealthy customers and friends. The Western Electrical Supply company has recently been pushing the telephone branch of the supply business with remarkable success, and it may be stated that the company desires it known that it is in no "telephone combination or trust," but is attending strictly to its own growing business.

The Belknap Motor company of Portland, Me., took advantage of the electrical show to explain the merits of the Chapman voltage regulator for alternating or direct-current systems. This device insures steady lights in spite of changing speed and varying loads. It compensates for line loss and automatically keeps a constant voltage at any chosen center of distribution, however distant. The regulator is sent on 30 days' trial. The Belknap Motor company also manufactures water motors, woven-wire brushes, coffee mills, with electric and water-motor attachment.

It was a matter of regret that no one came East from the Central Electric company of Chicago. President George A. McKinlock was expected daily, as was also Secretary Charles Brown. The Central Electric company, however, is exceedingly busy at the present time, and the trade will be interested to know that it has recently secured the western agency of the high-grade machinery manufactured by the Bullock Electric Manufacturing company of Cincinnati. The Bullock company itself was represented at the show by Messrs. Bullock and Lozier, assisted by an efficient corps of lieutenants.

Of course R. Edwards, Jr., of Edwards & Co., New York, was on hand every moment of the time. Mr. Edwards, or, in army parlance, "Captain Edwards of the Eighth New York," is the man described by his friends as he "who fit and bled and did everything but die" at Chickamauga Park. Mr. Edwards did bring home with him a large amount of malaria, which he has never been able to shake off. Edwards & Co. issued a most attractive and comprehensive catalogue, which can be had for the asking; but, to quote Captain Edwards' own words, "if you don't send for it, you don't get it."

Where was Manager Kulp of the Marietta Manufacturing company of Marietta, Pa.? Mr. Kulp had intended to visit the electrical exhibition, but perhaps he was "lost in New York." The Marietta Manufacturing company is now so busy turning out the Kulp Crescent fans that he may have been detained in Marietta through pressure of business. It is said that 2,500 of these fans were recently shipped to St. Louis to the company's exclusive western agents, A. Riemann & Co. As a number of these fans will be kept in stock at 817 Market street, those having rush orders will know where to get a quick shipment of a Crescent fan.

Automobile companies were well represented, but none made a better showing than the Columbia Automobile company, whose exceptionally handsome display was in charge of J. M. Hill, manager of the company's New York office. It was interesting to note the care with which the vehicles were examined. Mr. Hill stated to a Western Electrician representative that he had to admit his surprise at the interest shown and the great number of orders booked. Manager Goodrich of the Hartford office of the company was also on hand during the exposition, and his courtesy to all interested in automobiles made many new friends for the Columbia company.

The popular New York manufacturers' agent, R. B. Corey, was, of course, on hand at all times, and, in company with H. B. Kirkland, did the honors for the American Circular Loom company of Chelsea, Mass. The company's exhibit consisted of samples of its electroduct in the form of a pyramidal coil of tubing, the largest sized duct beginning at the bottom, the coil gradually changing through smaller diameters as the apex of the pyramid is approached. The circular pyramid is about four feet high and stands on a square platform. At the back of the booth is displayed the trademark of the company, over which is an illuminated sign bearing the word "electroduct."

"Varley," of duplex-magnet fame, had given his solemn pledge to appear during the convention, and he may have done so; but his proverbial modesty, perhaps, kept him in the background. The Varley company is now enlarging its factory. Its business has expanded to a most remarkable extent, due, no doubt, to the phenomenal increase in the sale of telephonic apparatus of all sorts. The Varley company's special machinery for the production of its remarkable product, the duplex magnet, puts it in a position to command an enormous share of the trade in magnet coils in the United States. A magnifying glass used on a "duplex" coil reveals a most wonderful magnetic and electrical production.

Sterling arc lamps, manufactured by the Sterling Arc Lamp company of New York, as usual, made their mark. As is now quite generally known, the Sterling Arc Lamp company has placed its western agency in the hands of Messrs. Gates & Randolph of Chicago. Messrs. Gates & Randolph have warehouses in Chicago, where buyers are at all times furnished with facilities for testing the merits of the Sterling enclosed arc lamps for all circuits. Messrs. Gates & Randolph were missed at the convention. It had been hoped by Mr. Randolph's many New York friends particularly that he would remain over, but his new business ar-

range in Chicago necessitated his immediate procedure to that point.

Reflectors are now so extensively used in connection with electric lighting that the exhibit in charge of Frank Stout caught the eye of numerous visitors. The Frink window reflector, which is so extensively used in store windows, cluster reflectors and a general line of flat and cone shades was shown. A special feature of the exhibit was the ceiling light at the back of the booth. This light has a brass corona handsomely finished in polished brass, and is particularly suited for banks, offices and public buildings, stores and general use. It has a cluster of five lamps, at the center of which is a stalactite. Along the back of the booth were electric fixtures, the lamps of which are shaded by silk flowers, which gives a very pretty effect at night.

Machado & Roller of New York, general selling agents for the Whitney Electrical Instrument company, presented the Whitney glass-case switch-board machines for high-tension alternating current, extremely well adapted for high-tension work. The transformer type of alternating-current ammeter, also exhibited, whereby the heaviest current may be taken care of without difficulty and the instruments placed at any desired distance from the main buses without additional cost, is also of interest. Machado & Roller report that the dead-beat qualities of these goods resulted in making them favorites for electrolytic and other work where load fluctuations are so violent that the needle on the ordinary type of instruments would soon be broken.

From the attention that has been paid President Samuel Insull of the Chicago Edison company by the daily papers of recent date it is perfectly clear why he did not venture to visit the electrical show and participate in the gayeties of the National convention. Messrs. Ferguson and Holmes of the Chicago Edison company were in constant attendance at the meetings of the association. Mr. Ferguson, who has entire charge of the electrical engineering work of the Chicago Edison company, is looked upon as one of the brightest lights in the electrical engineering field. Mr. Holmes, of the supply department, found many old friends in New York, and was indefatigable in looking after the interests of the Chicago Edison company.

One of the most beautiful booths, among those arranged by the manufacturers of wires and cables, was that provided by General Manager Leonard F. Regua of the Safety Insulated Wire and Cable company of New York. Mr. Regua's designs for the electric-light effects, colors appearing and vanishing, and to tell the merits of Safety cables, attracted a great deal of attention. In fact, one could not pass this booth without reading the story of the "Safety seamless rubber-covered wire and cables." The Safety company recently made for the United States seamless rubber-covered wire and cables, Manila to the extent of 680 miles. The company is now manufacturing for the Metropolitan Street Railway company of New York over \$500,000 worth of rubber-covered and lead-encased feeder cable.

Gerald Hart, designer of the well-known Hart switches, took the opportunity to announce a new line of Diamond H push switches with pure mica insulation. Mr. Hart is the prime mover in the Hart Manufacturing company of Hartford, Conn. Up to a comparatively short time ago Mr. Hart was connected with the Hart & Hegeman company of Hartford, Conn., but he recently decided to organize a company of his own. It is Mr. Hart's purpose to make a number of improvements in switches, and produce a switch that is "right in every particular." In order to appreciate the new switches and fully understand what Mr. Hart means by pure mica insulation, one should possess a sample of this beautiful little mechanism. A mica washer of brushing of most ingenious construction has been introduced.

It is a matter of great regret that Manager Arthur Warren of the advertising department of the Westinghouse Electric and Manufacturing company of Pittsburgh could not have been on hand during the convention and exhibition. Mr. Warren had only returned recently from abroad in the interests of the Westinghouse company, and he was compelled, through pressure of urgent business, again to make a trip to Europe, where he is at the present time. Mr. Warren, in addition to handling the vast advertising interests of the several Westinghouse companies, does a great deal of special executive work. His extensive experience as a daily newspaper man has fitted him for his present responsible position, and, in addition to all this, he knows how to make friends for his company and hold them.

Where was General Manager Scoville of the Bossert Electrical Construction company of Utica, N. Y.? To be sure, Mr. Scoville was ably represented by R. B. Corey, but there were, nevertheless, many inquiries for the courteous president of the Bossert company. Mr. Corey made a display of the Bossert company's outlet, cut-out, switch, main-distribution and branch-circuit boxes, also steel panel boards lined with slate. These boxes are reinforced by malleable-iron legs, which also serve as a means of attaching the box to the wall. The Bossert company manufactures these boxes with the inside work complete, designed for any number or arrangement of circuits, with or without switches, and for either two or three-wire systems. These boxes are pro-

vided with plate-glass door set in a high, polished brass frame and fitted with lock and key.

The Dale company made an exhibit of a general line of fixture and operate, the most important feature being an arc lamp designed to burn on either alternating or direct current. This lamp is of the open-arc type and is known as Dale's pendant arc. It possesses the particular feature of economy, burning 100 hours on an average of 4 1/2 amperes and giving a brilliant and steady light of 1,200 candle power. It strikes the arc without pumping and burns at any angle, thus making it especially suitable for marine work. The lamp is claimed to be the simplest on the market, and has fewer parts than any. It weighs but 12 1/2 pounds and is 28 inches long. The company also displayed a complete line of desk portables, electric and combination chandeliers and brackets. The porcelain multiple receptacle requires no sockets, wiring, shade holder or insulating joint, and cannot be short-circuited. President J. H. Dale designed the booth.

John A. Roebbling's Sons company of Trenton, N. J., was, as usual, well represented. The exhibit included bare wires of all kinds in copper, from the largest trolley wire down to No. 36 gauge; office and magnet wires in great variety, electric-light cord, etc. The display included several 300-pound copper ingots, each of which contains enough material for 75 miles of No. 36 wire; samples of the latest Commercial cable, comprising the large shore ends, the intermediate sections and, finally, the deep-sea section. The conductor for this cable was furnished by the Roebbling company. An object of interest to railway men was the splice of the large three-phase cable for the Metropolitan Street Railway company. Another popular attraction was some pieces of the wire rigging of the steamer "Merimac," which was sunk by Hobson in Santiago harbor. R. M. Cockey, A. M. Whitaker, G. W. Swan and F. W. Harrington were constantly on hand, as was also Manager H. L. Shippy.

The Stanley Electric Manufacturing company of Pittsfield, Mass., has long since won an enviable reputation for its high-tension electrical apparatus, and its very interesting and complete exhibit of instruments attracted well-deserved attention. This display included the Stanley static voltmeters, static ground detectors, alternating and direct-current hot-wire ammeters and voltmeters, portable ammeters and voltmeters for both kinds of current, high-potential switches, lightning arresters, live cut-outs and fuse blocks, circuit breakers for alternating current and transformers. The latest types of these standard and well-known instruments are well displayed in a booth on the main aisle under charge of Mr. Barr. A special feature of the exhibit consisted in the new portable and station voltmeters. These instruments are compensated for all variations in temperature, are dead-beat and extremely accurate, being guaranteed to be within one-half of one per cent. in the portable type and within one per cent. in the station type. In addition to this they are capable of universal use, being adapted for service on direct or alternating currents of any frequency or wave form. Another good feature of these instruments is their flexibility.

Right down in the nest of automobiles, at the center of the main floor, was the handsome exhibit of the Woods Moto-vehicle company of Chicago, opening on four aisles, and containing several handsome automobiles. The leading features were the hansom cab with motor on the rear axle, the road-wagon with top, the stanhope, the brake, the park-trap and the coach-delivery wagon. The park-trap shown is that owned by Mr. Samuel Insull, in whose service in Chicago it has made over 8,000 miles. On these vehicles there are two independent motors for driving, dust and waterproof, with rawhide pinions. The front axle has steering knuckles and arms with ball bearings made to turn at an angle of 45 degrees. The running gear and axles are made of solid metal, and the wheels are rubber-tired with ball bearings. The brake is operated by the same lever that works the controller, and three speeds are obtained. The removal of a key from the reversing switch locks the vehicle when not in use. The batteries are sealed in hard-rubber cells. The running capacity is given at from 50 to 75 miles per day subject to charging facilities and duplication of battery. It was a matter of great regret that Designer Woods could not attend the show and convention, but I. H. Kuhl, who was in charge of the exhibit, did the honors in royal style.

Martin J. Insull of the General Incandescent Arc Light company of New York selected one of the most prominent locations for an exhibit in the garden. The moment one entered the building he was instantly confronted by the exceedingly handsome exhibit of this company, including goods made by the "G. I." company for itself and allied interests, such as the Wright Discount Meter company, the Paragon Fan and Motor company, the New York Electric Equipment company and the Chicago Rheostat company. A full line of direct-current and alternating-current arc lamps, plain type and interior or enclosed arcs for 110 and 220-volt circuits; standard knife switches, quick-break railway switches, new automatic knife switches, tablet and distribution boards, Paragon desk, bracket and ceiling fan motors, all of the 180 model; "G. I." incandescent lamp, Wright discount meters in operation, Hoyt discount meters in operation, Chicago Rheostat

company's rheostats, outlet boxes, flush receptacles; "G. I." flush switches, Molendo hooks and receptacles, and "G. I." underground apparatus (Tailleur patents) was shown. It will be seen that, excepting generating apparatus the exhibit covered a remarkably wide range of devices, appliances, fixtures and material. Mr. Insull was assisted by Messrs. Kruesie and Ritchie and other employes of Mr. Insull's several companies.

A device with merit, one that saves money for the purchaser, sells readily; and for this reason the McCay regulating socket for alternating incandescent lamps is meeting with a most flattering success at the New York Electrical Exhibition. This device, illustrated elsewhere in this issue, enables the consumer to raise and lower the light just as can be done with gas, and at the same time only use current in proportion to light obtained. Roughly speaking, the watts consumed can be reduced from, say, 50, down to five, thus lowering cost, according as the light is employed to a greater or less extent. The McCay Engineering company of Baltimore, which is manufacturing this socket, is one of the oldest and most experienced concerns in the Middle South engineering field. As an example of the high class of work done by the McCay company, it may be said that recent contracts undertaken are as follows: New Maryland penitentiary, 2,500 lights plant; Mount Royal pumping station, 500 lights; new Baltimore City College, 800 lights; Loyola College, 600 lights. The McCay company is also enlarging the electric-light and power plant of the Norfolk navy yard to the extent of an increase of the capacity of 6,000 lights; Crocker-Wheeler generators will be used. Incidentally it may be said that President H. Kent McCay of the company was formerly an officer in the United States navy, and resigned, as was the case with so many others, to enter the more promising electrical field.

Prindle Pump company of New York, hydraulic engineer and contractor for complete installation and centrifugal-pumping machinery, presented an exhibit conspicuous on account of the high lift to which one of the pumps is operating. A two-inch pump is discharging over 100 gallons per minute against a head of 60 feet, and is direct-connected to a $7\frac{1}{2}$ horse power Lundell motor. The company also had running a five-inch pump, direct-connected to a $7\frac{1}{2}$ horse power General Electric motor, and a six-inch pump, similarly driven by a horse power Westinghouse alternating-current inductor motor. These are designed for moderate lifts, and are suitable for a great variety of purposes, such as sewage disposal, irrigation, circulation for condensing and general factory service. The exhibit also included a vertical engine, direct-connected to a six-inch pump; also several belted pumps for dredging and other purposes. These pumps can be operated by any motive power, and can be depended upon for high efficiency at high as well as low lifts. Centrifugal pumps are especially adapted for use where large volumes of water are handled and where there is any solid or gritty matter suspended in the water to be pumped, as in sewage disposal or coffer-dam work. Among other large works, the Prindle company is just completing a pumping plant for the filtration of a portion of the water supply of the city of Albany, which is a model of its kind. The gentlemen in charge were Mr. Prindle and Electrical Engineer Arthur S. Ives.

The exhibit of the Wagner Electric Manufacturing company of St. Louis offered several attractions in specialties for the central-station managers who are trying to improve their day load. It comprised a $7\frac{1}{2}$ horse power 60-cycle 110-volt single-phase alternating-current motor, operating a six-kilowatt 110-volt direct-current generator. Current is taken from this generator through a switchboard on which are mounted direct-current voltmeters and ammeters and alternating-current ammeters and voltmeters, and indicating wattmeter for registering the current, which is supplied to an exhaust fan, electrically driven by a 110-volt motor. As evidence of the many uses to which the motors have been placed, a three horse power 60-cycle 110-volt single-phase motor is belted to a ventilating fan. The new type of switchboard instruments and the new switches which are about to be placed upon the market comprised another feature. As high-tension transmission transformers of large units and high potential are now in such demand for transmission of currents, reduction of ores, etc., the Wagner company presented a case of one of their high-tension transformers. A full line of standard lighting and motor transformer was also shown. A lot of well-illustrated views of 2,000 horse power transformers, the largest unit in the world, with photographs of switchboard and special-testing apparatus, proved interesting to visitors. The usual "Wagner corps" was on hand—Herbert A. Wagner and E. H. Abadie of St. Louis, John Mustard of Philadelphia, A. H. Maynard of New York and H. C. Buck of Boston.

One of the most interesting exhibits at the electrical fair to the scientist, the layman interested in scientific products, and the simple admirer of artistic display was the display of platinum and its application in the art made by Baker & Co. of Newark, N. J. A most perfect opportunity is given the visitor to observe the general uses made of this metal. In the small space of a few feet, artistically decorated in blue and white within a modest-sized show-case, an exhibit of many thousand dollars' worth of

platinum in the many forms given to it between the state of crude ore and the finished article of commerce. Samples of crude platinum sand and nuggets, from all parts of the world, including the largest nugget ever found in this hemisphere, are shown in an attractive form, together with many specimens of the associated metals of this group, such as iridium, palladium, rhodium, osmium, ruthenium and osmium. Grouped about these are many samples of the salts of these metals, exhibiting a beauty and variety of color and crystalline form. There are also many samples of platinum apparatus, such as are used by chemists, dentists, jewelers, electricians and incandescent-lamp manufacturers. Forming an interesting part of the exhibit are four cylindrical rods of pure gold, silver, platinum and aluminum of equal size, which are shown as illustrations of the relative weight and value of these metals. From the card attached it is seen that the gold weighs 10.19 ounces and is worth \$210; the silver 5.55 ounces, and \$3.50; the platinum 11.34 ounces, and \$196, and the aluminum 1.37 ounces, and nine cents. If one lifts first the platinum rod and then the aluminum, the difference in weight is almost startling. The walls of the booth are adorned with fine illustrations of the photographic art upon platinum paper. Taken all in all, this exhibit appeals strongly to the lover of artistic display and the seeker after knowledge.

The Cling-surface Manufacturing company of Buffalo, N. Y., was represented by Manager Albert B. Young and his electrical engineer, Mr. Foster. The company claimed that an average of 40 per cent. more power can be transmitted by a belt treated with cling-surface than with one not so treated. This is done by means of machines arranged in the following manner: A direct-current $7\frac{1}{2}$ horse power 110-volt motor, running at 750 revolutions per minute, drives, by means of two four-inch belts on its one pulley, two $\frac{3}{4}$ -kilowatt 125-volt multipolar dynamos, each running at 1,000 revolutions per minute. Thus the two dynamos, being of the same capacity and deriving their power from the same source, enable a comparison of the performance of the two belts, which are of the same size, and made from the same piece of leather. The tension on the belts is obtained by means of heavy spring scales, pulling at the back of the machines. The belt treated with cling-surface has a tension of 115 pounds, while that without cling-surface pulls on its machine with a tension of 200 pounds. The cling-surface belt runs slack, while the other one runs tight, and the slackness of the former belt may be varied within a considerable range with but little effect on the lamps. A similar variation in the tension on the tight belt, however, produces a marked change in the light. Tests are made to show that there is no slip on the cling-surface belt, while on the other there is constant slippage. It is claimed that belts treated with cling-surface do not slip, and that they will transmit power up to their breaking limit. In this exhibit the loose belt does twice the work of the tight belt, thus demonstrating the advantage to be gained by the use of cling-surface. The load on the machines consists of two lamp signs at the back of the booth, reading: "Without Cling-Surface" and "With Cling-Surface." These two signs enable a comparison of the results of using treated and untreated belts. A belt treated with cling-surface clings to the belted surface of the pulley rather than sticks to it in much the same way as a moist hand clings, but does not stick.

CORRESPONDENCE.

New York Notes.

New York, May 22.—Governor Roosevelt has called a special session of the Legislature to amend the Ford franchise-tax bill. It will meet to-day. The governor will probably suggest that the making of assessments on franchises be left with the state authorities rather than vested in local boards. Thus equity between franchises in different localities in the state will be preserved. The governor is also in favor of a provision that from the new franchise tax there shall be deducted the tax as now paid by the corporation.

Export night brought together at the electrical show in Madison Square Garden a large number of consular representatives of foreign countries and manufacturers. Shortly after nine o'clock the visitors were escorted through the exhibition by a committee of the exhibitors of which H. L. Shippy was chairman. Many new inventions intended for the foreign market were displayed. Nearly all the European and South American countries were represented by consuls in the party.

Mayor Van Wyck says that he expects to see a rapid-transit tunnel started during his term of office. Labor people are demanding that the city build the tunnel under existing law. Other tunnel schemes are coming up in addition to the north-and-south proposition for the borough of Manhattan that has been under consideration for years. The Manhattan Tunnel Railway company was incorporated on Wednesday in Albany with a capital of \$10,000, which may be increased to an unlimited amount. The corporation, it is stated, is to construct a sub-surface or tunnel railroad of standard gauge for the transportation of passengers and freight. The road is to have one terminus "on the

west side of the borough of Manhattan somewhere below Canal street." From there it will be run through an underground tunnel to the shore line of the Hudson River, going thence by tunnel under the Hudson to some terminus in Jersey City. The directors are Frederick Martin Lande, Charles S. Bradley, William E. Knight, Arthur P. Knight, William A. Courtland, John P. Laffin and David J. Newland of New York city, James V. Hulse of Brooklyn and Philip W. Hall of Cranford, N. J. Another plan is that of the New York and Brooklyn Railroad company, of which Emerson McMillin is president. This company proposes to build a tunnel under the East River from Park row and Ann street to Willoughby and Adams streets, Brooklyn. In addition to Mr. McMillin, the directors of the company are Silas B. Dutcher, Philip Lehman, Isidor Wormser, Jr., Frederick B. Esler and Henry M. Hutchinson. The secretary of the company, which was incorporated in 1896 and now has a resolution to perfect its franchise rights pending in the Municipal Assembly, is D. F. Bouthirt.

The work of equipping the Coney Island branch of the Brooklyn Rapid Transit company's elevated road with electric power is being pushed along rapidly, and although it was intended to operate the line by electricity on Decoration Day, this has been found to be impossible. It is said at the company's offices, however, that the new power will be in use by June 9th.

It is reported that the Third Avenue Railroad company will soon issue about \$20,000,000 additional stock to raise money to pay for the electrical equipment and for other purposes.

Twelve air-power cars for cross-town street-car service on the Metropolitan lines have been fitted up and are running on Twenty-third street at night. Each car is said to weigh 17,200 pounds. The air-compressing plant is at the company's shops at Twenty-fourth street and Eleventh avenue. The new cars are intended for use on the Twenty-eighth and Twenty-ninth street cross-town line, but until the tracks of that line are considerably strengthened the cars will not be set at their regular work there. M. S.

PERSONAL.

Marconi was entertained at dinner by John Henninger Heaton, M. P. for Canterbury, in the dining rooms of the House of Commons, on May 9th.

Dr. S. P. Langley of the Smithsonian Institution and Professor A. A. Michelson of the University of Chicago were elected honorary members of the Royal Institution of Great Britain at the distribution of honors in commemoration of the centenary of the institution.

Dr. J. M. Scott of Philadelphia, who is interested in William Morrison's new electro-mechanical system of vehicle propulsion, was in Chicago early in the week. Dr. Scott is extending his western trip to Colorado and Mexico, and will return East by way of Chicago in a few weeks.

Mr. Frank G. Bolles has accepted the management of the advertising department of the Bullock Electric Manufacturing company of Cincinnati. Mr. Bolles is a capable and experienced man in his department. He was for some time connected with the advertising bureau of the Westinghouse companies.

Mr. E. E. Keller, the vice-president and general manager of the Westinghouse Machine company of Pittsburg, was a Chicago visitor early in the week. Mr. Keller says that the volume of business in the Westinghouse shops is very large, and that the prospects of a good trade, both domestic and foreign, for some time to come, are excellent.

Albert Lynn Lawrence, after an association of several years with the patent-law firm of Barton & Brown, Chicago, announces that he has taken offices for the practice of law at 1445 Monadnock building, Chicago, devoting himself particularly to patent, trade-mark and copyright litigation and to the soliciting of United States and foreign patents.

Messrs. J. J. Wood and F. S. Hunting of the Fort Wayne Electric Works were in Chicago on Saturday and Sunday last, conferring with Mr. Charles Munson, the Chicago manager. They are confident that the business of the Fort Wayne factory has a great future. Plenty of orders are now on hand; a full force of men is employed, and all hands are imbued with energy and enthusiasm.

Announcement is made of the marriage of Mr. Samuel Insull of Chicago and Miss Margaret Anna Bird at the residence of the bride's mother in New York on May 23d. The Rev. James Millard Phillpott, pastor of the Lenox Avenue Union Church of the Disciples of Christ, officiated. It is understood that Mr. and Mrs. Insull will make a wedding journey to Europe, returning finally to Chicago, where they will live. The engagement of Mr. Insull and Miss Bird was announced last week, and Mr. Insull was overwhelmed with congratulations by his Chicago friends.

Henry L. Doherty, the president of the Northwestern Electrical association, is nothing if not versatile. It seems that he is now projecting his scientific thought along the line of experiments with the X-ray to kill disease germs, collaborating therein with a Milwaukee physician. The fact came out in

a brief interview that a reporter for the New York Tribune secured from Dr. Doherty during the convention of the electric-light men.

Professor Alfred E. Phillips of Columbia City, Ind., has been selected as the head of the new department of civil engineering in the Armour Institute of Chicago, of which he will take charge in September. Professor Phillips is a graduate of Union College, Schenectady, N. Y., where he took the degree of Ph. D. He afterward filled the chair of civil engineering in Purdue University, and was professor of hydraulic and bridge engineering in the University of Wisconsin.

Professor Thomas C. Roney, dean of the faculty of the Armour Institute of Technology of Chicago, died on May 20th. He was a graduate of the old Chicago University and a well-known instructor. Professor Roney was born in New Jersey in 1856. In 1883 he was married at Burlington, Ia., to Miss Sadie Newman, daughter of Judge T. W. Newman. His wife and three children survive him, also four brothers. These are William R. Roney of the firm of Westinghouse, Church, Kerr & Co., Pittsburgh Pa.; Charles J. Roney, former secretary of the Western Society of Engineers; Frank B. Roney of Denver, and Professor Henry B. Roney, the Chicago organist and concert manager.

A correspondent of the London Chronicle is reminded of an incident connected with the life of Faraday that has not, he believes, yet appeared in print. Lord Melbourne once announced to Faraday that it was his pleasing duty to offer him a pension, but, he added, "I suppose all this science is humbug." Faraday at once replied: "If that is your opinion, my lord, I decline the pension," and retired. Melbourne, on meeting some of his colleagues, said: "I have had a strange thing happen; a man has declined a pension." But these gentlemen knew Faraday's position and reputation better than the premier, and urged him to rectify the blunder. Faraday was again interviewed, but Melbourne was obliged to retract and apologize before the pension was accepted.

ELECTRIC RAILWAYS.

H. F. Atwood, secretary of the Rochester German Insurance company, has been appointed receiver of the Rochester and Irondequoit Railway company. The application was made by the Rochester Trust and Safe Deposit company to foreclose a \$500,000 mortgage given by that company to secure the payment of 5 per cent. bonds, in which default of interest has been made since April, 1898. The company owned a steam and trolley road, which was leased in April, 1898, for 10 years to the Rochester Railway company.

ELECTRIC VEHICLES.

And still they come! The Electric Automobile and Manufacturing company, with an authorized capital of \$500,000, was incorporated in New Jersey on May 17th. The company is empowered to manufacture and operate vehicles propelled by electricity or other power. The incorporators are Charles P. Scott of New York and Frederick W. Gaston and Edgar J. Runyon of Elizabeth.

Companies desiring to operate horseless-carriage lines for hire on the park boulevards of Chicago have a hard time. The South Park commissioners have refused to sanction such projects, and now automobile lines have been barred from the West Side boulevards and parks by the West Park commissioners. The Suburban Electric Carriage company offered to pay two per cent. of the profits for permission to run a line of automobiles from downtown to Garfield Park by way of the boulevards and another making the circuit of the parks. The proposition was rejected.

General Greely, chief signal officer of the United States army, has invited proposals for furnishing the army with three electric carriages, with which some interesting experiments will be conducted near Washington. It is General Greely's idea that the vehicles can be used for paying out a wire and promptly connecting two points between which communication is desired. At present it is necessary to load instruments into a wagon or on a horse and send them to their destination. This experiment is said to be one of a number that will be made to ascertain to what uses a horseless carriage can be put by the Signal Service.

Seventeen electric-vehicle transportation companies were incorporated in New Jersey on May 19th. These companies were formed by the Whitney-Elkins-Widener syndicate to operate automobiles in different states. Each concern has an authorized capital of \$100,000, except the one formed for the District of Columbia, which has an authorized capital of \$6,000,000. Except in this latter case, the amount of capital named in the certificate is nominal, and will probably be increased later. The incorporators in each case are James E. Hayes, a Jersey City lawyer, and clerks in his office. The states for which these companies are formed are Tennessee, Georgia, Ohio, Kentucky, New Jersey, Louisiana, Delaware, California, Michigan, Minnesota, Iowa, Maryland, Wisconsin, Indiana, Missouri, Virginia and the District of Columbia. A member of the parent organization said that a company would be planted in every state and territory of the Union, and that ultimately the

enterprise would be extended to Canada, Mexico, Cuba, South America and Europe.

INDUSTRIAL COMBINATIONS.

It was announced authoritatively in Boston last week that the consolidation of 33 electric street railways and electric-light companies in Massachusetts and Rhode Island will be made on June 1st. The company will be known as the Massachusetts Electric company. The concern will be a voluntary association, it is said, and will not be incorporated. The capitalization will be not less than \$24,000,000, one-half 4 per cent. cumulative preferred stock and one-half common. The stock of the new company will shortly be offered for public subscription at 105 for the preferred stock, each share of which will carry one-half share of common stock as a bonus. The stock has been underwritten. The new stock will be exempt from taxation in Massachusetts. The following is a list of the names of the companies which will be taken over: Lowell, Lawrence and Haverhill; Reading and Lowell, Lowell and Suburban, Rockport street railways, Nashua street railway, Gloucester street railway, Gloucester and Rockport, Gloucester, Essex and Beverly; Lynn and Boston, Milton and Brockton; Braintree street railways, Wakefield and Stoneham, Woburn street railways, West Roxbury and Roslindale and Needham and Boston, Norfolk Central, Norfolk Suburban, Boston, Milton and Brockton; Brockton street railway, Brockton and East Bridgewater, Brockton Bridgewater and Taunton; Quincy and Boston, Taunton street railways, Dighton, Somerset and Swansea; Providence and Taunton, Globe street railway (Fall River), Newport and Fall River, Newport street railway, Newport Illuminating company, Hyde Park Electric Light company.

PUBLICATIONS.

The Vindex Electric company of Chicago issues a neat little catalogue, in green and black, showing its '99 type of transformer. The instruments are carefully described and illustrated. Technical data and prices are given, and the closing pages are devoted to testimonials.

The front cover of the new catalogue of the Fischer Equipment company of Chicago shows a string of electric cabs and carriages, and the brochure bears the appropriate title, "In the Line of Progress." The catalogue is very handsomely illustrated and gives the desired information about the Woods motor-vehicles in compact form. A noteworthy feature is the large variety of electric carriages and wagons shown. One statement, relating to the capacity of the factory, contains an allusion of curious interest: "Our facilities for both regular and specialized work are large, and are being rapidly increased by the demand, though our plant has not yet attained the dimensions of that foreign factory in our line, where a recent suit for working overtime brought out the fact that they employ 100,000 hands!"

Circular No. 50 of the Electric Storage Battery company of Philadelphia describes the installation of accumulators in the Criminal Court building, New York. The generators in this plant run from 10 to 12 hours each day, during which time their load is practically uniform. This result is due to the fact that the battery is charging during these hours at a rate inversely proportional to the lighting load which the system is carrying at the same time. Usually, this uniform load is just sufficient for one generator, thus insuring a maximum efficiency of the plant, and in event of a temporary overload, the battery can be discharged in parallel with the generator to assist it over the peak. During the remainder of the 24 hours the battery carries the entire load, effecting a considerable saving in the labor and fuel accounts and acting as a reserve in case of accident to the steam or generating plant.

MISCELLANEOUS.

The Treasury Department has instructed the collector of customs at New York, that, on the exportation of electric-elevator engines complete, manufactured by the Otis Elevator company of New York, the motors of which are imported, and the winding machinery and bedplates or other parts required to make a complete mechanism are of domestic manufacture, a drawback will be allowed equal in amount to the duty paid on the imported motors so used, less the legal deduction of one per cent.

Within the last week or so electrical storms have been reported from all parts of the Atlantic coast and middle western states. A Baltimore dispatch of May 18th says: "Maryland from the mountains to the sea has been swept the last 48 hours by terrific rain, hail and electrical storms. Telephone service, trolley wires, cables and other electrical apparatus have been damaged by the unusually severe disturbances. Four persons and a considerable number of cows and horses have been killed by lightning, and a dozen or more people severely shocked." Deaths, casualties and fires are also reported from lightning in other localities.

A recent Boston dispatch says: "The Boston Elevated Railroad company has just received a consignment of 300 tons of steel guard rails from London, to be used on its new structure. General Ran-

croft, the general manager of the company, said that he had made every effort to place the order with some American firm, but that when he went into the market he found that competition in the particular rails (which are used as curves and weigh about 160 pounds to the yard) had been estimated and that he would have to pay the price established by the trust producing them if he was to use American-made rail. The price he considered exorbitant and he invited quotations from English sources. As a result the contract was given to Dick, Kerr & Co. of London at a price considerably under that made by the domestic mills, and which, when the rail being landed here duty paid at a rate of perhaps 25 per cent. over the price asked by the domestic concerns."

TRADE NEWS.

The New England Zinc company, with an authorized capital of \$1,000,000, filed articles of incorporation at Trenton, N. J. on May 19th.

The city clerk of Falls City, Nebraska will receive bids, until June 12th, for the equipment necessary for the proposed lighting plant for that town.

On Saturdays, from May 1st to the last of October, the Western Electric company, Chicago, closes its shipping room, store and factory at noon, and its offices at one o'clock.

The Central Electric company, Chicago, is exceedingly gratified with the results of its agency for the Bullock generators and motors. The applicability and reliability of the Bullock motors in driving printing presses is shown by both commendation and inquiry.

The Perret Storage Battery company of New York, with capital of \$100,000, was incorporated in New York state on May 20th. The directors are Frank A. Perret and Robert R. Clayton of Brooklyn, Omri F. Hibbard, J. Lester Kornicker and Walter I. McCoy of New York.

William M. Porter, manufacturers' agent, 708 Hammond building, Detroit, is handling the dynamos and motors of the Northern Electrical Manufacturing company of Madison, Wis., and will also sell electric vehicles. He will be glad to hear from manufacturers of good electrical specialties who wish representation in Northern Ohio and Michigan.

The J. B. McKeague company, 34 Dearborn street, Chicago, is the western representative for William T. Pringle of Philadelphia, manufacturer of switchboards, panel-boards, fuse panels, switches and flush receptacles. Mr. Pringle has just placed on the market a "new style" receptacle and attachment plug for which exceptional claims are made.

A finely executed steel engraving of General Grant was sent out by the American Electrical Works of Providence as a souvenir of Memorial Day, together with a brief statement of the principal events in the remarkable career of the great soldier of the War of the Rebellion. It is a very appropriate souvenir, and aside from its artistic merit will be gratefully received by the admirers of General Grant.

Canfield & Co. of Columbus, O., have entered into the electrical construction business, covering the territory of Ohio, erecting and selling electrical apparatus, both private and municipal. They desire to correspond with different manufacturers of electric specialties to be represented in the territory named. Mr. H. L. Canfield has been doing business in the construction line in this territory for the last 14 years.

George W. Patterson, 1530 Marquette building, Chicago, is desirous of securing a number of the most interesting electrical devices to exhibit at the entertainments he is giving in and about Chicago. "I can exhibit small articles of practical utility or novel use," says Mr. Patterson, "to the best possible advantage to great numbers of people who never go to an electrical supply house, and yet would buy if they knew what there was on the market."

The Walworth and Neville Manufacturing company of Bay City, Mich., has established at Beaumont, Texas, a factory for the manufacture of cross-arms for telephone and telegraph poles. The plant will begin operations in a short time. A contract has been closed with the Texas Iron and Lumber company of Beaumont for 3,000,000 feet of material for this year, much of which will be crosscut. This firm has another factory of this kind at Norfolk, Va.

The B. F. Sturtevant company, whose well-known "chimneyless" factory is situated at Jamaica Plain near Boston, is making an addition to its already large floor space for electrical work. Another story is being added to two of its shops, one 125 feet by 50 feet and the other 100 feet square, both of which will be used for this purpose. The increase in the business of this department has been large. The company is now making electric motors up to 125 horse power and generators up to 100 kilowatts.

A Riemann & Co., 824 Market street, St. Louis, formerly the A. C. Wolfram Electric company, electrical contractors and tin jobbers, have been in the tin business for 10 years, and are the sole western agents for the Maricotta Manufacturing company.

manufacturer of the well-known Crescent fan. The wide experience of Riemann & Co. enables them to secure their share of the fan business in the West. The firm reports that it is doing its utmost to keep up with its orders, and that its fans are giving the utmost satisfaction.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until May 31, 1899, for furnishing the New York navy yard with the following-named electrical supplies: Forty-eight thousand five hundred feet single and double conductor wire of navy standard, three testing generators (50,000 ohms), three portable direct-reading voltmeters, 24 knife switches, eight knife switches, two two-point ground-detector indicators, three engine indicators, three hand tachometers, three hand speed indicators, three sets of fuses for dynamo switchboard, three enameled rheostats, 544 16 candle power lamps, 36 32 candle power lamps, three waste tanks with covers, brass rod for switchboard and switch receptacles, ceiling fixtures, portables and steam-light globes. Intending bidders desiring specifications and blank forms of proposals can obtain them upon application to the bureau at Washington, D. C., or the Navy Pay Office at New York.

The Phoenix Battery Manufacturing company of St. Louis was recently organized, with a paid-up capital of \$250,000. Heretofore this company was known as the Phoenix Carbon Manufacturing company, which sold out its electric-light, carbon and motor-brush departments. The Phoenix Battery Manufacturing company is now giving its attention exclusively to the manufacture of batteries and carbon specialties. The company has just purchased an eight-acre tract of land in St. Louis, and will build and equip one of the largest plants of its kind in the world, which will enable it to do business on the largest scale. Colonel S. G. Booker, the well-known superintendent of the old Phoenix company, will still remain in charge. He is one of the oldest carbon men in the United States, and is known as one of the most active men in the business. It is confidently predicted that he will be as successful with the new Phoenix company as he was with the old.

The Bullock Electric Manufacturing company of Cincinnati will ship to England, about June 1st, one 25 horse power generator and two 30 horse power, one 40 horse power and two 50 horse power printing-press equipments for the Manchester Sporting Chronicle. One 25 horse power type C printing-press motor, with controller, will go to Cassell & Co., London, who are said to have the largest publishing house in England. A slow-speed motor for direct connection to lithograph press, with controller, will be forwarded to the Belfast Evening News, which will also take a 30 horse power printing-press equipment, with teaser and controller. Two 50 horse power motors, with teasers and controllers, will be dispatched to the London Daily News. These "teaser" equipments are intended to drive large newspaper presses. These shipments will be the most important consignments of electrical machinery that have ever been made from this country to newspaper establishments on the other

side. Other English orders, which will be executed soon, include a small motor for the Machinery Trust, Limited, of Chester; two 40 horse power slow-speed generators for the Thornycroft ship-building yards, one slow-speed motor of five horse power, to be supplied to Richard Moreland & Co. of London, and one four horse power motor for Charles Churchill & Co. of Birmingham. These orders represent about \$20,000. Smaller shipments are stated to have been made this month to other foreign countries.

BUSINESS.

Ball engines for electrical service have been recently sold by the Ball Engine company of Erie, Pa., for the St. Joseph Hospital, Philadelphia; Cleveland Rolling Mills, Cleveland, O.; Marion Electric Light company, Marion, O., and E. R. Behrend & Co.'s paper mills, Erie, Pa.

The Emerson Electric Manufacturing company of St. Louis says: "We have not advanced desk-fan prices. We are still quoting desk and bracket fans at the prices named in our schedule of March 1st, which was sent with fan-motor catalogue, and we shall not advance prices on desk fans unless absolutely forced to do so."

Mr. Thomas Burns, No. 5000 Halsted street, Chicago, has ordered one 60-kilowatt Western Electric generator installed in his building for light and power purposes. The work of installation is being done by the construction department of the Western Electric company. The Kroeschell Bros. Ice Machinery company, Chicago, has installed a 15 horse power Western Electric motor in its factory.

As an indication of the progressiveness of the Swarts Metal Refining company of Chicago it is stated that the company has just purchased 100,000 pounds of scrap copper wire from Cuba. The company pays the highest prices for old copper wire and other scrap metals, and those who desire to realize on these materials may find it to their advantage to communicate with the Swarts company.

The Victor Electric company, Chicago, manufacturer of fan motors, small electric motors and other electrical specialties, is now prepared to furnish small sparking dynamos for gas-engine work. The company states that it has been working on these machines for some time, and now has a number of them doing most satisfactory work. The Victor company takes pride in turning out only the finest work.

That the Whitney Electrical Instrument company is meeting the requirements of the trade in the line of electrical testing instruments is shown by its latest catalogue, which is a most complete list of electrical testing instruments. The Whitney instrument has established a reputation as a medium-priced, high-grade instrument. The Electric Appliance company, the general western agent, is prepared to supply new catalogues promptly on application.

The white-clay tubes as supplied to the trade by the Central Electric company, Chicago, are giving good satisfaction. The tubes, being straight, well vitrified and free from blemishes, are easily in-

stalled and produce lasting results. Prompt shipments come from good stocks, and the Central Electric company carries all standard sizes, but states that the five-sixteenth by three-inch size, with nine-sixteenths-inch outside diameter, is sold much more largely than any other.

Charles H. Besly & Co., 10 and 12 North Canal street, Chicago, carry a complete stock of the celebrated Pecora machinery paints, which have been on the market and have given excellent satisfaction since 1862. The flat steel color is in paste form for engines, tools and general machinery. The egg-shell gloss enamel finishing paint for engines, tools and general machinery is said to be dustproof in 10 minutes and to dry hard in 30 minutes. It is sold only in liquid form. The Dresden machine enamel imparts a rich, glossy appearance for radiators, gas engines, etc. The iron filler is used for making rough castings smooth, and the Pecora blow-hole cement is something new. This is claimed to be the one cement which will stand under the planer, lathe, file and other finishing operations. It comes dry and is worked with a knife. It stands 200 degrees heat and is gas and air-tight. A sample is sent free. C. H. Besly & Co.'s new May, 1899, catalogue is now ready for distribution. It is mailed free to any address on application.

Among the buildings which are now being wired for central-station service from the Chicago Edison company's plants may be mentioned these: The new fireproof factory for Bauer & Black, Twenty-fifth street and Armour avenue (in this building are installed about 30 motors, aggregating over 100 horse power, 43 constant-potential arcs and over 100 incandescents); new building erected by Frederick Ayer on Wabash avenue and since occupied by A. C. McClurg & Co. (150 arc lamps and 250 incandescent lamps, together with four electric elevators and two pumps); new block of buildings on the Lake Front, now in process of construction by Stanley McCormick (200 arc lamps and 156 incandescents, also eight electric elevators); at the southeast corner of Wabash avenue and Jackson street the old building is to be torn down to make room for the new Cable building, which will be wired for 29 arc lamps, 540 incandescent lamps, three electric elevators and two pumps; Michael Reese Hospital, Lake Front and Twenty-ninth street, 450 incandescent lamps and 16 horse power in motors; Lakeside building, southwest corner of Clark and Adams streets, which has just been remodeled (rewiring of the building in iron-armored conduit for 25 arcs and 300 incandescents and electric elevators); new building for the Western Methodist Book Concern now in process of construction at 57 Washington street (over 100 horse power in motors and 1,100 incandescent lamps); Merchants' Loan and Trust building, corner of Adams and Clark streets (capacity of upwards of 4,000 16 candle power lights and over 200 horse power of elevators and miscellaneous power); the new fireproof warehouse on Polk street (about 300 incandescents and four electric elevators); Hub clothing establishment's new addition at State and Quincy streets (about 1,200 lights); Marshall Field's wholesale building, Adams street and Fifth avenue (about 2,000 incandescent lamps).

ILLUSTRATED ELECTRICAL PATENT RECORD.

Issued May 16, 1899.

624,604. Electrical Switch Apparatus. William F. Bossert, Utica, N. Y. Application filed October 15, 1898.

A main conductor is formed integral and has its ends bent downwardly and secured to the base, that portion intermediate the downwardly bent ends being separated from the base by an interspace, and a branch conductor formed integral is passed through the interspace and has an upwardly projecting portion engaging the main conductor.

624,614. Trolley. Edwin Duty, Jr., Cleveland, O. Application filed February 10, 1898.

The trolley wheel has a lateral extension, and an insulated shoe is secured intermediately of the extension and the wheel periphery.

624,671. Electric Motor-starting Switch. Edwin H. Porter, Fort Wayne, Ind. Application filed January 19, 1899.

In an electric motor-starting rheostat switch two levers are employed, one carrying an operating handle and the other carrying the contact pieces for the rheostat, the levers being locked together, and electromagnets are adapted to lock and unlock the levers from each other.

624,676. Continuous-current Shunt Machine. Adolf Singer, Darmstadt, Germany. Application filed November 11, 1898.

In a shunt dynamo or shunt motor the connection of one end of the shunt with a point of the main line and the other end of the shunt with a fixed point of the armature winding.

624,699. Electric Motor. Hans O. Swoboda, New York, N. Y. Application filed November 15, 1897.

Current made for an expandable strip, a shaft with which the expandable strip is connected, a lever mounted on the shaft, a device acting to rotate the shaft and a solenoid mounted on the shaft.

624,699. Apparatus for Electrically Igniting Miners' Safety Lamps. William Best, Morley, England. Application filed December 23, 1897.

This device has a wick carried on a tube secured to the lamp bottom, and an adjustable wick tube combination with a central conductor insulated from the lamp bottom by an insulating material

carrying a cap together with a suitable apparatus for passing the current from the cap across the wick to the wick tube.

625,015. Battery Solution. Henry Blumenberg, Jr., New York, N. Y. Application filed September 17, 1898.

The battery solution described consists of a chlorate of an alkali metal or alkali-earth metal and a bisulphate of an alkali metal or alkali-earth metal in approximately equal proportions and mixed with water.

625,049. Illuminative Advertising and Decorative Apparatus. Timpron P. Martin, Liverpool, England. Application filed June 17, 1898.

In illuminative advertising and decorative apparatus there is the combination of the rotative cylinders with projecting changeable and adjustable studs thereon; a movable letter bar in the same plane as each of the rings of the stud holes in the cylinder; means for moving the letter bar and a series of conductors lying at right angles to the letter bars, the bars and conductors being in electric circuits in which electric lamps are disposed.

625,060. Apparatus for Controlling Movements of Electric Elevator Cars. Gustaf Rennerfeld, New York, N. Y. Application filed January 29, 1898.

An electric motor is provided with electromagnetic means for automatically closing the circuit through the field-magnet coils before it is closed through the armature coils. Additional electromagnetic means are provided for effecting such closure of the circuit through the armature coils.

625,080. Apparatus for Cleaning Hulls of Vessels. James S. Zerbe, New York, N. Y. Application filed August 26, 1898.

A hull cleaner is composed of a cylindrical shell having motors within and projecting shafts connected to the motors and carrying brushes on the outside of the shell, and lever-operated shafts carrying casters at their outer ends, projecting from the shell intermediate the brush-carrying shafts and adapted to be operated from within the shell for the purpose of bringing the brushes into and out of contact with the hull.

625,098. Electrical Distribution by Storage Batteries. Justus B. Entz, Philadelphia, Pa. Application filed February 1, 1899.

In a system of electrical distribution by storage batteries the combination with a booster interposed in a

battery conductor, of a practically constantly excited field coil for the booster and two series field coils, opposed to the coil and respectively interposed in a working conductor on the generator and service sides of its union with the battery conductor.

625,099. Electrical Distribution by Storage Batteries. Justus B. Entz, Philadelphia, Pa. Application filed February 3, 1899.

The combination in a system of electrical distribution by means of storage batteries of a compound-wound generator, a storage battery of small voltage in parallel with the series field of the generator and a booster and storage battery in multiple with the leads or working conductors.

625,100. System of Electrical Distribution. Justus B. Entz, Philadelphia, Pa. Application filed February 6, 1899.

Means are provided for causing a practically constant rate of current to flow over circuits between which there is a varying difference in voltage, which comprise a dynamo interposed between the circuits and having a constantly excited field and a series field oppositely it.

625,133. Flash-light Apparatus. Simon D. Alter and Lewis T. Young, Philadelphia, Pa. Application filed December 21, 1898.

A flash-light cartridge consisting of a box or casing containing a mass of flash powder, and having embedded in the latter an electric igniting device covered by insulating material susceptible of being inflamed by the passage of the current through the igniter, and serving when thus inflamed to fire the flash powder.

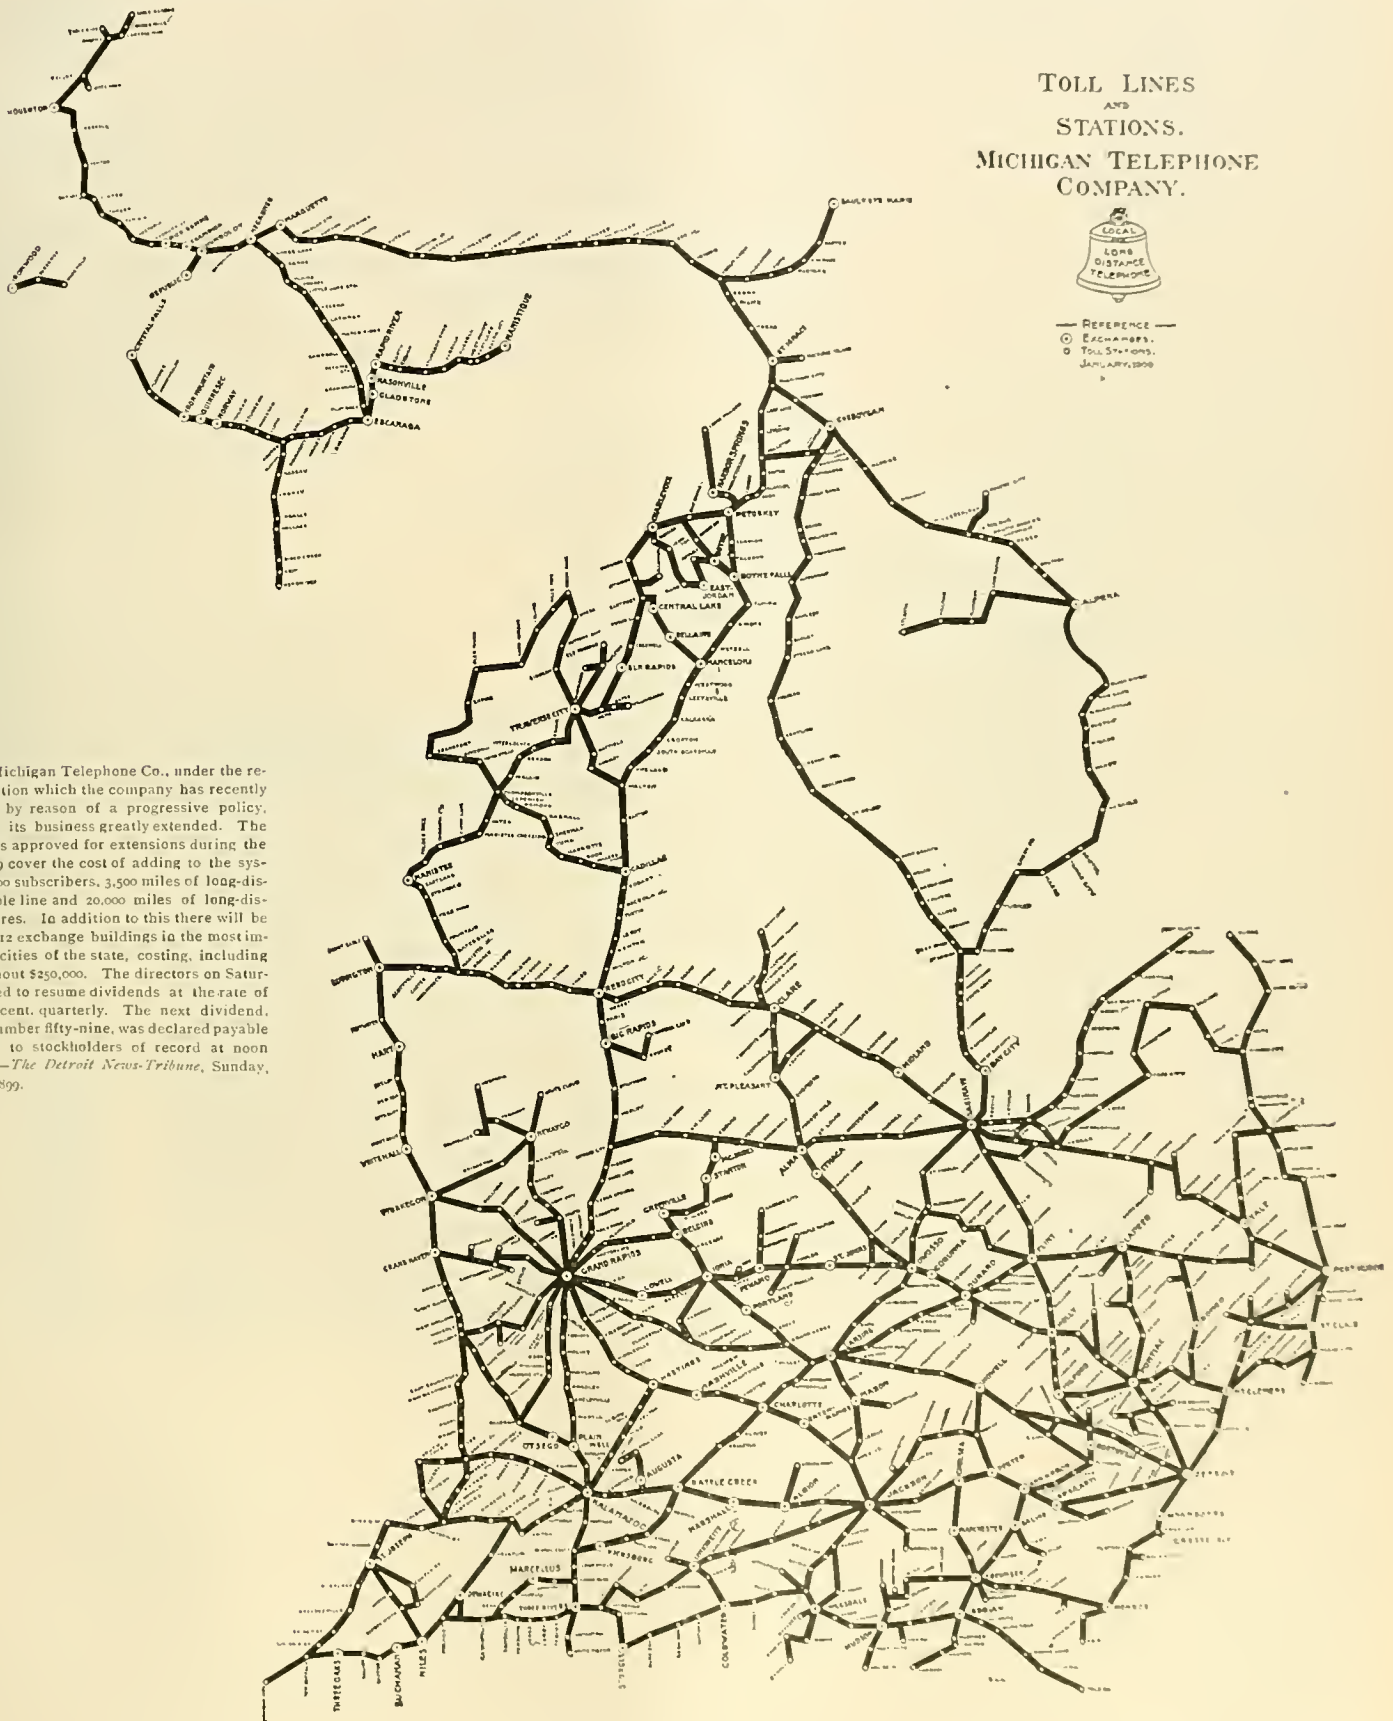

625,142. Telephone Receiver. Peter C. Burns, Chicago, Ill. Application filed February 23, 1899.

Claim is made for the combination with the shell of a magnet having a head thereon and an annular flange or rim on the head adapted to engage the edge of the shell, a diaphragm overlying the magnet and supported on the flange or rim and a cap overlying the diaphragm and secured directly to the shell, whereby the diaphragm and magnet are secured together in position.

625,151. Controller for Electric Motors. Harry P. Davis, Pittsburg, and Gilbert Wright, Wilkesburg, Pa. Application filed October 28, 1896. Renewed November 9, 1898.

The circuit making and breaking switch has a variable resistance between its terminals; an oscillatory head is

The directors of the Michigan Telephone Company have authorized the building of 3,500 miles of pole line and 20,000 miles of wire, connecting every city and town in the state with from one to ten circuits, as will be seen by the following diagram of the pole lines.

The Michigan Telephone Co., under the re-organization which the company has recently had and by reason of a progressive policy, has had its business greatly extended. The estimates approved for extensions during the year 1899 cover the cost of adding to the system 20,000 subscribers, 3,500 miles of long-distance pole line and 20,000 miles of long-distance wires. In addition to this there will be erected 12 exchange buildings in the most important cities of the state, costing, including land, about \$250,000. The directors on Saturday voted to resume dividends at the rate of 1 1/4 per cent. quarterly. The next dividend, being number fifty-nine, was declared payable May 15, to stockholders of record at noon May 11.—The Detroit News-Tribune, Sunday, May 7, 1899.

Illustrated Electrical Patent Record.

[Continued from page 306.]

geared to the movable member of the switch, and a rotatable shaft is provided with means for engaging and moving the head; a controller drum is loosely mounted upon the rotatable shaft and has a lost-motion connection therewith.

625,168. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa. Original application filed May 9, 1887. Divided and this application filed October 4, 1889.

Two continuous suspended working conductors supply currents of opposite polarities. They are arranged at different levels from the ground and in different vertical planes. A series of supporting poles is common to both conductors, a collector moving in contact with each of the conductors and making an underrunning or moving contact therewith, and there are independent upward and rearward connections between the collectors and an electrically propelled vehicle.

No. 624,986.

625,172. Apparatus for Manufacturing Material Having Insulating Properties. Frederick Lamplough, London, England. Original application filed May 31, 1898. Divided and this application filed November 11, 1898.

This apparatus comprises a tank, a heating coil therein, a plate in front of the coil, a steam-supply pipe, a flask adapted to contain a volatile fluid, a connection between the flask and steam-supply pipe, a pressure regulator in the connection and a pipe for supplying compressed air to the tank.

625,183. Electric Arc Lamp. Paul Mersch, Paris, France. Application filed November 10, 1897.

An electric arc lamp, comprising solenoid coils, cores movable therein, a carbon-holder connected to the cores directly, another carbon-holder connected to the first-named holder in such a manner as to move in the opposite direction, and electrical connections by which the solenoid coils are connected in parallel with each other and with the carbons.

625,202. Commutator. John Risbridger, North East, Pa. Application filed March 22, 1899.

This commutator comprises a body or cylinder with stub segments secured upon it, blocks having base flanges at their ends and located between the stub segments, and removable contact segments attached to the stub segments with their ends overlapping the flanges of the blocks.

625,204. Process of and Apparatus for Tanning Hides or Skins. Pedro G. Salom, Philadelphia, Pa. Application filed April 8, 1898.

The process of tanning hides or skins consists in impregnating the hides or skins with a chromate and an acid and mounting the skins in an electrolytic bath, consisting of a tank, a series of grids of conducting metal having spongy lead mounted thereon and forming the negative pole of a galvanic couple and arranged to receive between them the skins to be tanned or tawed by reducing action of nascent hydrogen electrolytically produced.

625,219. Electric Switch. Clarence Truitt, St. Louis, Mo. Application filed June 20, 1898.

An electric switch for incandescent lamps comprises a series of extended and concentrically arranged contacts having connections with the binding-posts of a multiple filament lamp or pair of lamps, a separate series of concentrically arranged contacts adapted to be engaged one with the other, and an axially pivoted or actuated lever having bridging contacts between the contacts.

625,223. Electric-railway System. Louis E. Walkins, Springfield, Mass. Application filed September 27, 1897.

There is the combination with an electric switch of an electric motor and circuit conductors, a centrifugal governor, operated by the motor when the circuit for the motor is closed, a movable member of the governor serving to operate the switch.

No. 625,680

625,224. Non-arcng Controller for Electric Motors. Alexander J. Wurtz, Pittsburg, Pa. Application filed January 31, 1895.

A switching mechanism comprising a superimposed auxiliary chamber, the partition separating the chambers being provided with a restricted opening and with a larger valved opening.

625,246. Self-starter for Electric Motors. Henry H. Carter, Chicago, Ill. Application filed December 27, 1897.

The combination includes a circuit-controlling arm or element, a series of contacts or terminals over which the arm is adapted to pass, means for moving the arm in one direction or gravity or its equivalent, a spring or other self-actuating device for moving the arm in the opposite direction when under strain, and an electromagnetic device for passing the spring under strain.

625,247. Telephone Repeater. William M. Davis, Chicago, Ill. Application filed February 21, 1898.

A microphone transmitter is connected directly in the line; a second telephone line has means for producing talking currents on the line, and a connecting device joins the lines together, comprising two pairs of terminals, one pair being adapted to be connected with the first line and having in circuit between the same a source of electricity, a microphone transmitter and the primary of an induction coil, the second pair of terminals being adapted to be connected with the second telephone line and having in circuit therewith the secondary of an induction coil and a receiver situated opposite the transmitter.

625,252. Electrical Furnace. Hilliary Eldridge, Daniel J. Clark and Sylvain Blum, Galveston, Texas. Original application filed September 29, 1897. Divided and this application filed January 18, 1898.

In an electrical furnace the combination with an inclosed furnace chamber having a cathode of a vertically adjustable fume-collecting hood suspended over the furnace chamber and an anode guided through and insulated from the hood.

625,255. Process of Producing Watermarks in or on Manufactured Paper. Thomas A. Goodchild and Archibald C. T. Bond, London, England. Application filed December 27, 1898.

The process described for producing in or on manufactured paper a disappearing but repeatedly revivable watermark which is invisible in a dry but visible in a moistened condition of the paper consists in placing on a platinum plate or sheet forming the anode a layer of absorbent material saturated with water, in placing on this and in a moistened state the paper which is to be watermarked and in pressing face downward on the paper a salient or other platinum design forming the cathode, so that the current from a source of electricity may pass through that portion of the paper which is in contact with the design on the cathode.

625,264. Electric Hand Fuse for Gas Burners. Friedrich Hoffmann and Wilhelm Ohlsen, Kiel, Germany. Application filed November 19, 1897.

The arrangement includes a gas burner and valve having a channel controlling the access of gas thereto, an auxiliary burner tube, carried by the valve and having the access of gas thereto controlled by the channel, a contact on the auxiliary burner tube and a fixed contact engaging therewith.

No. 625,133.

625,281. Electric-railway System. Louis E. Walkins, Springfield, Mass. Application filed March 7, 1898.

The first claim is for a series of conductor-rail divisions with separating intervals and a main-current feed wire, a series of electromagnets respectively provided adjacent each of the intervals and a metallic contact adjacent thereto, conductors joining the feed wire and the electromagnets and the adjacent metallic contact pieces, a movable device located at the separating intervals in line therewith and comprising as a part movable in unison therewith an armature adapted to be forced against the electromagnet by the passage of the car thereover, and having a portion also adapted to bear against the metallic contact piece and a conductor connecting the contacting armature with the conductor-rail division next in advance.

625,282. Electric-railway System. Louis E. Walkins, Springfield, Mass. Application filed January 14, 1899.

In an electric-railway system there is the third rail comprising separate longitudinally running current conductors, an alternating-current dynamo and current conductors connecting it with the third-rail members, and a motor car having thereon an alternating-current motor and a double-shoe trolley to bear on the conductor members, and circuit conductors connecting the shoes of the trolley with the motor, a direct-current dynamo mechanically driven by the alternating-current motor, and a direct-current car-propelling motor receiving its electrical energy from the direct-current dynamo.

625,283. Inverted Third-rail Electric-railway System. Louis E. Walkins, Springfield, Mass. Application filed January 21, 1899.

The inverted third rails, the brackets comprising risers and transversely extended portions at their tops, beneath which the inverted rails are sustained, insulating material between the rails and the brackets, and an insulating guard at the side of the riser toward the rail.

625,298. Galvanic Battery. George W. Frazier, Allegheny, Pa. Application filed April 6, 1898.

A zinc vessel is provided with a connector; a bag is constructed of asbestos cloth and adapted to fit the interior of the vessel closely, the bottom of the bag being closed by superimposed disks of asbestos cloth; a stick of carbon is placed centrally within the bag and provided with a conductor; ground carbon is packed about and beneath the carbon stick, filling the space within the bag, the particles of carbon being in conducting contact with each other and with the carbon stick and serving to prevent direct contact between the end of the stick and the asbestos disks; an excitant solution saturates the mass of ground carbon; the upper portion of the bag is folded inwardly against the carbon stick, and a body of asphaltum thereon seals the cell.

625,360. Electric Track and Wheel Brake. George B. Heath, San Francisco, Cal. Application filed August 27, 1898.

A combined electric track and wheel brake and a coil carried by the brake, the brake being vertically movable and slidingly mounted in relatively fixed guides to serve with either the front or rear wheels of a truck.

DESIGNS.

30,785. Motor Frame. Henry H. Wait, Chicago, Ill. Application filed April 12, 1899. Term of patent, seven years.

30,787. Incandescent Electric-lamp Shade. John Heskett Wright, Columbus, O. Application filed March 20, 1899. Term of patent, seven years.

30,792. Guard Rail for Street-railway Curves. Mason D. Pratt, Steelton, Pa. Application filed April 6, 1899. Term of patent, seven years.

30,794. Base and Casing for Portable Telephones, etc. Benjamin Le Vino, New York, N. Y. Application filed December 28, 1898. Term of patent seven years.

No. 625,098.

30,804. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent, 14 years.

30,805. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent, 14 years.

30,806. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent, 14 years.

30,807. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent, 14 years.

30,808. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 6, 1899. Term of patent, 14 years.

30,809. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 22, 1899. Term of patent, 14 years.

No. 625,183.

30,810. Manhole Cover. Thomas P. Greger, Philadelphia, Pa. Application filed April 22, 1899. Term of patent, 14 years.

30,811. Manhole-cover Frame. Thomas P. Greger, Philadelphia, Pa. Application filed April 22, 1899. Term of patent, 14 years.

30,812. Manhole-cover Plate. Thomas P. Greger, Philadelphia, Pa. Application filed April 22, 1899. Term of patent, 14 years.

Western Electrician

EVERY SATURDAY.

Vol. XXIV.

CHICAGO, JUNE 3, 1899.

No. 22

New Chicago Telephone Building.

The Chicago Telephone company is now erecting on the 40-foot lot adjoining on the east its present main building at the corner of Franklin and Washington streets, Chicago, an eight-story addition, which will be extended over the old building, making, when completed, a building about 80 by 90 feet in ground dimensions and eight stories in height, the seventh and eighth floors being entirely devoted to operating rooms and quarters for the operating force. The accompanying pictures show the front of the present building and a drawing of the enlarged building as it will appear when completed.

The new operating room, occupying the entire upper floor, will have a vaulted ceiling, lighted by high windows and skylight, and will be one of the largest and best appointed operating offices to be found anywhere. In it will be installed relay multiple switchboards of the standard design, which will be of sufficient capacity to provide in the one room for the service of about 10,000 telephones. The seventh floor, immediately below the operating office, will provide for the operators' lockers and retiring rooms, as well as the lunch room, reading room, matron's department, etc.

The wire chief's quarters, containing the battery plant, power plant and distributing boards, which are so intimately related to the operation of a modern telephone switchboard, are located in the northeast corner of the new building. The wires leading to the exchange will be contained in 200-pair cables, led through iron pipes along the east wall and into the subways on Franklin and Washington streets.

Upon the sixth floor will be placed the toll-line switchboards, providing for the distribution of toll-line calls, enabling a subscriber in any exchange of the company to be served with dispatch and accuracy by operators handling the toll lines of the company, which radiate in every direction from Chicago and make almost a part of that exchange. In addition to its 12 offices in Chicago, which, combined, constitute the Chicago exchange, the company now operates telephones in about 140 towns in the district immediately surrounding the city, the principal suburban exchanges being in Joliet, Evanston, Aurora, Elgin, Oak Park and Waukegan.

The remainder of the building will be occupied by the general offices of the company. The treasurer's office and the contract department are located on the ground floor, where they are most accessible to the public. The executive forces of the maintenance, equipment, underground and construction departments and of the order and record department are located on the second floor. The offices of the president, general manager, general superintendent and superintendent are on the third floor. The auditing department will occupy the entire fourth floor, while the chief engineer's forces, special agents and city manager will occupy the remaining space on the floors above.

The architects of the building, D. H. Burnham & Co., and the contractors, Griffiths & Co., give assurance of its completion during the month of August, and the installation of the new operating apparatus will be begun in that month, so that by the month of November the new exchange is expected to be in operation, providing for the service of the subscribers in the main-office district. Three large modern telephone offices will then be in operation in the downtown district of the city—Main, Central and Harrison offices.

Another new building of the company, now being erected on Sangamon street, near Monroe street, to be known as "Monroe office," will be opened about November 1st and will accommodate about

4,000 telephones. The company purchased some time ago a lot on Chicago avenue, near Clark street, and a new building will be built at that point before January 1st.

The chief obstacle the company has had to encounter has been the impossibility of securing the electrical apparatus for equipping its new offices as rapidly as it was needed. As soon as the apparatus for equipping them can be obtained the company expects to erect its own buildings in Lake View, the Stock Yards, Englewood and other districts. Ground for most of these offices has already been purchased. All the buildings of the company are fireproof, provided with ample light and opportunities for ventilation, and are liberal in the provision of room and accommodations for the employees. In the operating rooms of the new main-office building

Mr. C. J. Warner's Electrical Reminiscences.

One of the honored veterans of the electrical industry is Mr. C. J. Warner of the Western Electric company of Chicago, with which he has been connected for many years. Mr. Warner's son, Mr. E. P. Warner, is electrical engineer for the Western Electric company. The older man was persuaded to give a brief reminiscence sketch of his career at the recent annual dinner of the Chicago Electrical Association. The address was very interesting, but all too brief. Mr. Warner spoke as follows:

"Having been invited by your president and others to be present at your banquet this evening, and to give some of my early experiences in the field of electricity, I have endeavored to get together such incidents and dates as came most readily to my recollection.

"I was born in London, England, in 1823, and at the age of 12 left school, a very poor one by the way, and hired as a shop-errand boy for Mr. Kerby, who had a small factory in which he manufactured philosophical instruments, principally for Dr. Ritchie of London University.

"In 1836 Mr. Kerby made the first needle instruments for Cooke and Wheatstone, and from that time up to 1843, when I came to America, I had many opportunities to see the instruments and become familiar with their method of operation. I remember seeing these needle instruments used for train signaling, or dispatching, as we call it now, on the London and Blackwall railroad, a single-track road, about three miles in length, operated by means of a cable passing over drums at the end stations. Signals were given by means of a single-stroke bell. The instructions were given by the needle instruments, and the engineer controlled the movement of the car accordingly. The batteries used were of the well-known voltaic type, made in wooden troughs divided by slate partitions.

"At about the time of which I have been speaking, 1840-1843, my brother John was em-

ployed as a foreman in the shops of Mr. F. M. Clarke in London, and also as assistant manager in the Adelaide Gallery in London. Mr. Clarke, at that time, made many forms of electrical apparatus, principally for use in schools and frequent exhibitions of his interesting productions were made at the Adelaide Gallery and Polytechnic Institute. I recall standing in a ring with others and feeling the wonderful shock produced by the electric eel, also seeing a life size figure of the Queen of England on horseback, formed of small pieces of tin foil stuck on sheets of glass and made luminous by a chain of sparks passing from piece to piece of the tin foil. As I remember, the electrical discharge was produced by a steam-jet machine.

"In the spring of 1843 Mr. Kerby, then my brother-in-law, and myself started a little shop in Dutch street, New York, where, in addition to electrical work, we made a variety of things, such as candlesticks, which made their own candles as they burned away, and walking-stick umbrellas. Colonel Colt, the famous revolver man, was one of our patrons, and we did some of the work on his early experiments. The colonel brought Professor Morse to

Present Building.

Building with the Addition Now Making.

NEW CHICAGO TELEPHONE BUILDING.

the plan of ventilating which has been so successfully used in the present main building will be continued. This provides that the air entering the office be washed, then dried, heated in winter and cooled in summer, and forced into the rooms in such quantities that the entire volume is changed about once in three minutes. It is needless to say that the telephone operators employed in these rooms are afforded the cleanest and the best air for breathing purposes to be found anywhere in the city. It is also found that the delicate appliances making up telephone apparatus can be maintained in very much better condition when free from the soot and dirt which is blown through an open window in Chicago.

The commissioner of Indian affairs is inviting sealed proposals, until June 15th, for furnishing the materials and labor required to construct an electric-lighting system at the Chillicothe Indian Industrial School, Oklahoma. Further information may be obtained upon application to the Indian Office, Washington, D. C., the Indian warehouse, 1602 State street, Chicago, Ill., or to the superintendent of the school at Chillicothe.

our shop and we made some needle instruments for him.

"In 1854 I came West and settled in Ottawa, Ill., where I was employed by the Illinois and Mississippi Telegraph company as an instrument maker. Judge John D. Caton was at that time very actively engaged in the promotion of telegraph lines, and when the Western Union Telegraph company was formed it leased many of the lines which he had constructed, and took control of the shop at Ottawa. During the war of the Rebellion, from 1861 to 1865, the shop was mostly engaged in the manufacture of telegraph apparatus for use in the army, such as pocket relays, etc.

"With the exception of about three years, I remained with the Western Union Telegraph company until 1872, and I recall as one of the most interesting developments of that period, from '65 to '72, the efforts made to understand and adjust the resistance of telegraph instruments and lines. Operators had discovered that relays with many turns of wire and high resistance would operate on a line where those with but few turns and low resistance would not, and the consequence was that the operator who could manage to get his relay wound high, often without the knowledge of his superintendent, thought he had a great joke on his brother operators.

"President Orton of the Western Union Telegraph company made a trip to England, and on his return brought with him a Varley differential galvanometer and balancing rheostat; this was, I believe, the first resistance-measuring apparatus used in this country.

"In 1872 the shop of the Western Union Telegraph company at Ottawa was sold to be consolidated with another shop which had been operated by Gray & Barton in Chicago, and the Western Electric Manufacturing company was formed. In June of that year I entered the employment of the new company, and up to the time of the invention of the telephone in 1877 was engaged almost exclusively in the making of the Gray printing-telegraph instruments. When the first accounts of Professor Bell's wonderful invention appeared, I remember discussing its probable field of usefulness with others and hearing many express the belief that there would be little demand for it in actual business, and that there was not the least danger of it superseding the telegraph. I believe the most visionary and enthusiastic electrical promoter of that day did not reach in his imagination anything like the development of the present day. Gen. Anson Stager, who was one of the principal organizers of the Western Electric Manufacturing company and its first president, was a man of progressive ideas and quiet enthusiasm over new inventions, and I have always felt that he, perhaps, more nearly than any other man, at that time appreciated the immense possibilities of the telephone.

"Born when the steam-engine was a mere baby and the telegraph in swaddling clothes, I have watched the years roll by and the children grow and develop, unable, through lack of early education, to take a leading part in the training, but always most deeply interested, and adding my mite cheerfully to the performance of the great task."

Lightning Struck in the Pulpit.

The Rev. H. H. Baldwin, an aged preacher, was killed by lightning while conducting a religious service at Fountain, in Dewey County, Oklahoma, May 25th. For a week he had been conducting a revival and the little church was crowded. He gave out the hymns and led in prayer, and then went to the Bible and gave out his text. Then the storm broke. He appealed to the congregation to lead better lives and to feel a spiritual calm after a life of sin, the roughness and turbulence of which he compared with the violence of the storm raging out of doors.

Just then a crash of thunder came, while a brilliant flash almost blinded those in the front pews. When they recovered from the confusion the minister lay on the floor dead. The congregation was in a great state of fear, and the men in the audience, mostly cattlemen, feared to approach the body for some minutes. The women screamed and some fainted. Mr. Baldwin had been living in the territory several years, his home before that being in Illinois.

Lightning on Thunderbolt Hill.

'From the Cincinnati Enquirer.'

Lawrenceburg, Ind., May 24.—The frequency with which lightning has struck the summit of a towering hill on a farm of John P. Walker has attracted attention for years, but no explanation could ever be given for it. Sometimes as often as three or four times in succession during the brief period of an electrical storm would lightning strike there. Several days since John Mason, the expert, who is prospecting among the hills and hollows of the lands leased by the Sale Gold Mining company, was overtaken in the vicinity of "Thunderbolt Hill," as the electrical mountain has been nicknamed by the natives, and sought shelter beneath the spreading branches of a stubby oak on an adjacent ridge. While there he was treated to a display of celestial fireworks that for magnificence and grandeur surpassed his power of description. He made the discovery that the hill was filled with iron ore and other minerals so close to the surface as to attract the lightning.

Proposed Receiving Apparatus for Electrical Waves in Space.

Mr. J. J. O'Connell, one of the engineers of the Chicago Telephone company, who has devoted considerable study and experiment to the subject of sending electrical signals through space without connecting wires, thinks that it may be possible to substitute for the coherer used by Marconi and the other experimenters the receiving apparatus roughly outlined by the accompanying diagram.

Referring to the reference letters in the sketch, (B) is the ball or exposed surface of the "wireless-telegraph" system, connected to the diaphragm (D) of a receiver (R). Attached to the diaphragm is a wire of platinum or other metal, making a light brush contact (W) with the cylinder (C), which is revolved at a predetermined rate of speed by the motor (M). Also lightly contacting on the cylinder is a connection to ground (G).

Mr. O'Connell's plan contemplates the following

PROPOSED RECEIVING APPARATUS FOR ELECTRICAL WAVES IN SPACE.

method of operation: A smooth metallic cylinder slightly oxidized, or its equivalent, is set in motion. On it rests one end of a metallic rod or wire, the other end of which is attached to a diaphragm. As the cylinder revolves no motion is transmitted to the diaphragm, the friction being so slight and regular at the contact, but the moment an electric impulse takes place it flows over this slight contact and causes cohesion to take place, or slightly increases the friction, and the diaphragm is thrown into vibration. In this way, it is believed, signals may be received at great distances.

Lightning Flashes.

The fascinating study of atmospheric electricity, in which there has been so much general interest

for the Education of Deaf and Dumb, to contribute an interesting photograph of a lightning flash at Effingham, Ill., which he succeeded in getting on July 29, 1898, at 9:30 p. m. The accompanying cut is an exact reproduction of the original photograph.

COMMUNICATION.

Prof. Thomson's Comments on Lightning Phenomena.

To the Editor of the Western Electrician:

The magnificent picture of a lightning flash reproduced by you from a negative by Mr. W. C. Gibbon, and appearing in your issue of May 13th, interests me greatly. It shows in a most beautiful manner the character of the phenomenon of the lightning flash. I have never seen a picture which shows so much. It will be noticed that the ground flash is fed from several directions by forked streamers extending through the cloud mass. The increase in brightness of the branch at the extreme left simply indicates that that branch is nearer the observer or in the cloud directly overhead in front of the camera. The branch which streaks off to the left, and apparently downward, is probably in the cloud layer beyond the main flash or ground flash, its position being due to perspective. To the right there are also branches to feed the main flash, and a number of faint branches are to be seen here and there, which are probably so far distant within the cloud mass itself as to be partly obscured by the fog. The ground flash itself seems to have divided, sending off a vigorous branch to the right, at about one-third of its extent upward, as it appears.

The thunder produced by such a flash would probably be heard as a preliminary roll, followed by a tremendous explosive noise, and this again followed by a roll fading away. The first noise to reach the observer at the camera would be from that portion of the flash to the left, which you remark as increasing in brightness, and gradually the more distant portions of the flash would communicate their sound. The noise of the main ground flash would probably come as one terrific explosion, on account of the average distance from the observer at the camera to the streak not being greatly different for the different parts of the streak; while the more distant ramifications, both above it in the cloud layer and farther away than the ground flash, would contribute the final roll.

Many observers of thunder and lightning have been struck by the fact that, judging from the sound, the stroke has often been thought to be much nearer than it actually was found to be when the lightning struck some object and left a record of its action. The simple explanation is that the cloud discharges feeding the main flash may be directly overhead in part (as is beautifully indicated in the picture), or much nearer the observer than the main discharge, and the sound wave reaching the observer's ear begins, of course, with the noise produced by the nearest ramifications, and winds up with those farthest away.

Recently, here in Lynn, this condition of affairs had a fine illustration, inasmuch as a heavy discharge, which, by actual count of time to the beginning of the thunder, would not have been more than 2,000 feet away from where I was, in reality was about a mile away in a direct line. The thunder,

LIGHTNING FLASHES.

manifested of late, is receiving an impetus from the increasing use of the camera in recording the action of lightning. The publication in the Western Electrician of May 13th of a picture of a lightning flash in South Dakota has elicited interesting comments and suggestions from those interested in the same line of study and has prompted T. J. Mainline, an instructor in photography at the Illinois Institution

however, was characterized by an extremely violent and explosive noise, occurring at about the right time interval to correspond to the distance of the main or ground flash, and the thunder terminated by a minor series of rolling noises, which indicated that the flash had been fed from several directions in the cloud layer. ELIHU THOMSON.

Lynn, Mass., May 18, 1899.

Underground Distribution of Two-phase Current In New York City.¹

By E. A. LESLIE.

The purpose of this paper is to comment briefly upon certain features of two-phase distribution in New York city which may possibly be of interest to the members of this association.

The company with which I have the honor to be connected decided about two years ago to substitute two-phase for single-phase distribution, but one of the very first difficulties encountered was the subway situation, which, as you are all aware, is unusual and, perhaps, peculiar to New York alone. In the early days the high-tension companies operating in this city apparently imagined that they could go on lumbering up the streets with dangerous and unsightly poles and wires to an indefinite

FIG. 1. UNDERGROUND DISTRIBUTION OF TWO-PHASE CURRENT IN NEW YORK.—SWITCHBOARD AND REGULATING APPARATUS.

extent and for an indefinite period, and, relying upon the theory of vested rights, refused in the most peremptory fashion to devise and lay down their own underground systems. The result was special legislative enactment, the contracting by the state with a private concern for the furnishing of underground facilities and one general subway system of the simplest design for Manhattan Island, which all high-tension companies were obliged to use in common. Every engineer present will appreciate the difficulty of laying out an ideal underground system, even for one occupant, in a crowded and busy city like New York; yet to do so for a half dozen actively competing concerns, with almost as many different systems of operating, would be little short of a physical impossibility, and I therefore believe that the subway company is amply justified in assuming that its ducts, manholes and distributing boxes afford "adequate underground facilities" within the meaning of the law. The trouble is that with so many occupants it is not practicable to provide room under ground for junction boxes, large transformers and other apparatus necessary for a reliable system of meshed conductors, without which no company can, in my opinion, hope to compete to advantage with direct-current distribution.

Without junction boxes we were afraid to mesh our

FIG. 2. UNDERGROUND DISTRIBUTION OF TWO-PHASE CURRENT IN NEW YORK.—METHOD OF LOCATING FAULTS ON LIVE CIRCUITS.

conductors, and for this reason and the possibility of patent complications we adopted the four-wire method, consisting of two circuits, the currents thereon differing 90 degrees in phase. These circuits are operated practically the same as single-phase circuits, except that their distributing mains necessarily parallel each other, and, therefore, while with single-phase distribution we formerly employed but one distributing main in any given section, we now employ two. This is, of course, necessary to enable us to supply current for power purposes in units

1. Read before the National Electric Light association at New York, May 23-25, 1899.

of five horse power or over; but it also has this decided advantage, that it enables us to provide, at slight expense, a second source of supply for lighting and single-phase motors, in large and important installations, where an interruption of considerable duration might result in serious consequences. For this purpose a special non-arcing switch is provided, making it perfectly safe for anyone to throw over from one circuit to the other the heaviest loads our largest customers are ever likely to use. These loads sometimes reach as much as 100 kilowatts, but as our generators, ranging in capacity from 300 to 450 kilowatts each, all run in parallel, and the circuits consequently are all fed from common bus-bars, the unbalancing effect of such switching over is rarely felt to an annoying degree. Of course it is always desirable to preserve a fairly good balance, and these switches are frequently employed for this very purpose.

Another advantage over the three-wire, two-phase system is the comparative ease with which trouble may be located and removed, a "short," for instance, on one phase not necessarily affecting the other; whereas, with a three-wire underground cable, the insulation of all the wires is likely to be destroyed in case of trouble, and both phases consequently interrupted until repairs can be effected.

We also continued the house-to-house transformer method, except in blocks where one installation could be made to serve a number of customers; first, because to distribute from sub-stations would involve large sums for rental or compel their being shifted about from time to time at the caprice of the property owner; second, the operation of such sub-stations would involve more or less labor; third, the secondary wires would require large investment for copper, and, fourth, because the subway rental for the secondary wires would constitute a very heavy additional charge. We concluded, therefore, that the house-to-house method, under the conditions existing here, would be the more economical, and in the end afford more satisfactory returns. This, however, would not be the case with exclusive and what might be termed "extraordinary" subway facilities of our own providing.

The most serious difficulty encountered was the switchboard and regulating apparatus. Formerly our generators were small, not exceeding 60 kilowatts each, and as they were run independently, the number of lamps connected on each circuit was necessarily governed by the capacity of the machine, and the regulation of the pressure was usually effected on the machine itself. The boards rarely ex-

FIG. 4. UNDERGROUND DISTRIBUTION OF TWO-PHASE CURRENT IN NEW YORK.—USE OF TELEPHONE ON UNDERGROUND ELECTRIC LIGHT-CABLES.

ceeded 25 primary amperes, and could be switched from one generator to another without serious danger of arcing or practical interruption to the circuit. With the adoption of the two-phase system, however, generators of from 300 to 450 kilowatts were substituted and run in parallel; the number of circuits was largely reduced, and the loads on those remaining were increased to 100 amperes. We quickly found that we could not throw loads of 100 amperes at a pressure of 2,500 volts on the ordinary switchboard without dangerous arcing and annoying interruptions to lights and motors. Neither could we satisfactorily regulate our pressure. In order, therefore, to secure safety and convenience, and at the same time control the pressure of each circuit independently of the others, it became necessary to adopt a special form of switchboard and regulating apparatus, as shown in Fig. 1, which was devised by W. F. Wells, the assistant general manager of the Manhattan Electric Light company of this city, and a brief description of which may be of interest.

Our circuit records for the past 10 years made it plain that, with a constant pressure maintained at the different centers of distribution, the difference of potential required at the generating ends of the various circuits at any one time would not be more than 10 per cent. of the total. We therefore brought out a third lead from the stator armatures of our generators, as shown in sketch, so as to give us 10 per cent. of the total voltage; that is, with the machine generating 2,500 volts on each phase, we should have 250 volts between leads Nos. 1 and 2; 2,250 volts between Nos. 2 and 3, and 2,500 volts between Nos. 1 and 3. The six leads from each machine (three on each phase) are carried through a three-pole, double-throw switch in the switchboard to the bus-bars, of which there are two sets of six each, as shown. Ordinarily, but one set of bus-bars is used, as the generators are run in parallel, the other set being held for testing or the operation of a circuit singly, if desired. The circuits are connected to these bus-bars by similar switches. Lead No. 3 from the switch, after passing through an amperemeter, goes direct to the circuit. Leads Nos. 1 and 2 are connected to the terminals of a

single-wound transformer, one-tapped, called an "autotransformer" or "economy coil." This coil has 11 leads brought out, dividing the coil into 10 equal parts, each part representing one per cent. of the total primary voltage. These 11 leads are carried to an 11-point switch of the regulator-head type, so that any potential between 00 per cent. and full voltage of the machine (in one per cent. steps) may be run on the circuit. We are, therefore, able to keep the station end of the circuit correct within one-half of one per cent.

Owing to the cost of subway rentals and other reasons, we have been deterred up to the present time from using pressure wires from the centers of distribution. In order, therefore, to ascertain at least approximately what pressure is required at the generating station by each circuit at the various loads, we have taken a number of voltmeter readings at representative points on the distributing mains of each circuit and simultaneous readings at the switchboard, and from these have prepared sched-

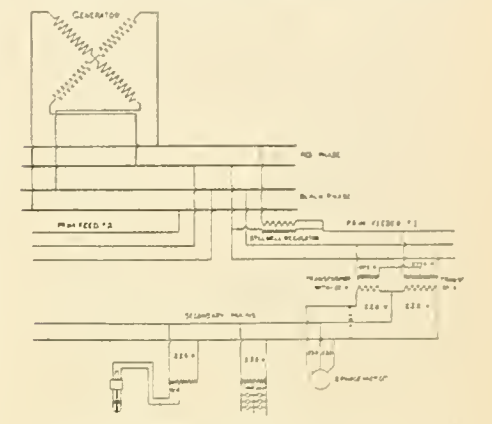

FIG. 5. UNDERGROUND DISTRIBUTION OF TWO-PHASE CURRENT IN NEW YORK.—MODIFICATION OF MER-SHON DISTRIBUTION SYSTEM.

ules showing the voltage required for each five amperes of load. In some cases we have placed on the amperemeter scale, directly underneath the ampere figures, the voltage required for any given load. These schedules require frequent checking and alteration whenever changes are made in the cables, or in case the centers of distribution vary with the season, the connection and disconnection of customers or the inductive characteristics of the load.

Plug and cable connections were also added to the board, in case greater subdivisions of circuits were needed than could be obtained on the two sets of bus-bars. The synchronizing devices and pilot lamps of the machines are connected across the 10 per cent. coils, and, therefore, switchboard transformers are not required for these purposes.

The instruments used are hot-wire Hartmann and Braun amperemeters, imported from Germany; Thomson inclined-coil voltmeters with transformers on the circuits, and Stanley static voltmeters on the generators.

TESTING FOR FAULTS.

Notwithstanding the greatest care in the selection of insulation and the most rigid specifications for the guidance of manufacturers, faults will occasionally develop in our cables, which are due, either to inherent defects or lack of proper mechanical protection. In such cases the necessary interruption to the circuit for purposes of repair is an exceedingly

FIG. 3. UNDERGROUND DISTRIBUTION OF TWO-PHASE CURRENT IN NEW YORK.—METHOD OF MEASURING INSULATION RESISTANCE ON LIVE WIRES.

important matter, and, if frequent or long drawn out, will invariably result in loss of prestige and business. Therefore, to facilitate the removal of the fault as much as possible, it was formerly our practice, whenever one of our alternating circuits became earthed, to isolate it from the other circuits by throwing it on the "test" bus in connection with a spare generator, and use a device for locating the trouble which was designed by Superintendent Sparrow of the Manhattan company. It includes the apparatus shown in Fig. 2, herewith.

A single-pole, double-throw switch (A) is at-

Means of Attaining Safety in Electrical Distribution.¹

By W. L. R. EMMET.

I have not selected this subject with the intention of fully discussing all its features, but rather for the purpose of bringing to the notice of this association certain matters of practical importance, concerning which radical differences of opinion exist among persons prominent in the electrical industry, and also for the purpose of pointing out some of the new problems which have been presented by recent developments of the electrical art, and which have not been fully considered in the adoption of the present standards of practice.

The persons most interested in the standardization of safe electrical methods are the fire underwriters; they have for years maintained a system by which statistics are carefully compiled and codes of rules adopted. These rules are revised from time to time, and their requirements in recent years have been

FIG. 1. MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

nearly uniform all over the country. They have at different times been indorsed by this association, and by other bodies representative of the electrical profession, and have, as a rule, been accepted as the standard by users of electrical apparatus. These rules are based upon experience gained from existing apparatus and methods, and, naturally, cannot consider or provide for future possibilities; consequently they must be modified from time to time in order that the progress of the art may not be obstructed.

The principal sources of danger in electrical distribution are: First, heating of conductors by current; second, failure of insulation; and, third, arcing when circuits are intentionally or accidentally broken. Of the first of these causes of trouble very little need be said, since the standard system, by which a cut-out protects every conductor, is an adequate safeguard,

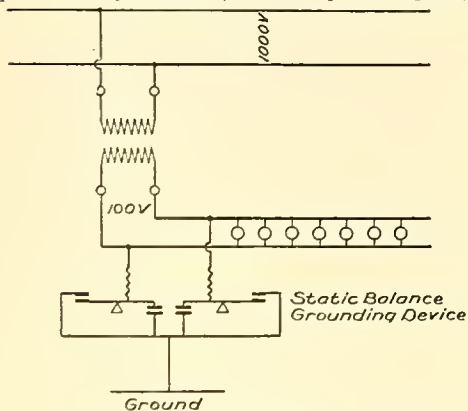

FIG. 4. MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

provided the cut-out is capable of safely breaking any current to which it can be subjected. The second source of danger that has been mentioned is insulation, and this subject is one that must always receive much consideration, since the mechanical possibilities with available insulating substances are strictly limited, and since the sources of deterioration are many and difficult to avoid.

The best path to safety in electrical distribution lies in the avoidance of high-potential differences in places where life or property can be endangered. The difficulties of insulation increase very rapidly as the voltage is raised, and while it is possible to insulate for very high voltages, in small space in special cases, the difficulties multiply themselves almost in proportion to the square of the voltage increase. In electrical distribution there are two ways by which danger from high voltage can be avoided. First, by abandoning high voltage altogether, and, second, by providing means by which it cannot exist on parts of the circuit where life or property can be endangered. We have good examples of the former of these

methods in the large, direct-current, three-wire systems operating from generators with about 125 volts on a side. With this voltage the dangers from failure of insulation are very small, and I think that an investigation would show that most of the fires that have been caused by such systems have arisen from heating of conductors or failure of circuit-opening devices. The scope of such low-tension distribution is, of course, restricted, while the use of high voltages enables us to distribute over large areas with much greater economy and efficiency than is possible with low voltage alone. The desire to effect these economies has led in many places to the installation of high-voltage apparatus for supplying power to these same three-wire systems. The existence of these conditions compels us to look for means of securing safety where power is transmitted at high voltage. There is but one sure means of accomplishing this end, and that is by preventing the existence of the high potential on parts of the circuits where life or property can be endangered. We will consider some of the methods by which this end can be accomplished.

Fig. 1 shows the simplest arrangement of a primary and secondary circuit as they are now generally installed in this country, and illustrates a condition under which this arrangement may become dangerous. The dotted lines show connections that may be accidentally made, one showing a cross between primary and secondary, either in the transformer or out of it, and the other, a connection of one of the primary leads to the ground. The primary voltage being 1,000 and the secondary 100, the making of these connections immediately establishes a potential difference of 1,100 volts between part of the secondary circuit and the ground. This pressure will, as a rule, be too much for the insulation of combination fixtures, and the first indication of trouble is likely to be a fire, if it be not a shock received by someone who happens to establish a cir-

FIG. 3. MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

cuit through his body between the ground and some lamp socket or other part that is not sufficiently insulated from the secondary circuit. The method of installation shown in this figure is almost universally adopted wherever alternating currents are being used in this country. It is, in fact, virtually compulsory upon the average station manager, since no established method of overcoming the difficulty is available that does not violate the fire underwriters' rule that all house wiring shall be free from any connection to ground. If this rule is disregarded, we may adopt the arrangement shown in Fig. 2, which entirely overcomes the difficulty, and which is open to no objection except that the insulation between one side of the secondary and ground is subjected to the voltage of the secondary circuit.

With the arrangement shown in Fig. 1 it is quite possible that the secondary insulation may be subjected to a considerable part of the primary voltage, even when there is no ground connection on the primary circuit. The potentials on insulated circuits carrying currents tend by static induction to balance themselves with respect to the ground, so that the potential of the ground is normally neutral to that of the two conductors. Where circuits are long, and operate at high potentials, a considerable flow of current between one conductor and ground may be required to materially disturb this neutrality. This has been illustrated to many of you by the lighting of ground-detector lamps from circuits that are perfectly insulated. When a secondary becomes crossed with a perfectly insulated primary, these static-capacity currents tend to flow to ground through the secondary insulation. We know by experience that under the most ordinary conditions, on 2,000-volt circuits, these currents are of sufficient volume to light ground-detector lamps, and we know that almost any current of ordinary potential-transmitting power enough to light a lamp may, under certain conditions, cause a fire.

So long as the secondary circuit remains insulated

from ground these dangers will exist. The remedy for the trouble must be either in the permanent connection to ground, as in Fig. 2, which is now prohibited by one of the underwriters' rules, or in the installation of some device by which the secondary is grounded automatically when the emergency arises. Figs. 3 and 4 show methods used to accomplish this purpose, and Fig. 5 shows a method for preventing contact between primary and secondary of a transformer by the introduction of a grounded shield, which has been used to some extent with a view to avoiding the danger above described.

The objections to this method are: First, that it affords no protection against crosses between primary and secondary which may occur outside of the transformer itself; second, that it introduces expense, since the shield must be made heavy enough to carry current sufficient to blow the primary fuses, and at the same time must be so arranged that it will not introduce serious eddy-current losses, and, third,

FIG. 2. MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

that it probably renders the transformer more subject to injury from lightning.

Fig. 3 shows the secondary separated from ground by films of insulating material, which are intended to puncture when the voltage to ground rises above a certain point. The objection to this method is that the films are likely to be uncertain and variable in their insulating qualities, and may, under certain conditions, be punctured by the secondary pressure.

Fig. 4 shows the same object accomplished by means of static balances, whose motion, by rise of potential difference, causes the circuit to be grounded. Another device has been suggested, in which a magnet is placed in series with a vacuum tube between the secondary and ground. When the potential difference rises the discharge through the

FIG. 5. MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

tube is increased, and the magnet starts mechanism which grounds the secondary circuit. The objection to these devices is that they are not perfectly instantaneous in their action, and that the secondary insulation may break down elsewhere before they accomplish the desired result. They are also necessarily more or less complicated, and liable to fail on that account.

As I have said, the permanent grounding of transformer secondaries is prohibited by the fire underwriters' rules, which prohibition is generally respected throughout the country, so that most secondary circuits are entirely unprotected from the trouble above described. There are, however, some very important exceptions that afford useful examples of the safety of operating secondary circuits with permanent ground connections. I allude to some of the large Edison companies, which have recently installed high-tension alternating apparatus to supply power to existing three-wire systems through rotary converters. In a rotary converter the collector rings and commutator connect to the same winding, so that the direct-current leads are

¹ Read before the National Electric Light Association at New York, May 23-25, 1899.

as much a part of the transformer secondary system as if they were connected directly to it. Most of these large Edison companies have for years been operating with neutral conductor grounded. This grounding has in most cases first occurred through chance or accident, and the practice has been persevered in, partly because it would be a difficult matter to avoid neutral grounds and partly because the grounded neutral is, for several reasons, very desirable.

Fig. 6 shows the condition existing in such cases. In these cases two rules of the National Board of Fire Underwriters are violated: First, the secondary system to which all house wiring is connected is permanently grounded, and, second, a primary voltage of 6,000 is used, while the underwriters' rules state that house wiring must not be connected to the secondaries of transformers whose primaries receive current at voltages above 3,000. In spite of these violations, the circuits are just as safe as they were before the high-tension power was used, and safer than they were before their neutrals were grounded, although at that time no high-tension apparatus had been installed. Both of these rules should, and in time will, be abandoned, the first, because it leads to danger rather than safety, and the second, because it endeavors to fix an unnecessary barrier to progress. The interests of insurance

very generally either grounded or protected by some such automatic devices as I have described. The prejudice against grounded circuits in buildings has always been very strong in this country, and, in my opinion, has been carried to unreasonable lengths. Grounded circuits of moderate potential can, with very simple precautions, be installed in buildings with perfect safety.

The third cause of danger in electrical distribution which I have mentioned is arcing through accidental opening of circuits or through failure of circuit-opening devices. Fuses, switches and circuit-breakers are subjects upon which a great deal could be said in discussing means of attaining safety. Many of the circuit-opening devices that have been introduced in the past have been capable only of breaking certain definite currents, and incapable of coping with the conditions existing when a very large system is short-circuited. Most of the switchboard devices that are now in use for alternating work are strictly limited in the range of their safe action, and would be valueless on a circuit capable of delivering a large amount of power.

In the past alternators have been generally used singly and in comparatively small units, the total power that could be delivered to one point being limited to the maximum output of one machine. In many of the installations now being made numbers

have not been much used. Their introduction naturally somewhat affects voltages, and for this reason may be considered undesirable. By judicious arrangement and proportioning, the objection can, to a great extent, be overcome, and there is little doubt that such devices will be much used in the future.

I have prepared sketches of a few circuit-opening devices that have resulted from recent investigations and experiments, and will briefly describe their design.

Fig. 7 shows a fuse block in which the fuse is in a state of tension between two hinged terminals; these terminals are pulled apart by springs and receive current through flexible connections. The fuse is punched out of sheet metal, the narrowest portion being at the middle. It is placed between two blocks of porcelain, a small amount of clearance being provided where the fuse passes through, so that its ends can be freely withdrawn by the movable terminals after the narrow part of the fuse has become ruptured. Around the narrow part of the fuse the porcelain blocks are recessed so as to provide an air chamber; this chamber is vented by a hole in the upper block. The whole device is firmly clamped together, so that the only opening to the outer air is through this one vent-hole. The fuse, being under tension, does not quite reach the melting point before the break occurs. It loses its tensile strength at a low red heat and pulls apart. It is quickly withdrawn by the springs from the air chamber in which it has been broken. A very small amount of the metal is volatilized and its gas is blown out of the vent-hole. For the purpose of preventing any deposit of metal fumes on the porcelain surfaces, these surfaces are lined with muslin that has been treated with shellac or varnish and pressed into the desired shape. This lining covers the interior of the chamber in which the fuse is broken, and the porcelain surfaces between which the fuse is drawn. These linings are supplied with the new fuses, and are renewed if any appreciable amount of burning has occurred.

With a fuse of this type, occupying a space of six inches by three inches on a switchboard, I have repeatedly broken 300 amperes at 13,000 volts without the slightest injury to the device.

Fig. 8 illustrates the principle of a circuit-breaker that has produced excellent results. Two terminals are placed side by side on a vertical board, and are separated, both in front and behind the board, by high barriers. Into the metal surrounding these terminals stout fiber tubes are attached, which extend downward on either side of the barrier. Two copper rods, connected at the bottom by a cross-head, are inserted in these tubes, and forced upward until they make contact in the terminals; the circuit is thus established through the copper rods and the cross-head, around the lower extremity of the barrier, and through the fiber tubes. The cross-head carries a piston, and this piston moves in a long, air dash-pot. To set the circuit-breaker, the rods are forced upward, by means of a wooden rammer, until the contacts are made; in this position the rods are held by a latch, controlled by a solenoid. When the proper amount of current is put through this solenoid the latch is released; a spring starts the rods downward, so that the circuit is broken in both tubes; the gas produced by the arc expels the rods rapidly from the tubes, the acceleration being checked by the dash-pot. This device has been found very effective on the heavy circuits with which we have experimented. It occupies a small amount of space and is simple in its mechanical construction.

Fig. 9 illustrates the construction of a switch or circuit-breaker somewhat similar in principle to that shown in Fig. 8. In this case the terminals are at the lower end and are situated inside of vessels into which the fiber tubes project for a short distance. These vessels are partly filled with oil, the break occurring below its surface. In the switches of this type which we have designed the rods have been withdrawn from the tubes by a pneumatic cylinder. The presence of the oil materially increases the breaking power of the switch and reduces the violence of the explosive effect when the circuit is opened.

Fig. 10 shows a shunt-fuse device that has been used in connection with circuit-breakers at Niagara Falls and elsewhere. The object of the design is to produce a fuse that can be placed in shunt with the circuit-breaker, to open the circuit after the main contacts are broken. It is, of course, desirable so to design such fuses that they can be very easily replaced. The fuse is placed in a slot in a long, wooden rod; this wooden rod is covered by a paper tube, and part of the rod is cut away at three points so as to form air chambers inside of the paper tube. The rod is inserted in a long, wooden tube, provided with vents that come opposite to these air chambers, when the fuse is in place. The fuse is a small copper wire, and is attached to ferrules on the rod which make contact with springs at both ends of the tube. When the current is diverted into the fuse, which immediately volatilizes, the pressure in the chambers bursts the paper opposite the vents and the gas escapes through chimneys provided above the vents. The paper covering of the rod prevents the hot gas from getting into the interior of the tube; consequently the device can be used over and over again without any deterioration. These fuses have worked perfectly in parallel with circuit-breakers under the most difficult conditions that we have yet been able to produce.

Fig. 6.

Fig. 7.

MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

companies, as well as of users and manufacturers of electrical apparatus, are best served by the introduction of methods which conduce to economy in the broadest sense.

A forcible illustration of the danger of ungrounded secondaries is afforded by a recent occurrence in New Orleans. In a certain residence district, where houses were connected to a system of three-wire alternating mains, a cross caused by wind occurred between one of the main wires and a 2,000-volt primary wire in the same street. The result was that the insulation between wiring and ground was broken down in a large number of houses, the trouble being principally in combination fixtures where conductors were near gas pipes. Fires occurred in 20 houses, and several were totally destroyed, among which were some fine residences. The loss was over \$200,000. If the neutral of this system of mains had been grounded, this trouble could not have occurred.

There is but one condition necessary to safety with a properly grounded secondary; namely, that there be no possibility of the accidental introduction to the secondary system of sufficient primary current to blow the secondary fuses. No possible set of conditions can arise where this precaution cannot be provided, since portions of primary circuits occupying the same streets with secondary mains can easily be protected by fuses if the total primary-current capacity exceeds that of the fuses of the secondary mains in question.

One of the reasons why this subject has not come into prominence before is that systems of alternating secondary mains have not been much used till quite recently, and, consequently, the possibility of crosses between primary and secondary wiring in streets has not existed.

The rule of our underwriters which prohibits the grounding of secondary wiring is not supported by the practice of other countries. I am informed that in England and on the continent secondaries are

Fig. 8.

Fig. 9.

Fig. 10.

of large machines are being run in parallel, and the power that can be delivered at any point is consequently large, and the difficulty of breaking the current that flows in case of short-circuit is correspondingly great.

In the new station of the Metropolitan Railway company about 50,000 kilowatts will be delivered to a single set of bus-bars and from there distributed all over the city. Wherever a sub-station or other installation is connected to these lines, means must be provided by which the circuit can be broken instantly in case a short-circuit occurs. The power of this station is generated and distributed at 6,000 volts, and the loss in lines will be small, so that the violence of a short-circuit in a sub-station will be almost as great as if it were on the main bus-bars.

We have recently done a great deal of work on circuit-opening devices for such heavy duty. One of the principal troubles in such work is the difficulty of making experiments. We have a testing outfit at Mechanicville, with which we can get from 300 to 400 amperes at 15,000 volts with an inductive load, and at Niagara Falls I have tested some devices with 700 amperes and 13,000 volts and a highly inductive load, the voltage rising to 18,000 when the circuit was opened. In comparison with past experiences these conditions seem heavy, but they are light when compared to those which must be met in some plants that are now being installed.

There is, of course, a limit to the capacity of every circuit-opening device, and as power units become enlarged it will be necessary to provide means for limiting the total amount of power that can be delivered to individual branches. This object can be accomplished by inserting reactances in these branches; such reactances can be so proportioned that they do not materially interfere with the normal operating conditions, and, at the same time, they can so limit the total power delivered that it is kept within the safe range of the circuit-opening devices. Up to the present time such reactances

EVERY SATURDAY.

PUBLICATION OFFICES:

Suite 510 Marquette Building, CHICAGO. TELEPHONE, MAIN 1746.

Eastern Office: 148 Times Building, New York.

Trade Supplied by Western News Co.

COPYRIGHT - Not only the title but the entire contents of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, \$3.00 for a full year of 52 numbers; in clubs of four or more, \$2.50, with free extra copy for eight subscriptions; foreign countries, \$5.00 a year; single copies, 10 cents. When change of address is requested, the old address as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING - THE WESTERN ELECTRICIAN - the only general electrical paper published in the West - thoroughly covers a territory exclusively its own. THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers desiring western trade will appreciate the UNEQUALLED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished or amplified.

HIGH WATER MARK CIRCULATION, 20,000.

CONTENTS OF THIS NUMBER.

Table listing contents of the issue with page numbers. Includes sections like 'New Chicago Telephone Building', 'Mr. C. J. Warner's Electrical Reminiscences', 'Lightning Struck in the Pulpit', 'Lightning on Thunderbolt Hill', 'Proposed Receiving Apparatus for Electrical Waves in Space', 'Lightning Flashes', 'Communication', 'Prof. Thomson's Comments on Lightning Phenomena', 'Underground Distribution of Two-phase Current in New York City', 'Means of Attaining Safety in Electrical Distribution', 'Editorial', 'Wireless Telegraphy', 'Cost of Chicago's Street Lamps', 'Detroit Street-railway Ownership', 'Pan-American Exposition', 'New England Street-railway Consolidation', 'Electric Railways in the Netherlands', 'The X-ray in Dentistry', 'Development of the Telephone Field', 'Telephone News from the Northwest', 'Manufacturers and Dealers', 'Novel Telephone Litigation', 'Finances of Central Union Telephone Company', 'New Companies', 'Personal', 'Telephone Progress in the South', 'Municipal Electricians at Wilmington', 'Diamond H' Push-button Switches', 'Steel-plate Electric Fan With Enclosed Motor', 'Electricity for Private Mansions and Hotels', 'Visit to Schenectady Factories of the General Electric Company', 'Automobiles for the Army', 'American and German Iron Workers Compared', 'Taxation of Franchises', 'Telegraph Line to Dawson', 'The Gorge Railroad Sold', 'Captain E. H. Tilly Reported Dead', 'Electrical Development of Las Vegas', 'Stole 700 Feet of Live Wire', 'Communications', 'Electric Lighter for Fire-engine Boiler Wanted', 'New Rheostats for Old'.

CONVENTIONS AND EXPOSITIONS.

- International Electrical Exposition in Commemoration of Volta Como, Italy, May 26th to October 25th. American Institute of Electrical Engineers, Boston, June 26th to 29th. American Society of Civil Engineers, Stockton Hotel, Cape May, N. J., June 27th to 30th. Canadian Electrical Association, Hamilton, Ont., June 28th to 30th. Southern Telephone Association, Memphis, Tenn., July 5th. American Association for the Advancement of Science, Columbia, O., Aug. 21st to 25th. National Association of Municipal Electricians, Wilmington, Del., September 5th and 6th. Philadelphia Exposition of American Manufactures for Export, September 10th to November 30th. American Electro-therapeutic Association, Willard's Hotel, Washington, D. C., September 17th to 21st. Chicago Exposition of Electrical Arts, Tattersall's, September 25th to October 9th. International Exhibition of Motor-vehicles, Berlin, Germany, during September. American Street Railway Association, Tattersall's, Chicago, October 15th to 20th.

The Johnson brothers, Tom and Al., are going to England with a view of establishing electric street-railway lines in London and other cities. Tom will probably continue to preach free trade, single tax and government ownership of natural monopolies, while Al. secures franchises and conducts the street-railway business along the usual lines. It's a great combination.

The latest announcement concerning the construction of the British cable in the Pacific indicates that there is a wide difference of opinion between the interests involved. The government of New South Wales has taken the Pacific-cable question up for fresh consideration, and announces that it dissents from the views of the imperial government. It agrees with Canada that the cable should be jointly owned, and not subsidized. This may result in a postponement of the project and prevent the completion of the work until after the American cable to Manila is laid.

The plan of extending the telegraph service into the far North is worthy of careful consideration. Meteorologists in Europe have for many years desired telegraphic connection with Iceland, Faroe Islands and Greenland, and it is pointed out that daily telegraphic reports from Iceland would be of the utmost importance to the weather service of this country as well as to the large fishing interests in the North Atlantic. The British fishing interests have recently petitioned the government to grant a yearly subsidy to the proposed cable. The Danish government looks favorably upon the plan, although it does not believe in government aid. The Great Northern Telegraph company of Copenhagen is willing to construct and operate the cable, provided a certain sum is guaranteed by the governments, corporations and individuals interested. The Royal Danish Meteorological Office in Copenhagen has issued circulars to similar institutions throughout the world, requesting them to subscribe to daily weather bulletins from Iceland and Faroe Islands, and the subject is being seriously considered by other bodies, especially in Great Britain. The attention of the American government has been directed to the project.

It seems that the opinion of the attorney-general and the policy of the War Department have not settled the question of establishing a new cable between this country and Cuba. The present lines are controlled by the Western Union and the West India and Panama Cable companies. When the Commercial Cable company sought the right to lay a cable the government responded that it was without power to consent to the construction of a new line landing in Cuba. As there is no government in the island other than that of the United States, it was thought that there was no power competent to grant the right sought, and would be none until the status of Cuba was determined by developments, and therefore that no new cable line could be constructed for some time. It is said now, however, that the capitalists who are ready to construct the new line are of opinion that if the United States government is without power to consent to the laying of a new cable, it is also without power to prevent the construction of another line to the island; hence, they purpose going ahead with the work, feeling that they can assume risk of the future protection of their property and in the meantime make money. The government might, however, refuse the company permission to land its cable in this country and thus effectually prevent the opening of the new line.

The controversy over the question of extending the trolley system into the down-town district and substituting it on the cable trunk lines is commanding attention among merchants and owners of real estate in Chicago, as well as the street-railway men and members of the City Council. One point that is conceded by all is the need of improved service. The cable lines are now loaded to their utmost capacity, and the demands upon them are constantly growing. The companies must introduce an electric system of some kind, and they are anxious to secure overhead-trolley franchises. The opposition to overhead wires in the business district does not seem to diminish. Every suggestion to introduce

the overhead trolley calls forth a storm of indignant protests. The case of New York is cited to prove that the underground-conduit system is practicable, and all arguments showing that the conditions in the two cities differ widely are unavailing. There is no doubt that the down-town merchants want the electric system extended to all parts of the city, but they are not prepared to give the companies permission to place poles and string wires in the principal streets. It has been proposed as a compromise to grant the companies permission to install a temporary system of overhead trolleys, with the understanding that at the expiration of four years they will put in the underground-conduit system. Such an arrangement, however, would be unsatisfactory to the public and corporations alike.

A great deal of attention has been devoted to the design and construction of the coherer, and much experimental work has been done. Among the more advanced workers in this field is T. Tommasina, who discovered that a sensitive coherer might be constructed by inclosing a drop of mercury in a glass tube between two cylindrical brass electrodes. This fact led him to investigate the properties of liquids with reference to electromagnetic waves. For this purpose he immersed a copper disk and a pendulum bob in distilled water. Both conductors had previously been coated with a film of electrolytic copper and well washed. On passing a current through the two electrodes a black deposit was formed in the disk, which grew until a chain of particles, probably cupric oxide, joined the two electrodes. On increasing the distance between them the current was not interrupted, but the chain grew until it again united both electrodes, even when three centimeters apart. The chain followed the pendulum bob on displacing the latter to the right or to the left, although the chain is sometimes invisible. If a small incandescent lamp is inserted in the circuit, and the bob suddenly removed to three centimeters, the lamp continues to burn even before a visible chain is formed. When the distance between the electrodes is very small, a chain may be formed simply by the action of electromagnetic waves. Tommasina constructed a coherer on that principle, with a very thin layer of distilled water.

Another compliment has been paid the American patent system by English experts who have been engaged upon the problem of preparing a parliamentary bill providing for an effective examination of all applications for patents and a proper registration of those issued by the British Patent Office. The practice in this country has been adopted as a standard, and the recommendations of those who have given much thought to the subject embody the essential features of the American patent system. One English authority declares that the wholesale manner in which patents have been granted without any discrimination in the past has been a disgrace to the British Patent Office, and although patent agents have rendered valuable services to their clients in making searches and giving advice generally, the performance of the work has been difficult, owing to the method of indexing adopted at the Patent Office. It is said that the patents registered in London have not been properly indexed for nearly 20 years, and that for this reason the officials concerned are unable to state whether a patent has been anticipated or not during that period. As a result an English patent has had little value, and has not been accepted as evidence of priority or title to invention. Should the proposed bill be enacted, the result will doubtless be to stimulate the energies of inventors and to induce them to take greater advantage of the facilities afforded by qualified patent agents if they wish to avoid disappointment at the hands of the Patent Office officials at the preliminary stage. The remarkable progress that the United States has made in the industrial arts is attributed largely to the protection afforded inventors under the patent laws, and the wisdom of the course pursued in this country is now universally recognized. In France and Germany, as well as in England, there is a growing demand for an effective patent system based upon the American principles.

Wireless Telegraphy.

In Mr. Preece's lecture before the Society of Arts at London on May 3d he related an interesting incident of the experiments with wireless telegraphy which is worth reproducing here:

When Mr. Marconi was showing the working at the South Foreland to the officials of the postoffice, he received a sharp shock. There was atmospheric electricity about, and Mr. Marconi repeated Franklin's experience. Sharp sparks were elicited from this miniature lightning, and at the same time erratic signals were observable at Boulogne. The speaking to Boulogne was not interfered with. The officers on board H. M. S. Vernon at Portsmouth one day observed similar disturbances, and obtained distinctly the letters A R E. Was this due to Mr. Marconi's experiments at the South Foreland, or was it due to atmospheric electricity? I think the latter, for I have frequently read letters, especially R, on Morse telegraphs when lightning was about.

The question of establishing communication by cable between Halifax, N. S., and Sable Island, which has been under consideration by the Canadian authorities for a long time, has led to a desire that wireless telegraphy be fully tested before the expense of laying a cable is undertaken. It is also proposed to make experiments with the wireless system between shore points and coast lighthouses, with a view to determining its value in connecting points closer together than Sable Island and the Nova Scotia mainland.

The British Admiralty, according to the London Globe, is devoting serious attention to the question of wireless telegraphy. The recent discoveries in that direction are of the utmost importance from a naval point of view, and it is extremely probable that experiments will shortly take place for the purpose of demonstrating to what extent wireless telegraphy can supersede the present methods of signaling by means of flags, semaphore or flashing lamp. In the opinion of some there is no reason whatever why communication between the several ships of a fleet should not be carried on entirely by the new method. The apparatus for transmitting and receiving messages could be fitted up on board any commissioned man-of-war in a few hours. For the purpose of signaling four miles it is only necessary to carry the insulated wire to a height of 20 feet, while to convey a signal to a ship on the horizon the main track of any ordinary vessel would be high enough for the purpose. It is believed that if the masthead of one ship is visible from the masthead of another wireless telegraphy can be carried on between the two without difficulty. The advantages of such a system are, obviously, enormous. All that has to be done by a flagship if she wants to communicate with the whole fleet is for her signalmen to "ring up," beginning with the "general" sign, or with the number of the ship's pennants, as the case may be. No matter whether it be night or day, clear weather or thick, the signal will pass from one ship to another with absolute ease. In a fog, too, communication will be as easy as on a clear day. It may be said that such a system in war time would be too dangerous, by reason of the risk of an enemy's ship "picking up" the signal. A moment's consideration, however, will show that there is no more danger in telegraphing a secret code than there is in signaling one by means of flags. Experiments are being made to perfect a method of sending wireless messages to one exclusive point by means of certain adjustments on the transmitting and receiving instruments. If successful, wireless telegraphy will in time entirely revolutionize the whole system of signaling in the navy.

The San Francisco Examiner reports some interesting experiments in wireless telegraphy at the Jesuit College in that city. The Rev. R. H. Bell, who conducted the experiments, is reported to have made the following deductions from his own investigations and the reports of others: "It is now certain that the Marconi coherer is not the only apparatus destined to play a part in the receivers of wireless telegraphy. From considerations on the constitution of matter, and from experiments, it seems clear to my mind that the whole phenomenon exhibited in the transmission of wireless messages is due to rapidly effected static induction waves."

Cost of Chicago's Street Lamps.

[From the Chicago Tribune.]

The municipal department of electricity reports that the average expense of maintaining a city arc light last year was \$68.52, and that the cost for 1899 will not exceed \$60, and may fall to \$55. That item of \$68.52 is made up of station expenses, salaries and "improvements to the system," the latter amounting to about three dollars per light. The cost of operating expenses in Detroit last year was \$51.85 per lamp. There were 300 less lamps here than there, but making allowance for the economies which can be made when doing business on a more extensive scale, the Detroit electrical department makes a better showing than the Chicago department does. It is also more business-like in its way of keeping accounts. It charges \$11.70 against each lamp on account of depreciation of plant. The Chicago department makes no such charge, although admitting that its plant will give excellent and economical service for only about 15 years. Nor does the Chicago department make any charge on account of interest on money invested in the plant. In a word, it does not keep its accounts in such a way as to show the actual cost of the light it is furnishing. The cost is understated, so as to make out a good case for mu-

nicipal management of the business. The department should keep its accounts in a business-like manner. Then it will be possible to tell whether it is saving money for the city or losing it.

Detroit Street-railway Ownership.

[Correspondence of the Western Electrician.]

Detroit, May 29.—The commissioners appointed to purchase the Johnson street-railway electric system of Detroit have made their report. No action will be taken by the Common Council until the result of the Supreme Court decision in the McLeod bill is announced. This bill, it will be recalled, is the special enabling act, hastily passed by the Legislature, in order that the deal with Johnson might be carried through.

The actual physical property was first carefully looked over and valued, at a fair estimate, at \$7,808,737.42. The street-railway company insisted that this amount was \$1,000,000 too low. After a thorough review of the claims of the company, the report reads: "For the purpose of our investigation, we fixed the value at \$8,000,000, in round numbers." After explaining that the words "franchise value" in the report mean the aggregate of profits that would be realized during the lives of the several franchises, reduced to present worth, the commission declares that operating expenses and interest on the physical property should be deducted from the earnings. The net earnings, as divulged by the railway company, in confidence, for the year ended April 1, 1899, were \$805,000, but from this amount Professor Bemis, the expert selected by the city and railway company, deducted \$55,000, to cover possible, if not probable, increase in operating expenses, etc. The report then continues: "Professor Bemis' computation is made on a basis of \$750,000 net earnings, deducting four per cent. on \$8,000,000, the value of the physical plant, and allowing four per cent. annual increase in income through increased traffic and earnings through the lives of the franchises. This franchise value, viz., \$8,478,563.86, added to the value of the physical plant, viz., \$8,000,000, makes the total value of the street-railway property and franchise rights \$16,478,563.86."

The report points out that the street-railway people objected to this computation on the ground that the allowance was made of only four per cent. for annual increase of business, whereas the gross earnings have for several years past increased at the rate of 6.3 per cent. per year. The company pointed out that if the last five years of the lives of the franchises were considered—the full term yet to run is about 17 years—the increase would be about eight per cent., counting on the approximate increase in population of Detroit for the period in question.

The company also objected, the report says, to Professor Bemis' arbitrary deduction of \$55,000 a year on the net earnings, claiming that this meant an aggregate loss of at least \$1,000,000 in the actual value of the franchises. In answer to the company, the commissioners, according to the report, justified their recognition of an increase of only four per cent. in business per year, whereas it had been actually 6.3, on the ground that if the city took control there should be some margin to allow for the introduction of three-cent fares. The report continues, in part:

"The railway owners insisted on demanding \$17,500,000, secured by blanket mortgage on the plant. We have strenuously endeavored to secure concessions in price, but succeeded in the following only: The company offered to turn over \$400,000 in bonds and \$300,000 additional, or \$700,000 in all, as a sinking fund for the city to assist in meeting future interest charges, thus reducing the price to \$16,800,000. We feel warranted in saying that no better price could be secured.

"The interest on \$16,800,000 is \$672,000. The sinking-fund provision for the first four years is \$50,000 a year, making a total fixed charge of \$722,000 annually, a sum \$83,000 below the net earnings as shown for the past year, and \$83,000 below such net earnings after making the deductions referred to for increased operating expenses, etc.

"If no increase in the earnings were made for 12 years to come, the present rate of earnings would still provide safely for meeting the entire bonded indebtedness, and the largest sum that will be required at any time, commencing approximately 25 years hence, would represent but \$122,000 more than the net earnings of last year, an amount that would be largely made up by having all deadhead tickets withdrawn and having everyone pay his fare on the new basis."

It is asserted that the reduction of fares from five to three cents will in itself save citizens from \$500,000 to \$800,000 a year. The report concludes with the suggestion that before the deal is closed or action taken by the Common Council, the whole matter be first decided affirmatively at a special city election.

Since the report was made public a new plan has been evolved. It is to leave the purchase price in the bonds at the figure practically agreed upon, \$16,800,000, sell only such amounts of the bonds as are necessary to secure the cash needed, and have the balance of the bonds to be available in case the universal three-cent rate does not prove a paying investment. However, many are opposed to the purchase altogether, owing to the great indebtedness involved.

Pan-American Exposition.

By a vote of 17 to four the directors of the Pan-American Exposition company have selected what is known as the Kumey site as the point for holding the proposed exposition of 1901 in Buffalo. The site includes 291 acres belonging to private owners and 145 acres belonging to the park system of Buffalo. It is estimated that the total cost of the site for the purpose of the exposition will be about \$200,000. Many persons regret that the company did not locate the exposition on the Niagara frontier, as the site selected is without any water front.

The preliminary prospectus of the exposition has been issued, and makes this reference to the proposed use of Niagara power: "The exposition site is within 40 minutes' ride of the Falls of Niagara, which can be reached by steamboats and by steam and electric cars. That majestic panorama of the wonders of nature, which is visited by millions of people every year, is well worth the journey across the continent or sea. This age of electricity will be signalized for the first time at an international exposition by the exclusive use of electrical power, which will be generated by the energy of that great cataract, carried over cables to the exposition grounds. Whatever the world now knows, whatever it may know in 1901, of the mysteries of electric fluid will be developed and illustrated with a fullness and beauty that only the power of Niagara could make possible. The street cars of Buffalo are propelled and its streets are lighted by electricity generated at Niagara Falls, and it is believed that all the industries of that city, which employ 70,000 mechanical and manufacturing hands and a capital of \$100,000,000, will be moved by the same subtle and mysterious force."

The New England Street-railway Consolidation.

[From the Boston correspondent of the Western Electrician.]

The name of the big combination of railways in Massachusetts and adjacent states has been decided upon. It will be known as the Massachusetts Electric companies. There are 33 companies in the combination. The position of general manager has been tendered to P. F. Sullivan, heretofore manager of the Lowell and Suburban railway, which is one of the plants absorbed in the deal. Mr. Sullivan will accept. He is president of the Street Railway association of New England, has been to Europe twice on inspection tours, grew up in the street-railway business, and is thoroughly equipped for the duties of his new and important position. His management will extend over 700 miles of trackage. During the past year the companies in the consolidation carried 69,767,439 passengers, employing 2,200 men and operating 1,240 cars. Concentration of power and power houses and other savings in operation are expected to increase the earnings materially. The office of the companies will be in Boston, and temporary quarters have been secured for Manager Sullivan at 8 Congress street. There will be four divisions, each under a sub-manager, responsible to the chief. E. F. Foster, now manager for the Lynn and Boston system, and R. S. Goff, manager of the Brockton system, are slated for two of these divisions.

Electric Railways in the Netherlands.

United States Consul Listoe at Rotterdam gives some information concerning the electric-railway industry in the Netherlands in an official communication to the State Department. He says that at the time of writing, April 6th, there were only two electrically-operated railway systems in the Netherlands—the road from Vaals to the German frontier, under the management of the Aachener Kleinbahn Gesellschaft, a little over half a mile in length, and the line from the Hague to Scheveningen, something over six miles. The cars on the latter, he says, carry their own motors [probably meaning storage batteries], as the trolley system is not allowed. "Concessions of franchises must be obtained from the city governments, and from the state when public highways are to be occupied. Some municipalities—Rotterdam, for instance—seem to be prejudiced against the electric system; in others, however, concessions could doubtless be readily obtained. On the island of Walcheren the project of building an electric line from Flushing or Middelburg to Domburg and Vere has long been agitated; but things move slowly in this country, and there would probably be a good opening for enterprise. People here have great respect for American energy." The field, however, should be personally inspected, he adds.

The X-ray in Dentistry.

Among the later applications of the X-ray is its use as a help in dental surgery. Many cases occur in every dentist's practice where skiagraphs of the jaws would be a valuable aid. The subject was discussed at the recent meeting of the Illinois State Dental Society in Chicago. At a clinic in the Northwestern Dental College Mr. W. C. Fuchs made a practical demonstration of the application of the X-ray in dentistry before a large number of spectators. The dentists were greatly interested and impressed.

DEVELOPMENT OF THE TELEPHONE FIELD.

Telephone News from the Northwest.

[From the Minneapolis correspondent of the Western Electrician.]

The Board of Aldermen of St. Paul has passed an ordinance granting the American Telephone and Telegraph company a franchise for long-distance and local-exchange connections.

The announcement is made from Milwaukee that the Wisconsin Telephone company, operating the Bell system in that state, has passed into the hands of the Erie syndicate, and it is understood Wisconsin, Minnesota, North and South Dakota will now be under one management. Just what the change may indicate is unknown, but it is supposed that a more vigorous campaign will henceforth be made in Wisconsin, where the company has had the same kind of troubles as in the other states, viz., aggressive and growing independent exchanges in every town of any size.

The People's Telephone company of Waupun, Wis., will extend its lines to Randolph and Fox Lake, Wis.

The Wassau (Wis.) Telephone company has let the contract to the American Electric Telephone company of Chicago for a new improved switch-board.

Following the lead of Polk and Clinton counties, the county assessor will assess telephone and telegraph companies at Fort Dodge, Ia.

The application of the Wright County Telephone company at Clarion, Ia., for a telephone franchise was voted down.

The Gilmore City (Ia.) Telephone company has begun work installing an exchange.

The Citizens' Telephone exchange of Montevideo, Minn., has been incorporated, with \$10,000 capital stock.

The Waseca (Minn.) Telephone company will hereafter give continuous service on Sunday, instead of a few hours, as heretofore.

Negotiations have been completed for the sale of the Home Telephone company's system in Sioux City, Ia., and elsewhere to F. L. Eaton, T. H. Johnson, R. M. Dott and F. W. Lohr. Out of the re-organization will result a rich and powerful company, which, according to report, will make a formidable rival to the Bell company. The Home company has an exchange at Sioux City, Ia., an exchange at Vermillion, S. D., and 225 miles of toll wire. Alliances will be made with all the independent companies in its vicinity.

The Interstate Telephone company will establish an exchange at Appleton, Minn.

The telephone company at Bancroft, Ia., has made free service from that place to Swea City, Ledyard, Germania and Buffalo Center. The reason for this is unknown, but it is supposed to be directed against the new line to be put in by the Germania Telephone company.

The Winona (Minn.) Telephone company will order a 1,200-drop switchboard, to cost about \$3,000.

The Central Telephone company of Des Moines, Ia., has been granted a franchise for a telephone exchange at Pella, Ia.

The instruments of the Iowa Telephone company have been replaced in the court house at Sioux City, Ia. They were ordered out by the county supervisors a few months ago.

The La Crosse Telephone company now has 35 patrons in Onalaska, Wis., and finds it necessary to enlarge the switchboard.

The town of Hawarden, Ia., has proposed to put in a municipal telephone exchange, but is compelled to refrain, as the laws of Iowa do not authorize the municipalities to engage in the telephone business.

A telephone line has been completed between Manitowoc, Wis., and Francis Creek.

The New Ulm (Minn.) Telephone company has sold all its outside lines to the Minnesota Central Telephone company.

The Mississippi Valley Telephone company has been contesting with Judge Giffillan in Minneapolis for the right to plant a telephone pole in front of the judge's property. The judge won, but not until after an encounter with the workmen. The council changed the ordinance to bring the disputed point within the underground district, and policemen stood guard day and night to see that no pole was put up during the passage of the ordinance and the time of its going into effect.

The People's Telephone company of Superior, Wis., has increased its capital stock from \$50,000 to \$100,000, and will soon start work on the new exchange. The same company is preparing to begin work at once on the exchange in Duluth.

Kulm, N. D., is to have long-distance telephone connection soon.

MANUFACTURERS AND DEALERS.

The Central Telephone and Electric company of St. Louis reports that its business during the last few months has been the best in the history of the company. President James S. Cuming has built up an excellent trade, and as the company endeavors to be up to date in all its products, the Central company is bound to receive its share of the telephone business.

Novel Telephone Litigation.

[Special correspondence of the Western Electrician.]

Detroit, May 27.—A unique telephone case is attracting interest at Ann Arbor, Mich. N. B. Trimm held a chattel mortgage on the goods of P. W. Shute, a hotel proprietor of Ypsilanti. Perrine and Cramer, witnesses, claim to have overheard a telephone conversation between Shute and his wife on the long-distance line of the New State Telephone company. It is claimed Shute was in Detroit and directed his wife over the wire to have the goods in question ready at 11 o'clock at night, as two vans would come from Detroit to take them away. Trimm heard of the plan in a round-about way and took legal steps to protect his interests. Shute then sued Trimm on the charge of slander. The judge took the case from the jury and directed a verdict for the defendant.

Shute now sues the telephone company for \$10,000 damages, alleging, first, that the stories of Perrine and Cramer were false, and, secondly, that even if they were true, the message should have been held inviolable by the company and that secrecy should be strictly observed, according to the provisions in the company's charter for the protection of private business entrusted to telephone agents. The telephone company has answered that Perrine and Cramer did not represent the company, whatever might have been their stories. But the company goes farther and alleges that the statements overheard and reported by Perrine and Cramer were justifiable if used to prevent the commission of a crime; that while the purpose of the company is to aid in the speedy transaction of public business, its lines cannot be made use of to plan crime or commit fraud, and, finally, that it is under no obligation to keep secret the conversations of criminals who use the telephone service. G.

Finances of Central Union Telephone Company.

[From the Economist, Chicago.]

The recent strength of the stock, in the face of the fact that no dividend is to be expected this year, is explained by a very remarkable growth of late in the company's business. The increase in the number of subscribers thus far indicates that the company will put 15,000 additional instruments in use this year, bringing the total number by the end of the year up to 60,000. This will be an increase of 33 per cent. this year and will make an increase of 100 per cent. in four years. Gross receipts, of course, do not increase in the same ratio, the tendency in this as in other lines being toward a larger volume of business with a smaller unit of profit. The company will spend about \$1,000,000 on construction this year, if it can get the materials required. This will be the largest amount spent in one year on that account. Construction expenditures, with the increased number of instruments, have been as follows, including the above estimate for 1899:

	Spent for Construction.	Inc. in No. Inst.
1896	\$ 688,602	2,011
1897	802,192	4,667
1898	888,748	8,875
1899	1,000,000	15,000

In addition to the above expenditures it has been the policy of the company to make liberal charges for maintenance of plant. In 1898 \$480,000, and in 1897 \$360,000, was expended for that purpose and charged to operating expenses.

NEW COMPANIES.

The Western Automatic Telephone Exchange company of San Francisco has been incorporated by Archie Borland, Oakland; S. Calhoun, Andrew White, John H. Miller and A. C. Aiken of San Francisco.

The Antiseptic Mouthpiece company has been incorporated with \$100,000 capital stock. The purpose is to make mouthpieces for telephones. The officers are: President, Charles W. Hutchings of Boston; clerk, William M. Bradley; treasurer, Gideon M. Mansfield of Boston.

The Pendleton Telephone company is a new corporation with a capital stock of \$8,000. The incorporators are R. W. Fletcher, W. J. Furnish and J. Despain. The company will operate and construct telephone systems in the state of Oregon. A line will be extended from Pendleton to Long Creek, 100 miles south of Pendleton.

PERSONAL.

E. G. Drew has been appointed purchasing and supply agent of the Chicago Telephone company, to succeed J. C. Kenny, resigned.

Alfred A. Beamer, manager of the Michigan Telephone company at Lansing since 1880, has resigned and will be succeeded by John H. Lyons of Detroit.

A dinner was given in Young's Hotel, Boston,

May 23d, in honor of Heman J. Pettengill, by his friends. He retires from the superintendency of the Eastern division of the Postal Telegraph-cable company to take the position of vice-president of the Erie Telephone company.

At the meeting of the Mexican Telephone company's directors, held in Boston, May 17th, Ezra H. Baker resigned and Godfrey Morse was chosen as his successor. The officers of the company, with this exception, were re-elected.

Telephone Progress in the South.

Albany, Tenn., will soon have a telephone exchange.

The new telephone line from Lexington, N. C., to Thomasville is finished.

Porter Springs and Dahlonga, Ga., will be connected by telephone within 60 days.

The Gainesboro Telephone company is putting in an exchange at Crossville, Tenn.

L. Hill & Son of Pittsburg, Texas, will soon establish a telephone exchange at Smithville, Texas.

A local company will build a telephone line from McKee, in Jackson County, Ky., to Richmond, Ky., 25 miles.

Lufkin, Texas, will soon have telephone communication with Nacogdoches and with Conroe via Cleveland.

The Cumberland Telephone and Telegraph company is completing a line from Cornersville to Ostell, Tenn.

The new telephone line, connecting Lexington, Tenn., with Decaturville and all intervening points is completed.

Plans for the Southwestern Telegraph and Telephone company's building to be erected at Austin, Texas, have been completed.

The telephone line between Parsons and Lexington, Tenn., is finished, and an extension from the former town to Perryville is under way.

The Southwestern Telegraph and Telephone company's new long-distance telephone line from Longview to Houston is rapidly nearing completion.

R. L. Durett is about ready to begin the work of construction of his telephone exchange for San Marcos, Texas. Nearly 100 subscribers have been secured.

Telephone connections between Linville, Tenn., and Fry, Hickman, Yokely and Brown's Distillery have been completed by the Cumberland Telephone and Telegraph company.

The Lowell and Greenbrier Valley Telephone company, chartered by J. H. Miller of Hinton, W. Va., and others, will operate a line from Hinton via Wiggins, Talcott, Lowell, Stock Yards and Wolf Creek, to Alderson.

The McMinnville (Tenn.) Telephone company has bought the Smithville Telephone company's line from Smithville to Dibrell via Sulphur Springs, and is extending it to McMinnville.

The Interstate Telephone company has bought the Elmira Telephone company's line, from Raleigh via Selma, Smithfield, Dunn, Princeton and Clayton, to Goldsboro, and is building a line from Goldsboro to Wilinston and another from Raleigh to Greensboro, via Durham.

An ordinance has been passed in the City Council of Waco confining the two operating telephone companies of that city, Southwestern and Independent, to six feet of perpendicular space on their poles for stringing wires, and to 40 wires to the pole. The independent company is putting its wires underground in certain limits, but there seems to be a disposition to compel both companies to put their wires underground within the fire limits of the city.

The Blue Ridge and East Texas Telephone company is a new organization that is building a telephone line throughout Collin County, in the northern portion of the state. This company has completed its line from Leonard, Fannin County, to McKinney, quite a city of Collin County, where it connects with both the long-distance and local telephone systems. It passes through the following Collin County villages: Kuox, Pike, Blue Ridge, Valdosta, Chambliss and Melissa.

The Southwestern Telegraph and Telephone company has recently made a change in the organization for the state of Texas. Superintendents E. K. Baker and J. A. Farnsworth, of Austin and Dallas respectively, have been promoted to the office of general manager of the southern and the northern districts, created for them. A. E. Jeavons of Houston has been selected as the general superintendent of the southern district. Mr. Tom Milburn of Dallas is the new general superintendent for the northern district.

The Marion (Va.) telephone exchange, which has been in operation about five years, has been sold to the Pulaski Telephone company, of which D. D. Hull, Jr., is president. The latter company has a successful exchange at Pulaski, Va., is building a system at Radford, is preparing to build at Wytheville, and is negotiating for the purchase of an exchange at Abingdon. It proposes to run them all under one management, and will at once connect all the towns with a through line from Bristol to Radford, and extend the line to Roanoke east and Bigstone Gap west, a total distance of over 200 miles.

Underground Distribution of Two-phase Current in New York.

[Continued from page 311.]

tached to the test bus, and from the center of this switch a lead is carried through the primary of a transformer which has a red lamp connected across its secondary; then through the amperemeter to the diagonally opposite outside poles of a double-throw, double-pole switch (B); from the other outside poles a wire is carried to ground. Current is supplied to the center connections of this switch by a small direct-current, shunt-wound generator having a capacity of about 10 amperes at 250 volts, and by means of this reversing switch the current can be sent through the circuit in either direction. In locating trouble the direct-current generator, which is belted to a five horse power motor, is started and the single-throw switch (B) thrown on either side of the bus. If the red lamp lights up, it indicates that the ground is on the other leg, and the switch is thrown over. The direct current is then brought up to about seven amperes and the reversing switch (B) is thrown about every 15 seconds, which reverses the direction of the direct current flowing through the cable to the ground. The subway workmen then start out with a compass and go to a manhole through which the circuit in question passes. If, on laying the compass on the cable, the needle reverses every 15 seconds, they know the ground is farther from the station; if, however, the needle is not affected every 15 seconds, it indicates that the trouble is between the manhole opened and the station, and they then open another manhole nearer the station. In this way they are able, without cutting the cables, to locate the trouble in a section between two manholes or handholes, or possibly in a manhole; whereas, prior to the use of this device, we were frequently obliged to cut in 15 or 20 places before locating the fault. In some cases, if the trouble is slight, we are able to repair it without shutting down the circuit, as the men are provided with rubber boots and rubber gloves drawn on over buckskin gloves, and an insulated box to stand upon, and can safely and quickly make a temporary joint that will answer every purpose until such time, say early the next morning, as the circuit can be shut down without detriment to the customers. If, however, the trouble is extensive, the circuit is shut down at once and the repair made as promptly as circumstances permit. Unfortunately, however, the subway company objects to the circuit being run, even on an independent generator, while we are locating the trouble, and therefore we now pull the circuit at once and make the test in the same way, except that we use two compasses, as the direct current flows through the primaries of the transformers and tends to mislead the men if they use but one. A compass is placed on each cable, and as long as both needles are similarly affected they know that the trouble is beyond them; when, however, the needles tend to point in opposite directions, they know that they have passed the trouble and its location is then easily determined.

It is, perhaps, curious to note that when the alternating current is on the circuit the direct current apparently does not flow through the primaries of the transformers. Trouble on series arc circuits is also located in this way, except that not more than about four amperes of current is used, because otherwise the cut-out magnets tend to act and throw the regular lamp magnets in circuit, the resistance of which practically stops the flow of the current.

TESTING FOR INSULATION RESISTANCE ON LIVE CIRCUITS.

It often happens in running a large number of circuits from a common bus that phenomena will arise that have a suspicious look and make it desirable to find out which particular circuit or circuits has caused the disturbance. It would have been disastrous to the money-making end of the business if every time something unusual manifested itself we had made a practice of pulling circuit after circuit until the delinquent had been detected, and it therefore became desirable to be able to make reliable insulation tests while the circuits were in actual operation. In order to accomplish this an arrangement of apparatus was devised, such as is shown in Fig. 3, and which is described as follows:

A spare generator is started and connected through its switches to the test bus. From this bus a line is carried through a high-tension switch and then through the primary coils of four transformers in series, the secondaries being left open, as shown in the diagram. This line is then carried through the galvanometer, which is provided with the usual short-circuiting key and shunt; thence it goes to a battery of 100 chloride cells equipped with reversing key, and from thence to earth. The transformers used are of the ordinary 2,000-volt type (which is the pressure used on the system), and are of about two-kilowatt capacity each, which we have found by experience to be about the right size. The coils being in series, they offer very high inductive resistance to the passage of alternating current, but their resistance is practically nothing when measuring megohms with direct current.

In making the test we first ascertain the insulation resistance of the generator, test bus, leads, etc. The circuit is then thrown on the test bus and tested in the same manner as if it were not connected to a high-tension generator, with the excep-

tion that it is not necessary to allow any time for charging or discharging the cable. This is called a "hot" test. The results are the same on testing either leg of the circuit, and the insulation resistance is generally found to be anywhere from 15 per cent. to 75 per cent. lower when tested "hot" than when the circuit is disconnected from the generator and tested in the ordinary way, that is; "cold," although the lower the insulation of the circuit, the closer the two tests appear to agree. For instance, recent tests on five circuits gave the following:

Circuit No. 21—Hot,	.693 Megohms.	Cold,	.83 Megohms.
" " 25—	.519 "	" "	1.31 "
" " 27—	.975 "	" "	1.39 "
" " 29—	1.95 "	" "	2.44 "
" " 16—	4.75 "	" "	10.25 "

When this device was first put into service, and we had convinced ourselves that the readings obtained were really useful, we became impressed with the idea that perhaps we might be able to note the actual effect of the strain of the pressure upon the insulating material surrounding the conductors, and to this end a special set of tests was made, with the following results:

Length of circuit, 4.36 miles.
First test, all converters in (22): Hot, 4.39 megohms total. Cold, 12.94 megohms total.
Second test, all converters out: Hot, 7.56 megohms total. Cold, 28.55 megohms total.
Third test, all converters out except one mounted on glass insulators: Hot, 7.56 megohms total. Cold, 26.4 megohms total.
Fourth test, all converters in after ends had been paraffined: Hot, 4.28 megohms total. Cold, 16.6 megohms total.

While these results are admittedly too indefinite to be regarded as at all conclusive, they nevertheless point to the fact that the insulation of a circuit does depreciate, for the time being, while under the influence of high potentials.

TELEPHONE IN UNDERGROUND TESTING.

It has been found by experience that underground circuits, particularly those employed for series arc lighting, need periodical overhauling, otherwise weak spots will accumulate to such an extent as to bring down the total insulation resistance below the standard requirements. At such times a great many galvanometer tests are necessary, and it was found that the work could be done much more quickly if the galvanometer were set up in the station instead of being moved from place to place along the street. The great objection to this, however, was the necessity for frequent communication between the foreman of the subway gang and the tester in charge of the galvanometer, obliging the former to use the public telephones a great many times during the day, which was decidedly inconvenient and involved much loss of valuable time. To overcome this serious objection, Mr. Sparrow and his assistant, L. A. Jenkins, caused to be constructed a special telephone set for use on underground cables, which works very satisfactorily.
